ENCYCLOPÆDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digested into the form of distinct
TREATISES OR SYSTEMS,
COMPREHENDING
THE HISTORY, THEORY, and PRACTICE, of each,
According to their last Discoveries and Improvements;
AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS,
and the ECONOMY OF LIFE.
TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General HISTORY, Ancient and Modern, of the different Empires, Kingdoms, and States;
AND
An Account of the LIVES of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best authors in several languages; the most approved Dictionaries, as well of general Science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.
ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE-HOUSE, NO 41, SOUTH SECOND-STREET.
M.DCC.XCVIII.
[Copy Right secured according to law.]
CICERO, (Marcus Tullius) the celebrated Roman orator, was born in the year of Rome 647, about 107 years before Christ. His father Marcus Tullius, who was of the equestrian order, took great care of his education, which was directed particularly with a view to the bar. Young Tully, at his first appearance in public, declined with such vehemence against Sylla's party, that it became expedient for him to retire into Greece, where he heard the Athenian orators and philosophers, and greatly improved both his eloquence and knowledge. Here he met with T. Pomponius, who had been his school-fellow; and who, from his love to Athens, and spending a great part of his days in it, obtained the surname of Atticus; and here they revived and confirmed that noted friendship which subsisted between them through life with so celebrated a constancy and affection. From Athens he passed into Asia; and after an excursion of two years came back again into Italy.

Cicero was now arrived at Rome; and, after one year more spent at the bar, obtained, in the next place, the dignity of quaestor. Among the causes which he pleaded before his quaestorship, was that of the famous comedian Roscius, whom a situation of the place, between them through life with so celebrated a constancy the friends of mankind. The result was, that, by his marriage with Terentia; but it is supposed to have been celebrated immediately after his return from his travels to Italy, when he was about 30 years old. He was now disengaged from his quaestorship in Sicily, by which first step, in the legal gradation and ascent of public honours, he gained an immediate right to the senate, and an actual admission into it during life; and settled again in Rome, where he employed himself constantly in defending the persons and properties of its citizens, and was indeed a general patron. Five years were almost elapsed since Cicero's election to the quaestorship, which was the proper interval prescribed by law before he could hold the next office of aedile; to which he was now, in his 37th year, elected by the unanimous suffrages of all the tribes, and preferably to all his competitors. After Cicero's election to the aedileship, but before his entrance upon the office, he undertook the famed prosecution of C. Verres, the late praetor of Sicily; who was charged with many flagrant acts of injustice, rapine, and cruelty, during his triennial government of that island. This was one of the most memorable transactions of his life; for which he was greatly and justly celebrated by antiquity, and for which he will, in all ages, be admired and esteemed by the friends of mankind. The result was, that, by his diligence and address, he so confounded Hortensius, though the reigning orator at the bar, and usually styled the king of the forum, that he had nothing to lay for his client. Verres, despairing of all defence, submitted immediately, without expecting the sentence, to a voluntary exile; where he lived many years, forgotten and deserted by all his friends. He is said to have been relieved in this miserable situation by the generosity of Cicero; yet was proscribed and murdered after all by Mark Antony, for the sake of those fine statues and Corinthian vessels of which he had plundered the Sicilians.

After the usual interval of two years from the time of his being chosen aedile, Cicero offered himself a candidate for the praetorship; and, in three different assemblies convened for the choice of praetors, two of which were dissolved without effect, he was declared every time the first praetor by the suffrages of all the centurions. He was now in the career of his fortunes; and in right, as it were, of the consulship, the grand object of his ambition: and therefore, when his praetorship was at an end, he would not accept any foreign province, the usual reward of that magistracy, and the chief fruit which the generality proposed from it. He had no particular love for money, nor genius for arms; so that those governments had no charms for him: the glory which he purposed was to shine in the eyes of the city as the guardian of its laws; and to teach the magistrates how to execute, the citizens how to obey them.

Being now in his 43d year, the proper age required by law, he declared himself a candidate for the consulship along with six competitors, L. Ecullanus Galba, L. Sergius Catiline, C. Antonius, L. Cassius Longinus, Q. Cornificius, and C. Licinius Saevidos. The
two first were patricians; the two next plebeians, yet noble; the two last the sons of fathers who had first imported the public honours into their families: Cicero was the only new man, as he was called, among them, or one of equestrian rank. These were the competitors; and in this competition the practice of bribing was carried on as openly and as shamefully by Antonius and Catiline as it usually is at the elections in Britain. However, as the election approached, Cicero's interest appeared to be superior to that of all the candidates: for the nobles themselves, though always envious and desirous to deprive him, yet out of regard to the dangers which threatened the city from many quarters, and seemed ready to burst out into a flame, began to think him the only man qualified to preserve the republic, and break the cabals of the desperado by the vigour and prudence of his administration. The method of choosing consuls was not by an open vote; but by a kind of ballot, or little tickets of wood distributed to the citizens, with the names of the several candidates inscribed upon each. But in Cicero's case the people were not content with this hectic and silent way: but, before they came to any scrutiny, loudly and universally proclaimed Cicero the first consul: so that, as he himself says, "he was not chosen by the votes of particular citizens, but the common suffrage of the city; nor declared by the voice of the crier, but of the whole Roman people."

Cicero had no sooner entered upon his office than he had occasion to exert himself against P. Servilius Rullus, one of the new tribunes, who had been alarming the Senate with the promulgation of an agrarian law; the purpose of which was to create a decemvirate, of ten commissioners, with absolute power for five years over all the revenues of the republic, to distribute them at pleasure to the citizens, &c. These laws used to be greedily received by the populace, and were proposed therefore by factious magistrates as oft as they had any point to carry with the multitude against the public good; so that Cicero's first business was to quiet the apprehensions of the city, and to baffle, if possible, the intrigues of the tribune. Accordingly, in an artful and elegant speech from the rostra, he gave such a turn to the inclinations of the people, that they rejected this law with as much eagerness as they had ever received one. But the grand affair which fell to him in a moment of his consulship, and has transmitted his name with such lustre to posterity, was the skill he showed, and the unwearied pains he took, in suppressing that horrid conspiracy which was formed by Catiline and his accomplices for the subversion of the Commonwealth. For this great service he was honoured with the glorious title of pater patriae, "the father of his country," which he retained for a long time after.

Cicero's administration was now at an end; but he had no sooner quitted his office, than he began to feel the weight of that envy which is the certain fruit of illustrious merit. He was now, therefore, the common mark, not only of all the factious, against whom he had declared personal war, but of all of the party not lost dangerous, the envious too; whose united spleen never left him from this moment till they had driven him out of that city which he had so lately preferred. Cicero, upon the expiration of his consulship, took care to fend a particular account of his whole administration to Pompey, who was finishing the Mithridatic war in Asia; in hopes to prevent any wrong impressions there from the calamities of his enemies, and to draw from him some public declaration in praise of what he had been doing. But Pompey being informed by Metellus and Caesar of the ill humour that was rising against Cicero in Rome, answered him with great coldness; and instead of paying him any compliment, took no notice at all of what had passed in the affair of Catiline; upon which Cicero expostulates with him in a letter which is still extant.

About this time Cicero bought a house of M. Caius on the Palatine-hill, adjoining to that in which he had always lived with his father, and which he is now supposed to have given up to his brother Quintus. The house cost him near L. 30,000, and seems to have been one of the noblest in Rome. It was built about 20 years before by the famous tribune M. Livius Drusus, on which occasion he is told, that when the architect promised to build it for him in such a manner that none of his neighbours should overlook him; "But if you have any skill (replied Drusus), contrive it rather so that all the world may see what I am doing." The purchase of so expensive a house raised some cenfure on his vanity; and especially as it was made with borrowed money. This circumstance he himself does not deny; but says merrily, "I have no sooner quitted the servitude of the commonwealth. For this great among the other female servants. Here he was served.

The most remarkable event that happened in this year, which was the 45th of Cicero's life, was the pollution of the mysteries of the bona dea by P. Clodius: which, by an unhappy train of consequences, involved Cicero in a great and unexpected calamity. Clodius had an intrigue with Caesar's wife Pompeia, who, according to annual custom, was now celebrating in her house those awful sacrifices of the gods, to which no male creature ever was admitted, and where every thing masculine was so scrupulously excluded, that even pictures of that sort were covered during the ceremony. It alarmed Clodius's imagination greatly to gain access to his mistress in the midst of her holy ministrations; and with this view he drest himself in the dress of a woman's habit, that by the benefit of his smooth face, and the introduction of one of the maids, he might pass without discovery: but by some mistake between him and his guide, he lost his way when he came within the holy, and fell in unluckily among the other female servants. Here he was detected by his voice, and the servants alarmed the whole company by their shrieks, to the great amazement of the matrons, who threw a veil over their sacred mysteries, while Clodius found means to escape. The story was presently spread abroad, and raised a general scandal and horror throughout the city. The whole defence which Clodius made when, by order of the Senate, he was brought to a trial, was to prove himself absent at the time of the conspiracy; but still he produced two men to swear that he was then at Tarentum, about two or three days journey from the city. But Cicero being called upon to give his testimony, depoised, that Clodius had been with him that very morning.
Cicero, in his house in Rome. Irritated by this, Clodius formed a scheme of revenge. This was to get himself chosen tribune, and in that office to drive Cicero out of the city, by the publication of a law, which, by some stratagem or other, he hoped to operate upon the people. But as all patriots were incapable of the triumph by its original institution, so his first step was to make himself a plebian, by the pretense of an adoption into a plebian house, which could not yet be done without the suffrage of the people. The first triumvirate was now formed; which was nothing else in reality but a tristerious conspiracy of three of the most powerful citizens of Rome, to extort from their country by violence what they could not obtain by law. Pompey's chief motive was to get his acts confirmed by Cæsar in his consulship, which was now coming out. Cæsar, by giving way to Pompey's glory, to advance his own; and Cæfarius, to gain that ascendency by the authority of Pompey and Cæsar, which he could not sustain alone. Cicero might have made what terms he pleased with the triumvirs; and been admitted even a partner of their power, and a fourth in their league; but he would not enter into any engagements with them. Both Cæsar and Pompey secretly favored his scheme; upon which they intended to ruin Cicero, but only to keep him under the law; and if they could not draw him into their measures, or make him at least keep quiet, to let Clodius looie upon him. Cæsar, in particular, wanted to distress him so far as to force him to a dependence on himself: for which end, while he was privately encouraging Clodius to pursue him, he was proposing expedients to Cicero for his security. But though his fortunes seemed now to be in a tottering condition, and his enemies to gain ground daily upon him; yet he was unwilling to owe the obligation of his safety to himself. He had taught the rules of eloquence; those thoughts of giving it up and returning to the province Cæsar, which he could not refuse which rendered him the more amiable in all the other parts of his life; and the fame tenderness of disposition which made him love his friends, his children, and his country, more passionately than other men, made him feel the loss of them more sensibly. When he had been gone a little more than two months, a motion was made in the senate by one of the tribunes, who was his friend, to recall him, and repeal the laws of Clodius; to which the whole house readily agreed. Many obstructions, as may be easily imagined, were given to it by the Clodian faction; but this made the Senate only more resolute to effect it. They passed a vote, therefore, that no other business should be done till Cicero's return was carried: which at last it was: and in so splendid and triumphant a manner, that he had reason, he says, to fear, left people should imagine that he himself had contrived his late flight for the sake of so glorious a restoration.

Cicero, now in his 50th year, was restored to his former dignity, and soon after to his former fortunes; satisfaction being made to him for the ruin of his estates and houses; which last were built up again by one of the Clodian party. But he had domestic grievances about this time which touched his first principles. He was near expiring, he seems to have had reason, he says, to fear, lest people should imagine that he himself had contrived his late flight for the sake of so glorious a restoration.

In the 56th year of his age, he was made proconsul of Cilicia; and his administration there gained him great honour. About this time the expectation of a breach between Cæsar and Pompey engaged the general attention. Cæfarius had been destroyed by his army some years before in the war with the Parthians; and Julia the daughter of Cæsar, whom Pompey married, and whom, while she lived, was the cement of their union, was also dead in child-bed. Cæsar had put an end to the Gallic war, and reduced the whole province to the Roman yoke: but though his commission was near expiring, he seemed to have no thoughts of giving it up and returning to the condition of a private subject. He pretended that he could not possibly be safe if he parted with his army; especially while Pompey held the province of Spain; prolonged
C i c e r o.

prolonged to him for five years. This disposition to a breach Cicero soon learned from his friends, as he was returning from his province of Cilicia. But as he forewore the consequences of a war more clearly and fully than any of them, so his first resolution was to apply all his endeavours and authority to the mediation of peace; though, in the event of a breach, he was determined within himself to follow Pompey. He clearly forewore, what he declared without scruple to his friends, that which side soever got the better, the war must necessarily end in a tyranny. The only difference, he said, was, that if their enemies conquered, they should be proscribed; if their friends, they would be lives.

He no sooner arrived at the city, however, than he told, as he tells us, into the very flame of civil discord, and found the war in effect proclaimed: for the senate had just voted a decree, that Cæsar should disband his army by a certain day, or be declared an enemy; and Cæsar's sudden march towards Rome effectually confirmed it. In the midst of all this hurry and confusion, Cæsar was extremely solicitous about Cicero; not so much to gain him, for that was not to be expected, as to prevail with him to stand neutral. He wrote to him several times to that effect; and employed all their common friends to prevail with him on that subject: all which was done; but in vain, for Cicero was impatient to be gone to Pompey.

In the mean time, these letters give us a most sensible proof of the high esteem and credit in which Cicero flourished at this time in Rome; when, in a contest for empire, which force alone was to decide, we see the chiefs on both sides so solicitous to gain a man to their party, who had no peculiar skill in arms or talents for war. Pursuing, however, the result of all his deliberations, he embarked at length to follow Pompey, who had been obliged to quit Italy some time before, and was then at Dyrrachium; and arrived safely in his camp with his son, his brother, and his nephew, committing the fortunes of the whole family to the fate of that battle of Philonæa, in which Pompey was defeated, Cicero returned into Italy, and was afterwards received into great favour by Cæsar, who was now declared dictator the second time, and Mark Antony his master of horse. We may easily imagine, what we find indeed from his letters, that he was not a little displeased at the thoughts of an interview with Cæsar, and the indignity of offering himself to a conqueror against whom he had been in arms: for though upon many accounts he had reason to expect a kind reception from Cæsar, yet he hardly thought his life, he says, worth begging: since what was given by a master might always be taken away again at pleasure. But at their meeting he had no occasion to say or do anything that was below his dignity: for Cæsar no sooner saw him than he alighted, ran to embrace him; and walked with him alone, conversing very familiarly, for several hours.

Cicero was now in his 61st year, and forced at last to part with his wife Terentia; whose humour and conduct had been long uneasy to him. She was a woman of an imperious and turbulent spirit: and though he had borne her peevishness in the vigour of health, and flourishing state of his fortunes; yet, in a declining life, foured by a continual feecession of mortifications from abroad, the want of ease and quiet at home was no longer tolerable to him. But he was immediately oppressed by a new and most cruel affliction, the death of his beloved daughter Tullia, who died in child-bed soon after her divorce from her third husband Dolabella. She was about 32 years old at the time of her death; and, by the few hints which are left of her character, appears to have been an excellent and admirable woman. She was most affectionately and piouily obser vant of her father; and, to the usual graces of her sex, having added the more solid accomplishments of knowledge and polite letters, was qualified to be the companion and delight of his age; and was justly esteemed not only as one of the best, but the most learned, of the Roman ladies. His affliction for the death of this daughter was so great, that, to shun all company as much as he could, he removed to Atticus's house, where he lived chiefly in his library, turning over every book he could meet with on the subject of moderating grief. But finding his residence here too public, and a greater resort to him than he could bear, he retired to Aituria, one of his seats near Antium; a little isle on the Latian shore, at the mouth of a river of the same name, covered with woods and groves cut into shady walks; a few of all others the fittest to indulge melancholy, and where he could give a free course to his grief. "Here (says he to Atticus) I live without the speech of man; every morning early I hide myself in the thickest of the wood, and never come out till the evening. Next to yourself, nothing is so dear to me as this solitude; and my whole conversation is with my books." Indeed his whole time was employed in little else than reading and writing during Cæsar's administation, which he could never cheerfully submit to; and it was within this period that he drew up one of the gravest of those philosophical pieces which are still extant in his works.

Upon the death of Cæsar, Octavius his nephew and heir coming into Italy, was presented to Cicero by Hirtius and Panfilus, with the silvery profeffions of the young man that he should be governed entirely by his direction. Indeed Cicero thought it necessary to cherish and encourage Octavius, if for nothing else yet to keep him at a distance from Antony; but could not yet be persuaded to enter heartily into his affairs. He suspected his youth and want of experience; and that he had not strength enough to deal with Antony; and, above all, that he had no good disposition towards the conspirators. He thought it impossible he should ever be a friend to them; and was persuaded rather, that if ever he got the upper hand, his uncle's acts would be more violently enforced, and his death more cruelly revenged, than by Antony himself. And when Cicero did consent at last to unite himself to Octavius's interests, it was with no other view but to arm him with a power sufficient to oppose Antony; yet so checked and limited, that he should not be able to oppose the republic.

In the hurry of all these politics, he was still prosecuting his studies with his usual application; and, besides some philosophical pieces, now finished his book of offices, or the duties of man, for the use of his son: A work admired by all succeeding ages as the most perfect system of Heathen morality, and the noblest effort
Cicero. and specimen of what reason could do in guiding man through life with innocence and happiness. However, he paid a constant attention to public affairs; missed no opportunities, but did every thing that human prudence could do for the recovery of the republic: for all that vigour with which it was making this last effort for itself, was entirely owing to his counsels and authority. This appears from those memorable Philippics which from time to time he published against Antony, as well as from other monuments of antipathy: for though Antony’s army was entirely defeated at the siege of Modena, which made many people imagine that the war was at an end, and the liberty of Rome established; yet the death of the consuls Pansa and Hirtius in that action gave the fatal blow to all Cicero’s schemes, and was the immediate cause of the ruin of the republic.

Octavius having subdued the senate to his mind, marched towards Gaul to meet Antony and Lepidus; who had already passed the Alps, and brought their armies into Italy, in order to have a personal interview with him; which had been privately concerted for settling the terms of a triple league, and dividing the power and provinces of Italy among themselves. The place appointed for this interview was a small island about two miles from Bononia, formed by the river Rhinns which runs near that city. Here they met, and spent three days in a clofe conference to adjust the plan of their accommodation: and the last thing they adjusted was the lift of a prosecution which they were determined to make of their enemies. This, as the writers tell us, occasioned much difficulty and warm contests among them; till each in his turn conferred to sacrifice some of his best friends to the revenge and resentments of his colleagues. Cicero was at his Tusculan villa, when he first received the news of the prosecution, and of his being included in it. It was the design of the triumvirs to keep it a secret, if possible, to the moment of execution; in order to surprize those whom they had destined to destruction, before they were aware of their danger, or had time to make their escape. But some of Cicero’s friends found means to give him early notice of it; upon which he set forward to the sea-side, with a design to transport himself out of the reach of his enemies. There, finding a vessel ready, he presently embarked; but the winds being adverse, and the sea uneasy to him, after he had failed about two leagues along the coast, he was obliged to land, and spend the night on shore. From thence he was forced, by the imprudence of his servants, on board again: but was soon afterwards obliged to land at a country-seat of his a mile from the shore, weary of life, and declaring he was resolved to die in that country which he had so often faved. Here he slept soundly for some time, till his servants once more forced him away in a litter towards the ship, having heard that he was pursued by Antony’s assassins. They were scarce departed when the assassins arrived at his house; and, perceiving him to be fled, pursued him immediately towards the sea, and overtook him in a wood that was near the shore. Their leader was one Popilius Lenas, a tribune of the army, whose life Cicero had formerly defended and faved. As soon as the soldiers appeared, the servants prepared to defend their master’s life at the hazard of their own; but Cicero commanded them to let him down and make no resistance. They threw cut off his head and his hands, returning with them to Rome as the most acceptable present to their cruel employer. Antony, who was then at Rome, received them with extreme joy, rewarding the murderer with a large sum of money, and ordering the head to be fixed upon the forum between two hands: a sad spectacle to the city; and what drew tears from every eye, to see those enraged members which used to exert themselves so gloriously from that place in defence of the lives, the fortunes, and the liberties of the Roman people, so lamentably exposed to the scorn of fycophants and traitors. The deaths of the rest, says an historian of that age, caufed only a private and particular sorrow; but Cicero’s an universal one. It was a triumph over the republic itself; and seemed to confirm and establish the perpetual slavery of Rome.

A modern writer, however, is of opinion, that * Scipio, "poulturity has been too much seduced by the name of * Scipio, worn, Try on Cicero, and that better citizens were sacrificed to the jealousy of the triumvirs without exciting so much indignation. If we take an impartial survey of the whole of Cato’s correspondence, and trace him through all the labyrinths of his contradictory letters, we shall find more to blame than to admire; and discover, that the desire of advancing his fortunes, and making himself a name, were, from his outset in life, the only objects he had in view. The good of his country, and the dictates of stern steady virtue, were not, as in Brutus and Cato, the constant springs of his actions. The misfortunes that befel him after his confufion, developed his character, and showed him in his true colours; from that time to his death, pusillanimity, irrefolution, and unworthy repining, tainted his judgment, and perplexed every hope he wilfully to take. He flattered Pompey and cringed to Caesar, while in his private letters he abused them both alternately. He acknowledges in a letter to his friend, the time-serving Atticus, that, although he was at present determined to support the cause of Rome and liberty, and to bear misfortune like a philosopher, there was one thing, which would gain him over to the triumvirs, and that was their procuring for him the vacant magistracy; so pitiful was the effufion of personal hatred. He therefore caused Cicero to be killed, as an angry man that has been stung by a venemous animal that comes within reach of his foot. The cloak he threw over the body of Brutus, and the speech he pronounced at the sight of that hero when dead, differ widely from the treat-ment he gave the remains of Cicero; and show, that he
CICERO

Cicero, made a distinction between a Roman who opposed him from political motives, and one whose enmity arose from private pique."

Cicero’s death happened on the 7th of December, in the 64th year of his age, about ten days from the settlement of the first triumvirate; and with him expired the short empire of eloquence among the Romans. As an orator he is thus characterized by Dr Blair. “In all his orations his art is conspicuous. He begins commonly with a regular exordium; and with much address prepossesses the hearers, and studies to gain their affections. His method is clear, and his arguments are arranged with exact propriety. In a superior clearness of method, he has an advantage over Demosthenes. Every thing appears in its proper place. He never tries to move till he has attempted to convince; and in moving, particularly the softer passions, he is highly successful. No one ever knew the force of words better than Cicero. He rolls them along with the greatest beauty and magnificence; and in the structure of his sentences is eminently curious and exact. He is always full and flowing, never abrupt. He amplifies every thing; yet though his manner is generally diffuse, it is often happily varied and accommodated to the subject. When an important public object roused his mind, and demanded indignation and force, he departs considerably from that loose and declamatory manner to which he at other times is addicted, and becomes very forcible and vehement. This great orator, however, is not without his defects. In most of his orations there is too much art, even carried to a degree of ostentation. He seems often deficient of obtaining admiration rather than of operating conviction. He is sometimes, therefore, flowery rather than solid, and diffuse where he ought to have been urgent. His sentences are always round and honorious. They cannot be accused of monotony, since they possess variety of cadence; but from too great a fondness for magnificence, he is on some occasions deficient in strength. Though the services which he had performed to his country were very considerable, yet he is too much his own panegyrist. Ancient manners, which imposed fewer restraints on the side of decorum, may in some degree excuse, but cannot entirely justify, his vanity."

CHICHORIUM, SUCCOMY: A genus of the polygama aequalis order, belonging to the syngenetica class of plants; and for the natural method ranking under the 49th order, Compositae. The receptacle is a little paleaceous; the calyx calculated; the pappus almost quinquedentated, and indifferently hairy.

Species. 1. The intybys, or wild succory, grows naturally by the sides of roads, and in shady lanes, in many places of Britain. It sends out long leaves from the roots, from between which the stalks arise, growing to the height of three or four feet, and branching out into smaller ones. The flowers come out from the sides of the stalks, and are of a fine blue colour. They are succeeded by oblong seeds covered, inclosed in a down. 2. The spinofum, with a prickly forked stalk, grows naturally on the sea-coasts in Sicily, and the islands of the Archipelago. This sends out from the root many long leaves which are inclosed on their edges, and spread flat on the ground; from between these arise the stalks, which have very few leaves, and those are small and entire; these stalks are dilated and spread in forks upward, and from between them come out the flowers, which are of a pale blue colour, and are succeeded by seeds shaped like those of the common endivia, or succory, with broad crested leaves, differing from the wild sort in its duration, being only annual, whereas the wild sort is perennial. 3. The endivia, or succory, with broad crested leaves, differs from the wild sort in its duration, being only annual, whereas the wild sort is perennial. 4. The last species may be considered both as an annual and biennial plant. If sown early in the spring, or even any time before the beginning of June, the plants very commonly fly up to feed the same summer, and perish in autumn. If sown in June and July, they acquire perfection in autumn, continue till the next spring, then shoot up stalks for flower and seed, and soon after perish. The inner leaves are the useful parts. These when blanched white to render them crisp and tender, and reduce them from their natural strong taste to an agreeably bitter one, are then fit for use. They are valued chiefly as ingredients in autumn and winter salads, and for some culinary uses. The principal season of them is from the latter end of August till Christmas or longer, according to the temperature of the season; though the curled kinds generally relish the frosts of our ordinary winters, and remain in tolerable perfection till March or April. They are propagated by seeds sown in an open spot of ground, from which the plants are to be removed into open beds or borders, where they may remain to grow to full size. The season for sowing these seeds is from the beginning of June to the end of July; and to have a regular supply of plants, it is proper to perform three different sowings at about three weeks or a month’s interval. The great excellence of endive is to have its inner leaves finely whitened or blanched. They naturally incline to whiteness of themselves; but this may be greatly improved by art when the plants are arrived at full growth. Different methods are practiced for this purpose, such as tying the leaves together; or taking up the plants, and replanting them directly, almost to their tops, in ridges of dry earth, laying boards or tiles flat-ways on the top of the plants; but the first is found to answer the purpose most effectually. The proper time for beginning this work is, when the leaves are already full grown; that is, when they are so far advanced that the leaves of the different plants interfere with one another, and their hearts are full and buoyant; but they are not all to be tied up at once, only a due supply of the largest and forwardest plants, once every ten or twelve days according to the demand; for the blanching takes up about three weeks. Blanching in ridges of earth, however, is sometimes practiced in winter when a severe frost is settling in; for by burying them in the earth almost to their tops, they are more out of the power of the cold. In November, or December, when hard weather is approaching, let a piece of light ground, that lies warm, be trenched up in one or more sharp ridges, two or three feet wide at bottom, and near as much in height; sideways to the sun, making the sides as deep as possible, that the wet may run quickly off; then, in a dry day, take up a quantity of your full grown plants,
Inflanls. The roots and leaves of the wild secory, and seeds of the endive, are articles of the materia medica. The first has a moderately bitter taste, with some degree of roughness: the leaves are somewhat less bitter; and the darker coloured and more deeply jagged they are, the bitterer is their taste. Wild secory is an useful detergent, aperient, and attenuating medicine, acting without much irritation, tending rather to cool than to heat the body; and, at the same time, corroborating the tone of the intestines.

All the parts of the plant, when wounded, yield a milky sapaneous juice. This, when taken in large quantities, so as to keep up a gentle diarrhrea, and by the verses of Petrarch in compliment to the beautiful Laura, and his numerous imitators.

CICINDELIA, the SPARKLER, in zoology, a genus of insects belonging to the order of coleoptera. The antennae are fetoceous; the jaws are prominent; and furnished with teeth; the eyes are a little prominent; and the breast is roundish and marginated. There are 14 species. The campestris, or field SPARKLER, is one of the most beautiful of the genus. The upper part of its body is of a fine green colour, rough, and rather bluish. The under side, as also the legs and antennae, are of a shot colour, gold and red, of copperish cast. The eyes are very prominent, and give the head a broad appearance. The thorax is angular, and narrower than the head; which constitutes the character of the cicindela. It is rough, and of a green colour tinged with gold, as well as the head. The elytra are delicately and irregularly dotted. Each of them has fix white spots, viz. one on the top of the elytron, at its outward angle: three more along the outward edge, of which the middlemost forms a kind of lunula; a fifth, on the middle of the elytra, opposite the lunula; and that one is broader, and tolerably round; lastly, a sixth, at the extremity of the elytra. There is also sometimes seen a black spot on the middle of each elytron, opposite to the second white spot. The upper lip is also white, as is the upper side of the jaws, which are very prominent and sharp. This insect runs with great swiftness, and flies easily. It is found in dry sandy places, especially in the beginning of spring. In the same place its larva is met with, which resembles a long, sooty, whitish worm, armed with fix legs, and a brown scaly head. It makes a perpendicular round hole in the ground, and keeps its head at the entrance of the hole to catch the insects that fall into it: a spot of ground is sometimes entirely perforated in this manner. The insects belonging to this genus are generally very beautiful, and merit the attention of the curious in their microscopic observations; some are minute, though not inferior in splendor, therefore best suited for the amusement. Living subjects are everpreferable to dead ones. The larve of all this genus live under ground; and are, as well as the perfect insects, tigers in their nature, attacking and destroying all they can overcome.

CICISBEO, an antilalian term, which in its etymology signifies a whisperer; which has been believed in Italy both on lovers, and on those who to outward appearance act as such, attending on married ladies with as much attention and respect as if they were their lovers. This Italian custom has been spoken of very respectfully by some writers: Mr. Baretti has taken great pains to vindicate it. He ascribes it to a spirit of gallantry, derived from the ages of chivalry, and much heightened and refined by the revival of the Platonic philosophy in Italy, about the thirteenth century; and by the verses of Petrarch in compliment to the beautiful Laura, and his numerous imitators.

CICLUT, or CICLUCH, a strong frontier town of Dalmatia, situated on the river Norenthia, in E. Long. 17. 40. N. Lat. 45. 20. It is surrounded with walls built in the ancient manner, and was taken by the Venetians from the Turks in 1694.

CICONES, a people of Thrace near the Hebrus. Ulysses at his return from Troy conquered them, and plundered their chief city Iamarus. They tore to pieces Orpheus for his obscene indulgencies.

CICUTA, properly signifies an hollow intercepted between two knots, of the stalks or reeds of which the ancient shepherds used to make their pipes. It is now, however, generally used to signify the water hemlock, and also the common fperm; but Linnaeus has described the latter under the old name of CONIUM. See that article.

There are three species of water-hemlock; the virofa, the bubiferba, and the maculata. Of these the first is the only one remarkable, and that for the poisonous qualities of its roots, which have been often known to destroy children who eat them for parsnips.

CICUTA is also used, chiefly among the ancients, for the juice or liquor expressed from the above plant, being the common poison wherewith the state criminals at Athens were put to death: Though some have suggested, that the poisonous draught to which the Athenians doomed their criminals was an impregnated juice compounded of the juice of cicuta and some other corrosive herbs.

Socrates drank the cicuta.—Plato, in his dialogue on the immortality of the soul, observes, that “The executioner advised Socrates not to talk, for fear of causing the cicuta to operate too quickly.” M. Petit in his Observationes Miscellaneae, remarks, that this advertisement was not given by the executioner out of humanity, but to save the cicuta; for he was only allowed to much poison per annum, which, if he exceeded, he was to furnish at his own expense. This construction is confirmed by a passage in Plutarch: the executioner who administered the cicuta to Phocion, not having enough, Phocion gave him money to buy more; observing by the way, that it was odd enough, that at Athens a man might pay for every thing, even his own death.

CID (Roderigo Dias le), a Caftilian officer, who was very successful against the Moors, under Ferdinand II. king of Castile; but whose name would hardly have been remembered, if Corneille had not made
CILC, the eye-lashes. See Anatomy, p. 766, col. 1.

CILIATED LEAF, among botanical writers, one surrounded with parallel filaments somewhat like the hairs of the eye-lids.

CILICIA, an ancient kingdom of Asia, lying between the 36th and 40th degree of north latitude; bounded on the east by Syria, or rather by Mount Amanus, which separates it from that kingdom; by Pamphylia, on the west; by Iauria, Cappadocia, and Armenia Minor, on the north; and by the Mediterranean sea, on the south. It is so surrounded by steep and craggy mountains, chiefly the Taurus and Amanus, that it may be defended by a handful of refolute men against a numerous army, there being but three narrow passes leading into it, commonly called Pyia Cilicia, or the gates of Cilicia; one on the side of Cappadocia, called the Pafs of Mount Taurus; and the other two called the Pafs of Mount Amanus, and the Pafs of Syria. The whole country was divided by the ancients into Cilia Afrca, and Cilia Campesria, the former called by the Greeks Trachrea or Stony, from its abounding with stones; and to this day the whole province is called by the Turks, Tas Wigleeth, or the Stony Province.

According to Josephus, Cilicia was first peopled by Tarshish the son of Javan, and his descendants, whence the whole country was named Tarbus. The ancient inhabitants were in process of time driven out by a colony of Phoenicians, who, under the conduct of Cilix, first settled in the island of Cyprus, and from thence puffed into the country which, from the leader, they called Cilicia. Afterwards, several other colonies from different nations settled in this kingdom, particularly from Syria and Greece; whence the Cilians in some places used the Greek tongue, in others the Syriac; but the former greatly corrupted by the Persian, the predominant language of the country, being a dialect of that tongue. We find no mention of the kings of Cilicia after the settlement in that country, till the time of Cyrus, to whom they voluntarily submitted, continuing subject to the Persians till the overthrow of that empire, but governed to the time of Alexander. He, being a conqueror, reduced all the provinces of the kingdom, and made Cilicia a province of the empire, and named it Thraciae and Cilicia. This province was divided by the Euphrates, into two parts called Thracae and Cilicia. The whole province is reckoned wholesome; but that on the sea-coast very dangerous, especially to strangers.

The rivers of any note are the Pyramus, which rises on the north side of Mount Taurus, and empties itself into the Mediterranean between Ifius and Magarais; and the Cydnus, which springs from the Antitaurus, passes through Tarbus, and diles the Mediterranean. This laft is famous for the rapidity of its stream, and the coldness of its waters, which prov'd very dangerous to Alexander the Great.

The Cilians, as we believe the Greek and Roman historians, were a rough unpolished race of people, unfair in their dealings, cruel, and liars even to a proverb. In the Roman times, they became greatly addicted to piracy. They first began, in the time of the Mithridatic war, to infest the neighbouring provinces along with the Pamphylians; and, being emboldened with success, they soon ventured as far as the coasts of Greece and Italy, where they took a vast number of slaves, whom they sold to the Cypriots and the kings of Egypt and Syria. They were, however, at last defeated and entirely suppressed by Pompey the Great. See (History of) Rome.

CILICIA TERRA, in the natural history of the ancients, a bituminous substance improperly called earth, which, by boiling, became tough like bird-line, and was used instead of that substance to cover the flocks of the vines for preferring them from the worms. It probably served in this office in a sort of double capacity,
CIM

CIMABUE, (Giovanni) a renowned painter, born at Florence in 1240, and the first who revived the art of painting in Italy. He painted, according to the custom of those times, in fresco and in different colours in oil not being then found out. He excelled in architecture as well as in painting; and was concerned in the fabric of Santa Maria del Fior at Florence: during which employment he died at the age of 60, and left many disciples.

CIMABRI, an ancient Celtic nation, inhabiting the northern parts of Germany. They are said to have been descended from the Alaric Cimmerians, and to have taken the name of Cimbrum when they changed their old habitations. When they first became remarkable, they inhabited chiefly the peninsula now called Jutland, and by the ancients Cymatium, or Chersefus. About 153 years before Christ, they left their peninsula with their wives and children; and joining the Teutones, a neighbouring nation, took their journey southward in quest of a better country. They first fell upon the Boii, a Gaulish nation situated near the Hercynian forest. Here they were repulsed, and obliged to move nearer the Roman provinces. The republic being then alarmed at the approach of such multitudes of barbarians, sent an army against them under the confuls Papirius Carbo. On the approach of the Roman army, the Cimbri made proposals of peace. The consul pretended to accept it; but having thrown them into a disadvantageous situation, treacherously attacked their camp. His perfidy was rewarded as it deserved; the Cimbri ran to arms, and not only repulsed the Romans, but, attacking them in their turn, utterly defeated them, and obliged the shattered remains of their forces to conceal themselves in the neighbouring woods. After this victory the Cimbri entered Transalpine Gaul, which they quickly filled with slaughter and devastation. Here they continued five or six years, when another Roman army under the consuls Silius marched against them. This general met with no better success than Carbo had done. His army was routed at the first onset; in consequence of which, all Narbonne Gaul was exposed at once to the ravages of these barbarians.

About 105 years before Christ, the Cimbri began to threaten the Roman empire itself with destruction. The Gauls marched from all parts with a design to join them, and to invade Italy. The Roman army was commanded by the proconsul Capio, and the consul Mallius; but as these two commanders could not agree, they were advised to separate, and divide their forces. This advice proved the ruin of the whole army. The Cimbri immediately fell upon a strong detachment of the consular army commanded by M. Aurelius Scaurus, which they cut off to a man, and made Scaurus himself prisoner. Mallius being greatly intimidated by this defeat, desired a reconciliation with Capio, but was haughtily refused. He moved nearer the consuls, however, with his army, that the enemy might not be defeated without his having a share in the action. The Cimbri, by this movement, imagining the commanders had made up their quarrel, sent ambassadors to Mallius with proposals of peace. As they could not help going through Capio's camp, he ordered them to be brought before him; but finding they were empowered to treat only with Mallius, he could scarcely be restrained from putting them to death. His troops, however, forced him to confer with Mallius about the proposals sent by the barbarians; but as Capio went to the consuls tent against his will, so he opposed him in every thing; contradicted with great obstinacy, and insulted him in the grossest manner. The deputies on their return acquainted their countrymen that the misunderstanding between the Roman commanders still subsisted; upon which the Cimbri attacked the camp of Capio, and the Gauls that of Mallius. Both were forced, and the Romans slaughtered without mercy. Eighty thousand citizens and allies of Rome, with 40,000 servants and followers, perished on that fatal day. In short, of the two Roman armies only 10 men, with the two generals, escaped to carry the news of so dreadful a defeat. The conquerors destroyed all the spoil, pursuant to a vow they had made before the battle. The gold and silver they threw into the Rhone, drowned the horses they had taken, and put to death all the prisoners.

The Romans were thrown into the utmost consternation on the news of so terrible an overthrow. They saw themselves threatened with a deluge of Cimbri and Gauls, numerous enough to over-run the whole country. They did not, however, despair. A new army was raised with incredible expedition; no citizen whatever who was fit to bear arms being exempted. On this occasion also, fencing-masters were first introduced into the Roman camp; by which means the soldiers were soon rendered in a manner invincible. Marius, who was at that time in high reputation on account of his victories in Africa, was chosen commander, and waited for the Cimbri in Transalpine Gaul: but they had resolved to enter Italy by two different ways; the Cimbri over the eastern, and the Teutones and other allies over the western Alps. The Roman general therefore marched to oppose the latter, and defeated the Ambroges and Teutones with great slaughter. The Cimbri, in the mean time, entered Italy, and struck the whole country with terror and remorse. Catullus and Sylla attempted to oppose them; but their soldiers were so intimidated by the fierce contemnaces and terrible appearance of these barbarians, that nothing could prevent their flying before them. The city of Rome was now totally defenceless.
The Cimbri, or Bug, in zoology, a genus of insects belonging to the order of hemiptera. The rostrum is inflected. The antennæ are longer than the thorax. The wings are folded together crossed-wise; the upper ones are coriaceous from their base towards their middle. The back is flat; the thorax margined. The feet are formed for running.

This genus is divided into different sections, as follows: 1. Thoe without wings. 2. Thoe in which the efchewon is extended so far as to cover the abdomen and the wings. 3. The coleopterati, whose elytra are wholly coriaceous. 4. Thoe whose elytra are membranaceous; these are very much deprefted like a leaf. 5. In which the thorax is armed on each side with a spine. 6. Thoe which are of an oval form, without spines on the thorax. 7. In which the antennæ become facets towards their point. 8. Thoe of an oblong form. 9. Thoe whose antennæ are facetous, and as long as the body. 10. Thoe which have their thighs armed with spines. 11. Thoe whose bodies are long and narrow. Linnaeus enumerates no fewer than 121 species, to which several have been added by other naturalists. A very peculiar species was discovered by Dr. Sparman at the cape, which he has named *Cimex paradoxi*. He observed it as at noon-tide he fought for shelter among the branches of a shrub from the intolerable heat of the sun. "Tho' the air (says he) was extremely still and calm, so as hardly to have shaken an leaf, yet I thought I saw a little withered, pale, crumpled leaf, eaten as it were by caterpillars, fluttering from the tree. This appeared to me to be of extraordinary, that I thought it worthy my while suddenly to quit my verdant bower in order to contemplate it; and I could scarcely believe my eyes, when I saw a live insect, in shape and colour resembling the fragment of a withered leaf, with the edges turned up and eaten away, as it were, by caterpillars, and at the same time all over beset with prickles. "Nature, by this peculiar form, has certainly extremely well defended and concealed, as it were, in a mask, this insect from birds and its other diminutive foes; in all probability with a view to preserve it, and employ it for some important office in the system of her economy; a system with which we are too little acquainted, in general too little investigate, and, in every part of it, can never sufficiently admire with that respect and veneration which we owe to the great Author of nature and Ruler of the universe."

The larvae of bugs only differ from the perfect insects by the want of wings; they run over plants; grow and change to chrysalids, without appearing to undergo any material difference. They have only rudiments of wings, which the last transformation unfolds, and the insect is then perfect. In the two first stages they are unable to propagate their species. In their perfect state, the female, fecundated, lays a great number of eggs, which are often found upon plants, placed one by the side of another; many of which, viewed through a glass, present singular varieties of configuration. Some are crowned with a row of small hairs, others have a circular fillet; and most have a piece which forms a cap; this piece the larva pushes off when it forces open the egg. Related by nature from their prison, they overspread the plant on which they feed, extracting, by the help of the rostrum, the juices appropriated for their nourishment; even in this state, the larvae are not all so peaceably inclined; some are voracious in an eminent degree, and spare neither sex nor species they can conquer. In their perfect state they are mere cannibals, glutting themselves with the blood of animals; they destroy caterpillars, flies, and even the coleopterous tribe, whose hardnecs of elytra one would imagine was proof against.
CIMIEFIGA, gainst their attacks, have fallen an easy prey to the
sharp piercing nature of the rottcrum of the bug, and
the uncautious naturalist may experience a feeling se-
verity of its nature. The cimex lectularius or house-
bug, is particularly acceptable to the palace of spiders
in general, and is even fought after by wood-bugs;
which is not indeed farprizing, when the general
vocality of this genus is considered.

The methods of expelling house-bugs are various, as
oil of turpentine, the smoke of corn-mint, of narrow-
leaved wild cres, of herb-robert, of the reddish agarine,
of maltard, Guirivs pepites, peats or turf, &c. (See
also Bug and CINIFUGA).

CIMIEFIGA, in botany: A genus of the poly-
andria order, belonging to the diccia clus of plants.
The male calyx is almost pentathylous; there is no cor-
olla; the flamina are 20 in number; the female calyx
is almost pentathylous; no corolla; the flamina 20,
and barren; the capsules from 4 to 7, polypermous.
Mefcherhmidius, in the Isis Siberica, gives it the fol-
lowing character and name: Cimiefiga satida, with the
leaves of the herb Christopher, bearing a thyrsis of
and that its
leaves of the herb Chriil:opher, bearing a thyrsis of
veffel
the

The money that he obtained by his

CIMMERII, anciently a people near the Palus
Mapoa. They invaded Asia Minor 1284 years before
Christ, and seized upon the kingdom of Cyaxares.
After they had been masters of the country for 28
years, they were driven back by Alyattes king of Ly-
dia.—The name also of another nation on the western
coast of Italy. The country which they inhabited
was supposed to be so gloomy, that to express
a great obscurity the exprefion of Cimmerian darknoff has pro-
verbially been used; and Homer, according to Plu-
tarch, drew his images of hell and
fas the earth; but which latter ages have suppor
ted to be on other than our tobacco-pipe clay and fuller's
cloth.

The cimolia terra of the ancients was found in fef-
eral of the islands of the Archipelago; particularly
in the island of Cimolus, from whence it has its name.
It was used with great success in the crypelas, in-
flammations, and the like, being applied by way of
catataphlum to the part. They also used, as we do,
what we call cimolia, or fuller's earth, for the cleaning
of clothes. This earth of the ancients, though not so long
regarded, and by many supposed to be lost, is yet
very plentiful in Argentiere (the ancient Cimolus),
Spanto, and many of those islands. It is a mafi of
the lax and crumby texture, and a pure bright white
colour, very fott to the touch. It adheres firmly to
the tongue; and, if thrown into water, raises a little
bubbling and ebullition, and moulders to a fine powder.
It makes a considerable effervescence with acids, and
suffers no change of colour in the fire. These are the
characters of what the ancients called simply terra ci-
nolia; but besides this, they had, from the same place,
another earth which they called by the fame general
name, but distinguished by the epithet purple, purp-
re-refcns. This they described to be fatitious, cold to the
touch, of a mixed purple colour, and nearly as hard
as a stone. And this was evidently the subflance we
call flesites, or the foap-rock; common in England
and also in the island of Argentiere, or Cimolus.

CIMOSIA ALBA, the officinal name of the earth of
which tobacco-pipes are made. Its distinctive charac-
ters are, that it is a dense, compact, heavy
earth, of a dull white colour, and very close texture;
it will not easily break between the fingers, and slight-
ly stains the skin in handling. It adheres firmly to
the tongue; melts very slowly in the mouth, and is not
readily diffusible in water. It is found in many places.
That of the isle of Wight is much esteemed for its co-
figure. Great plenty of it is found near Pole in Dorset-
shire and Wedensbury in Staffordhire, England.

CIMOSIA NIGRA, is a dark lead colour, hard, dry,
and heavy; of a smooth compact texture, and not vitifid:
itis not colour the hands; crumbles when dry;
adheres to the tongue; diffuses slowly in water;
and it is not acted upon by acids. It burns perfectly
white, and acquires a considerable hardmess. The chief
pits for this clay, in Britain, are near Northampton,
where it is used in the manufacture of tobacco-pipes.
It is also mixed with the critiche clay of Derbyshire, in
the proportion of one part to three, in the manufacture
of the hard redbrick ware.

CIMOLUS, (anc. geog.) one of the Cyclades, now
called Argentriere.

CIMON, an Athenian, son of Miltiades and He-
glippe. He was famous for his debaucheries in his
youth, and the reformation of his morals when arrived
to years of discretion. He behaved with great cour-
age at the battle of Salamis, and rendered himself pop-
ular by his munificence and valour. He defeated
the Persian fleet, took 200 ships, and totally routed
their land army, the very same day, A. U. C. 284.
The money that he obtained by his victories was not
applied for his own private use, but with it he fortified
and embellished the city. He some time after left all

B 2

his
On its first introduction into Europe, it was reprehended by many eminent physicians; and at different periods long after, it was considered a dangerous remedy; but its character, in processes of time, became very universally established. For a number of years, the bark which is rolled up into short thick quills, with a rough coat, and a bright cinnamon colour in the inside, which broke brittle, and was found, had an aromatic flavour, a bitter astringent taste, with a degree of aromatic warmth, was esteemed the best; though some esteemed the large pieces as of equal goodness. During the time of the late war, in the year 1779, the Hafiar frigate took a Spanish ship, loaded principally with Peruvian bark, which was much larger, thicker, and of a deeper reddish colour than the bark in common use. Soon after it was brought to London, it was tried in St Bartholomew's Hospital, and in other hospitals about town, and was said to be more efficacious than the quill bark. This put practitioners on examining into the history of the bark, on trying experiments with it, and on making comparative trials of its effects with those of the bark in common use on patients labouring under intermittent complaints. In July 1782, Dr William Saunders published an account of this red bark; in which he says, that the small quill bark used in England, is either the bark of young trees, or of the twigs or branches of the old ones; and that the large bark, called the red bark from the deep colour, is the bark of the trunk of the old trees; and he mentions a Mr Arnot, who himself gathered the bark from the trees in Peru; and Mons. Condamine, who gives an account of the tree in the Memoirs of the Academy of Sciences at Paris in the year 1738; who both say, that taking the bark from an old tree effectually kills it; but that the molt of the young trees which are barked, recover, and continue healthy; and that for these reasons the Spaniards now barked the younger trees for foreign markets, though they still imported into Spain some of the bark of the old trees, which they esteemed to be much more efficacious than what was got from the young. From these accounts Dr Saunders concludes, that the large red bark brought to London in the year 1779 was of the same kind as that used by Sydenham and Morton, as answering to the description of the bark used in their time, which is given by Dale and other writers on the materia medica, who were their contemporaries. Dr Saunders says, that it is not only stronger and more reinos, but likewise more efficacious and certain in its effect, than the common bark, and had cured many agues after the other had failed.

A species of cinchona has also been discovered in the West India Islands, particularly in Jamaica: It is accurately described by Dr Wright, under the title of *Cinchona Jamaicaefis*; in a paper published in the Philosophical Transactions. In Jamaica it is called the *fruit-side beech*, and grows from 20 to 40 feet high. The white, furrowed, thick outer bark is not used; the dark-brown inner bark has the common flavour, with a mixed kind of a taste, at first of horse-radish and ginger, becoming at last bitter and astringent. It seems to give out more extraneous matter than the cinchona officinalis. Some of it was imported from St. Lucia, in consequence of its having been used with advantage in the army and navy during the late war; and it has lately been treated of at considerable length by Dr. 
Cinchona.

Dr. Keith, under the title of St Lucia bark. The fresh bark is found to be considerably emetic and cathartic, which properties it is said to lose on drying.

The pale and the red are chiefly in use in Britain. The pale is brought there in pieces of different sizes, either flat or quilled, and the powder is rather of a lighter colour than that of cinnamon. The red is generally in much larger, thicker, flatish pieces, but sometimes also in the form of quills, and its powder is reddish like that of Armenian balsam. As already observed, it is much more resinous, and possesses the febile qualities of the cinchona in a much higher degree than the other sorts; and the more nearly the other kinds resemble the red bark, the better they are now considered. The red bark is heavy, firm, found, and dry; friable between the teeth; does not separate into fibres; and breaks, not shivery, but short, close, and smooth. It has three layers: the outer is thin, rugged, of a reddish brown colour, but frequently covered with mossy matter; the middle is thicker, more compact, darker coloured, very resinous, brittle, and yields a tint to the pemoe: the innermost is more woody, fibrous, and of a brighter red.

The Peruvian bark yields its virtues both to cold and boiling water; but the decoction is thicker, gives out its taste more readily, and forms an ink with a chalky white more suddenly than the fresh cold infusion. This infusion, however, contains at least as much extractive matter, but more in a state of solution; and its colour, on standing some time with the chalybeate, becomes darker, while that of the decoction becomes more faint. When they are of a certain age, the addition of a chalybeate renders them green; and when this is the case, they are found to be in a state of fermentation, and effete. Mild or caustic alkalies, or lime, precipitate the extractive matter, which in the case of the caustic alkali is redissolved by a farther action of the alkali. Lime-water precipitates lefs from the fresh infusion than from a decoction; and in the precipitate of this last some mild earth is perceptible. The infusion is by age reduced to the same state with the fresh decoction, and then they depose nearly an equal quantity of mild earth and extractive matter; so that lime-water, as well as a chalybeate, may be used as a test of the relative strength and perishable nature of the different preparations, and of different barks. Accordingly cold infusions are found by experiments to be less perishable than decoctions; infusions and decoctions of the red bark than of the pale; those of the red bark, however, are found by length of time to separate more mild earth with the lime-water, and more extractable matter. Lime-water, as precipitating the extractive matter, appears an equally improper and disagreeable menstruum.

Water is found to suspend the resin by means of much less gum than has been supposed. Rectified spirit of wine extracts a bitterness, but no astringency, from a residuum of 20 infusions of cold water; and water extracts astringency, but no bitterness, from the residuum of as many infusions of rectified spirit. The residua in both are impure.

From many ingenious experiments made on the Peruvian bark by Dr. Irvine, which are now published in a dissertation which gained the prize-medal given by the Harveian Society of Edinburgh for 1783, the power of different menstrua, as acting upon Peruvian Cinchona, is ascertained with greater accuracy than had before been done: and it appears, that with respect to comparative power, the fluids after mentioned are in the order in which they are placed.

Dulcified spirit of vitriol.
Caustic lea.
French brandy.
Rhenish wine.
Soft water.
Vinegar and water.
Dulcified spirit of nitre.
Mild volatile alkali.
Rectified spirit of wine.
Mild vegetable alkali.
Lime-water.

The antiseptic powers of vinegar and bark united are double the sum of those taken separately. The astringent power of the bark is increased by acid of vitriol; the bitter taste is destroyed by it.

The official preparations of the bark are, 1. The powder: of this, the first parcel that passes the sieve being the most resinous and brittle layer, is the strongest. 2. The extract: the watery and spirituous extract conjoined form the most proper preparations of this kind. 3. The tincture: this cannot perhaps be obtained separate from the gummy part, nor would it be desirable. 4. Spirituos tincture: this is best made with proof-spirit. 5. The decoction: this preparation, though frequently employed, is yet in many respects inferior even to a simple watery infusion.

The best form is that of powder; in which the constituent parts are in the most effectual proportion. The cold infusion, which can be made in a few minutes by agitation, the spirituous tincture, and the extract, are likewise proper in this respect. For covering the tafes, different patients require different vehicles; liquorice, aromatics, acids, port-wine, small beer, porter, milk, butter milk, &c. are frequently subjected, and may be given in form of electuary or with brandy or rum.

Practitioners have differed much with regard to the mode of operation of the Peruvian bark. Some have ascribed its virtues entirely to a stimulant power. But while the strongest and most permanent stimuluses have no means the same effects with bark in the cure of diseases, the bark itself shows hardly any stimulant power, either from its action on the stomach, or on other febile parts to which it is applied. From its action on dead animal fibres, there can be no doubt of its being a powerful astringent; and from its good effects in certain cases of disease, there is reason to presume that it is a still more powerful tonic. To this tonic power some think that its action as an antiseptic is to be entirely attributed; but that, independently of this, it has a very powerful effect in retarding the septic process to which animal substances are naturally subjected, appears beyond all dispute, from its effects in retarding purification, not only in dead animal solids, but even in animal fluids, when entirely detached from the living body.

But although it be admitted that the Peruvian bark acts powerfully as an astringent, as a tonic, and as an anti-
CINCHONA. antifeptic; yet these principles will by no means explain all the effects derived from it in the cure of diseases. And accordingly, from no artificial combination in which these powers are combined, or in which they exist even in a higher degree, can the good consequences resulting from Peruvian bark be obtained. Many practitioners, therefore, are disposed to view it as a specific. If by a specific we mean an infallible remedy, it cannot indeed be considered as intituted to that appellation; but in as far as it is a very powerful remedy, of the operation of which no satisfactory explanation has yet been given, it may with great propriety be denominated a specific. But whatever its mode of operation may be, there can be no doubt that it is daily employed with success in a great variety of different diseases.

It was first introduced, as has already been said, for the cure of intermittent fevers; and in these, when properly exhibited, it rarely fails of success. Practitioners, however, have differed with regard to the mode of exhibition; some prefer giving it just before the fit, some during the fit, others immediately after it. Some, again, order it in the quantity of an ounce, between the fits; the dose being the more frequent and larger according to the frequency of the fits; and this mode of exhibition, although it may perhaps sometimes lead to the employment of more bark than is necessary, we consider as upon the whole preferable, from being less liable to muffle stomachs. The requisite quantity is very different in different cases; and in many, vernal intermittent fevers, it is daily employed with success in a great variety of different diseases.

It often pukes or purges, and sometimes oppresses the stomach. These, or other effects which may take place, are to be counteracted by remedies particularly appropriated to them. Thus, vomiting is often restrained by exhibiting it in wine; looseness by combining it with opium; and oppression at the stomach, by the addition of an aromatic. But unless for obviating particular occurrences, it is more successful when exhibited in its simple state than with any addition; and there seems to be little ground for believing that its powers are increased by crude sal ammoniac, or any other additions which have frequently been made.

It is now given, from the very commencement of the disease, without previous evacuations, which, with the delay of the bark, or under doses of it, by retarding the cure, often seems to induce abdominal inflammation, fcarlet, jaundice, hectic, dropy, &c. Symptoms formerly imputed to the premature or intemperate use of the bark, but which are but infrequent by its early and large use. It is to be continued not only till the paroxysms cease, but till the natural appetite, strength, and combination return. Its use is then to be gradually left off, and repeated at proper intervals to secure it against a relapse; to which, however unaccountable, independently of the recovery of vigour, there often seems to be a peculiar disposition; and especially when the wind blows from the east. Although, however, most evacuants conjoined with the Peruvian bark in intermittent fevers are rather prejudicial than otherwise, yet it is of advantage, previous to its use, to empty the alimentary canal, particularly the stomach; and on this account good effects are often obtained from premixing an emetic.
Cinna, (L. Corn.) a Roman who oppressed the slaves he defeated his enemies, and made tavius for attempting to make the fugitive subject at one end from the base, and at the other from the capital. Cincture, in architecture, a ring, lid, or ori-lo, at the top and bottom of the shaft of a column, separating the shaft at one end from the base, and at the other from the capital.

CINEAS, a Thessalian, minister and friend to Pyrrhus king of Epirus. He was sent to Rome by his master to sue for a peace, which he, however, could not obtain. He told Pyrrhus that the Roman senate was a venerable assembly of kings; and observed, that to fight with them was to fight against another Hydra. He was of such a retentive memory, that the day after his arrival at Rome he could call every senator and knight by his name.

CINERITIOUS, an appellation given to different substances, on account of their resembling ashes either in colour or consistence; hence it is that the cortical part of the brain has sometimes got this epithet.

CINNA, (L. Corn.) a Roman who oppressed the republic with his cruelties. He was banished by the populace for the heinous crimes he committed, and was afterward considered as a traitor to his enemies, and made himself useful even to a fourth time. He massacred so many citizens at Rome, that his name became odious; and one of his officers assassinated him at Ancona, as he was preparing war against Sylla.

CINNA, (C. Helvius) a poet intimate with Cæsar. He went to attend the obsequies of Cæsar, and being mistaken by the populace for the other Cinna, he was torn to pieces.—Also a kinsman of Pompey’s. He conspired against Augustus, who pardoned him, and made him one of his most intimate friends. He was consul A. U. C. 758, and made Augustus his heir.

CINNABAR, in natural history, is either native or fabricated.

The native cinnabar is an ore of quicksilver, moderately compact, very heavy, and of an elegant striated red colour.

Fabricatus cinnabar is a mixture of mercury and sulphur sublimed, and thus reduced into a fine red globe. It is a very valuable substance, being of a high colour, and full of fibres like needles. See Chemistry, p. 1404.

The chief use of cinnabar is for painting. Although the body is composed of sulphur, which is of a light colour, and mercury which is white as silver, it is nevertheless of an exceeding strong red colour. Lumps of it are of a deep brown red without brilliancy; but when the too great intensity of its colour is diminished by bruising and dividing it into small parts, (which is a method generally used to lessen the intensity of all colours), the red of the cinnabar becomes more and more excelled, flame-coloured, and exceedingly vivid and brilliant; in this state it is called vermilion.

Cinnabar is often employed as an internal medicine. Hoffman greatly recommends it as a sedative and antispasmodic: and Stahl makes it an ingredient in his temperant powder. Other intelligent physicians deny that cinnabar taken internally has any medicinal quality. Their opinion is grounded on the insolvency of this substance in any menstruum. This question concerning its internal utility cannot be decided without further researches and experiments; but cinnabar is certainly used in succeas to procure a mercurial “fa- vor” in the patient, when that method of cure is proper in vesicular diseases. For this purpose it is burnt in an open fire on red-hot coals, by which the mercury is difengaged and forms vapours, which, being applied to the body of the diseased person, penetrate through the pores of the skin, and produce effects similar to those of mercury administered by friction.

CINNAMON, the bark of two species of laurus. The true cinnamon is from the Laurus cinnamomum; and the bafe cinnamon, which is often fold for the true, is from the laurus callis. See Laurus.

CINNAMON-WATER, is made by distilling the bark first infused in spirit of wine, brandy, or white wine.

Close-Cinnamon, is the bark of a tree growing in Brazil, which is often substituted for real cloves.

White Cinnamon, called also Winter’s bark, is the bark of a tree frequent in the isle of St Domingo, Guadeloupe, &c. of a sharp biting taste like pepper. Some use it instead of nutmeg; and in medicine it is esteemed a homoeopathic and antiscorbutic. See Cinnamomum.

CINNAMOMUM, a Greek historian, wrote a history of the eastern empire, during the reigns of John and Manuel Comnenus, from 1118 to 1143. His style is reckoned the best of the modern Greek authors. He died after 1183.

CINNAR, CINNAR, Chinnerth, (Moses); or Genefareth, (anc. geog.) a lake of the Lower Galilee; called the Sea of Galilee, (Matthew); of Thibe­rius, (John). Its name Genefareth is from a small cunominal district upon it. In breadth 40 stadia, in length 140. The water fresh and fit to drink, and abounding in fish.

CINQUEFOIL, in botany. See POTENTILLA.

CINQUE-PORTS, five havens that lie on the east port of England, towards France: thus called by way of eminence on account of their superior importance, as having been thought by the kings to merit a particular regard for their preservation against invasion. Hence they have a particular policy, and are governed by a keeper, with the title of Lord-warden of the Cinque-ports.
CINQ appointed a warden of the Cinque-ports: but King John first granted them their privileges; and that up­on condition they should provide 80 ships at their own charge for 40 days, as often as the king should have occasion in the wars; he being then thrainted for a navy to recover Normandy.

The five ports are, Hastings, Romney, Hythe, Dover, and Sandwich.—Thorn tells us, that Ha­flings provided 21 vessels, and in each vessel 21 men. To this port belong Seaford, Pevensey, Hedney, Winchelsea, Rye, Hamine, Wakebourn, Creneth, and Fortclipe.—Romney provided five ships, and in each 24 men. To this belong Brounhal, Lyde, Of­wardstone, Dangemares, and Romenhal.—Hythe fur­nished five ships, and in each 21 seamen. To this belongs Westmesteth.—Dover the same number as Haflings. To this belong Folkeston, Feverham, and Marge.—Lastly, Sandwich furnished the same with Hythe. To this belong Fordwich, Reculver, Serre, and Deal.

The privileges granted to them in consequence of these services were very great. Among others, they were each of them to fend two barons to represent them in parliament; their deputies were to bear the canopy over the king's head at the time of his coro­nation, and to dine at the uppermost table in the great hall on his right hand; to be exempted from fuf­ficiencies and other aids; their heirs to be free from personal wardship, notwithstanding any tenure; to be impleaded in their own towns, and not elsewhere; not to be liable to tolls, &c.

The Cinque-ports give the following titles: Ha­flings, a barony to the ancient family of Huntington: Romney, to the Marthams: Dover, new barony, to a branch of the York family; formerly a dukedom (now extinct) to the Queenenberry family: Sandwich, an earldom to a branch of the Montagues.

CINTRA, a cape and mountain of Portugal, in the province of Estremadura, usually called the Rock of Lisbon. It lies on the north side of the entrance of the river Tajo; and there is a town of the same name situated thereon. W. Long. 15. N. Lat. 59°. 8'.

CINUS, or CYRUS, a famous civilian of Ptolema in the 14th century. His commentary on the Code was finished in 1313: he also wrote on some parts of the digests. He was no less famous for his Italian poems; He was no less famous for his Italian poems; generally translated eithera, lyra, or psalterium, are the same. It was made of wood, and was played on in the temple of Jerusalem. Josephus says that the cynthia of the temple had ten strings, and that it was touched with a bow. In another place he says that Solomon made a great number of them with a precious kind of metal called eleuthra; wherein he contradicts the scriptures, which inform us that Solomon's cinnors were made of wood.

CINVRAS, (fab. hist.) a king of Cyprus, son of Paphus. He married Cenchreis, by whom he had a daughter called Myrrha. Myrrha fell in love with her father, and in the absence of her mother she introduced herself into his bed by means of her nurse. Cin­yras had by her a son called Adonis; and when he knew the incest he had committed, he attempted to stab his daughter, who escaped his pursuit and fled to Arabia, where, after she had brought forth, she was changed into a tree which still bears her name. Cinyras, ac­cording to some, flabled himself.

CION, or CION, in gardening, a young shoot, sprout, or sprig, put forth by a tree. Graffing is per­formed by the application of the cion of one plant upon the fock of another. To produce a flock of cions for grafting, planting, &c. the gardeners sometimes cut off the bodies of trees a little above the ground, and only leave a lump or root standing: the redundant sap will not fail next spring to put forth a great number of shoots. In dressing dwarf-trees, a great many cions are to be cut off.

CIOBAT, a sea-port town of Provence in France; famous for Muchaline wine. It is seated on the bay of Laques, between Marcelli and Toulon; and the harbour is defended by a strong fort. E. Long. 5°. N. Lat. 42°. 10'.

CIPHER, or CYPHER, one of the Arabic charac­ters or figures used in computation, formed thus, 0. See ARITHMETIC.

Cipher is also a kind of enigmatical character, com­posed of several letters interwoven, which are generally the initial letters of the persons names for whom the ciphers are intended. These are generally used on seals, coaches, and other moveables.—Anciently, merchants and tradesmen were not allowed to bear arms: in lieu thereof, they bore their ciphers, or the initial letters of their names, artfully interwoven about a crofs; of which we have divers instances on tombs, &c. See DEVISE.

Cipher, denotes likewise certain secret characters disguised and varied, used in writing letters that contain some secret, not to be understood but by those between whom the cipher is agreed on.

De la Guillctiere, in his Lacedamou ancien and mo­dern, endeavours to make the ancient Spartans the in­ventors of the art of writing in cipher. Their cytala, according to him, was the first sketch of this mysteri­ous art: thes cytala were two rollers of wood, of equal length and thickness; one of them kept by the ephori; the other by the general of the army lent on any expedition against the enemy. Whoneover those magistrates would send any secret orders to the general, they took a flip of parchement, and rolled it very justly about the cytala which they had reserved; and in this state wrote their intentions, which appeared perfect and consistent while the parchement continued on the roll: when taken off, the writing was maimed, and without connexion: but was easily re­trieved by the general, upon his applying it to his cytala.

Polybius says, that Aneas Tactitus, 2000 years ago, collected together 20 different manners of writing so as not to be understood by any but those in the fe­cret; part whereof were invented by himself, and part used before his time.—Thithemiush, Cap. Porta, Vigene­rre, and P. Niccron, have written expressely on the subject of ciphers.

As the writing in cipher is become an art; so is the reading or unravelling thereof, called deciphering.—The rules of deciphering are different in different lan­guages. By observing the following, you will soon make out any common cipher written in English.

1. Observe
1. Observe the letters or characters that most frequently occur; and let them down for the six vowels, including y, and of these the most frequent will generally be e, and the least frequent u.

2. The vowels which most frequently come together are ea and au.

3. The consonant most common at the ends of words is s, and the next frequent r and t.

4. When two similar characters come together, they are most likely to be the consonants f, l, or r, or the vowels e or u.

5. The letter that precedes or follows two similar characters is either a vowel, or f, m, n, or r.

6. In deciphering, begin with the words that consist of a single letter, which will be either a, f, m, or r.

7. Then take the words of two letters, one of which will be a vowel. Of these words the most frequent are, an, to, ly, ot, or, no, fo, at, if, in, it, he, me, my, us, we, am.

8. In words of three letters there are most commonly two consonants. Of these words the most frequent are, the, and, not, but, yet, for, the, how, why, all, you, the, his, her, or, who, may, can, did, was, are, has, had, let, one, two, six, ten, &c. Some of these, or those of two letters, will be found in every sentence.

9. The most common words of four letters are, this, that, the, there, this, with, when, from, here, some, none, they, them, whom, mine, your, self, maif, will, have, four, four, four, nine, &c.

10. The most usual words of five letters are, these, those, which, more, while, since, their, shall, might, could, would, ought, three, seven, eight, &c.

11. Words of two or more syllables frequently begin with double consonants, or with a preposition; that is, a vowel joined with one or more consonants. The most common double consonants are bl, br, dr, fl, fr, gl, gr, ph, pl, pr, fr, lb, sb, fl, th, tr, wh, wh, &c. and the most common prepositions are com, con, de, dis, ex, in, in, int, mis, per, pro, re, sb, sup, un, &c.

12. The double consonants most frequent at the end of long words are, ck, cl, ls, ma, ad, ng, ri, rs, re, ri, &c. and the most common terminations are, ed, en, er, es, ex, ing, ly, son, for, you, time, able, ence, ent, ment, full, less, neil, &c.

On Plate CXXXVII.* fig. 7, is given an example of a cipher wrote in arbitrary characters as is commonly practiced. It will be easily deciphered by observing the rules: but when the characters are all placed close together, as in the example fig. 8, and as they always should be, the deciphering is much more difficult.

To decipher a writing of this sort, you must first look for those characters that most frequently occur, and let them down for vowels as before. Then observe the similar characters that come together; but you must remember that two such characters may here belong to two words. You are next to remember the combinations of two or three characters that are most frequent; which will be some of the words in the seventh and eighth of the foregoing rules; and by observing the other rules, you will infallibly discover, with time and attention, any cipher wrote on these principles.

When the words are wrote all close together, if the key to the cipher were to be changed every word, according to a regular method agreed on between the parties, as might be done by either of the methods mentioned in No. II. below, with very little additional trouble, the writing would then be extremely difficult to decipher. The longer any letter wrote in cipher is, the more easy it is to decipher, as then the repetitions of the characters and combinations are more frequent.

The following are the contents of the two foregoing ciphers: in which we have inverted the order of the words and letters, that they who are desirous of trying their talent at deciphering, may not, inadvertently, read the explanation before the cipher.

Unen ton dna shtmmol cowl ech, smadisrep dna leare o noinai & cndrup kof klkl liw noy: on, roist, teelgen & cenerfedihni si t. ylrosh retel a en dnes ot sneam emof diif rehit, trach eht morf semoc ti tahc eec em tel &; erom ecay ym ees or erad reu ven ro. evlew fo ruoh eht ta thign silt, ledatic eht fo etag eht crosf ebmelwa llwh snicrif rau lla. ruoh eht ot lautemdep eb: deraperp lom eqnun dna, ytrebl ruoy niager ot, ylevar eed ro. thign eht si silt, su sekam rehitc tah, etiq xu seudro no.

Contrivances for communicating intelligence by Cypher.

1. By means of a pack of cards. The parties must previously agree in what manner the cards shall be first placed, and then how they shall be shuffled. Thus suppose the cards to be first placed in the order hereafter follows, and then shuffled by taking off 3 from the top, putting the next 2 over them, and the following 3 under them, &c. and so alternately. Therefore the parties who sends the cipher first writes the contents of it on the on a separate paper, and then copies the first 32 letters on the cards, by writing one letter on every card; lie then shuffles them in the manner described, and writes the second 32 letters: lie shuffles them a second time, by 2 to put and writes the third 32 letters, and so of the rest. All under is to be written as this may make this plain. Suppose the letter to last be as follows:

I am in full march to relieve you; within three days
I shall be with you. If the enemy in the mean time
should make an assault, remember what you owe to your country, to your family, and yourself. Live with boulour, or die with glory.

Order of the cards before the 1st shuffle.

Queen.
You may as a Cipher.

He left at each end of the two weights being right line will be much more obvious than in the other

and at the beginning of your letter you make boards, ILMN, moveable round the centre

ed: then for one of the letters of the alphabet.

The same intention

exam. Suppose you would write as follows: "If you will come over to us, you shall have a petition, and you may still make a firm opposition." You begin with the letters Ma, which show how the dial is fixed: then for If you, you write an jue, and for the rest, as you will see at fig. 6.

The same intention may be answered by a ruler, the upper part of which is fixed and the lower part made to slide: but in this case the upper part must contain two alphabets in succession, that some letter of that part may constantly correspond to one in the lower part.

The divisions standing directly over each other in a straight line will be much more obvious than in the circumference of a circle. Or two straight pieces of pasteboard regularly divided, the one containing a single and the other a double alphabet, would answer exactly the same purpose. In this case a blank space may be left at each end of the single alphabet, and one or two weights being placed on both the pieces will keep them steady.

III. The corresponding spaces. Take two pieces of pasteboard or stiff paper, through which you must cut long squares, at different distances, as you will see in the following example. One of these pieces you keep yourself, and the other you give to your correspondant.

When you would send him any secret intelligence, you lay the pasteboard upon a paper of the same size; and in the spaces cut out, you write what you would have understood by him only, and then fill up the intermediate spaces with somewhat that makes with those words a different sense.

I shall be much obliged to you, as reading [alone] engages my attention at [present], if you will lend me any one of the [eight] volumes of the Spectator. I hope you will excuse [this] freedom, but for a winter's [evening] I don't [know] a better entertainment. If I fail to return it soon, never trust me for the time to come.

A paper of this sort may be placed four different ways, either by putting the bottom at the top, or by turning it over; and by these means the superfluous words may be the more easily adapted to the sense of the others.

This is a very eligible cipher, as it is free from suspicion, but it will do only for short messages: for if the spaces be frequent, it will be very difficult to make the concealed and obvious meanings agree together: and if the sense be not clear, the writing will be liable to suspicion.

IV. The musical cipher. The construction of this cipher is similar to that of No. II. The circle EFGH (fig. 3) is to be divided into twenty-six equal parts, in each part there must be written one of the letters of the alphabet: and on the anterior circle ILMN, moveable round the centre O, there is to be the same number of divisions: the circumference of the inner circle must be ruled in the manner of a music paper; and in each division there is to be placed a note, differing either in figure or position. Lastly, within the musical lines place the three keys, and on the outer circle, the figures that are commonly used to denote the time.

Then provide yourself with a ruled paper, and place one of the keys, as figure of that of F, against the time two-fourths at the beginning of the paper, which will inform your correspondant how to fix his circle. You then copy the notes that answer to the several letters of the words you intend to write, in the manner expressed at fig. 5.

A cypher of this sort may be made more difficult to discover by frequently changing the key, and that will not in the least embarras the reader. You may likewise add the mark $ or $ to the note that begins a word, which will make it more easy to read, and at the same time give the music a more natural aspect. This cipher is preferable to that of No. II. above, as it may be enclosed in a letter about common affairs, and pass unsuspected.

CIPUS, in antiquity, a low column, with an inscription, erected on the high roads, or other places, to show the way to travellers: to serve as a boundary; to mark the grave of a deceased person, &c.
CIR, (St) a village of France, two miles from Versailles, remarkable for a nunnery founded here by Louis XIV. The nuns are obliged to take care of the education of 250 girls, who must prove their families to have been noble from the 4th generation on the father's side. They cannot enter before 7, nor after 12 years of age; and they continue there till they are 20 years and 3 months old. The house is a most magnificent structure.

CIRCASSIA, Enchanters Nightshade: A genus of the monogynia order, belonging to the diadema class of plants; and in the natural method ranking under the 48th order, Aggregata. The corolla is dipetalous; the calyx diphyalous, superior, with one bilocular seed. There are two species, one of which is a native of Britain, and the other of Germany. They are low herbaceous plants with white flowers, and polished of no remarkable property.

Circassia, a large country of Asia, situated between 45 and 50 degrees of north latitude, and between 40 and 50 of east longitude. It is bounded by Russia on the north; by Afiiran and the Caspian sea on the east; by Georgia and Dagistian on the south; and by the river Don, the Palsus Meoris, and the Black Sea, on the west. This country has long been celebrated for the extraordinary beauty of its women; and here it was that the practice of inoculating for the small-pox first began. Terki, the principal city, is seated in a very spacious plain, very swampy, towards the sea-side, in 43 deg. 23 min. north latitude: it is about three miles in compass, well fortified with ram-parted bastions in the modern style, well flored with cannon, and has always a considerable garrison in it, under the command of a governor. The Circassian prince who resides here, is allowed five hundred Ruffians for his guard, but none of his own subjects are permitted to dwell within any part of the fortifications. Ever since the reduction of those parts to the obedience of Russia, they have put in all places of strength, not only Russian garrisons and governors, but magistrates, and priests for the exercise of the Christian religion; yet the Circassian Tartars are governed by their own princes, lords, and judges; but those adminis- ter justice in the name of the emperor, and in matters of importance, not without the presence of the Ruffian governors, being all obliged to take the oath of allegiance to his imperial majesty. The apparel of the men of Circassia is much the same with that of the Nagays; only their caps are something larger; and their cloaks being likewise of coarse cloth or sheep skins, are fastened only at the neck with a string, and as they are not large enough to cover the whole body, they turn them round according to the wind and weather. The men here are much better favoured than those of Nagaya, and the women extremely well shap- ped, with exceeding fine features, smooth clear complexions, and beautiful black eyes, which, with their black hair hanging in two tresses, one on each side the face, give them a most lovely appearance: they wear a black coif on their heads, covered with a fine white cloth tied under the chin. During the summer they all wear only a smock of divers colours, and that open so low before, that one may see below their navels: this, with their beautiful faces always uncovered (con- trary to the custom of most of the other provinces in their parts), their good humour and lively freedom in conversation, altogether render them very attractive; notwithstanding which they have the reputation of being very chaste, though they seldom want opportunity; for according to the accounts of a late traveller, it is an established point of good manners among them, that as soon as any person comes in to speak to the wife, the husband goes out of the house, but whether this contin­ uency of theirs proceeds from their own generosity, to compensate their husbands for the confidence they put in them, or has its foundation only in fame, he pretends not to determine. Their language they have in common with the other neighbouring Tartars, although the chief people among them are also not ignorant of the Russian; their religion is Paganism; for notwithstanding they are circumcised among them, they have neither priest, alcoran, or mosque, like other Mahometans. Every body here offers his own sacrifice at pleasure; for which, however, they have certain days, establisht rather by custom than any positive command: their most solemn sacrifice is offered at the death of their nearest friends: upon which occasion both men and women meet in the field to be present at the offering, which is an he goat; and having killed, they flay it, and stretch the skin with the head and horns on, upon a cros at the top of a long pole, placed commonly in a quickset hedge (to keep the cattle from it); and near the place the sacrifice is offered by boiling and roasting the flesh, which they afterwards eat. When the feast is over, the men ride, and having paid their adoration to the skin, and muttered over some prayers, the women withdraw, and the men conclude the ceremony with drinking a great quantity of aquavitae; and this generally ends in a quarrel before they part. The face of the country is pleasantly diversified with mountains, valleys, woods, lakes, and rivers; and though not much cultivated, is far from being unfruit- ful. In summer the inhabitants quit the towns, and encamp in the fields like the neighbouring Tartars: occasionally shifting their stations along with their flocks and herds. Besides game, in which the country greatly abounds, the Circassians eat beef and mutton; but that which they prefer to all others is the flesh of a young horse. Their bread consists of thin cakes of barley meal, baked upon the hearth, which they always eat new; and their usual drink is water or mares milk; from the latter of which they distil a spiri-tis, as most of the Tartar nations. They allow no fixed hours for the refreshments of the table or sleep, which they indulge irregularly, as inclination or convenience dictates. When the men make excursions into an enemy's country, they will pass several days and nights successively without sleeping; but, at their return, de­vote as much time to repose as the space in which they had before with-held from that gratification. When they eat, they sit cross-legged on the floor, the skin of some animal serving them instead of a carpet. In removing from one part of the country to another, the women and children are carried in waggons, which are a kind of travelling houses, and drawn by oxen or camels, they never using horses for draught. Their breed of the latter, however, is reckoned exceeding good; and they are accustomed to swim almost any river on horseback. The women and children smoke tobacco as well as the men; and this is the most accept-
Circles. which indeed are come among them. — The principal branch of their traffic is the Greek church; but there are also both Mahometans and Pagans among them. The others, are said to be extremely careful of their own children, especially their daughters, whom they sell for the sake of the feragels in Turkey and Persia, where they frequently marry to great advantage, and make the fortune of their families. The merchants who come from Constantinople to purchase those girls, are generally Jews, who, as well as the notion at Colchis, whom to Paphia the wife of Minos.

She was expelled by her subjects, and married by her father upon the coasts of Italy in an island called Aera. Ulysses, at his return from the Trojan war, visited her coasts; and all his companions, who ran headlong into pleasure and forget his glory in Circe's arms. At his departure the nymph adviced him to descend to hell the first, and have their periphery either on its moveable surface, or in another immovable, concentric, and equidistant surface. See SPHERE. Most of the feasts of the Romans were accompanied with Circean games; and the magistrates, and other officers of the republic, frequently presented the people with them, in order to procure their favour. The grand games were held five days, commencing on the 15th of September. See CIRCUS.

CIRCLES in geometry, a plane figure comprehended by a single curve line, called its circumference, to which eight lines drawn from a point in the middle, called the centre, are equal to each other. See GEOMETRY.

Circles of the Sphere, are such as cut the mundane sphere, and have their periphery either on its moveable surface, or in another immovable, concentric, and equidistant surface. See SPHERE. Hence arise two kinds of circles, moveable and immovable. The first, those whose peripheries are in the moveable surface, and which therefore revolve with its diurnal motion; as, the meridians, &c. The latter having their periphery in the immovable surface, do not revolve; as the ecliptic, equator, and its parallels, &c. See GEOGRAPHY.

Circles of Altitude, otherwise called almucantar, are circles parallel to the horizon, having their common pole in the zenith, and still diminishing as they approach the zenith. See ALMUCANTAR.

Diurnal Circles, are moveable circles, supposed to be described by the seven stars, and other points of the heavens, in their diurnal rotation round the earth; or rather, in the rotation of the earth round its axis. The diurnal circles are all unequal: the equator is the biggest.

Horary Circles, in dialing, are the lines which show the hours on dials; though these be not drawn circular, but nearly straight. See DIALING.

Circles of Latitude, or Secondaries of the Equator, are great circles parallel to the plane of the equator, passing through the poles thereof, and through every star and planet. They are so called, because they serve to measure the latitude of the stars, which is nothing but an arch of one of these circles intercepted between the star and the equator. See LATITUDE.

Circles of Longitude, are several lesser circles, parallel to the equator; still diminishing, in proportion as they recede from it. On the arches of these circles, the longitude of the stars is reckoned.

Circles of perpetual Apparition, one of the lesser circles, parallel to the equator; described by any point of the sphere touching the northern point of the horizon; and carried about with the diurnal motion. All the stars included within this circle never set, but are ever visible above the horizon.

Circles of perpetual Occultation, is another circle at a like distance from the equator; and contains all those stars which never appear in our hemisphere. The stars situated between these circles alternately rise and set at certain times.

Polar Circles, are immovable circles parallel to the equator; and at a distance from the poles equal to the greatest declination of the ecliptic. That next the northern pole is called the Arctic; and that next to the southern one the Antarctic.

Fairy-Circle. See FAIRY-CIRCLE.

Druidal Circles, in British topography, a name given to certain ancient inclosures formed by rude stones circularly arranged, in the manner represented on Plate CXXXV.* Thefe, it is now generally agreed, were temples, and many writers think also places of solemn assemblies for councils or elections, and feats of judgment. Mr Borlace is of this opinion. "Instead therefore (says he), of detaining the reader with a dispute, whether they were places of worship or council, it may with great probability be affirmed, that they were used for both purposes; and having for the most part been first dedicated to religion, naturally became afterwards the curiae for the same community." These temples, though generally circular, occasionally differ as well in figure as in magnitude: with relation to the first, the most simple were composed of one circle: Stonehenge consisted of two circles and two ovals, respectively concentric; whilst that at Borricke near St Just in Cornwall is formed by four intersecting circles. And the great temple at Abury in Wilshire,
CIR

CIRCLES of the Empire, such provinces and principalities of the German empire as have a right to be considered alternately by each other, both directly and indirectly. The Emperor, as in logic, or Logical Circle, is when the same terms are proved in orbem by the same terms; and the parts of the syllogism alternately by each other, both directly and indirectly. CIRCLES of the Empire, such provinces and principalities of the German empire as have a right to be presented at diets. Maximilian I. divided the empire into six, and four years after into ten circles. This last division was confirmed by Charles V. The circles, as they stand in the Imperial Matricola, are as follows: Austria, Burgundy, the Lower Rhine, Bavaria, Upper Saxony, Franconia, Swabia, Upper Rhine, Westphalia, and the Lower Saxony.

CIRCONCELLIONES, a species of fanatics, so called because they were continually rambling round the houses in the country. They took their rise among the donatists, in the reign of the emperor Constantine. It is incredible what ravages and cruelties these vanguards committed in Africa through a long series of years. They were illiterate, savage, brutal, and understood only the Punic language. Intoxicated with a barbarous zeal, they renounced agriculture, professed continence, and assumed the title of "Vindicators of Justice, and Protectors of the Oppressed." To accomplish their mission, they enthrall'd slaves, scour'd the roads, forced markets to alloys from their chariots, and run before their slaves, whom they obliged to mount in their place; and discharged debars, killing the creditors if they refused to cancel the bonds. But the chief objects of their cruelty were the catholics, and especially those who had renounced donatism. At first they used no words, because God had forbidden the use of one to Peter; but they were armed with clubs, which they called the "clubs of Israel" and which they handled in such a manner as to break a man's bones without killing him immediately, so that he languished a long time and then died. When they took away a man's life at once, they looked upon it as a favour. They became locs scrupulous afterwards, and made use of all sorts of arms. Their font was "Pray for us to God." These words in their mouths were the signs of their hatred, more terrible than the roaring of a lion. They had invented an unheard of punishment, which was to cover with lime dipped with vinegar, the eyes of those unhappy wretches whom they had crushed with blows, and covered with wounds, and to abandon them in that condition. Never was a stronger proof what horrors superstition can beget in minds destitute of knowledge and humanity. These brutes, who had made a vow of chastity, gave themselves up to wine and all sorts of impurities, running about with women and young girls as drunk as themselves, whom they called "sacred virgins," and who often carried proofs of their incontinence. Their chiefs took the name of Chiefs of the Saints. After having glutted themselves with blood, they turned their rage upon themselves, and fought death with the same fury with which they gave it to others. Some scrambled up to the tops of rocks, and cast themselves down headlong in multitudes; others burned themselves, or threw themselves into the sea. Those who proposed to receive the title of martyrs, published it long before; upon which they were feated and fattened like oxen for the slaughter; after those preparations they set out to be destroyed. Sometimes they gave money to those whom they met, and threatened to murder them if they did not make them martyrs. Theodorat gives an account of a stout young man, who meeting with a troop of these fanatics, contented to kill them, provided he might bind them; and having by this means put it out of their power to defend themselves, whipped them as long as he was able, and then left them tied in that manner. Their bishops pretended to blame them, but in reality made use of them to intimidate such as might be tempted to forfake their faith; they even honoured them as saints. They were not, however, able to govern those furious monsters; and more than once found themselves under a necessity of abandoning them, and even of imploring the assistance of the secular power against them. The counts Ursin and Taninus were employed to quell them; they destroyed a great number of them, of whom the donatists made as many martyrs. Ursin, who was a good catholic and a religious man, having lost his life in an engagement with the barbarians, the donatists did not fail to triumph in his death, as an effect of the vengeance of heaven. Africa was the theatre of these bloody scenes during a great part of Constantine's life.

CIRCUIT, in law, signifies a longer course of proceedings than is needful to recover the thing sued for.

CIRCUIT, in England, also signifies the journey or progress, which the judges take twice every year, through several countries of England and Wales, to hold courts and administer justice, where recourse cannot be had to the king's courts at Westminster; hence England is divided into six circuits, viz. the Home circuit, Norfolk circuit; Midland circuit; Oxford circuit; Western circuit, and Northern circuit. In Wales there are but two circuits, North and South Wales: two judges are assigned by the king's commissio to every circuit.

In Scotland, the judges of the supreme criminal court, or court of judicature, are divided into three separate courts, consisting of two judges each; and the kingdom into as many districts. In certain counties, a rouls of every district, each of these their by rota-
Circulation

As to the velocity of the circulating blood, and the time wherein the circulation is completed, several computations have been made. By Dr. Kell’s account, the blood is driven out of the heart into the aorta with a velocity which would carry it twenty-five feet in a minute; but this velocity is continually abated in the progress of the blood, in the numerous divisions or branches of the arteries; so that before it arrive at the extremities of the body, its motion is greatly diminished. The space of time wherein the whole mass of blood ordinarily circulates, is variously determined. Some state it thus: Supposing the heart to make two thousand pulses in an hour, and that at every pulse there is expelled an ounce of blood; as the whole mass of blood is not ordinarily computed to exceed twenty-four pounds, it must be circulated seven or eight times over in the space of an hour.

The curious, in microscopic observations, have found an easy method of seeing the circulation of the blood in the bodies of animals: for these require it is necessary to choose such animals as are small, and easily manageable, and which are either wholly or in part transparent. The observations made by this means are preferable to any others we can have recourse to; since, in diseased states, the animal is in a state of pain, or dying; whereas in animals small enough to be thus viewed, all is left in its usual course, and we see what nature does in her own undisturbed method. In these creatures also, after viewing, as long as we please, the natural state and current of the blood, we may, by pressure, and several other ways, impede its course; and by putting various mixtures into the creature’s water, induce a morbid state, and finally see the creature die, either by means of this or by any other method; and we may thus accurately observe all the changes it undergoes, and see what occasions the trembling pulse, etc. of dying people.

The current of the blood in small animals, that is, its passage on through the vessels, either to or from the heart, is very easily seen by the microscope; but its circulation, that is its running to the extremities of the parts, and thence returning, is more difficult; because the vessels where this should be seen are so extremely minute, as not easily to come under observation. The larger arteries are easily distinguished from the veins by the motion of the blood through them, which in the veins is always smooth and regular; but in the arteries by several propulsions after the manner of pulsation. But this difference is not to be found in the more minute vessels; in all which, as well arteries as veins, the motion of the blood is even and regular.

The transparent membrane, or web between the toes of a frog’s hinder foot, is a very proper object to observe the circulation of the blood in. The tails or fins of fishes are also very fine objects; and when the fish is very small, these are manageable, and afford a view of a great number of veins and arteries, with a very quick and beautiful succession of blood through them. The tail of a flounder may be very conveniently placed before the double microscope on a plate of glass; and its body being supported by something of equal height, the fish will lie still, and the circulation may be seen very agreeably. In the minute vessels thus examined, the blood always appears pale.

CIRCULAR, in a general sense, any thing that is described, or moved in a round, as the circumference of a circle, or surface of a globe.

CIRCULAR Numbers, called also spherical ones, according to some, are such whose powers terminate in the roots themselves. Thus, for instance, 5 and 6, all whose powers do end in 5 and 6, as the square of 5 is 25; the square of 6 is 36, etc.

CIRCULAR Sailing, is the method of failing by the arch of a great circle. See Navigation.

CIRCULATION, the act of moving round, or in a circle; thus we say, the circulation of the blood, etc.

CIRCULATION of the Blood, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart into all parts of the body, by the arteries, from whence it is brought back to the heart again by the veins. See Anatomy, n° 125.

In a foetus, the apparatus for the circulation of the blood is somewhat different from that in adults. The septum, which separates the two auricles of the heart, is pierced through with an aperture, called the foramen ovale; and the trunk of the pulmonary artery, a little after it has left the heart, sends out a tube into the descending aorta, called the communicating canal.

The foetus being born, the foramen ovale closes by degrees, and the canal of communication dries up, and becomes a simple ligament.
Circulation, pale or colourless, but in the large ones it is manifestly red. The arteries usually branch out extremely before they join the veins to carry the blood back to the heart: but this is not always the case; for Mr. Lewenhoek has observed, that on each side of the little gristles which give a diffuse to the tail of a fish, there may be seen a very open communication of the veins and arteries; the blood running towards the extremities through arteries, and returning back again through veins, which were evidently a continuation of those arteries, and of the same diameter with them. The whole fish on the tail of which this examination was made, was not more than half an inch in length, it is easy to conceive, therefore, how small the tail must be; and yet in it there were six veins which carried and returned the blood; and yet these vessels were far from being the most minute of all. How inconceivably numerous then must the circulations in the whole human body be? Mr. Lewenhoek is of opinion, that a thousand different communications are continually carried on in every part of a man's body in the breadth of a finger nail. The tail of a newt or water-lizard affords also a very entertaining prospect of the circulation of the blood through almost numberless small vessels; but no object flows it so agreeably as one of these animals while so young as not to be above an inch long; for then the whole body is so very transparent, that the circulation may be seen in every part of it, as well as in the tail; and, in these objects, nothing is more beautiful than the course of the blood into the toes and back again, where it may be traced all the way with great ease. Near the head there are also found three small fins which afford a very delightful prospect: all are divided like the leaves of polypody; and in every one of the branches of these, the blood may be very accurately traced, running to the end through the artery, and there returning back again by a vein of the same size, and laid in the same direction; and as the vessels are very numerous and large in this part, and the third or fourth magnifier may be used, there are sometimes seen 30 or 40 channels of running blood at once; and this the more as the globules of blood in the newt are large, and are fewer in number, in proportion to the quantity of serum, than in any other animal: and their figure, as they are protruded through the vessels, changes in a very surprising manner. The immense occasioning the circulation, is great enough in some animals to raise the blood six, seven, or eight feet high from the blood-vessel it springs out at; which, however, is far exceeded by that of the sap of a vine in bleeding time, which will sometimes rise forty feet high.

Circulation of the Jap of Plants. See Plants, and Anatomy, p. 132.

Circulation, in chemistry, is an operation where-by the same vapour, raised by fire, falls back, to be returned and distilled several times.

Circulation of the Spirits, or Nervous Fluid. See Anatomy, p. 132.

Subterranean Circulation. See Springs.

Circulus, in chemistry, an iron instrument in form of a ring, which being heated red-hot, and applied to the necks of retorts and other glass vessels till they grow hot, a few drops of cold water thrown upon them, or a cold blast, will make the necks fly regularly and evenly off.

Another method of doing this, is to tie a thread, first dip it in oil of turpentine, round the place where you would have it break; and then setting fire to the thread, and afterwards sprinkling the place with cold water, the glass will crack exactly where the thread was tied.

Circumambient, an appellation given to a thing that surrounds another on all sides; chiefly used in speaking of the air.

Circumcelliones. See Circumcelliones.

Circumcision, the act of cutting off the prepuce; a ceremony in the Jewish and Mahometan religions, wherein they cut off the foreskin of their males, who are to profess the one or the other law. Circumcision commenced in the time of Abraham; and was, as it were, the seal of a covenant stipulated between God and him. It was in the year 2173, that Abraham, by divine appointment, circumcised himself, and all the males of his family; from which time it became an hereditary practice among his descendants.

The ceremony, however, was not confined to the Jews: Herodorus and Philo Judeus observe, that it obtained also among the Egyptians and Ethiopians. Herodorus says, that the custom was very ancient among each people; so that there was no determining which of them borrowed it from the other. The same historian relates, that the inhabitants of Colchis also used circumcision; whence he concludes, that they were originally Egyptians. He adds, that the Phcenicians and Syrians were likewise circumcised; but that they borrowed the practice from the Egyptians. And lastly, that a little before the time when he wrote, circumcision had palled from the Colchis, to the people inhabiting near Thermodoxon and Parthenius.

Marham is of opinion, that the Hebrews borrowed circumcision from the Egyptians; and that God was not the first author thereof; citing Diodorus Siculus, and Herodorus, as evidences on his side. This latter historian seems directly contrary to the testimony of Moses, who affiems, Gen. xvii. that Abraham, tho' 99 years of age, was not circumcised till he had the express command of God for it. But as to the former position of Marham, it will admit of more debate. The arguments on both sides may be seen in one view in Spencer de Legibus Hebraeorum. l. 2. c. 4.

Be this as it will, it is certain the practice of circumcision among the Hebrews differed very considerably from that of the Egyptians. Among the first it was a ceremony of religion, and was performed on the eighth day after the birth of the child. Among the latter, a point of mere decency and cleanliness; and, as some will have it, of physical necessity; and was not performed till the 1st year, and then on girls as well as boys.

Among the Jews, the time for performing this rite was the eighth day, that is, six full days, after the child was born: the law of Moses ordained nothing with respect to the person by whom, the instrument with which, or the manner how, the ceremony was to be perform-
CIRCUMCISION. The child is usually circumcised at home, where the father, or godfather, holds him in his arms, while the operator takes hold of the prepuce with one hand, and with the other cuts it off; a third person holds a pincer, with hand in it, to catch the blood; than the operator applies his mouth to the part, and, having sucked the blood, spits it into a bowl of wine, and throws a hyposic powder upon the wound. This ceremony was usually accompanied with great rejoicings and feasting; and it was at this time that the child was named in presence of the company. The Jews invented several superstitious customs at this ceremony, such as placing three tolls, one for the circumcisor, the second for the person who holds the child, and the third for Elijah, who, they say, affists invisibly at the ceremony, &c.

The Jews distinguished their proleutes into two forts, according as they became circumcised or not: those who submitted to this rite were looked upon as children of Abraham, and obliged to keep the laws of Moses; the uncircumcised were only bound to observe the precepts of Noah, and were called noachites.

The Turks never circumcise till the seventh or eighth year, as having no notion of its being necessary to salvation. The Persians circumcise their boys at 13, and their girls from 9 to 15. Tho' of Madagascar cut the file at three several times; and the most zealous of the relations present, catches hold of the preputium and swallows it.

Circumcision is practised on women by cutting off the foreskin of the clitoris, which bears a near resemblance and analogy to the preputium of the male penis. We are told that the Egyptian captive-women were circumcised; and also the subjects of Prester John.

CIRCUMCISION is also the name of a feast, celebrated on the first of January, in commemoration of the circumcision of our Saviour.

CIRCUMDUCTION, in Scots law. When parties in a suit are allowed a proof of allegiances; after the time limited by the judge for taking that proof is elapsed, either party may apply for circunduction of the time of proving; the effect of which is, that no proof can afterwards be brought, and the cause must be determined as it stood when circunduction was obtained.

CIRCUMFERENCE, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense, for the curve line which bounds a circle, and otherwise called a periphery; the boundary of a right-lined figure being expressed by the term perimeter.

CIRCUMFERENCE, or circumferentor, an instrument used by surveyors for taking angles.

It consists of a brass index and circle, all of a piece. The index is commonly about 14 inches long, and an inch and a half broad; the diameter of the circle is about seven inches. On this circle is made a chart, whose meridian line answers to the middle of the breadth of the index, and is divided into 360 degrees. There is a brass ring foldered on the circumference of the circle, on which screws another circumference, with a flat glass in it, so as to form a kind of box for the needle, suspended on the pivot in the centre of the circle. There are also two sights to screw on, and slide up and down the index; as also a square and socket screwed on the back side of the circle for putting the head of the staff in.

How to observe the Quantity of an Angle by the Circumferentor. Let it be required to find the quantity of the angle EKG; first place your instrument at E, with the flower-de-luce of the chart towards you; then direct your sights to E, and observe what degrees are cut by the south end of the needle, which let be 256; then, turning the instrument about, direct your sights to G, noting then also what degrees are cut by the south end of the needle, which suppose 247. This done, always subtract the lesser from the greater, as in this example, 247 from 256, the remainder is 9 degrees, which is the true quantity of the angle EKG.

A circumferentor is made by Mr Jones of Holburn on an improved construction. From a very simple contrivance, it is rendered sufficient to take angles with the accuracy of a common theodolite; and by it angles of altitude or depression may be observed as readily as horizontal ones. The improvement chiefly consists in an arm or index (G), so applied to the centre of the compass box, and within it, that, at the time of observing, by only flipping a pin (a) out, the circle of degrees alone may move round, and leave the index (G) fixed. This index will remain stationary, from its being attached to the socket that screws on the head of the staffs. On the end of this index, next the degrees in the box, there is graduated a nonius scale, by which the circle of 360 degrees is subdivided into 5 minutes or less if desired. To take angles of altitude or depressions, the instrument is turned down on its ball and socket into a perpendicular position, and adjusted to its level by a plumb line (i), that is hung on a pin at the back of the box, and made to coincide with a mark made thereon. Then by looking through the small sight holes (e) purposely made, the angles are shown on the circle of degrees by the nonius as before. The arms (AA) of the instrument slip off (at BB), and the whole packs into a case but 3¼ inches square and 3 deep.

CIRCUMFLEX, in grammar, an accent, serving to note or distinguish, a syllable of an intermediate sound between acute and grave; and generally somewhat long.—The Greeks had three accents, the acute, the grave, and the circumflex; formed thus, ' ' ' ' ' ' In Latin, English, French, &c. the circumflex is made thus:—The acute raises the voice, and the grave falls or lowers it: the circumflex is a kind of modulation, or wavering of the voice, between the two. It is seldom used among the moderns, unless to show the omission of a letter which made the syllable long and open; a thing much more frequent in the French than among us: thus they write pain for pains; tete for tete; faimes for faumes, &c. They also use the circumflex in the participles; some of their authors writing connue, pue, others connue, pue, &c. Father Buffler is at a loss for the reason of the circumflex on this occasion.

The form of the Greek circumflex was anciently the same with that of ours, viz. "; being a composition of the
the other two accents a in one—But the copyists, changing the form of the characters, and introducing the running-hand, changed also the form of the circumflex accent; and instead of making a just angle, rounded it off, adding a daff, through too much haste; and thus formed an s, laid horizontally, which produced that figure " instead of this ".

CIRCUMGIRDATION, denotes the whirling motion of any body round a centre; such is that of the planets round the sun.

CIRCUMLOCATION, an ambages, or tour of words, used either when a proper term is not at hand, to express a thing naturally and immediately by; or when one chooses not to do it, out of respect, or for some other reason. The word comes from circle location, “ I speak about.”

CIRCUMLOCUTION, in oratory, is the avoiding of something disagreeable or inconvenient to be expressed in direct terms; by intimating the sense thereof in a kind of paraphrase, so conceived as to soften or break the force thereof.

Thus Cicero, unable to deny that Claudius was slain by Milo, owns it, with this circumlocution, “ Milo’s “ friends being prevented from affixing their mallet, “ who was reported to be killed by Claudius; they, in " his absence, and without his privity, or consent, did " what every body would expect from their own " wants on such an occasion.”

CIRCUMPOLAR STARS, an appellation given to those stars, which, by reason of their vicinity to the pole, move round it without setting.

CIRCUMPOTATIO, in antiquity, a funeral feast provided in honour of the dead. This was very frequent among the ancient Romans, as well as among the Athenians. Solon at Athens, and the decemviri at Rome, endeavoured to reform this custom, thinking it absurd that mirth and drunkenness should mingle with sorrow and grief.

CIRCUMSCRIBED, in geometry, is said of a figure which is drawn round another figure, so that all its sides or planes touch the inscribed figure.

CIRCUMSCRIPTION, in natural philosophy, the termination, bounds, or limits, of any natural body.

CIRCUMSTANCE, a particularity, which, though not essential to any action, yet doth some way affect it.

CIRCUMSTANTIAL EVIDENCE, in law, or the doctrine of presumption, takes place next to positive proof; circumstances which either necessarily or usually attend facts of a particular nature, that cannot be demonstratively evinced, are called presumptions, and are only to be relied on till the contrary be actually proved.

CIRCUMSTANTIBUS, in law, a term used for supplying and making up the number of jurors (in case any impannelled appear not, or appearing are challenged by any party), by adding to them so many of the persons present as will make up the number, in case they are properly qualified.

CIRCUMVALLATION, or Line of Circumvalation, in the art of war, is a trench bordered with a parapet, thrown up quite round the besieger’s camp, by way of security against any army that may attempt to relieve the place, as well as to prevent defection.

CIRCUMVOLUTION, in architecture, denotes the torus of the spiral line of the Ionic order.

CIRCUS, in antiquity, a large building, either round or oval, used for the exhibiting of shows to the people. Some derive the word from Circus, to whom Tertullian attributes the invention. Callisthenes says, Circus comes à circuitu. The Romans, Servius observes, at first had no other circus but that made by the Tiber on one side, and a palisade of naked swords on the other. Hence, according to Hidore, came the term ludi circenses, quaerit circumfero. But Scaliger ridicules that etymology.

The Roman circus was a large oblong edifice, arch’d at one end; encompassed with porticos, and furnished with rows of seats, placed ascending over each other. In the middle was a kind of foot-bank, oreminence, with obelisks, statues, and pots at each end. This served them for the courses of their biga and quadrigae. There were no less than ten circuses at Rome: the largest was built by the elder Tarquin, called Circus Maximus, between the Aventine and Palatine mounts. It was so called, either because of its vast circumference, or because the great games were celebrated in it; or again, because it was consecrated to the great gods, viz. to Vertumnus, Neptune, Jupiter, Juno, Minerva, and the Dii Penates of Rome. Livy says it was three stadia and a half in length, and four jugera broad; and those measures, according to Pliny, allowing to the Roman stadiα 625 Roman feet, each of which is 12 inches, will give for the length 2187 Roman feet, or somewhat more than three English furlongs; and as to the breadth, allowing for each of the jugera 240 Roman feet, it will be 950 Roman feet. It was beautified and enlarged by the Roman emperors, so as to seat 250,000 spectators. The most magnificent circuses were those of Augustus and Nero. There are still some remains of the circuses at Rome, at Nîmes, and other places. The Romans were excessively fond of the games exhibited in the circus; witness that verve in Juvenal, 

Atque dies tantum res animi opus, 
Panem & circenses –

The Games of the Circus, which some call Circensive Games, were combats celebrated in the circus, in honor of Conatus the god of concuits; and hence also called Consualia. They were also called Roman Games, Ludi Romani, either on account of their antiquity, as being coeval with the Roman people, or because established by the Romans; and the games held there, the great games, ludi magni, because celebrated with more expense and magnificence than others; and because held in honour of the great god Neptune, who was their Conatus. Those who say they were instituted in honor of the sun, confound the pompa circensis, or procession of the circus, with the games. The games of the circus were instituted by Evander, and re-established by Romulus: the pomp, or procession, was only a part of the games, making the prelude thereof, and confisting of a simple cavalcade of chariots. Till the time of the elder Tarquin, they were held on an island of the Tiber; and were called Roman games: after that prince had built the circus, they took their name therefrom; as being confantly there. There were six kinds of exercises in the
CIRENCETER, an ancient town of Gloucestershire in England. It was strongly fortified with walls and a castle in the time of the Romans. The ruins of the walls and street are, or were lately, to be seen in the adjacent meadows, where many Roman coins, chequered pavements, and inscriptions on marble, have been found. Two of the Roman confular ways cross each other at this town. The folle-way, which comes from Scotland, passes through this county and town to Totnes in Devonshire. The other, called Irminstreet, comes from Gloucester, and runs along to Southampton. Not many years ago they discovered, by digging in a meadow near the town, an ancient building under ground, 50 feet long, 40 broad, and 4 high, and supported by two brick pillars, curiously inlaid with stones of various colours, supposed to have been a Roman bath. Cirencester has now but one church, in the windows of which are the remains of very valuable painted glasses. The town is governed by 2 high constables, and 14 wardens, who govern 7 distinct wards; and it sends 2 members to parliament. It has a free school, a charity school, with several almshouses; and is seated on the river Churn, 36 miles north-east of Bristol, and 83 west by north of London. W. Long. o. 2. N. Lat. 51. 42.

CIRENZA, a city of Naples, capital of the Basilicata, with an archbishop's see. It was formerly a colony, but is not of very small consequence. It is seated on the river Bradano, at the foot of the Apennine mountains, in E. Long. 16. 44. N. Lat. 45. 49.

CIRO-FERRI, an excellent Italian painter and architect, was born at Rome in 1614, and was the disciple of Peter de Cortona, whose designs he imitated with such exactness that he is difficult to distinguish from them. He was elected by pope Alexander VII. and his three successors, and died at Rome in 1689.

CIRRUS, or CIRRHUS, in botany, a clasper or tendril; that fine spiral string or fibre put out from the foot-stalks, by which some plants, as the ivy and vine, fasten themselves to walls, pales, or trees, for support. The term is synonymous to the capreolus, clavicula, and viticulus of other botanists; and is ranked by Linnaeus among the fulcra, or parts of plants that serve for protection, support, and defence.

Tendrils are sometimes placed opposite to the leaves, as in the vine; sometimes at the side of the foot-stalk of the leaf, as in passion-flower; and sometimes, as in winged pea, pi ken ochrus, they are emitted from the leaves themselves. With respect to composition, they are either simple, that is, composed of one fibre or chord, as in the vetch; or compound, that is, consist of two, three, or more, as in the everlasting pea. Bitter sweet, solanum, dulcamara, bignonia, and ivy, send forth tendrils which plant themselves like roots in the adjacent walls, or the bark of the neighbouring trees. Claspers, says the ingenious Dr Grew, are like trunk-roots, a mean between a root and a trunk, but a compound of both, as may be gathered from their circumvolutions, in which they mutually ascend and descend. In the mounting of the trunk, continues the same author, claspers serve for support. Thus in vines, the branches being very long, fragile, and flender, would be liable to frequent breaking, unless, by means of their claspers, they were mutually contained together; so that the whole care is divided between the gardener and nature: the former, with his ligaments of leather, secures the main branches; and nature, with those of her own providing, secures the leaf. Their attitude to this end is seen in their convolutions, a motion not proper to any other part: and also in their toughness, which is so much the more remarkable, as they are flenderer than the branches from which they proceed. In the trailing of the trunk, tendrils serve for stability and shade: thus, in cucumbers, the trunk and branches being long and fragile, would be driven to and fro by the winds, to the great prejudice both of themselves and their tender fruits; were they not, by these ligaments, held fast together, and preferred in association and good fellowship. The same claspers serve likewise for shade so that a natural arbour is formed by the branches of the cucumber, in the same manner as an artificial one is made by twining together the twigs of trees; for the branches, by the linking of their claspers, being couched together, the tender fruits lie under the shade of abower made of their own leaves. Most of the pea-bloom flowers have twining claspers, that is, which wind to the right and back again.

CIRRI, in ichthyology, certain oblong and soft appendages, not unlike little worms, hanging from the undershadows or mouths of some fishes: these claspers, commonly translated beards, afford marks to distinguish the different species of the fishes on which they are found.

CIRTA, (anc. geog.) the metropolis and royal residence, not far from the river Ampsiga, in the inland parts of Numidia Propria. A colony, named Colonia Sittianorum, very rich, when in the hands of Syphax. The colony was led by one P. Sittius, under the auspices of Caesar, and was named Julia. Now called Conflantina, in Algiers. E. Long. 7. o. Lat. 35. 30.

CISALPINE, any thing on this side the Alps. The Romans divided Gaul and the country now called Lombardy into Cisalpine and Transalpine. That which was Cisalpine with regard to the Romans, is Transalpine with regard to us.

CISLEU, in Hebrew chronology, the ninth month of their ecclesiastical, and third of their civil, year, answering nearly to our November.

CISPADANAGALLIA, (anc. geog.) a district of Italy, to
CISTERCIANS. [27] CISTERN.

to the south of the Po, occupied by the Gauls in the time of the kings of Rome, separated from Liguria on the west, as is thought by the Iria, running from south to north into the Po; bounded on the south by the Apennine, and on the east by the Adriatic. The term is formed analogically, there being much mention in Ciceron, Taccius, Diogenes, and ancient inscriptions, made of the Transpadani; which and Gipadani are terms used with respect to Rome. Ptolemy calls the Gipadana peculiarly Calla Tagata, extending between the Po and Apenine, to the Sapis and Rubicon.

Cissa, or Cissum, (anc. geog.) a town of the Iberian Spain, in Lacteria, on the east side of the Iberus, (thought to be Grissena.) Where the Carthaginians were first defeated by Scipio. Another Cissi of Thrace, situated on the River Agos Potamus, which Scylax seems to call Cresia, or Gressia; so that the reading is doubtful.

Cissampelos, in botany: A genus of the monocarpean order, belonging to the dioecia class of plants; and in the natural method ranking under the 11th order, Sarmentae. The male calyx is tetraphyllous; no corolla; the nectarium wheel-shaped; poor stamina with their filaments grown together. The female calyx is monophyllous and ligulatus roundish, or like a piece of garrer a little roundish. There is no corolla; three styles; and a monoporous berry. There are two species, the pareira and caspeba, both natives of the warmest parts of America. The root of the second, applied externally, is said to be an antidote against the bites of venomous serpents. The plant being infused in water, quickly fills the liquor with a mucilaginous substance, which is as thick as jelly; whence the name of freezing-myth, by which this genus of plants has been disfigiluted by the Brazilians.

Cissoid, in geometry, a curve of the second order, first invented by Diocles, whence it is called the cissis of Diocles. See FLUXIONS.

Cissus, the Wild Grapes. A genus of the monogynia order, belonging to the tetrandria class of plants; and in the natural method ranking under the 46th order, Hederaceae. The berry is monoporous, surrounded by the calyx, and a quadriradial corolla. There are four species, all of them natives of the island of Jamaica, and some of the other islands in the warm parts of America. They send out slender branches, having tendrils at their joints, by which they fasten to the neighbouring trees, bushes, and any other support, mounting to a considerable height. The fruit of some of the species are eaten by the negroes.

Cistercians, in church-history, a religious order founded in the 11th century by St Robert, a Benedictine. They became so powerful, that they governed almost all Europe, both in spirituals and temporals. Cardinal de Vitri describing their observances, says, they neither wore skins nor shirts; nor ever eat flesh, except in sickness; and abstained from fish, eggs, milk, and cheese: they lay upon straw-beds, in tunics and cowls: they rose at midnight to prayers; they spent the day in labour, reading, and prayer; and in all their exercises observed a continual silence. The habit of the cistercian monks is a white robe, in the nature of a cassock, with a black capulary and hood, and is girt with a woollen girdle. The nuns wear a white tunic, and a black capulary and girdle.

Cistern, denotes a subterranean reservoir of rain-water; or a vessel serving as a receptacle for rain or other water, for the necessary uses of a family. They are likewise lead-cisterns, jar-cisterns, &c.

Authors mention a cistern at Constantinople, the vultures of which are supported by two rows of pillars, 212 in each row, each pillar being two feet in diameter. They are planted circularly, and in radius tending to that of the centre.

Anciently there were cisterns all over the country in Palestine. There were some likewise in cities and private houses. As the cities for the most part were built on mountains, and the rains fell regularly in Judea at two feasons in the year only, in spring and autumn, people were obliged to keep water in cisterns in the country for the use of their cattle, and in cities for the convenience of the inhabitants. There are still cisterns of very large dimensions to be seen in Palestine, some whereof are 150 paces long, and 54 wide. There is one to be seen at Ramah of 32 paces in length, and 26 in breadth. Wells and cisterns, springs and fountains, are generally confounded in scripture-language.

Cistus, the Rock Rose. A genus of the monogynia order, belonging to the polyandria class of plants; and in the natural method ranking under the 20th order, Rutaceae. The corolla is pentatetalous; the calyx pentaphyllous, with two of its leaves smaller than the rest. The seeds are contained in a capsule. There are 37 species, most of them natives of the southern parts of Europe, but hardy enough to bear the open air in England. They are beautiful evergreen shrubs, generally very branchy; quite from the bottom, and forming diffused heads. They are very ornamental in gardens, not only as evergreens, making a fine variety at all seasons with their leaves of different figures, sizes, and shades of green and white, but also as first-rate flowering shrubs, being very profuse in most elegant flowers of white, purple, and yellow colours. These flowers only last for one day; but there is a continual succession of new ones for a month or six weeks on the same plant; and when there are different species, they will exhibit a constant bloom for near three months. They are propagated either by seeds or cuttings, and thrive best in a dry soil. Their proper situation in shrubbery works should be towards the front of the clumps and other compartments, in assemblage with the choicest shrubs of similar growth, disposing them so as to make a variety, and to have shelter from the other plants; but they ought by no means to be crowded. Gum labdanum is found upon a species of cistus which grows naturally in the Levant, and is therefore called labdanifera. See Labdanum.

Citadel, a place fortified with five or six bastions, built on a convenient ground near a city, that it may command it in case of a rebellion.

Citadella, the capital town in the island of Minorca, in the Mediterranean, with a new harbour. This, with the whole island, were taken by general Stanhope and the confederate fleet in 1708, and ceded to
to Great Britain by the treaty of Utrecht in 1713: it was taken by the French, after a brave defence, in 1756; and restored by the peace. In 1782, it was taken by the Spaniards, and confirmed to them at the subsequent peace. It is 27 miles west of Port Mahon. E. Long. 3. 30. N. Lat. 39. 58.

CITADINESCA, in natural history, a name given by some writers to the Florentine marble, which is supposed to represent towns, palaces, ruins, rivers, &c. These delineations are merely accidental, and are commonly represented of a ill proper pieces from the mass, and disposed in the skill of the workmen, who always pick out the best parts from the mass, and dispose them in the work so as to represent what they please.

CITATION, in ecclesiastical courts, is the same with summons in civil courts. See SUMMONS.

CITATION, is also a quotation of some law, authority, or passage of a book.

CITÀERÓN, (anc. geog.) a mountain and forest of Bocota, celebrated both in fable and fong. To the well it ran obliquely, a little above the Sinus Citlélus, taking its rife contiguous to the mountains of Megara and Attica; then levelled into plains, it terminates at Thebes, famous for the fate of Pentheus and Aëtæo, the former torn by the Bacchiæ, the latter by the dogs; as also for the orgia, or revels of Bacchus.

CITHARA, in antiquity, a musical instrument, the specific structure of which is not known; some think it resembled the Greek delta; and others the shape of a half moon. At first it had only 3 strings, but the number was at different times increased to 8, to 11, and lastly to 24. It was used in entertainments and private houses, and played upon with a plectrum or quill, like the lyre.

CITHAREXYLON, PILLAR-WOOD: A genus of the angiopermia order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, Perforatae. The calyx is quinquedentate, campanulate, wheel-shaped, and inclining to be funnel-shaped, with the segments villous on the upper side, equal. The fruit a dimerous berry; the seeds biocular. There are two species, both natives of the warm parts of America, where they grow to be large trees, and are adorned with white flowers growing in spikes. In Britain they appear only as shrubs, and must be constantly retained in the stove, where they make a fine appearance, being beautiful evergreens. They may be propagated either by seeds or cuttings.

CITIUM, CETIUM, or CITIUM, (anc. geog.) a town of Cyprus, situated in thesouth of the island; famous for the birth of Zeno, author of the fect called Eotechnics; different two hundred miles to the west of Salamis (Diodorus Siculus). A colony of Phoenicians, called Chitim; and hence it is that not only Cyprus, but the other islands and many maritime places, are called Chitim by the Hebrews; now called Chitti.

CITIZEN, a native or inhabitant of a city, vested with the freedom and liberties of it.

A citizen of Rome was distinguished from a stranger, because he belonged to no certain commonwealth subject to the Romans. A citizen is either by birth or election; and sons may derive the right from their fathers. To make a good Roman citizen, it was necessary to be an inhabitant of Rome, to be enrolled in one of the tribes, and to be capable of dignities. Those to whom were granted the rights and privileges of Roman citizens, were only honorary citizens. It was not lawful to scourge a citizen of Rome.

CITRINUS, in natural history, the name of a peculiar species of sprig crystal, which is of a beautiful yellow. Many of the common crystals, when in the neighbourhood of lead mines, are liable to be accidentally tinged yellow, by an admixture of the particles of that metal; and all these, whether finer or coarser, have been too frequently confounded together under the name citrine; but Dr Hill has ascertained this to be a peculiar species of crystal different from all the others in form as well as in colour; and distinguished by the name of ellipsonacroxylym lucidum flavescens, pyramide brevis. It is never found colourless like the other crystals, but has great variety of tinges, from that of the deeper ochres to a pale lemon-colour.

It is very plentiful in the West Indies, and is sometimes found in Bohemia. Our jewellers have learned from the French and Italians, who are very fond of it, to call it citrine; and often cut stones for rings out of it, particularly out of the pyramid, which is always finer than the column; and these, after they have passed through two or three hands, are generally mistaken for topazes.

CITRON-TREE, in botany. See CITRUS.

CITRON-WATER, a well known strong water or cordial, which may be thus made: Take of fine thin lemons-peel, 18 ounces; of orange-peel, 9 ounces; perfect nutmegs, 4 ounces; the finest and best rectified spirit of wine, 2 gallons and a half. Digest in balneo mariae for one night: draw off with a low fire; then add as much water as will just make the matter milky (which will be about 7 quarts or 2 gallons); and, lastly, add 2 pounds of fine sugar. This composition may be improved by fresh elder flowers, hung in a cloth in the head of the hill, sprinkled with ambergris in powder, or its essence.

CITRON-WOOD, the wood of an American tree, called by the natives candle-wood; because, being cut into splinters, it burns like a candle. The tree is frequent in the Leeward Islands, and grows to a considerable size: the leaves are like those of the bay-tree, but of a finer green; the flower is sweet, and much like the orange; the fruit preceding the leaves is black, and of the size of a pepper-corn. The trunk is so like the yellow saunders in colour, that there was once an opinion that it was the same tree; but of it was imported into Europe, and sold as such: but they were soon found to be different; the saunders being of a sweet scent, and but moderately heavy and resinous; but the citron-wood considerably heavy, very oily, and of a firmer smell. It is of no known use in medicine; but is used in France and Germany by the turners, being a fine firm-grained wood, and taking
CITRUS, the CITRON-TREE: A genus of the polyadelphe order, belonging to the icofandria class of plants. The calyx is quinquefid; the petals oblong, and five in number; the andhire 20, with their filaments grown together so as to form various pencils.

The fruit is an unilocular berry. The species.

I. The Medicis, or Citron-tree, hath an upright smooth trunk, divided at top into a branchy strong-shooting, full head, from about 5 to 15 feet high, adorned with large, oval, pear-shaped, thick leaves, having linear footstalks, and numerous flowers from the sides of the branches, succeeded by very large oblong oval, pointed, rough-rinded fruit. The varieties are, with flowers, with double flowers, with varietics, with large oval fruit; with sweetish fruit; with very large fruit called imperial lemon; with pear-shaped fruit; with furrowed fruit; with chilting fruit; with whithit fruit; with tricolor striped fruit; with silver striped leaves; and with double flowers.

II. The Lima, or Lemon-tree, hath an upright smooth trunk, divided upwards into a branchy regular head; from 12 to 15 feet high; large, oval, pear-shaped, pointed, slightly fawed leaves, on linear footstalks; and many flowers from the sides of the branches succeeded by large oval fruit prominent at the top. The varieties are, the lemon-tree with four fruit; with sweetish fruit; with very large fruit called imperial lemon; with pear-shaped fruit; with furrowed fruit; with chilting fruit; with whithit fruit; with tricolor striped fruit; with silver striped leaves; and with double flowers.

III. The Aurantium, or Orange-tree, hath an upright trunk dividing upward into a branchy, regular head; from 5 to 10 or 12 feet high; oval, pear-shaped, entire leaves, having winged footstalks and numerous white flowers at the sides of the branches, succeeded by globular fruit comprised at both ends. The most noted varieties are, 1. The Seville orange. This is a very handfome tree, and the hardihest of all; as in Britain it shoots freely, produces large and beautiful leaves, flowers stronger, &c. The fruit is large, rough, rided, and four, of excellent quality for economical uses. 2. The China orange. This tree has moderately fized leaves, and a smooth, thin-rinded, sweet fruit, of which there are several varieties in warm countries, where they grow in the open ground. 3. The great Shaddock, or pumplemos, grows larger and stronger than the foregoing, with large, thick, and somewhat serrated leaves, and very large fruit, having a reddish pulp. It derives the name of Shaddock from one of that name that first brought it from the East Indies. 4. The Forbidden-fruit-tree, in trunk, leaves, and flowers, very much resembles the common orange-tree; but the fruit, when ripe, is larger and longer than the biggest orange. It has somewhat the taste of a shaddock, but far exceeds that, as well as the best orange, in its delicious taste and flavour. 5. The Horned orange is a tree of moderate size, producing fruit which divide, and the rind runs out into divisions like horns. 6. The Hermaphrodite orange is a common fized tree, producing fruit shaped partly like an orange and partly like a citron. 7. The Dwarf orange tree, or nutmeg orange, has a long stem and small bulky head, growing two or three feet high; small oval leaves in clusters; and numerous flowers in clusters, covering the branches, succeeded by very small fruit. These are the most remarkable varieties of the three foregoing species of citrus; but besides these there are a great number of others; and indeed in those countries where they grow naturally, the varieties may be multiplied without end, like those of our apples and pears. The flowers of all the species and varieties are formed each of five spreading petals appearing in Britain principally in May and June; and the fruit continue setting in June and July, and ripen the year following.

IV. The Trifoliatum, or Japonéce citrus, is a thorny shrub growing naturally in Japan, where it is likewise known by the names of Gees, and Karatsal banna. The trunk, we are told by Kaempfer, acquires by age and culture the thickness of a tree. The branches and shoots are unequal; in some parts compressed, in others swelling, especially about the spines. These proceed singly from the stem and branches; are straight, run out from a broad base into a very sharp point; and are protruded from the wood, with the common bark of which they are likewise invested. The wood is loose and soft; the bark of a shining green, moist and easily parting from the wood. The leaves are few in number, sawed on the edges, veined, placed without order, but generally growing under the spines. They grow by threes, like thistles of trefoil, upon the extremity of a common footstalk which is furnished on each side with a membraneous fringe or margin, somewhat resembling the pedicles of the orange. The upper surface of the leaves is of a bright lucid green, the lower dark and herbaceous. The flowers, which resemble those of the medlar, proceed singly from the arm-pits of the leaves; are white, potlied of no great degree of fragrance, and consist of five petals. The fruit is equally beautiful with a middle-sized orange; their internal structure is also pretty much the fame; only the pulp is glutinous, of an unpleasant smel, and a harsh disagreeable taste. The seeds have the same taste with the pulp, and are shaped exactly like those of the orange.

Culture. The three first species merit particular attention. They are elegant evergreens, rising in Britain from about 5 to 10 feet in height; forming full and handsome heads, closely garnished with beautiful large leaves all the year round, and putting forth a profusion of sweet flowers in spring and early in summer; which even in this climate are often succeeded by abundance of fruit that sometimes arrive at tolerable perfection. Though all the varieties were originally obtained by seed, yet the only certain method of continuing the approved varieties is by budding or inserting them on flocks raised from seed to a proper size. As the young trees, however, are brought in plenty from abroad, this method is not long practiced in Britain; but for curiosity, it may be done by those who are so inclined, in the following manner: Early in the spring procure some kernels, which may be had in plenty from rotten fruits, or others that are properly ripened, observing that for flocks the citron, lemon, and Seville-orange, as being the freest growers, are to be preferred; and of these the citron is the strongest. Sow the kernels in March, in pots of rich light earth half an inch deep, and plunge them in a heat-
The operation for budding is performed in the month of August, and is done in the common way, only the buds must be taken from a tree of a good kind, that bear well. As soon as the operation is finished, the pots with their plants must be placed in the greenhouse, or in a glass-case; or, where there is the convenience of a spare bark pit, where the heat of the bark is almost exhausted, the pots may be plunged therein for two or three weeks. In either case, however, the air must be admitted freely by opening the front glasses; allowing also a slight shade of mats in the middle of hot sunshine days, and fapplying them with water every two or three days during this kind of weather. In three or four weeks the buds will be united with the stock, when it will be proper to loosen the bandages, that they may have room to swell; the buds, however, will all remain dormant till the next spring. They may also be propagated by inarching, which is done in the common way; but the method of budding is found to produce much handier trees, and therefore is to be preferred. But the most cheap and expeditious method of procuring a collection of these kind of trees is by having recourse to such as are imported from Spain, Italy, and Portugal. These come to Britain in ships, without any earth to their roots, having their roots and heads a little trimmed; they are commonly from one inch to two or three in diameter in the stem; from two to four; or five feet in height; and by the assistance of a bark-bed they readily take root and grow freely, forming as good trees in two or three years, as could be raised there by inarching or budding in 15 or 20. They are sold in the Italian warehouses in London. Their price is from three shillings a gallon each, according to their size; and they are generally advertised as soon as they arrive, which is early in the spring, and the sooner the better. In the choice of these trees, it must be observed, that they are commonly budded at such height in the stem, as to form heads from about two to four or five feet high; and as they are frequently furnished with two buds, one on each side of the stem, these should be chosen preferably to others; as they will form the most regular heads. Preparatory to their planting they must be planted in a tub or tubs of water to plump their bark and roots; after this they must be washed and cleaned, their branches trimmed to half a foot long, and the roots freed from diseased parts, and all the small dried fibres. Then they are to be planted in pots filled with light rich earth; and plunged in a tan-bed, where they are to remain for three or four months; after which they are to be trained to the open air, but will not bear it longer than from the end of May till the middle or end of October.

Sometimes these trees, instead of being kept in pots or tubs, are planted in the full ground; and where this can be done, it is by far the most eligible method. Where this is intended, there must be frames erected for the support of glafs and other covers, to defend the plants during inclement weather; and in this situation the trees generally shoot strongly, produce large fruit, and may be trained either as wall or standard trees. A south wall, in a dry situation, is proper for training them as wall-trees; against which may be erected wooden frame-work sloping, either fixed or moveable, for the support of glass frames for winter; likewise for the greater protection of the trees in fewer fruits, there may be a fire-place with a flue or rows of oranges may be planted, sheltering them to run up as standards with only some necessary pruning just to preserve their regularity. In some places there are lofty moveable glass-cases, so that two or three rows of trees are planted in a conspicuous part of the pleasure-ground. In winter the frame is put over them, and in summer wholly taken away; so that they appear like a little orange-grove growing in the open ground. The flowering and fruit-setting season of all the sorts of citrus is in June and July. They are often, especially the orange-trees, greatly loaded with blossoms; and when these stand very thick, it is proper to thin them a little, taking off the smallest. It is also to be observed, that as the trees continue blowing and setting their fruit for three months, when a full crop of fruit is set, it is of benefit to the trees and fruit to gather off the superabundant blossoms as they are produced; though none permit them to remain on account of their appearance.

Uses. The fruits of the citron, lemon, and orange trees, yield very agreeable acid juices; which, besides the virtues to which they are commonly applied, answer commendable purposes in medicine. When Commodore Anson failed round the world, his men were so surprisingly recovered from the fever by the oranges which they found at the island of 'Tinian, that it was afterwards thought worthy of the attention of government to inquire into the virtues of these fruits as an antiscorbutic medicine. In Captain Cook's last voyage, he was supplied with a quantity of orange and lemon juice infiltrated to a rob; but his opinion of its efficacy is by no means great. The dearnefs of it is a great objection; and, unless in conjunction with other things, he has not observed its good effects. Sir John Pringle, in his discourse before the Royal Society, when Captain Cook was presented with a medal by that respectable body, differs a little from the Captain's opinion, and thinks that in the tea-scurvy these fruits must necessarily be very efficacious. He approves, however, more of
CIT

CIT

the juices themselves depurated, than the extract of them; as this cannot be prepared without dissipating many of the finer parts. The juice of lemons is very frequently used for neutralizing alkaline faults for false draughts. The citron is seldom used in Britain; though its peel, as well as that of the lemon, is candied, and sold as a sweetmeat. The yellow peel of the lemon is an agreeable aromatic, as is also that of the orange; and in cold phlegmatic constitutions they prove excellent for stomachies and carminatives, promoting appetite, warming the habit, and strengthening the tone of the viscera. Orange-peel, however, is very considerably warmer than that of lemons, and abounds more in essential oil: to this circumstance, therefore due regard ought to be had in the use of these medicines. The flavour of orange-peel is likewise less perishable than that of lemons. Both are ingredients in many official preparations.

The young fruit of the Seville orange dried are used in medicine under the name of aurantium curassavantia. They are moderately warm bitterish aromatics, of a sufficiently agreeable flavour. The flowers of the orange-tree have been for some time past in great esteem as a perfume. They are highly odoriferous, of a somewhat warm and bitter taste. They yield their flavour by infusion to rectified spirit, and in distillation both to spirit and water. The bitter matter is dissolved in water, and on evaporating the decoction remains entire in the extract. The distilled water was formerly kept in the shops; but on account of the great scarcity of the flowers is now laid aside; it is called by foreign writers aqua naphe. An oil distilled from these flowers is brought from Italy under the name of oleum, or essentia neroli.

CITTERN, a musical instrument much resembling the guitar, for which it has been frequently mistaken. Anciently it was called the cithrum, and till lately was held in great contempt both in France and Britain. The practice on it being very early, it was formerly the amusement and recreation of lewd women, and their visitors; infomuch, that in many of the old English dramatic writers, it is made the emblem of a woman that lived by prostitution. It was also the common amusement of waiting customers in barbers shops, as being the most easy of all instruments to play on, and therefore it was thought that almost every body could make use of it.

CITY, according to Cowel, is a town corporate which hath a bishop and cathedral church; and is called civitas, oppidum, and urbs: civitas, in regard it is governed by justice and order of magistracy; oppidum, because it contains a great number of inhabitants; and urbs, because it is in due form surrounded with walls.

Kingdoms have been said to contain as many cities as they have seats of archbishops and bishops; but, according to Blount, city is a word that hath obtained since the conquest; for, in the time of the Saxons, there were no cities, but all the great towns were called burghs, and even London was then called Londonburgh, as the capital of Scotland is called Edinburgh. And long after the conquest the word city is used profusely with the burgh, as in the charter of Leicester, where it is both called civitas and burgus: which shows that those writers were mistaken who tell us every city was, or is, a bishop's see. And though the word city signifies in Britain such a town corporate as hath usually a bishop and a cathedral church, yet it is not always so.

As to the ancient state of cities and villages, whilst the feudal policy prevailed, they held of some great lord on whom they depended for protection, and were subject to his arbitrary jurisdiction. The inhabitants were deprived of the natural and most unalienable rights of humanity. They could not dispose of the effects which their own industry had acquired, either by a latter-will or by any deed executed during their life. They had no right to appoint guardians for their children during their minority. They were not permitted to marry without purchasing the consent of the lord on whom they depended. If once they had commenced a law-suit, they durst not terminate it by an accommodation, because that would have deprived the lord, in whose court they pleaded, of the perquisites due to him on ensuing his sentence. Services of various kinds no less disgraceful than oppressive were exacted from them without mercy or moderation. The spirit of industry was checked in some cities by absurd regulations, and in others by unreasonable exactions: nor would the narrow and oppressive maxims of a military arithocracy have permitted it ever to rise to any degree of height or vigour.

The freedom of cities was first established in Italy, owing principally to the introduction of commerce. As soon as they began to turn their attention towards this object, and to conceive some idea of the advantages they might derive from it, they became impatient to shake off the yoke of their insolent lords, and to establish among themselves such a free and equal government as would render property secure and industry flourishing. The German emperors, especially those of the Franconian and Saubian lines, as the seat of their government was far distant from Italy, possessed a feeble and imperfect jurisdiction in that country. Their perpetual quarrels, either with the popes or their own turbulent vassals, diverted their attention from the interior policy of Italy, and gave conflagration employment for their arms. The circumstances, induced a general movement of the Italian cities, towards the beginning of the 11th century, to assume new privileges; to unite together more closely; and to form themselves into bodies politic, under the government of laws established by common consent. The rights which many cities acquired by bold or fortunate usurpations, others purchased from the emperors, who deemed themselves gainers when they received large sums for immunities which they were no longer able to withhold; and some cities obtained them gratuitously from the facility or generosity of the princes on whom they depended. The great increase of wealth which the crusades brought into Italy, occasioned a new kind of fermentation and activity in the minds of the people, and excited such a general passion for liberty and independence, that, before the conclusion of the last crusade, all the considerable cities in that country had either purchased or had extorted large immunities from the emperors.

This innovation was not long known in Italy before it made its way into France. Louis the Great, in order to create some power that might counterbalance those potent vassals who controlled or gave law to the
CIV. Good civet is of a clear, yellowish, or brownish colour; not fluid nor hard, but about the consistence of butter or honey, and uniform throughout; of a very strong smell, quite offensive when undiluted, but agreeable when only a small portion of civet is mixed with a large one of other substances. It unites easily with oils both expressed and distilled, but not at all with water or spirit of wine: nor can it be rendered miscible with water by the mediation of sugar. The yolk of an egg seems to dissolve it with water; but in a very little while the civet separates from the liquor, and falls to the bottom, though it does not prove of such a reinous tenacity as when treated with sugar and spirit of wine. It communicates, however, some share of its smell both to watery and spirituous liquors: hence a small portion of it is often added in odoriferous tinctures, and suspended in the still-head during the distillation of odoriferous waters and spirits. It is rarely if ever employed for medicinal purposes. The Italians make it an ingredient in perfumed oils, and thus obtain the whole of its scent; for oils wholly dissolve the substance of it. It is very rare, however, to meet with civet unadulterated. The substances usually mixed with it are lord and butter; which agreeing with it in its general properties, render all criteria for distinguishing the adulteration impossible. A great trade of civet is carried on at Calicut, Bahia, and other parts of the Indies, and in Africa, where the animal that produces the perfume is found. Live civet-cats are to be seen also in France and Holland. The French keep them only as a rarity; but the Dutch, who keep a great number, draw the civet from them for sale. It is mostly used by confectioners and perfumers.

CIVET-CAT, the English name of the animal which produces the civet. See Viverra.

CIVIC CROWN, was a crown given by the ancient Romans to any soldier who had saved the life of a citizen in an engagement.

The civic crown was reckoned more honourable than any other crown, though composed of no better materials than oak-boughs. Plutarch, in the life of C. M. Coriolanus, accounts as follows for using on this occasion the branches of this tree before all others: because, says he, the oak-wreath being sacred to Jupiter, the great guardian of the city, they thought it the most proper ornament for him who had preferred the life of a citizen. Pliny, speaking of the *Lib. xvi. merit longed this crown, says, "They who had once obtained it, might wear it always. When they appeared at the public spectacles, the senate and people swore to do them honour, and they took their seats on these occasions among the senators. They were not only per-

*See Lord Lyttleton's History of Henry II. Vol. II. P. 317.
CIVIL

personally excused from all troublesome offices, but procured the same immunity for their father and grand-father by the father's fide.

CIVIDAD-DE-LAS-PALMAS, the capital town of the island of Canary, with a bishop's see, and a good harbour. The houses are well built, two stories high, and flat-roofed. The cathedral is a very handomne structure; and the inhabitants are gay and rich. The air is temperate, and free from extremes of heat and cold. It is defended by a small castle feated on a hill, W. Long. 14. 35. N. Lat. 28. 0.

CIVIDAD-Real, a town of Spain, in New Cadiile, and capital of La Mancha. The inhabitants are noted for dressing leather extremely well for gloves. W. Long. 4. 15. N. Lat. 39. 2.

CIVIDAD-Rodrigo, a strong and considerable town of Spain, in the kingdom of Leon, with a bishop's see. It is feated in a fertile country, on the river Aquada, in W. Long. 6. 52. N. Lat. 40. 38.

CIVIDAD-di-Friuli, a small but ancient town of Italy, in Friuli, and in the territory of Venice; feated on the river Natisna. E. Long. 13. 25. N. Lat. 46. 15.

CIVIL, in a general fenfe, fomething that regards the policy, public good, or peace, of the citizens or subjects of the state; in which fenfe we fay, civil government, civil law, civil right, civil procedure in an action, &c.

CIVILIAN, in a popular fenfe, is applied to a complainant and humane behaviour in the ordinary intercourse of life. See CIVILITY.

CIVIL, in a legal fenfe, is also applied to the ordinary procedure in an action, relating to some pecuniary matter or intereft; in which fenfe it is opposed to criminal.

Civil Death, any thing that cuts off a man from civil society; as a condemnation to the galleys, perpetual banifhment, condemnation to death, outlawry, and execution.

CIVIL Law is properly the peculiar law of each state, country, or city; but what we ufually mean by the civil law, is a body of laws compiled out of the best Roman and Grecian laws, compiled from the laws of nature and nations; and, for the most part, received and obferved throughout all the Roman dominions for above 1200 years. See Law, Part I. n° 43, 44.

It was firt brought over into England by Theobald a Norman abbot, who was elected to the fee of Canterbury in 1138; and he appointed a professor, viz. Roger firnamed Vivacius, in the university of Oxford, to teach it to the people of that country. Neverthelefs, it gained ground very slowly. King Stephen iffued a proclamation, prohibiting the study of it. And though the clergy were attached to it, the laity rather wished to preserve the old confitution. However, the zeal and influence of the clergy prevailed; and the civil law acquired great reputation from the reign of King Stephen to the reign of King Edward III. both inclusive. Many tranfcripts of Julfian's Institute are to be found in the writings of ancient authors, particularly of Bracton and Rolls; and Judge Blackfcone obferves, that the common law would have been lost and over-run by the civil, had it not been for the incident of fixing the court of common pleas in one certain fpot, and the forming the prefession of the municipal law into an aggregate body.

It is allowed, that the civil law contains all the principles of natural equity; and that nothing can be better calculated to form good fefe and found judgment. Hence, though in feveral countries it has no other authority but that of reason and juftice, it is every where referred to for authority. It is not received at this day in any nation without some alterations: and sometimes the feudal law is mixed with it, or general and particular customs; and often ordinances and statutes cut off a great part of it.

In Turkey, the Bailies are only used. In Italy, the canon law and customs have excluded a good part of it. In Venice, custom hath almost an abolute government. In the Milanese, the feudal law, and particular customs, bear fway. In Naples and Sicily, the constitutions and laws of the Lombards are faid to prevail. In Germany and Holland, the civil law is esteemed to be the municipal law: but yet many parts of it are there grown obfolute; and others are altered, either by the canon law or a different usage. In Frieeland, it is obeyed with more strictnefs; but in the northern parts of Germany, the jus Saxonicum, Lubecence, or Culmene, is preferred before it. In Denmark and Sweden, it hath scarce any authority at all. In France, only a part of it is received, and that part in fome places as a customary law; and in fome provinces near to Italy it is received as a municipal written law. In criminal caufes, the civil law is more regarded in France; but the manner of trial is regulated by ordinances and edicts. In Spain and Portugal, the civil law is connected with the jus regium and eumon. In Scotland, the statutes of the federunt, part of the regaz majeffatis, and their customs, control the civil law.

In England, it is used in the ecclefaftical courts, in the high court of admiralty, in the court of chivalry, in the two universities, and in the courts of equity; yet in all thefe it is restrained and directed by the common law.

CIVIL Society. See Law, Part I. n° 12.

CIVIL State, in the British polity, one of the general divisions of the LAITY, comprehending all orders of men from the highest nobleman to the meaneft peafant that are not included under the MILITARY or MARITIME states: though it may fometimes include individuals of these as well as of the CLERGY; fince a nobleman, a knight, a gentleman, or a peafant, may become either a divine, a soldier, or a feaman. The division of this state is into NOBILITY and COMMONALITY. See these articles.

Civil War, a war between people of the fame state, or the citizens of the fame city.

CIVIL Year, is the legal year, or annual account of time, which every government appoints to be used within its own dominions; and is fo called in contradiftinction to the natural year, which is measured exactly by the revolution of the heavenly bodies.

CIVILIANS, in general, denotes something belonging to the civil law; but more efepecially the doctors and profeflors thereof are called civilians.

CIVILITY, a term used in common life as synonymous with complaisance or good-breeding. Civility is juftly inculcated by didactic writers as a duty of no flight consideration. Without civility, or good-breeding, a court would be the seat of violence and de-

E folation.
However just the complaints of the misery of life, yet great occasions for the display of benevolence and liberality do not often occur. But there is an hourly necessity for the little kind offices of mutual civility. At the same time that they give pleasure to others, they add to our own happiness and well being of the soul, because all pursuits what but few can obtain; there, if enemies did not embrace, they would flail; there, amities are often put on to conceal tears; there, mutual services are professed, while mutual injuries are intended; and there, the guilt of the serpent simulates the gentleness of the dove. To what a degree must good-breeding adorn the beauty of truth, when it can thus soften the deformity of falsehood? On this subject we have the following elegant observations in Knox's Essays, No. 95.

thrown away. It is probable, however, that among the immense number of these apartments that yet remain to be opened, many paintings and inscriptions may be found sufficient to form a very useful and entertaining work. At present this great scene of antiquities is almost entirely unknown, even in Rome. Mr Jenkins, resident at Rome, was the first Englishman who visited it.

\textit{Civita Vecchia}, a sea-port town of Italy in the patrimony of St Peter, with a good harbour and an arsenal. Here the pope's galleys are stationed, and it has lately been made a free port; but the air is very unwholesome. E. Long. 12. 31. N. Lat. 45. 5.

\textit{Civoli}, or \textit{Cicoli}, (Lewis), an Italian painter, whose family-name was \textit{Cardi}, was born at the castle of Cigoli, in Tuscany, in the year 1559. His \textit{ese bome}, which he performed as a trial of skill with Barochio and Michael Angelo da Caravaggio, was judged better than those executed by them. He excelled in designing, and was employed by the popes and princes of his time. He died at Rome in 1613.

\textit{Clus}, (anc. geog.) a town and river of Bithynia. It was afterward called \textit{Prusia}, Clus having been destroyed by Philip father of Perseus, and rebuilt by Prusias king of Bithynia. In the river, Hydas, the favourite boy of Hercules, was drowned; (Apollo son Rhodus.)

\textit{Clac}, among countrymen. To clack wool, is to cut off the sheep's mark, which makes the weight less, and to the less subject to the king.

\textit{Clackmannan}, the name of a small thire in Scotland, not exceeding eight miles in length and five in breadth. It is bounded on the south by the river of Forth; on the north and west by Perthshire; and on the east by Fife. The country is plain and fertile towards the frith, producing corn and pasture in abundance. It likewise yields great quantities of excellent coal, which is exported to England, France, and Holland. It is watered by the rivers Forth and Devan, and joins the thire of Kinros in sending a member alternately to parliament.

\textit{Clackmannan}, a small town of Scotland, and capital of the county of that name, is situate on the northern shore of the Forth, in W. Long. 3. 40. N. Lat. 56. 15. It stands on a hill, on the top of which is the castle, commanding a noble prospect. It was long the seat of the chief of the Bruces, who was hereditary thirfe of the county before the jurisdiction were abolished. The large square tower is called after the name of \textit{Robert Bruce}; whose great sword and cañque are still preserved here. The hill is pretty wooded; and, with the tower, forms a picturesque object. Clackmannan is still the seat of the Bruces of Kenket.

\textit{Clagenfurt}, a strong town of Germany, and capital of Carinthia, is situated in E. Long. 13. 56. N. Lat. 46. 50.

\textit{Claget}, (William) an eminent and learned divine, born in 1646. He was preacher to the society of Gray's Inn; which employment he exercised until he died in 1688, being then also one of the king's chaplains. Archbishop Sharp gives him an excellent character; and bishop Burnet has ranked him among those worthy men whose lives and labours contributed to rescue the church from the reproaches with which the follies of others had drawn upon it. Dr Claget pu-billished several things; but his principal work is his \"Difcourfe concerning the Operations of the Holy Spirit\"; not mit it be forgotten that he was one of those excellent divines who made a noble stand against the designs of James II. to introduce popery. Four volumes of his letters were published after his death by his brother Nicholas Claget, archdeacon of Salisbury, father of Nicholas Claget afterward bishop of Exeter.

\textit{Claim}, in law, a challenge of interest in anything that is in the possession of another.

\textit{Clair}, obscure. See \textit{Claro-Objeux}.

\textit{Clairault}, (Alexis) of the French academy of sciences, was one of the most illustrious mathematicians in Europe. He read to the academy in 1736, when he was not 13 years old, a memoir upon four new geometrical curves of his own invention; and supported the character he thus laid a foundation for by various publications from time to time. He published, \textit{Elémens de Géométrie}, 1741, in 8vo; \textit{Elémens d'Algèbre}, 1746, in 8vo; \textit{Théorie de la Figure de la Terre}, 1743, in 8vo; \textit{Tables de la Lune} 1754, in 8vo. He was concerned also in the \textit{Journal des Savans}, which he furnished with many excellent extracts. He died in 1765. He was one of the academicians who were sent into the north to determine the figure of the earth.

\textit{Clam}, in zoology, a shell-fish. See \textit{Venus}.

\textit{Clamp}, a piece of wood joined to another.

\textit{Clamp} is likewise the term for a pile of unburnt bricks built up for burning. These clamps are built much after the same manner as arches are built in kilns, viz. with a vacuity betwixt each brick's breadth for the fire to ascend by; but with this difference, that instead of arching, they truss over, or over-span; that is, the end of one brick is laid about half way over the end of another, and so till both sides meet within half a brick's length, and then a binding brick at the top finishes the arch.

\textit{Clamp in a ship}, denotes a piece of timber applied to a mast or yard to prevent the wood from burfting; and also a thick plank lying fore and aft under the beams of the first orlop, or second deck, and is the same that the riling timbers are to the deck.

\textit{Clamp-Nails}, such nails as are used to fasten on clamps in the building or repairing of ships.

\textit{Clampedia}, (anc. geog.) a town of the Bruti, one of those which revolted from Hannibal, (Livy) called \textit{Lampetia} by Polybius. Now \textit{Anamia}, or \textit{Mantia} a town of Calabria Ultra, near the bay of Euphemia. E. Long. 16. 20. N. Lat. 39. 15.

\textit{Clamping}, in joinery, is the fitting a piece of board with the grain to another piece of board cross the grain. Thus the ends of tables are commonly clamped, to prevent their warping.

\textit{ClanDESTINE}, any thing done without the knowledge of the parties concerned, or without the proper solemnities. Thus a marriage is said to be clandestine when performed without the publication of bans, the consent of parents, &c.

\textit{Clans}, in history, and particularly in that of Scotland. The nations which over-ran Europe were originally divided into many small tribes; and when they came to parcel out the lands which they had conquered, it was natural for every chieftain to bestow a portion.
in the first place, upon those of his own tribe or family. These all held their lands of him; and as the safety of each individual depended on the general union, these small societies clung together, and were distinguished by some common appellations, either patronymical or local, long before the introduction of surnames or enigns armorial. But when these became common, the descendants and relations of every chief shell assumed the same name and arms with him; other vaials were proud to imitate their example; and by degrees they were communicated to all those who held of the same superior. Thus clanships were universal, which was at first a great measure imaginary, was believed to be real. An artificial union was converted into a natural one: men willingly followed a leader, whom they regarded both as the superior of their lands and the chief of their blood; and served him not only with the fidelity of friends, but with the affection of brothers. In the other feudal kingdoms, we may observe such unions as we have described, imperfectly formed; but in Scotland, whether they were the production of chance, or the effect of policy, or strengthened by their preserving their genealogies both genuine and fabulous, clanships were universal. Such a confederacy might be overcome; it could not be broken; and no change of manners or government has been able, in some parts of the kingdom, to dissolve associations which are founded upon prejudices so natural to the human mind. How formidable were the nobles at the head of followers, who, counting that cause just and honourable which their chief approved, were ever ready to take the field at his command, and to sacrifice their lives in defence of his person or of his fame! Against such men a king contended with difficulty, as baronets, knights, esquires, on the south of the Trent; whence he is called Jurroy or footroy, in contradistinction to norroy.

CLARENCE, the second king at arms, so called from the duke of Clarence, to whom it first belonged: for Lionel, 3d son to Edward III. having by his wife the honour of Clare in the county of Thomond, was afterwards declared Duke of Clarence; which dukedom afterwards (he being Edward IV.) he made this earl a king at arms. His office is to marshal and difpofe of the funerals of all the lower nobility, as baronets, knights, esquires, on the south side of the Trent: whence he is called Jurroy or footroy, in contradistinction to norroy.

CLARENDO, (Earl of.) See Hyde.

CLAREST, a market-town of Suffolk, 13 miles south of Bury. E. Long. o. 35. N. Lat. 52. 15. It gives the title of Earl to the Duke of Newcastle.

CLARE is also the capital of a country of the same name in the province of Connaught, in Ireland, situated about 17 miles north-west of Limerick. W. Long. 9. o. N. Lat. 52. 40.

CLARENCEUX, the second king at arms, of certain constitutions made in the reign of Henry II. A. D. 1164, in a parliament held at Clarendon; whereby the king checked the power of the Pope and his clergy, and greatly narrowed the total exemption they claimed from feudal jurisdiction.

CLARKNZA, a name given by the French to such of their red wines as are not of a deep or high colour.

CLARICHORD, or MANTICHORD, a musical instrument in form of a spinet. It has 49 or 50 stops, and 70 strings, which bear on five bridges; the first whereof is the highest, the rest diminishing in proportion. Some of the strings are in unison, their number being greater than that of the stops. There are several little mortises for passing the jacks, armed with brass-hooks, which stop and raise the chords instead of the feather used in virginals and spinets: but what distinguishes it most is, that the chords are covered with pieces of cloth, which render the sound sweeter, and deafen it so that it cannot be heard at any considerable distance: whence it comes to be particularly in use among the nuns, who learn to play, and are unwilling to disturb the silence of the dormitory.

CLARIFICATION, the act of cleaning or fining any fluid from all heterogeneous matter or feculencies.

The substances usually employed for clarifying liquors, are whites of eggs, blood, and finings. The two first are used for such liquors as are clarified without boiling
Clarigatio boiling hot; the last for those which are clarified in the cold, such as wines, &c. The whites of eggs are beat up into a froth, and mixed with the liquor, upon which they unite with and entangle the impure matters that floated in it; and presently growing harder by the heat, carry them up to the surface in form of a foam no longer dissoluble in the liquid. Blood operates in the same manner, and is chiefly used in purifying the brine from which salt is made. Great quantities of tinctures are consumed for fining turbid wines. For this purpose some throw an entire piece, about a quarter of an ounce, into a wine cask; by degrees the glue dissolves, and forms a skin upon the surface, which at length subsiding, carries down with it the feculent matter which floated in the wine. Others previously dissolve the tincture; and having boiled it down to a limy consistence, mix it with the liquor, roll the cask strongly about, and then suffer it to stand to settle. Neuman questions the wholefonenes of wines thus purified; and advices us that he himself, after drinking only a few ounces of sack thus clarified, but not settled quite fine, was seized with sickness and vomiting, followed by such a vertigo, that he could not stand upright for a minute together. The giddiness continued with a nausea and want of appetite for several days.

Clarigatio, in Roman antiquity, a ceremony that always preceded a formal declaration of war. It was performed in this manner: first four heralds crowned with vervain, were sent to demand satisfaction for the injuries done the Roman state. These heralds taking the gods to witnesses that their demands were just, one of them, with a clear voice, demanded reparation within a limited time, commonly 33 days; which being expired without satisfaction made, then the pater patriae, or prince of the heralds, proceeded to the enemies frontiers, and declared war.

Claros Apollinis Fanum, (Strabo, Pliny) a temple and grove of Apollo, situated between Colophon and Lebedos, in Ionia; called Claros (Thucydides, Ovid). The name also of a town and mountain there (Nicander); and of a fountain (Clemens Alexandrinus); the waters of which inspired with prophetic fury. Clarus the epithet of Apollo (Strabo).

Clarion, a kind of trumpet, whose tube is narrower and its tone more piercing and thrilling than that of the common trumpet. It is said that the clarion, now used among the Moors and Portugeese, who borrowed it from the Moors, served anciently for a treble to several trumpets, which founded tenor and bass.

Clarisisses, an order of nuns so called from their founder St Clara or St Clare. (See St Clare). She was in the town of Assisi in Italy; and having renounced the world to dedicate herself to religion, gave birth to this order in the year 1211; which comprehends not only those nuns that follow the rule of St Francis, according to the strict letter, and without any mitigation, but those likewise who follow the same rule softened and mitigated by several popes. It is at present one of the most flourishing orders of nuns in Europe. After Ferdinand Cortez had conquered Mexico for the king of Spain, Isabella of Portugal, wife of the emperor Charles V, sent thither some nuns of the order of St Clara, who made several settlements there. Near their monasteries were founded communities of Indian young women, to be instructed by the claras in religion, and such works as were suitable to persons of their sex. These communities are so considerable that they usually consist of four or five hundred.

Clarke, (Dr Samuel) a preacher and writer of considerable note in the reign of Charles II. was, during the inter-regnum, and at the time of the ejection, minister of St Bennet Fink in London. In November 1660, he, in the name of the Presbyterian ministers, presented an address of thanks to the king for his declaration of liberty of conscience. He was one of the commissioners of the Savoy, and behaved on that occasion with great prudence and moderation. He sometimes attended the church as an hearer and communicant; and was much esteemed by all that knew him, for his great probity and industry. The most valuable of his numerous works are said to be his Lives of the Puritan Divines and other persons of note, 22 of which are printed in his martyrology: the rest are in his Lives of Emminent Persons in this latter age, folio; and in his Harow of Ecclesiastical History, in folio and quarto. He died in 1680.

Clarke, (Samuel) the son of the former, was fellow of Pembroke-hall in Cambridge: but was ejected from his fellowship for refusing to take the engagements, as he was also afterwards from his rectory of Grendon in Buckinghamshire. He applied himself early to the study of the scriptures; and his annotations on the Bible, printed together with the facred text, is highly commended by Dr Owen, Mr Baxter, and Dr Calamy. He died in 1701, aged 75.

Clarke, (Dr Samuel) a very celebrated English divine, was the son of Edward Clarke, Esq; a alderman of Norwich, and one of its representatives in parliament for several years; and born there October 11, 1675. He was instructed in classical learning at the free-school of that town; and in 1691 removed thence to Caius college in Cambridge, where his uncommon abilities soon began to display themselves. Though the philosophy of Des Cartes was at that time the established philosophy of the university, yet Clarke easily mastered the new system of Newton; and in order to his first degree of arts, performed a public exercise in the schools upon a question taken from it. He greatly contributed to the establishment of the Newtonian philosophy by an excellent translation of, and notes upon, Rohault’s “Physics,” which he finished before he was 22 years of age. The system of natural philosophy then generally taught in the university was that written by Rohault, founded altogether upon Cartesian principles, and very ill translated into Latin. Clarke gave a new translation, and added to it such notes as might lead students insensibly and by degrees to other and truer notions than could be found there. “And this certainly (says Bishop Hoadly) was a more prudent method of introducing truth unknown before, than to attempt to throw aside this treatise entirely, and write a new one instead of it. The success answered exceedingly well to his hopes; and he may justly be styled a great benefactor to the university in this attempt. For by this means the true philosophy has, without any noise, prevailed; and to this day his translation of Rohault is, generally speaking.
Upon which we have the following note: "Those who, from the effects in this visible world, deduce the eternal power and Godhead of the first cause, though they cannot attain to an adequate idea of the Deity, yet discover so much of him as enables them to see the end of their creation and the means of their happiness: whereas they who take this high priori road, as Hobbes, Spinoza, Des Cartes, and some better reasoners, for one that goes right, ten lose themselves in mists, or ramble after visions, which deprive them of all sight of their end, and mislead them in the choice of wrong means." Clarke, it is probable, would not have denied this; and the poet perhaps would have spared his better reasoners, and not have joined them with such company, had he recollected our author's apology for using the argument à priori. Undoubtedly, as the present editor of Biographia Britannica observes, the grand, the proper, the decisive proof of the existence, predestination, and providence of the Deity, must be drawn from his works. On this proof, as being equally satisfactory to the profoundest philosopher and the meanest peasant, the cause of religion will ever stand secure. Nevertheless, if there be such a thing as an argument à priori, why may not speculative men be employed in its examination? Several able divines and philosophers have thought, and still think, that this argument for the being and attributes of God, will stand the test of the severest scrutiny; and therefore they cannot be blamed for endeavouring to set it in a convincing light to others. As to the merit, indeed, of the whole work under consideration, including the evidences of natural and revealed religion, it is undoubtedly the first order. Difficulties may be raised on particular points, and the ablest and most candid inquirers may sometimes fee cause to hesitate with regard to the validity of the reasoning: but still, in general, the books reflect the honour on the age as well as the author that produced it, and will descend, with distinguished reputation, to a late posterity. The defence, in particular, of the sacred original and divinity of the Christian Revelation, is admirably conducted.

In 1706 he published "A Letter to Mr Dodwell," wherein all the arguments in his epistolary discourse against the immateriality of the soul are particularly answered, and the judgment of the fathers, to whom Mr Dodwell had appealed concerning that matter, truly reprented. Bishop Hoadly observes, that in this letter he anfwered Mr Dodwell in so excellent a manner, both with regard to the philosophical part, and to the opinions of some of the primitive writers, upon whom these doctrines were fixed; that it gave universal satisfaction. But this controversy did not stop here; for the celebrated Collins, coming in as a second to Dodwell, went much farther into the philosophy of the dispute, and indeed seemed to produce all that could possibly be said against the immateriality of the soul, as well as the liberty of human actions. This enlarged the scene of the dispute; into which our author entered, and wrote with such a spirit of clearness and demonstration, as at once showed him greatly superior to his adversaries in metaphysical and physical knowledge; and made every intelligent reader rejoice, that such an incident had happened to provoke and extort from him that plenty of strong reasoning and perspicuity of expression, which were indeed very much
much wanted upon this intricate and obscure subject. "And I am persuaded (continues the bishop), that as what he has writ in this controversy comprehends the little that the ancients had said well, and adds still more evidence than ever clearly appeared before, and all in words that have a meaning to them, it will remain the standard of good sense on that side of the question, on which he spent so many of his thoughts, as upon one of his favourite points. Clarke's letter to Dodwell was soon followed by four defences of it, in four several letters to the author of "A Letter to the learned Mr. Henry Dodwell" containing some remarks on a pretended demonstration of the immanity and natural immortality of the soul, in Mr. Clarke's Answer to his late Epitomary Discourse, &c." They were afterwards all printed together; and the "Answer to Toland's Amory" added to them. In the midst of all these labours, he found time to show his regard to mathematical and physical studies, and exact knowledge and skill in them. And his natural affecion and capacity for these studies were not a little improved by the friendship of Sir Isaac Newton; at whose request he translated his "Optics" into Latin in 1706. With this version Sir Isaac was so highly pleased, that he presented him with the sum of L. 300, or L. 100 for each child, Clarke having then five children.

This year also, bishop Moore, who had long formed a design of fixing him more conspicuously, procured for him the rectorcy of St. Benet's, Paul's Wharf, in London; and soon after carried him to court, and recommended him to the favour of queen Anne. She appointed him one of her chaplains in ordinary; and, in consideration of his great merit, and at the request of the bishop, presemed him to the rectorcy of St. James's Westminster, when it became vacant in 1709. Upon his advancement to this station, he took the degree of D. D. when the public exercise which he performed for it at Cambridge was prodigiously admired. The questions which he maintained were these: 1. "Namque fidei Christianae dogma, verum scribatur traditum, est recta rationi diffamentum." that is, "No article of the Christian faith, delivered in the holy Scriptures, is disagreeable to right reason." 2. "Sine actionum humanarum liberrate nulla potest effer religio." that is, "Without the liberty of human actions there can be no religion." His thesis was upon the first of these questions; which being thoroughly sifted by that most acute disputer professor James, he made an extempore reply, in a continued discourse for near half an hour, with so little hesitation, that many of the auditors declared themselves affoiced; and owned, that if they had not been within sight of him, they would have supposed him to have verily read every word of it from a paper. After this, through the course of the sylllogistical disputation, he guarded so well against the arts which the professor was a complete master of; replied so readily to the greatest difficulties such an objector could propose; and pressed him so close and hard with clear and intelligible answers, that perhaps there never was such a conflict heard in those schools. The professor, who was a man of humour as well as learning, said to him at the end of the disputation, "Profecto, me probe exercituli," that is, "On my word, you have worked me sufficiently;" and the members of the university went away, admiring, as indeed they well might, that a man even of Clarke's abilities, after an absence of so many years, and a long course of busines of quite another nature, should acquit himself in such a manner, as if this sort of academical exercise had been his constant employment; and with such fluency and purity of expression, as if he had been accustomed to no other language in conversation but Latin. The same year, 1709, he revised and corrected Whifton's translation of the "Apologetic Constitutions" into English. Whifton tells us, that his own studies having been chiefly upon other things, and having rendered him incapable of being also a critic in words and languages, he delivered his great friend and great critic Dr. Clarke to revise that translation; which he was so kind as to agree to.

In 1712 he published a most beautiful and pompous edition of Cæsar's commentaries, adorned with elegant sculptures. It is intitled, "C. Julli Cæsaris que extant accuratissimè codices editis & mss. optimis collata, recognit, & correcta; acceperunt annotationes Samuei Clarke, S. T. P. item indices locorum, rerumque & verborum, utilissimi." It was printed in 1712, folio; and afterwards in 1720, 8vo. It was dedicated to the great duke of Marlborough, "at a time," says Bishop Hoadly, "when glory, called victories and successes had raised his glory to the highest pitch abroad, and softened his interest and favour at home." In the publication of this book, the doctor took particular care of the punctuation. In the annotations, he selected what appeared the best and most judicious in former editions, with some corrections and emendations of his own. Mr. Addison has spoken of this folio edition of Cæsar's commentaries in the following words: "The new edition, which is given us of Cæsar's commentaries, has already been taken notice of in foreign gazettes, and is a work that does honour to the English press. It is no wonder that an edition should be very correct; which has passed thro' the hands of one of the most accurate, learned, and judicious writers this age has produced. The beauty of the paper, the character, and of the several cuts with which this noble work is illustrated, makes it the finest book that I have ever seen; and is a true instance of the English genius, which, though it does not come first into any art, generally carries it to greater heights than any other country in the world." This noble work has risen in value from that time to the present. A copy of this edition in large paper, most splendidly bound in morocco, was sold at the Hon. Mr. Beauclerk's sale for forty-four pounds; and it was said to be purchased by the Duke of Grafton. "To a prince or a nobleman (fays Dr. Harwood), it was a cheap purchase; for it was the most magnificent book I ever beheld. The binding cofl Mr. Beauclerk five guineas.

The same year, 1712, he published his celebrated book intitled, "The Scripture Doctrine of the Trinity, &c." which is divided into three parts. The first is, a collection and explication of all the texts in the "New Testament," relating to the doctrine of the Trinity: in the second, the foregoing doctrine is set forth at large, and explained in particular and distinct propositions; and in the third, the principal passages in the liturgy of the church of England, relating to the
the doctrine of the Trinity, are considered. Bishop
Hoadly applauds our author's method of proceeding,
in forming his sentiments upon so important a point:
"He knew (says he), and all men agreed, that it was a
matter of mere revelation. He did not therefore retire
into his closet, and let himself to invent and forge a
plausible hypothesis, which might sit easily upon his mind.
He had not recourse to abstract and metaphysical rea-
sonings to cover or patronize any system he might have
embraced before. But, as a Christian, he laid open the
New Testament before him. He searched out every
word in which mention was made of three persons,
or any one of them. He accurately examined the
meaning of the words used about every one of them;
and by the best rules of grammar and critique, and
by his skill in language, he endeavoured to fix plainly
what was declared about every person, and what was
not. And what he thought to be the truth, he pub­
lished under the title of 'The Scripture Doctrine
of the Trinity.' "I am far (says the Bishop) from
taking upon me to determine, in so difficult a question
between him and those who made replies to him; but
this I hope I may be allowed to say, that every
Christian divine and layman ought to pay his thanks
for the method into which he brought the
Scripture, to Dr Clarke for the method into which he brought
the
Lord of the controversy; and for that
question, which passed between them was published in
1777. This performance of the doctor's is inscribed
to her late majesty queen Caroline, then princess of
Wales, who was pleased to have the controversy pass
through her hands. It related chiefly to the impor-
tant and difficult subjects of liberty and necessity.
In 1718, Dr Clarke made an alteration in the forms
of doxology in the singing psalms, which produced no
small noise and disturbance, and occasioned some pam-
phlets to be written. The alteration was this:
To God, through Christ, his only Son,
Immortal glory be, &c.
And,
To God, through Christ, his Son, our Lord,
All glory be therefore, &c.

A considerable number of these select psalms
and hymns having been disperfed by the Society for
Promoting Christian Knowledge, before the alteration
of the doxologies was taken notice of, he was charged
with a design of imposing upon the society; whereas,
in truth, the edition of them had been prepared by
him for the use of his own parish only, before the so-
ciety had thoughts of purchasing any of the copies:
and as the usual forms of doxology are not estab-
lished by any legal authority, ecclesiastical or civil, in
this he had not offended.

About this time he was presented by the lord Lech-
mere, the chancellor of the duchy of Lancaster, to the
masterhip of Whiston's hospital in Leicetser. In 1724,
he published 17 sermons preached on several occasi-
s, 11 of which were never before printed; and the year
following, a sermon, preached at the parish-church
of St James's upon the erecting a charity-school for
the education of women servants. In 1727, upon the
death of Sir Isaac Newton, he was offered by the cou-
the place of master of the Mint, worth communikus an-
is 1200 or 1500 a year. But to this secular prefer-
ment he could not reconcile himself; and therefore abso-
lutely refused it. Whitton seems to wonder, that
Clarke's eloquence should lay so little stress upon this
reproof, as to mention it not at all, or at least very negli-
gently; while "he takes it," he says, "to be one of
the most glorious actions of his life, and to afford un-
deniable confession, that he was in earnest in his re-
ligion." In 1728, was published, "A Letter from
Dr Clarke to Mr Benjamin Hoadly, F. R. S. oc-
casioned by the Controversy, relating to the Proportion
of Velocity and Force in Bodies in Motion;" and
printed in the "Philosophical Transactions." In
1729, he published the 12 first books of "Ho-
mer's Iliad." This edition was printed in 40, and
dedicated to the duke of Cumberland. The Latin
version is almost entirely new; and annotations are
added to the bottom of the pages. Homer, Bishop
Hoadly tells, was Clarke's admired author, even to a
degree of something like enthusiasm, hardly natural to
his temper; and that in this he went a little beyond
the bounds of Horace's judgement, and was so unwill-
ing to allow the favourite poet ever to nod, that he
has taken remarkable pains to find out, and give a
reason for every passage, word, and title, that could
create any suspicion. "The translation," adds the
Bishop, "with his corrections, may now be styled ac-
urate; and his notes, as far as they go, are indeed a
treasury of grammatical and critical knowledge.
He was called to his task by royal command; and he has per-
formed it in such a manner, as to be worthy of the
young prince, for whom it was labourd." The year
of its publication was the last of this great man's life.
Though not robust, he had always enjoyed a firm state
of health, without any indisposition bad enough to
confine him, except the small-pox in his youth; till,
Clarke. on Sunday May 17, 1729, going out in the morning to preach before the judges at Serjeant's-inn, he was there feized with a pain in his side, which made it impossible for him to perform the office he was called to; and quickly became so violent, that he was obliged to be carried home. He went to bed, and thought himself so much better in the afternoon, that he would not suffer himself to be bleded; against which remedy, it is remarkable that he had entertained strong prejudices. But the pain returningviolently about two the next morning, made bleeding absolutely necessary; he appeared to be out of danger, and continued to think himself so till the Saturday morning following; when, to the inexpressible surprize of all about him, the pain removed from his side to his head; and, after a very short complaint, took away his faints so, as they never returned any more. He continued breathing till between seven and eight of the evening of that day, which was May 17, 1729; and then died in his 54th year.

Soon after his death were published, from his original manuscripts, by his brother Dr John Clarke, dean of Sarum, "An Explication of the Church Catechism," and ten volumes of sermons, in 8vo. His "Explication" is made up of these lectures he read every Thursday morning for some months in the year, at St James's church. In the latter part of his time he revised them with great care, and left them completely prepared for the press. As to the sermons, few discourses in the English language are more judicious, and fewer still are equally instructive. The reasoning and the practical parts are excellent, and the explanations of scripture are uncommonly valuable. Though Dr Clarke had not the turn of mind which qualified him for moving the passions, and indeed did not make it his object, his sentiments, nevertheless, are frequently expressed with such a clearness of conception and such a force of language, as to produce in well disposed readers all the effect of the pathetic. Several volumes of sermons have been published since his times which are far superior in point of elegance and beauty, and we have the highest fence of their merit. But still, if we were called upon to recommend discourses, which abound with the most solid instruction and promise the most lasting improvement, we should never forget a Clarke and a Jortin. Three years after the Dr Clarke's death, appeared also the Twelve Laft Books of the Iliad, published in 4to by his son, Mr Samuel Clarke, who informs us, in the preface, that his father had finished the annotations to the three first of those books, and as far as the 259th verse of the fourth, and had revised the text and version as far as verse 510 of the same book. Dr Clarke married Catharine, the daughter of the Rev. Mr Lockwood, rector of Little Miftingham in Norfolk; in whose good fence and unblamable behaviour he was happy to his death. By her he had seven children, two of whom died before him, and one a few weeks after him.

Of the character of this great divine, the following short delineation appeared some years since in the Gentleman's Magazine: "Samuel Clarke, D. D., rector of St. James's Westminster; in each several part of useful knowledge and critical learning, perhaps with out a superior; in all united, certainly without an equal: in his works, the best defender of religion; in his practice, the greatest ornament to it: in his conversation communicative, and in an uncommon manner instructive; in his preaching and writings, strong, clear, and calm; in his life, high in the esteem of the wise, the good, and the great: in his death, lamented by every friend to learning, truth, and virtue." In the same publication some not incurious anecdotes concerning him are printed, collected by the Rev. Mr Jones of Welwyn. We learn from them, that Dr Clarke was of a very humane and tender disposition. When his young children amused themselves with tormenting and killing flies upon the windows, he not only forbade such practices, but calmly reazoned with them, in such a familiar manner, as was calculated to make a powerful impression upon their minds. He was very ready and coöperating in answering applications to him with respect to scruples; numberless instances of which occurred in the course of his life. One thing of which Dr Clarke was peculiarly cautious, was not to lose the least minute of his time. He always carried some book about with him, which he would read whilst riding in a coach, or walking in the fields, or if he had any leisure moments free from company or his other studies. Nay he would read even in company itself, where he might take such a liberty without offence to good manners. His memory was remarkably strong. He told Mr Pyle of Lyn, that he never forgot anything which he had once thoroughly apprehended and understood. The Doctor, with his intimate friends, was perfectly free and easy; but if strangers were introduced, he behaved with much circumspection, converging only upon common topics. When he visited Dr Sykes, his usual way was to sit with him upon a couch, and, reclining upon his back, to discourse with him, in the most familiar manner, upon such subjects as were agreeable to the taste and judgment of both. When Sir John Germaine lay upon his death-bed, and was in great confusion and trouble of mind, he sent for Dr Clarke, and requested to know of him whether he should receive the sacrament, and what he should do in his sad condition. The Doctor, who was well acquainted with Sir John's parfits and course of life, sedately replied, that he could not advise him to receive the sacrament, and that he did not think it likely to be of any avail to him with respect to his final welfare. Having said this, he departed without administering the communion, having first recommended the dying man to the mercy of God. Dr Clarke was of a cheerful, and even playful disposition. An intimate friend of his, the late Rev. Mr Bott, used to relate, that once when he called upon him, he found him swimming upon a table. At another time, when the two Dr Clarkes, Mr Bott, and several men of ability and learning were together, and amusing themselves with diverging tricks, Dr Samuel Clarke, looking out of the window, saw a grave blockhead approaching to the house; upon which he cried out, "Boys, boys, be wise, here comes a fool." This turn of his mind hath since been confirmed by Dr Warton, who, in his observations on the following line of Mr Pope,

"Unthongt of frailties cheat us in the wise," says, "Who could imagine that Locke was fond of romances; that Newton once studied astrology; that Dr Clarke valued himself for his agility, and frequent-
Mr. Nichols's Anecdotes of Bowyer, there are several letters and extracts of letters, written to that learned printer by Mr. Clarke, which display him to great advantage as a man of piety, a friend, and a scholar.

In a sketch of his character in the *Biographia Britannica*, furnished by Mr. Hayley, who was his intimate acquaintance, he is represented not only as a man of extensive erudition, but as possessing the pleasing talent of communicating his various knowledge in familiar conversation, without any appearance of pedantry or presumption. Antiquities were the favourite study of Mr. Clarke, as his publications sufficiently show; but he was a secretum, and by no means an uncleeful, votary of the muses. He wrote English verse with ease, elegance, and spirit. Perhaps there are few better epigrams in our language than the following, which he composed on seeing the words *Domus ultima* inscribed on the vault belonging to the dukes of Richmond in the cathedral of Chichester.

> Did he, who thus inscrib'd the wall,  
> Not read, or not believe St. Paul,  
> Who says there is, where'er it stands,  
> Another house not made with hands?  
> Or, may we gather from these words,  
> That house is not a house of Lords?

Among the happier little pieces of his sportive poetry, there were some animated stanzas, describing the character of the twelve English poets, whose portraits, engraved by Verrey, were the favourite ornament of his parlor: but he felt so modest and humble a value on his poetical compositions, that they were seldom committed to paper, and are therefore very imperfectly preserved in the memory of those to whom he sometimes recited them. His taste and judgment in poetry appears very striking in many parts of his learned and elaborate *Connection of Coins*. His illustration of Nestor's cup, in particular, may be esteemed as one of the happiest examples of that light and beauty which the learning and spirit of an elegant antiquarian may throw on a cloudy and mistaken passage of an ancient poet. In strict attention to all the duties of his station, in the most active and unwearied charity, he might be regarded as a model to the ministers of God. Though his income was never large, it was his custom to devote a shilling in every guinea that he received to the service of the poor. As a husband, as a husbandman, and a father, his conduct was amiable and endearing; and to close this imperfect sketch of him with his most striking feature, he was a man of genuine unaffected piety."

CLARKSON, (David) B. D. An eminent non-conformist divine, born in February 1621—2 at Bradford in Yorkshire. He was admitted fellow of Clare-Hall, Cambridge, in 1643 in the place of Doctor Peter Gunning, afterwards bishop of Ely, who was ejected by the parliament. On the 28th of April 1647, Mr. John Tillotson, afterwards Archbishops of Canterbury, being admitted a pensioner in the same college, was placed under his tuition; and so continued until the year 1651, when he resigned his fellowship, and put his pupils under the care of Mr. Tillotson, who became his successor. He, with Dr. John Owen, Dr. Thomas Jacomb, Dr. William Bates, Dr. James Collings, Mr. Peter Vinke, John Howe, and Benjamin Alford, in June
CLA

CLASMUM, in natural history, the name of a genus of fossils, of the clafs of the gypsium; the characters of which are, that they are of a soft texture, and of a dull opaque look, being composed, as all the other gypsiums, of irregularly arranged flat particles.

The word is derived from the Greek κλασμόν, a fragment or small particle; from the flaky small particles of which these bodies are composed. Of this genus there is only one known species; this is of a tolerably regular and even structure; though very coarse and harsh to the touch. It is of a very lively and beautiful red in colour; and is found in thick roundish flakes, which, when broken, are to be seen composed of irregular arrangements of flat particles; and emulate a flinty texture. It will neither give fire with steel nor ferment with acids; but calcines very freely and easily, and affords a very valuable plaster of Paris as do all the purer gypsiums. It is common in Italy, and is greatly esteemed there; it is also found in some parts of England, particularly Derbyshire, but there it is not much regarded.

CLASPERS, or TENDRILS. See CIRRHUS.

CLASS, an appellation given to the most general subdivisions of any thing: thus, animal is subdivided into the classes quadrupeds, birds, fishes, &c. which are again subdivided in ferises or orders; and these last into genera. See BOTANY and ZOOLOGY.

CLASS, is also used in schools, in a synonymous sense with form, for a number of boys all learning the same thing.

CLASSIC, or CLASSICAL, an epithet, chiefly applied to authors read in the classes at schools.

This term seems to owe its origin to Tullius Servius, who, in order to make an estimate of every person's estate, divided the Roman people into six bands, which he called classes. The estate of the first class was not to be under 200. and thefe by way of eminence were called classis, "classes"; hence authors of the first rank came to be called classici, all the rest being said to be infra classem; thus Aristotle is a classic author in philosophy; Aquinas in school divinity, &c.

CLASSICUM was the alarm for battle, given by the Roman generals; and sounded by trumpets and other martial music throughout the army.

CLATHRI, in antiquity, bars of wood or iron, used in securing doors and windows. There was a goddeff called Clathra, that preceeded over the clathri.

CLAVARIA, CLUB-TOP: A genus belonging to the cryptogamia class of plants, and of the order of fungi; the 5th in the natural method. The fungus is smooth and oblong. The hemotales, or oak leather club-top, exactly resembles tanned leather, except that it is thinner and softer. It is of no determined form. It grows in the clifts and hollows of old oaks, and sometimes on sith in Ireland and some places of England, &c. In Ireland it is used to dress ulcers, and in Virginia to spread plasters upon, instead of leather. The militaries, and one or two other species, are remarkable for growing only on the head of a dead insect in the nympha state.

A modern writer on natural history (Mr Miller), has afferted the whole genus of clavaria to belong to the tribe of zeophytes, that is, to the animal and not to the vegetable kingdom. According to his method, he ranks them among the Vermares, under a subdivision...
CLAVERIUM, which he terms *Fungus osellis atomiferis*; thereby understanding them to be compound animals with many orifices on their surface, from which are protruded atoms or animalcules which he supposes to be visible from natural motion, something similar to what is now acknowledged to be a fact with regard to a numerous class of marine bodies termed *corallines*. This motion, however, has not been observed by other naturalists. Schöffer has figured the seeds of several clavariæ as they appeared to him through the microscope; and none of these fungi, when burnt, emit the deface, and repaint again.

CLAVARIVM, in antiquity, an allowance the Roman soldiers had for furnishing nails to secure their shoes with. They raised frequent mutinies, demanding largesse of the emperors under this pretence.

CLAVATA VESTITENCTA, in antiquity, habits adorned with purple clavi, which were either broad or narrow. See CLAVUS.

CLAUBERGE, (John) a learned professor of philosophy and divinity at Delft, was born at Solingen in 1622. He travelled into Holland, France, and England, and in each country obtained the esteem of the learned. The Elector of Brandenburg gave him public testimonies of his esteem. He died in 1665. His works were printed at Amsterdam in 2 vols 4to.

The most celebrated of these is his treatise, entitled *Logica vetus et nova*, &c.

CLAUDE OF LORRAIN, or Claude Colet, a celebrated landscape painter, and a striking example of the efficacy of industry to supply, or at least to call forth, genius. Claude was born in 1600; and being dull and heavy at school, was put apprentice to a pastry-cook: he afterwards rambled to Rome to seek a livelihood; but being very ill-bred, and unaccustomed with the language, no body cared to employ him. Chance threw him at last in the way of Augustino Trafo, who hired him to grind his colours, and to do all his household drudgery, as he kept no other servant. His matter pioneering how to make serviceable to him in some of his greatest works, taught him by degrees the rules of perspective and the elements of design. Claude at first did not know what to make of those principles of art; but being encouraged, and not failing in application, he came at length to understand them. Then his soul enlarged itself space, and cultivated art with wonderful eagerness. He exerted his utmost industry to explore the true principles of painting by an incessant examination of nature, that genuine source of excellence; for which purpose, he made his studies in the open fields; where he very frequently continued from fun rise till the dusk of the evening compelled him to withdraw himself from his contemplations. It was his custom to sketch whatever he thought beautiful or striking; and every curious tinge of light, on all kinds of objects, he marked in his sketches with a similar colour; from which he perfect his landscapes with such a look of real nature, and gave them such an appearance of truth, as proved superior to any artist that ever painted in that style.

The beauties of his paintings are derived from nature herself, which he examined with uncommon fidelity; and Sandrart relates, that Claude used to explain to him, as they walked through the fields, the causes of the different appearances of the same prospect at different hours of the day, from the reflections or refractions of light, from dews or vapours, in the evening or morning, with all the precision of a philosopher. He worked on his pictures with such perseverance as to bring them to perfection, by touching them frequently over again; and if any performance did not answer his idea, it was customary with him to alter, to deface, and repaint it again several times over, till it corresponded with that image pictured in his mind. But whatever struck his imagination, while he observed nature abroad, it was so strongly imprinted on his memory, that on his return to his work, he never failed to make the happiest use of it.

His skies are warm and full of light, and every object is properly illuminated. His distances are admirable, and in every part a delightful union and harmony not only excite our applause but our admiration. His invention is pleasing, his colouring delicate, and his tints have such an agreeable sweetness and variety, as have been but imperfectly imitated by the best frequent artists, but were never equalled. He frequently gave an uncommon resemblance to his finished trees by glazing; and in his large compositions which he painted in fresco, he was so exact that the different species of every tree might readily be distinguished. As to his figures, if he painted them himself, they are very indifferent; and he was so conscious of his deficiency in this respect, that he usually engaged other artists who were eminent to paint them for him; of which number were Courtois and Filippo Laura. His pictures are now very rare, especially such as are undamaged; and those at this time so valued, that no price, however great, is thought to be superior to their merit. In order to avoid a repetition of the same subject, and also to detect such copies of his works as might be injurious to his fame, by being sold for originals, it was his custom to draw (in a paper-book prepared for this purpose) the designs of all those pictures which were transmitted to different countries; and on the back of the drawings, he wrote the name of the person who had been the purchaser. That book, which he entitled *Libro di Verita*, is now in the possession of the duke of Devonshire.

CLAUD, (John) a Protestant divine, born in the province of Angenois in 1619. Meff. de Port Royal using their utmost endeavours to convert M. de Turenie to the catholic faith, presented him with a piece calculated to that end, which his lady engaged Mr Claude to answer; and his performance gave rise to the most famous controversy that was ever carried on in France between the Roman Catholics and the Protestants. On the revocation of the edict of Nantes, he retired to Holland, where he met with a kind reception, and was honoured with a considerable pension by the prince of Orange. He died in 1687; and left a son Isaac Claude, whom he lived to see minister of the Walloon church at the Hague, and who published several excellent works of his deceased father.

CLAUDIA, a vestal virgin at Rome, who being suspected of unchastity, is said to have been cleared from that imputation in the following manner: the image of Cybele being brought out of Phrygia to Rome in a barge, and it happening to stick fast in the river Tyber that it could not be moved, the tying her girdle, the badge of chastity, to the barge, drew
Claudianus, it along to the city, which a thousand men were unable
Claudianus to do.

Claudius Aquæ, (Frontinium) water conveyed to Rome
by a canal or aqueduct of eleven miles in length, the
contrivance of Appius Claudius the censor, and the
first structure of the kind, in the year of Rome 441.
Called also Aqua Appia.

Claudia Copia, (Inscriptions) a name of Lugdunum,
or Lyons in France; the birth-place of the emperor
Claudius: A Roman colony, called Claudia; from its
benefactor the emperor; and Copia, from its plenty of
all necessaries, especially corn. See Lugdunum.

Claudia, or Claudia Via, (Ovid) was that road
which, beginning at the Pons Milvius, joined the
Flaminia, passing through Etruria, on the south side of the
Lacus Sabatius, and striking off from the Cala,
and leading to Luca (Antonine): large remains of it
are to be seen above Bracciano (Holstenius).

Claudius Lex, de Comitiis, was enacted by M. Cl.
Marcellus in the year of Rome 702. It ordained, that
at public elections of magistrates no notice should be
taken of the votes of such as were absent. Another,
de Ufura, which forbade people to lend money to minors,
on condition of payment after the decease of their
parents. Another, de Negationibus, by Q. Claudius the
tribune, 535. It forbade any senator, or father of a
senator, to have any vessel containing above 300 amphi-
cole, for fear of their engaging themselves in commercial
schemes. The same law also forbade the same thing to
the fathers and plupartane of the quellers, as it
was naturally supposed that people who had any com-
mercial connections could not be faithful to their trust
nor promote the interest of the state. Another, 576,
permitted the allies to return to their respective
cities, after their names were enrolled. Liv. 41,
c. 9. Another, to take away the freedom of the
city of Rome from the colonists which Caesar had
carried to Novicoom.

Claudianus, (Claudius) a Latin poet, flour-
rished in the 4th century, under the emperor Theo-
dosit, and under his sons Arcadius and Honorius. It
is not agreed of what country he was a native; but
had a birth, and in the year of which he
was about 30 years old; and there infirnified himself
into Stilicho's favour; who being a person of great
abilities both for civil and military affairs, though a
Goet by birth, was so considerable a person under
Honorius, that he may be said for many years to have
ruled the western empire. Stilicho afterwards fell
into disgrace, and was put to death; and it is more
than probable that the poet was involved in the mis-
fortunes of his patron, and feverely persecuted in his
person and fortunes by Hadrian, an Egyptian by birth,
who was captain of the guards to Honorius, and suc-
ceded Stilicho. There is reafon, however, to think
that he rofe afterwards to great favours; and obtained
fme connections both civil and military. The emperors
Seronas had a great esteem for Claudian, and recom-
ended and married him to a lady of great quality
and fortune in Libya. There are a few little poems
on sacred subjects, which though notd have been
ascribed by some critics to Claudian; and fo have made
him be thought a Christian. But St Anflin, who was
contemporary with him, expressly fays that he was a
Heathen. The time of Claudian's death is uncertain,

nor do we know any further particulars of his life then
what are to be collected from his works, and which
we have already related above. He is thought to
have more of Virgil in his style than all the other imi-
tators of him.

Claudius I. Roman emperor, A. D. 41. The
beginning of his reign was very promising; but it was
soon discovered that little better than an idoe filled
the throne, who might easily be made a tyrant: ac-
cordingly he became a very cruel one, through the
influence of his emperors, the infamous Meallina: af
her death, he married his niece Aripippus, who caused
him to be poisoned to make way for Nero, A. D. 54.
See (History of) Rome.

Claudius II. (Aurelius), famned Gothus, sig-
nalized himself by his courage and prudence under the
reigns of Valerian and Julian; and on the death of the
latter was declared emperor in 268. He put to death
Aureolus, the murderer of Galienus; defeated the
Germans: and in 269 marched against the Goths, who
raeved the empire with an army of 300,000 men,
which he at flart harassed, and the next year entirely
defeated: but a cancer disease, which had spread
through that vast army, was caught by the Romans:
and the emperor himself died of it a short time after,
aged 56. Pollio says, that this prince had the
moderation of Augustus, the virtue of Trajan, and the
piety of Antoninus.

Claves insule, a term used in the Isle of Man;
where all weighty and ambiguous causes are referred
to a jury of twelve, who are called claves infulte,
the keys of the island.

Clavighord, and Clavightherium, two mu-
sical instruments used in the 16th century. They were
of the nature of the spinet, but of an oblong figure.
The first is still used by the nuns in convents; and
that the practitioners may not disturb the singers in
the dormitory, the strings are muffled with small bits of
fine woolen cloth.

Clavicle. See Anatomy, No 46.

Clavicymbalum, in antiquity, a musical in-
strument with 30 strings. Modern writers apply the
name to our harpsichords.

Clavi vestium, were flowers or studs of purple
interwoven with or fewed upon the garments of
knights or senators; only, for distinction, the former
used them narrow, the latter broad.

Clavis properly signifies a key; and is some-
times used in English to denote an explanation of some
obscure passages of any book or writing.

Clavius, (Christopher) a German Jesuit born at
Bamberg, excelled in the knowledge of the mathema-
tics, and was one of the chief persons employed to
rectify the calender; the defence of which he also
undertook against those who cenfured it, especially
Seiliger. He died at Rome in 1612, aged 75. His
works have been printed in five volumes folio; the
principal of which is his commentary on Euclid's ele-
mens.

Clause, in grammar, denotes a member of a pe-
riod or sentence.

Clasr signifies also an article or particular si-
apation in a contract, a charge or condition in a re-
ment, &c.

Mr Beaume has formed a new hypothesis concerning

M. Beaume has formed a new hypothesis concerning

M. Gerhard has found it soluble in a crucible of chalk, though not in one of clay.

The common clays are never free from siliceous earth: the best method of obtaining the argillaceous earth in perfect purity is, by dissolving Roman alum in water, filtering the solution, and precipitating it by mild volatile alkali. When procured by this method, its specific gravity is about 1.250; it is soluble in acids with a little effervescence; it forms alum with the vitriolic acid; and deliquescence sets with the nitrous and marine. When dry it absorbs water greedily, and becomes soft, and acquires such a tenacity that it may be moulded at pleasure; it contrasts, however, greatly in the fire, by which numerous cracks are occasioned. With a certain degree of heat it becomes so hard as to strike fire with steel, and by thus burning it loses its tenacity, the water being excluded by the approach of its particles towards each other. After

having this property, it cannot be made to assume it again without being dissolved in an acid; and then precipitated from it. Fixed alkalies also dissolve it in the dry way, as acids do in the moist; but of these last the vitriolic is the most proper, as it may be most easily concentrated.

According to Mr Kirwan, the specific gravity of this earth, when pure, does not exceed 2.000. It is exceedingly diffusible in water, though scarcely more soluble than magnesia. It is combinable with acids, from whence it may be separated like magnesia, but can scarce be precipitated by the vitriolic acid, with which it forms alum, a salt that always contains an excess of acid, and has an astringent taste. When in combination with any of these acids, it cannot be precipitated by acid of sugar; a criterion by which it is distinguished from all the other earths; every one of which (terra ponderosa alone excepted, which when united to the vitriolic acid, is not affected by any other excepting that of flour) is precipitated from the vitriolic, nitrous and marine acids, by that of sugar. The precipitation of these earths, however, does not take place if there be not the excess of the mineral acids, nor does it always appear before the liquors are evaporated. Though clay is hardened by a very strong heat, it cannot be made thereby to assume the properties of lime. By a mixture with calcareous earth it readily melts; and hence M. Gerhard has found it soluble in a crucible of chalk, though not in one of clay. Its fusion is not promoted by fixed alkali, but borax and microcosmic salt dissolve it; the former with a very slight effervescence, but the latter with a more perceptible one. It is less affected by calces of lead than the calcareous earths are.

M. Beaume has formed a new hypothesis concerning this earth; supposing the basis of alum, or pure argillaceous earth, to be nothing else than flint; and common clay to be siliceous earth combined with a little vitriolic acid. This opinion has been examined by Mr Scheele, who began by trying, in the following manner, whether the siliceous earth be in reality soluble in vitriolic acid. He took an ounce of mountain crystal reduced to powder, and mixing it with three ounces of salt of tartar, melted the whole by a strong fire. The mass was then dissolved in 20 ounces of water, and as much diluted vitriolic acid poured upon it as was more than sufficient for saturation. The liquor being then filtered and evaporated, yielded a drachm and an half of alum, besides a quantity of sub-acid vitriolated tartar. It now remained therefore to determine whether the precipitated siliceous earth, by a repetition of the same process, would still continue to yield alum. The operation was therefore repeated seven times, and a quantity of alum procured at each operation. But when our author was about to be confirmed in his opinion that Mr. Beaume was in the right, he happened to inspect his crucibles, and perceived them to be full of little cavities, and every where rough and uneven on the inside. Thus he began to suspect that the alkali had dissolved part of the clay of his crucibles, by which means the alum had been produced; and this supposition was verified by his afterwards using a crucible of iron, when he could not obtain a single particle of alum, nor perceive the smallest mark of solution on the siliceous earth.

M.
M. Beurné also pretends that clay contains a little vitriolic acid, and is therefore soluble in a large quantity of boiling water. Mr Scheele likewise tried this experiment; but found, that of several kinds of argillaceous earth not the smallest quantity was dissolved; and he likewise made several experiments in order to obtain vitriolic acid from pure clay, but without success: neither was he able to obtain any hepar either by means of alkalies of tartar or with charcoal; nor could he obtain with clay a vitriolic neutral salt from the residuum of the distillation of vitriolic and nitrous acid.

The contraction of clay by heat has afforded Mr Wedgewood an opportunity of constructing by its means an instrument for measuring those degrees of heat which are above the reach of the scale of common thermometers, as described under the article Thermometer.

Mr Scheele has made several experiments to discover the properties of alun when mixed with other substances. A solution of alun, he finds, is decomposed by lime-water; and if no more of the water be added than is exactly requisite for the precipitation, the earth of alun forms a transparent precipitate like boiled itch; and if the clear water be filtered, it is found to be a solution of alun. On adding more lime-water than is necessary for precipitation, the precipitated matter is definite of the gelatinous appearance just mentioned. If the whole be allowed to stand for a quarter of an hour, and frequently agitated during this time, no gypsum, nor even lime, is found in the filtered liquor, unless too much lime-water has been used. On examining the precipitate in this case, our author found it to consist of earth of alun, selenite, and lime. This was discovered first by treating it with muriatic acid, which dissolved the aluminous earth, leaving the gypsum behind. The addition of caustic volatile alkali threw down a transparent gelatinous mass, which was the earth of alun; and on straining it again, and then adding a fixed alkaline lixivium, the lime was thrown down; whence it appeared, that the lime and gypsum had separated from the water, and united with the earth of alun.

To understand the reason of this uncommon precipitation, Mr Scheele next poured into a solution of alun a quantity of caustic volatile alkali more than sufficient to saturate the acid, in order to be certain of having it all taken off. The precipitated earth was then eludefcorated, and mixed with a solution of gypsum, that he might observe whether the gypsum would separate from the water, and precipitate with the earth of alun; which, however, did not take place. On mixing lime-water with the precipitate, he found that the former very soon lost its caustic taste, and that the earth of alun became opaque. Some part of the water was strained, and lixivium tartari dropped into it; but it remained clear, nor was any precipitate formed by a solution of corrosive sublimate. He afterwards added muriatic acid to the last precipitate, which it dissolved entirely without leaving any gypsum behind; whence our author concludes, that the earth of alun had united with the lime into a peculiar kind of compound.

Lastly, he now imagined, that this compound of earth of alun and lime might be capable of separating gypsum from water. To try this, he prepared a large quantity of the compound earth, mixed it with a solution of gypsum, and let it rest for a quarter of an hour; when he found, to his surprize, that the gypsum still remained suspended in the water, and that the precipitate was entirely soluble in muriatic acid. He now mixed a solution of gypsum with lime-water, adding earth of alun at the same time; when he found, that the whole was precipitated as before, the lime and aluminous earth having fallen to the bottom along with the gypsum, leaving the water pure. On the whole, our author concludes, 1. That the vitriolic acid in gypsum is capable of combining with more lime than is necessary to an exact saturation. 2. That calcareous earth is capable of forming an union with the earth of alun. 3. That gypsum cannot combine with the earth of alun; but that if a superfluous quantity of lime be united with vitriolic acid, it will then serve as a bond of union to combine gypsum with the earth of alun, and thus form a new compound consisting of three earths. Pure clay has no effect upon limewater.

Cronstedt is of opinion, that common clay, especially the blue, grey, and red kinds, may derive their origin from mud; and as the mud proceeds from vegetables, it will then follow, that the varieties of clay just mentioned are nothing else but the common mould altered, after a length of time, by means of water. This opinion, he thinks, receives considerable strength from the following circumstances; viz. that a great quantity of sea-plants rot every year in the lakes, and are changed into mud; very little of which, however, is seen upon the shores after the water is dried in the summer-time; and that the clay begins where the mud ceases. Professor Bergman has likewise hinted, that pure clay may be a calcareous earth combined with some acid not yet discovered; but (says he) compositions of this kind ought to be considered as primitive substances, with respect to our knowledge of them, till they shall be experimentally decomposed; for no found knowledge in natural philosophy can be obtained from the consideration of mere possibilities; since daily experience shows, that even the most probable suppositions have proved false, when the means of putting them to the test have afterwards been found out."

"Now, therefore, (says M. Magellan), that the argillaceous is acknowledged to be a simple primitive earth, which cannot be decomposed into any other principles, nor formed by the combination of any other simple substances we know, we ought to rest satisfied at present without endeavouring to account for its formation."

The principal species of the argillaceous earths or clays are,

1. The argilla aerata, or laca lune. It is generally found in small cakes of the hardness of chalk; and which, also, it marks white. Its hardness is nearly like that of the flettites, and it feels less than clays commonly do. It is of a snow-white colour, and about the specific gravity of 1.669. When examined with a microscope, it is found to consist of small transparent crystals; and, from Mr Schreber's experiments, appears to be an argillaceous earth saturated with fixed air, in consequence of which it effervesces with acids. It contains also a small quantity of calcarious earth, and sometimes of gypsum, with some slight traces of iron. It is found at Halles.

2. The argilla aerys, porcelain clay, the kaolin of
the Chinefe, is very refractory in the fire, and cannot in any common strong fire be brought into fusion farther than to acquire a tenacious softness without losing its form. When broken, it has then a dim shining appearance, and is of a solid texture; strikes fire with ease; and has consequently the best chemical properties of any substance whereof vessels can be made. It is found of an excellent quality in Japan, and likewise in different parts of Europe. In Sweden it is met with in coal-pits between the strata of coal. Cronstedt informs us, that he has seen the root of a tree entirely changed into this kind of earth.

M. Magellan remarks, that we must be careful to distinguish between the pipe-clay of which there is plenty in Devonshire in England, and that used in the porcelain manufactures. The former, in a strong fire, burns to a bluish grey or pigeon colour, the latter remains white. The porcelain clay, according to our author, seems to be only a decayed feldspar; and, consequently, according to Mr Bergman, contains magnesia. British porcelain clay contains likewise quartz, crysflats, and mica, parts of the granite which it originally composed. Before it is used, the quartz must be separated, but the mica remains.

3. Combined with phlogiston, and including the white tobacco-pipe clay, with others of a grey, black, or violet colour. Mr Kirwan observes, that many of the white clays become grey in a low degree of heat, because the mineral oil with which they are mixed burns to a kind of coal, and tinges them; but being confumed in a stronger heat, they again become white. The other clays evidently contain phlogiston; in consequence of which, they become quite black in any common fire. When boiled in water, they are also found alfo in the Austrian Flanders in the barony of Hiersges, near Niverle, belonging to the Duke of Arenberg. It was flowed to M. Magellan by the Duke's chancellor; who, from the unprincipled of his behaviour, has obtained the honourable appellation of Jean de Bieu. At present it is only found in separate mafles; but M. Magellan is of opinion, that some considerable strata of it might be met with, if properly searched for on the spot, by digger the ground to a considerable depth.

To this species also belongs the yellowish-brown earth called terra lemmia; which is of a shining texture, and falls to pieces in water with a cracking noise. According to Mr Bergman, this is a compound of the argillaceous, siliceous, and magnesian earths. Its component parts are the same as those of the tale, but looser, and in different proportions. M. Cronstedt remarks, that "the terra lemmia cannot properly be called a fuller's earth, as it is never used in the fulling business, nor is likely to be applicable to it, as being besides very scarce. The true fuller's earth of England agrees entirely with the description of the stone-marrow already given, and in colour and texture resembles that from Sweden, which is compose of coarse particles. The Hampshire fuller's earth is of a dusky brown, inclining to green, with veins of a faint yellow; and contains a small portion of muriatic acid, and of a yellow oily matter. Every fine clay that does not communicate a colour, is in general fit for the business of fulling; even the excrements of hogs, mixed with human urine, are used for this purpose in various woolen manufactures. The properties required in a good fuller's earth are, that it shall carry off the oily impurities of the woollen cloth, and at the same time thicken it by causing the hairs or fibres to curl up. The best is composed of fine siliceous earth with argila, and a little calcareous earth without vitriolic acid; a little martial calx, however, is not hurtful, if not attended with any active menstruum."

The terra lemmia is so called from the island of Lemnos, now Statimane, in the Egyptian Sea, from whence it is procured. It is likewise called the Turkish earth, on account of its being imported with the seal of the Grand Signor.

The Swedish fuller's earth is found in a mountain named Ofmund at Ratwick in East Dalecarlia. The stratum is three feet thick, and the mountain itself is chiefly calcareous. It is of an ash colour; harder, and of finer particles than the Lemnian earth.

"All these substances (the fuller's earths)," says M. Magellan, "are akin to zeolites, and likewise resemble some marles. But in the Ofmundian earths, the connection of the parts is not merely mechanical, as in marles; which on that account effervesce strongly with acids, though they often contain a smaller quantity of calcareous earth or magnesia than the litho marga."

The following table shows the proportion of ingredients in each of the fuller's earth.

5. **Bole**, bole, or iron clay, is a fine and dense clay of various colours, containing a large quantity of iron, so that it is very difficult, or even impossible, to know the natural and specific qualities of the bole itself. It is not so easily softened in water when indurated as the porcelain and common clays; but either falls to pieces in the form of small grains, or repels the water, and cannot be made ductile. In the fire it glows black, and is then attracted by the lodestone.

M. Kirwan thinks the term *bole* a word of such uncertain figuration, that it ought to be banished from common use, or at least from every mineralogical treatise. *Some (says he) with this name upon very smooth compact clays, consisting of the finest particles: others require besides, that their colour should be red, yellow, or brown, and that they should contain iron.* The red generally blacken in the fire: but according to Rinman, without becoming magnetic.

The yellow, when heated, become first red; and, in a strong heat, brown or black. What the Italians call *Calamita Bianca*, according to Ferber, is a white bole friated like albicots. The true *figillata rura* contains calcareous earth; and, according to Rinman, becomes magnetic after torrefaction. The yellow, red, and brown clays contain moft iron, sometimes dispersed through their substance, and sometimes united to the calcareous part; in this case they are friated with greater difficulty. The yellow calx of iron is more dephlogogitated than the red, and the red than the brown. These clays do not become magnetic after calculation, unless they contain 14 or 15 per cent. of iron.

The soft boles are of various colours, as red, yellow, green, grey, and bluish grey. The red kind is that used in medicine under the name of *Armenian bole*; an indurated kind of which affords the material for the red pencils. Formerly, when the terra figurata were esteemed in medicine, the druggists endeavoured to have them of all different colours; for which reason they not only sealed up all the natural forts of clay, but such as had been mixed and coloured artificially; whence the name of boles was proposed to be much more numerous than it really is. Cronstedt concludes, that *since the most part of these terra figurata contain iron, the bole must be a martial clay; and such it seems to be more fit for medical ues than other clays, if any dead earth must be used internally, when there is such an abundance of finer substances*. The indurated bole or flate is of a reddish brown or grey colour, and is found in most costelleries between the seams of coal. It is met with frequently in pieces like nuts of various sizes; which, when broken, exhibit impressions of plants, as the nodules of copper slate from Rinneus contain filth.

6. With fical particles, the *horn-blends* of the Swedes. This is called *horn rock-stone* by Wallerius, who places it among the aphyrous stones; but Linneus has put it among the calcareous stones by the name of *horn flag, talcum corneus*. It is named *calcareum frutium* by Rinman; and has the following properties:

1. Its specific gravity is never less than 2.660, and frequently rises to 3.860. 2. It has a strong earthy smell, which is particularly sensible on breathing upon it, or pouring hot water on it. 3. A toughened or vitreous is perceived on pounding it in a mortar, as is the case with mica and horn; from which last it derives its name. 4. When pounded it affords a greenish-grey powder. 5. It is said to be fusible per ferit; though Mr Kirwan informs us, that he could never melt this stone even by the assistance of a blow-pipe. This stone is frequently mixed with pyrites. It is distinguished from the martial glimmer or mica by the scales being less shining, thicker, and rectangular. It is of two kinds, black, and greenish. The former, when rubbed fine, affords a green powder. It is the *cornuau nitens* of Wallerius, and is either of a lamellated or granular texture; the former being sometimes to soft as to be scraped with the nail, and its surface frequently as glossy as if it had been ground; the specific gravity being from 2600 to 3680. It does not detonate with nitre, but becomes of a smufi-colour when heated, and then slightly effervescences with diluted nitrous acid; the solution assuring a greenish colour. In order to discover the principal on which the smell of this stone depends, Mr Kirwan boiled its powder in water; but could not discover, either by the taste or by any other method, that any thing had been communicated to the fluid. An hundred parts of the lamellar fort contain 37 of siliceous earth, 22 of pure argillaceous earth, 16 of magnesia, and two of calcareous earth, both in a small dose, together with 23 of calx of iron not much deplogogitated. The greenish kind is of a granular texture, or friated; the specific gravity of a specimen examined by Mr Kirwan was 2638. The common pale, greenish-grey whetstone seems to belong to this species.

7. The *zeolite* was first discovered by Cronstedt, and by him reckoned a genus distinct from every other; but on a proper chemical analysis, both Kirwan and Bergman have reckoned them among the argillaceous earths; and here M. Magellan observes, that *it is not so much the quantity as the intensity or predominancy of property that should in general direct us in the classification of mineral bodies; not to mention, that if the rule respecting quantity were rigorously adhered to, the two primitive earths, magnesia and argill, would not be found among the earths; which would doubtless be an absurdity, as Bergman has rightly observed.*

The properties of zeolite are. 1. It is a little harder than the flours, and other calcareous spars, but is scratched by steel, and does not strike fire with it. 2. It melts easily in the fire, with an ebullition like borax, into a white forthy flag, which cannot, without great difficulty, be brought into a solid transparent flate. 3. It dissolves more readily in the fire by the help of mineral alkali, than that of borax or microcosmic salt. 4. It does not ferment with the latter as lime does, nor with the former as those of the gypseous kind. 5. It dissolves very slowly, and without effervescence, in acids, as oil of vitriol, and spirit of nitre. With the former a great heat arises, and the powder unites into a mass. By distillation with nitrous acid, some fixed and deplogogitated airs are procured. Some forts of zeolite, however, found in Sweden, do not melt by themselves in the fire, but are readily dissolved by the acid of nitre into a kind of jelly. 7. The furnible kinds, in the very moment of fusion, emit a phosphoric light.
With regard to the component parts of zeolite, M. Bayen is of opinion that it consists of equal parts of siliceous and argillaceous earths, which is also confirmed by M. Guettard; but according to Mr Bergman's analysis, the red zeolite of Adelfores contains 80 per cent. of siliceous earth; 9.5 of argillaceous; 6.5 of pure calcareous earth; and four of water. The white, oval, radiated zeolite of Feroe in Iceland, contains, according to M. Pelletier, 50 of filex; 20 of argillaceous earth; 8 of pure calcareous earth; and 22 of water. According to Mr Mayer's analysis, a radiated zeolite yielded 58.33 per cent. of filex; 17.5 of argill; 6.66 of lime; and 17.5 of water. In general the crystallized kind contain more water than the other. At any rate, though the proportions of ingredients are various, filex always seems to predominate.

In general the zeolites are of a crystalline form, composed of imperfect pyramids turned towards a common centre; their form is sometimes globular, but seldom prismatic. Meliss Faugas and Rome de l'isle mention zeolites, of cubic and other forms, found in Iceland, the Cyclops Islands near Etna in Sicily, the island of Bourbon, &c. their specific gravity is from 2.100 to 3.150; but this last is very rare. Fabroni mentions a fennit trasparent zeolite from Garphytyn in Sweden, which has an electric power. To the species of zeolite also belongs the lapis lazuli, from which ultramarine is made. See Lapis Lazuli, and Ultramarine.

The sparry zeolite resembles a calcareous spar; but is of a more irregular figure, as well as more brittle. It is found in Sweden of a light red or orange colour.

The crystallized zeolites are met with in greater plenty than the other kinds; and are found in Sweden of various forms and colours. Brunihs informs us, that in the north, the countries of the zeolites and of the chalcedony and catholong, pieces are shown as curiosities, in which the zeolite is inclosed in the chalcedony; but this is not sufficient to prove that the one was produced from the other.

Cronfeldt observes, that the zeolites have nearly the same qualities in the fire as the boles. The property of swelling in the fire, like borax, is peculiar to zeolites. The sensitive zeolite is of a more irregular figure, as well as more brittle or mixed with phlogilithon and a large quantity of vitriolic acid; in which case it constitutes the ores of alums. It is also found in this state, however, it is not fusible than any of them. In this country also is found a species called, by Cronfeldt, fermenting clay, argilla intumescent. It is very like the preceding as to the external appearance and other qualities: but, when both are found in the same place, they seem to be different in regard to the fermenting property of this variety. "This fermentation (says our author) cannot be the effect of the sand mixed with it, because sand is found in them both: and besides, this kind ferments in the same manner when it is mixed with gravel or stones; and then it ferments later in the spring than the other, since by the stones, perhaps, the frost is longer retained in it.

This kind of clay is also found mixed with calcareous earth, in which case it is called MARLE. It is also found in an indurated state, and that either pure or mixed with phlogilithon and a large quantity of vitriolic acid; in which case it constitutes the ores of alums. It is also found in this state mixed with calcareous earth, forming those marls.

10. Argillaceous Soffia stones. The most remarkable of these are, 1. The scifus regularis, or common house-flake. It is of a bluish purple colour, does not strike fire with steel, and may be slightly scraped with the nail. It is very brittle, of a lamellar texture, and of the specific gravity 2.876; giving a clear sound when in pieces of half an inch thick. It is never transparent, but has a moderately fine grain, effervescing slightly with acids when powdered, but not otherwise. In the fire it loses upwards of 2 per cent. of its weight; detones slightly with nitre, and then affumes a brownish red colour; but this is not rendered magnetic by calcination. By a vehement heat, it is fusible per fe, and melts into a black scoria. It melts with difficulty in the dry way with mineral alkali, but more easily with borax, and microcosmic salt, with little effervescence; and it melts with equal ease in chalk or clay vesels. By digestion for two months in dephtlogifaced spir it of nitre, the menstrfum affumes a green colour. According to Mr Kirwan, it contains 26 parts of argillaceous earth; 46 of siliceous; 8 of magnesia; 4 of calcareous earth; and 14 of iron. Part of the iron seems to be phlogilicated by a mineral oil united with it; and part dephtlogilicitated, or in a red calx. This last is united to the argillaceous part as well as to the siliceous, and cannot be separated without great difficulty. The colour of this flate varies to the pale, to the slightly purple, and to the bluish. The laminæ of the leaf are thicker, their texture coarser, and they contain more siliceous earth and
Clay, and left iron than the foregoing. Other clays are also made use of for covering houses; but their laminæ are much thicker, their surface more uneven, and their texture coarser. They belong chiefly to the sand-clays, or to the calcareous kinds. The dark blue schistus scriptorius contains more magnesia and left iron than the foregoing, and therefore effervesces more briskly with acids. Its specific gravity is 2.701. 2. The pyritaceous schistus, to which also belongs that from which alum is made, is of a grey, blue, brown, or black colour; and is more or less decomposable by its exposure to air, according to the quantity of the pyrites, and the state of the iron in it. When the iron is in a semiphlogilis tate, the schistus will be easily decomposed; but much more slowly, if at all, when the clax is much dephlogilis tated. 3. The bituminous schistus is generally black, of a lamellar texture, and various degrees of hardness. It never gives fire with fuel, but emits a strong smell when heated, and sometimes without being heated. When scraped it does not produce any white mark like the other schistus. M. Magcillan mentions a speci men found in Yorkshire which burned like coal, with a strong smell of bitumen.

There are various other species of argillaceous earths, as the flag-clay, sand or fre clay, toad-flone, &c. for a description of which see these articles.

Clays are of very extensive use in common life. Some varieties of the porcelain clay become perfectly white in the fire; and it is not to be doubted but these are used in the porcelain manufactories. The induced porcelain clay, however, cannot be easily heated without cracking, and therefore we can go no great length in hardening it. The boles have almost lost their value as medicines; but are still employed to make bricks, potter’s ware, &c. Trilopi is of indiff erent use in the binnels of polishing, and is likewise used in many occasions, being a mould of metals in.

In agriculture, clay is indifferently necessary; excepting, however, according to Cronfiedt, the white and fermenting clays abovementioned, for which no use has yet been discovered. By its coherency clay retains humidity; on which perhaps its chief power of promoting vegetation depends.

Dr Black observes, that clay, when mixed with a large proportion of water, and kneaded a little, becomes a remarkable ductile adhesive mass, which is not easily dissolved in more water, and to render it thin and fluid requires great trouble. Hence it is employed for confining large quantities of water, as in making canals and dykes; but the soil must either contain a great quantity of clay naturally, or some quantity of it must be spread on the bottom; or the water itself must deposit a quantity of clay sufficient to render it tight. Hence also we see the bad effects of allowing cattle to tread much in clay-grounds when wet; for the clay is reduced to such an adhesive mass as to not to admit the roots to penetrate the soil, or the water to enter to the roots.

Clay is used in the refining of sugar; for which no other property is requisite than that it may dry too soon; but that species used in fulling must, if we were to judge a priori, besides the fineness of its properties, be of a dry nature, or such as attracts oils; tho’ this quality perhaps may not be found in all those clays that are now employed in the business. According to Fabroni, the pure white clay being calcined in a strong heat, acquires a phosphorecent quality.

Clay, a town of Norfolk in England, seated on an arm of the sea between two rivers, in L. Long. 0. 30. N. Lat. 47. 28.

Clay-Lands, those abounding with clay, whether black, blue, yellow, white, &c. of which the black and the yellow are the best for corn.

All clay-foils are apt to chill the plants growing on them so as to freeze their roots, as they retain too much water: in dry seasons, on the contrary, they turn hard and choke the plants. Their natural produce is weeds, goat-gras, large daisies, thistles, docks, poppies, &c. Some clay-foils will bear clover and rye-gras; and, if well manured, will produce the best grain: they hold the moisture best of all lands; and the most proper for them are horse-dung, pigeons dung, some kinds of marle, folding of sheep, malt-duft, ashes, chalk, lime, foot, &c.

Clayton, (Dr Robert) a prelate of great learning, of distinguished worth and probity, and a respectable member of the royal and Antiquarian Societies of London, was advanced to the bishopric of Killala, Jan. 23, 1729; translated to the see of Cork, Dec. 19, 1735; to that of Clogher, Aug. 26, 1745: and died much lamented, Feb. 25, 1758. His publications are, 1. A Letter in the Philosophe Transactions, n° 461, p. 813, giving an account of a Frenchman 70 years old (at Inisihan, in his diocese of Cork), who said he gave suck to a child.—2. The Chronology of the Hebrew Bible vindicated, &c. 1751, 4to.—3. An impartial Inquiry into the Time of the Coming of the Messiah; 1751, 8vo.—4. An Essay on Spirit, 1751, 8vo.—5. A Vindication of the Histories of the Old and New Testament, in Answer to the Objections of the late lord Bolingbroke: in Two Letters to a young Nobleman, 1752, 8vo, reprinted in 1753. —6. A defence of the Essay on Spirit under the name of Remarks on the several pretended Answers; and which may serve as an Antidote against all that shall ever appear against it, 1753, 8vo. 7. A Journal from Grand Cairo to Mount Sinaï, and back again, translated from a Manuscript written by the Prefetto of Egypt, in Company with some Missionaries de propaganda fide at Grand Cairo; to which are added, Remarks on the Origin of Hieroglyphics, and the Mythology of the ancient Heathens, 1753, 8vo, two editions 4to and 8vo. It was soon after this publication that his Lordship became (in March 1754) a fellow of the Society of Antiquaries.—8. Some Thoughts on Self-love, Inmate Ideas, Free-will, Taste, Sentiments, Liberty, and Necessity, &c. occasioned by reading Mr Hume’s Works, and the short Treatise written in French by Lord Bolingbroke on Compassion, 1754, 8vo.—9. A Vindication of the Histories of the Old and New Testament, Part II. Adorned with several Explanatory Cuts, 1754, 8vo.—10. Letters between the bishop of Clogher and Mr William Penn, concerning Baptilism, 1755, 8vo.—11. A Speech made in the House of Lords in Ireland, on Monday, Feb. 2, 1756, for omitting the New Ceren
CLEANthes, a Stoic philosopher, disciple of Zeno, flourished 240 years before Christ. He maintained himself in the day by working in the night: being questioned by the magistrates how he subsisted, he brought a woman for whom he kneaded bread, and a gardener for whom he drew water; and refused a present from them. He composed several works, of which there are now only a few fragments remaining.

CLEAR, as a naval term, is variously applied to the weather, the sea-coasts, cordage, navigation, &c. The weather is said to be clear when it is fair and open, as opposed to cloudy or foggy. The sea-coast is called clear when the navigation is not interrupted, or rendered dangerous by rocks, sand, or breakers, &c. It is expressed of cordage, cables, &c., when they are unembarrassed or disentangled, so as to be ready for immediate service. It is usually opposed to foul in all these senses.

CLEARCHUS, a tyrant of Heraclea in Pontus, who was killed by Chion and Leonidas, Plato's pupils, during the celebration of the festivals of Bacchus. He had enjoyed the sovereign power during 12 years. A Lacedaemonian sent to quiet the Byzantines. He was recalled, but refused to obey, and fled to Cyrus the younger, who made him captain of 13,000 Greek soldiers. He obtained a victory over Artaxerxes: who was so enraged at the defeat, that when Clearchus fell into his hands by the treachery of Tissaphernes, he put him immediately to death.

CLEATS, in naval affairs, pieces of wood having one or two projecting ends whereby to fasten the ropes; some of them are fastened to the throns below for this purpose, and others nailed to different places of the ship's deck or sides.

CLECHE, in heraldry, a kind of cross, charged with another cross of the same figure, but of the colour of the field.

CLEDDGE, among miners, denotes the upper stratum of fuller's earth.

CLEDONISM, Cledonismus, a kind of divination in use among the ancients. The word is formed from aedon, which signifies two things, rumor, "a report," and avis, "a bird." In the first sense, cledonism should denote a kind of divination drawn from words occasionally uttered. Cicero observes, that the Pythagoreans made observation not only of the words of the gods, but of those of men; and accordingly believed the pronouncing of certain words, e.g., incendium, at a meal, very unhappy. Thus, instead of prison, they used the word domicilium; and to avoid erinyes, furies, said somnium. In the second sense, cledonism should seem a divination drawn from birds; the same with ornithomantia.

CLEEVERS, See Clivers.

CLEF, or CLIFF, in music, derived from the Latin word clavis, a key, because by it is expressed the fundamental found in the diatonic scale, which requires a determined succession of tones or semitones, whether major or minor, peculiar to the note from whence we set out, and resulting from its position in the scale. Hence, as it opens a way to this succession, and discovers it, the technical term key is used with great propriety. But clefs rather point out the position of different musical parts in the general system, and the relations which they bear one to another.

A clef, says Rousseau, is a character in music placed at the beginning of a clave, to determine the degree of elevation occupied by that clave in the general clavitory or system, and to point out the names of all the notes which it contains in the line of that clef.

Anciently the letters by which the notes of the gamut had been signified were called clefs. Thus the letter A was the clef of the note la, C the clef of ut, E the clef of mi, &c. In proportion as the system was extended, the embellishment and superfluity of this multitude of clefs were felt.

Guî d'Arezzo, who had inverted them, marked a letter or clef at the beginning of each line in the clave; for as yet he had placed no notes in the spaces. In process of time they marked no more than one of the seven clefs at the beginning of one of the lines only; and this was sufficient to fix the position of all the rest, according to their natural order: at last, of these seven lines or clefs they selected four, which were called claves dignatae, or discriminating clefs; because they satisfied themselves with marking one of them upon one of the lines, from which the powers of all the others might be recognized. Prefently afterwards they even retrenched one of these four, viz. the gamma, of which they made use to mark the /d\ below, that is to say, the hypoprolambanomena added to the system of the Greeks.

In reality Kircher afferts, that if we understood the characters in which ancient music was written, and examined minutely the forms of our clefs, we should find that each of them represents the letter a little altered into its form.
the clef of $\dot{f}a$ was originally a $G$, the clef of $nt$ a $C$, and
the clef of $fa$ an $F$.

We have then three clefs, one a fifth above the other: the clef of $F$, or $fa$, which is the lowest; the clef of $nt$, or $C$, which is a fifth above the former; and the clef of $f_{o}l$, or $G$, which is a fifth above that of $nt$. These clefs, both as marked by foreigners in Britain, may be seen in art. 170 of Music; upon which it is necessary to remark, that by a remnant of ancient practice, the clef is always placed upon a line and never in a space. It deserves notice, that the clef of $fa$ is marked in three different manners: one in music which is printed; another in music which is written or engraven; and a third in the full harmony of the chorus.

By adding four lines above the clef of $f_{o}l$, and three lines beneath the clef of $fa$, which gives both above and below the greatest extent of permanent or established lines, it appears, that the whole scale of notes which can be placed upon the gradations relative to these clefs amounts to $24$; that is to say, three octaves and a fourth from the $F$, or $fa$, which is found beneath the first line, to the $f_{1}$, or $B$, which is found above the last, and all this together forms what we call the general claviary; from whence we may judge, that this compass has, for a long time, constituted the extent of the system. But as at present it is continually acquiring new degrees, as well above as below, the degrees are marked by leger lines, which are added above or below as occasion requires.

Instead of joining all the lines, as has been done by Roufleau in his Dictionary, (plate A, fig. 5.) to mark the relation which one clef bears to another, they separate them five by five; because it is pretty nearly within the degrees to which the compass of ordinary voices extends. This collection of five lines is called a stave; and in these they place a clef, to determine the names of the notes, the positions of feminines, and to show what station the stave occupies in the claviary or general scale.

In whatever manner we take five successive lines in the claviary, we shall find one clef comprehended; may, sometimes two; in which case one may be retrenched as useless. Custom has even preferred which of the two should be retrenched, and which retained; it is this likewise which has determined the number of positions assigned to each clef.

If I form a stave of the first five lines in the claviary, beginning from below, I find the clef of $fa$ in the fourth line. This then is one position of the clef, and this position evidently relates to the lowest note; thus likewise it is that of the bass clef.

If I wish to gain a third in ascents, I must add a line above; I must then obliterate one below, otherwise the stave will contain more than five lines. The clef of $fa$ then is found transferred from the fourth to the third, and the clef of $nt$ is likewise found upon the fifth; but as two clefs are useless, they retrench here that of $nt$. It is evident, that the stave of this clef is a third higher than the former.

By throwing away still one line below to gain another above, we have a third kind of stave, where the clef of $fa$ will be found upon the second line, and that of $nt$ upon the fourth. Here we leave out the clef of $f_{o}l$, and retain that of $nt$. We have now gained another third above and lost it below.

By continuing these alterations from line to line, we pass successively through four different positions of the clef of $nt$. Having arrived at that of $fa$, we find it placed upon the second line, and then upon the first. This position includes the five highest lines, and gives the sharpest disunion which the clefs can signify.

The reader may see in Roufleau's Musical Dictionary, Plate A, fig. 5, this succession of clefs from the lowest to the highest; which in all constitutes eight staves, clefs, or different positions of clefs.

Whatever may be the character and genius of any voice or instrument, if its extent above or below does not far surpass that of the general claviary, in this number may be found a stave and a clef suitable to it; and there are, in reality, clefs determined for all the parts in music. If the extent of a part is very considerable, so that the number of lines necessary to be added above or below may become inconvenient, the clef is then changed in the course of the music. It may be plainly perceived by the figure, what clef it is necessary to choose, for raising or depressing any part, under whatever clef it may be actually placed.

It will likewise appear, that in order to adjust one clef to another, both must be compared by the general claviary, by means of which we may determine what every note under one of the clefs is with respect to the other. It is by this exercise repeated that we acquire the habit of reading with ease all the parts.

From this manoeuvre it follows, that we may place whatever note we please of the gamut upon any line or space whatever of the stave, since we have the choice of eight different positions, which is equal to the number of notes in the octave. Thus you may mark a whole tune upon the same line, by changing the clef at each gradation. The 7th fig. of the same plate in Roufleau's Musical Dictionary, to which we formerly referred, shows by the series of clefs the order of the notes, $re$, $fa$, $la$, $nt$, $mi$, $f_{o}l$, $fi$, $re$, rising by thirds, although all placed upon the same line. The fig. following represents upon the order of the same clefs the note $nt$, which appears to descend by thirds upon all the lines of the stave; and further, which yet, by means of changing the clef, still preserves its unison. It is upon such examples as this, that scholars ought to exercise themselves, in order to understand at the first glance the powers of all the clefs, and their simultaneous effect.

There are two of their positions, viz. the clef of $fa$ upon the first line, and that of $fa$ upon the third, which seem daily to fall more and more into defectitude. The first of these may seem less necessary, because it produces nothing but a position entirely similar to that of $fa$ upon the fourth line, from which however it differs by two octaves. As to the clef of $fa$, it is plain, that in removing it entirely from the third line, we shall no longer have any equivalent position, and that the composition of the claviary, which is at present complete, will by these means become defective.

Thus much for Roufleau's account of clefs. He proceeds to explain their transposition; but as this would render
render the present article too long and intricate, we
remit the curious to his *Musical Dictionary*, vol. 1.

CLEFT, in a general sense, is a space made by the
separation of parts. Green timber is very apt to split
and cleave in several places, after it is wrought into
form; and these cracks in it are very disagreeable to
the sight. The common method of the country carpenters
is to fill up these cracks with a mixture of
grease and sawdust; but the neatest way of all is,
the soaking both sides well with the fat of beef-broth,
and then dipping pieces of sponge into the fame broth,
and filling up all the cracks with them: they swell
out so as to fill the whole crack; and accommodate
themselves so well to it, that the deficiency is hardly
seen.

**CLEFTS, or Cracks**, in farriery, appear on the
ought of the patterns, and are caused by a sharp
and malignant humour. See *Farriery*, feet. xxxii.

CLEMA, in antiquity, a twig of the vine, which
serves as a badge of the Centurion's office.

**CLEMATIS, virgin's-bower**: A genus of the
polygynia order, belonging to the polyandra class
of plants; and in the natural method ranking under the
26th order, *Multifilique*. There is no calyx; the petals
are four, rarely five; the seeds have a train. There
are twelve species; all of which, except two are shrub-
by climbing plants, very hardy, and adorned with
quadrupetalous flowers of red, blue, purple, white, and
greenish colours. They are very easily propagated
by layers or cuttings. The vitis alba, one of the spe-
cies, is very acrid to the taste, and without any smell.
It is frequently used as a caustic, and for cleansing old
ulcers. The root is said to be purgative. The leaves
of all the species bruised and applied to the skin, burn
it into carbuncles as in the plague; and if applied to
the nostrils in a faltry day immediately after being
cropped, will cause the same uneasy sensation as a flame
applied to that part would occasion. Hence the title of
*flammula*, or "little flame," by which this genus of
plants was formerly distinguished.

**CLEMENCY**, denotes much the same with mercy
and implies a remission of severity towards offenders.
The term is most generally used in speaking of the
forgiveness exercised by princes or persons of high
authority. It is the result, indeed, of a disposition
which ought to be cultivated by all ranks, though its
effects cannot be equally conspicuous or extensive.
In praise of clemency joined with power, it is observed,
that it is not only the privilege, the honour, and the duty of a prince, but it is also
his security, and better than all his garisons, forts, and
guards, to preserve himself and his dominions in safety:
That that prince is truly royal, who masters himself;
looks upon all injuries as below him; and gov-
erns by equity and reason, not by passion or caprice.
In illustration of this subject, the following examples
are selected out of many recorded in history.

Sueton. c. 9.

1. Two patricians having confpired against
Titus the Roman emperor, were discovered, convicted,
and sentenced to death by the senate: but the good-na-
tured prince sentenced them, in private admonished
them, that in vain they aspired to the empire, which
was given by destiny; exhorting them to be satisfied
with the rank in which by Providence they had been
placed, and offering them any thing else which was
in his power to grant. At the same time he dispatched
a messenger to the mother of one of them, who was
then at a great distance, and under deep concern about
the fate of her son, to assure her, that her son was not
only alive, but forgiven.

2. Licinius having raised a numerous army, Zon.
inus says 130,000 men, endeavoured to wrest the
government out of the hands of his brother-in-law
Constantine the emperor. But his army being defeated,
Licinius fled with what forces he could rally to
Nicomedea, whither Constantine pursued him, and imme-
diately invested the place; but on the second day of
the siege, the emperor's filler interreating him, with
a flood of tears, by the tendernefs he had ever
shown for her, to forgive her husband, and grant him at least
his life, he was prevailed upon to comply with her re-
quest; and the next day, Licinius, finding no means
of making his escape, presented himfelf before the
conqueror, and throwing himself at his feet, yielded
to him the purple and the other ensigns of sovereignty.
Constantine received him in a very friendly manner,
entertained him at his table, and afterwards sent him to
Thessalonica, affuring him, that he should live un-
molested for long as he raised no new disturbances.

3. The council of thirty, established at Athens by
the conqueror, committed the most execrable cruelties.
Upon pretence of retaining the multitude within
their duty, and to prevent seditions, they had caused
guards to be affigned them, had armed 3000 of the
citizens for that purpose, and at the same time dis-
armed all the rest. The whole city was in the utmost
terror and difmay. Whoever opposed their injustice
and violence fell a victim to their resentment. Riches
were a crime that never failed of drawing a sentence
upon their owners, always followed with death and the
confignation of estates; which the thirty tyrants di-
vided amongst themselves. They put more people to
death (says Xenophon) in eight months of a peace,
than their enemies had done in a war of thirty years.

Sueton. c. 9.

2. Two patricians having confpired against
Titus the Roman emperor, were discovered, convicted,
and sentenced to death by the senate: but the good-na-
tured prince sentenced them, in private admonished
them, that in vain they aspired to the empire, which
was given by destiny; exhorting them to be satisfied
with the rank in which by Providence they had been
placed, and offering them any thing else which was
in his power to grant. At the same time he dispatched
a messenger to the mother of one of them, who was
then at a great distance, and under deep concern about
the fate of her son, to assure her, that her son was not
only alive, but forgiven.

2. Licinius having raised a numerous army, Zon.
inus says 130,000 men, endeavoured to wrest the
government out of the hands of his brother-in-law
Constantine the emperor. But his army being defeated,
Licinius fled with what forces he could rally to
Nicomedea, whither Constantine pursued him, and imme-
diately invested the place; but on the second day of
the siege, the emperor's filler interreating him, with
a flood of tears, by the tendernefs he had ever
shown for her, to forgive her husband, and grant him at least
his life, he was prevailed upon to comply with her re-
quest; and the next day, Licinius, finding no means
of making his escape, presented himfelf before the
conqueror, and throwing himself at his feet, yielded
to him the purple and the other ensigns of sovereignty.
Constantine received him in a very friendly manner,
entertained him at his table, and afterwards sent him to
Thessalonica, affuring him, that he should live un-
molested for long as he raised no new disturbances.
Clemency, troops, and a battle ensued. The tyrants were overthrown. Critias, the most savage of them all, was killed on the spot: and as the army was taking to flight, Thrasylalus cried out, “Wherefore do you fly from me as from a victor, rather than allow me as the avenger of your liberty? We are not enemies, but fellow-citizens; nor have we declared war against the city, but against the thirty tyrants.” He continued with bidding them to remember, that they had the same origin, country, laws, and religion: he exhorted them to compassionate their exiled brethren, to restore their country to them, and resume their own liberty. This discourse had the desired effect. The army, upon their return to Athens, expelled the thirty, and substituted ten persons to govern in their room, whose conduct proved no better than theirs: but king Pausanius, moved with compassion for the deplorable condition to which a once so flourishing, was reduced, had the generosity to favour the Athenians in secret, and at length obtained a peace for them. It was sealed with the blood of the tyrants, who having taken arms to reinstate themselves in the government, were all put to the sword, and left Athens in the full possession of its liberty. All the exiles were recalled. Thrasylalus at that time proposed the celebrated Amnesty, by which the citizens engaged upon oath, that all past transactions should be blotted out, and the people were re-established upon its ancient foot, the laws were restored to their primitive vigour, and magistrates elected with the usual form.

This (says Rollin) is one of the finest events in ancient history, worthy the Athenian clemency and benevolence, and has served as a model to successive ages in all good governments. Never had tyranny been more cruel and bloody than that the Athenians had lately thrown off. Every house was in mourning, every family bewailed the loss of some relation: it had been a series of public robbery and rapine, in which licence was bloody than that the Athenians had lately thrown off. Every house was in mourning, every family bewailed the loss of some relation: it had been a series of public robbery and rapine, in which licence was}

4. Such conduct, after great troubles in a state, has always seemed, with the ablest politicians, the most certain and ready means to restore the public peace and tranquillity. Cicero, when Rome was divided into two factions upon the occasion of Caesar’s death, who had been killed by the conspirators, calling to mind this celebrated amnesty, proposed, after the example of the Athenians, to bury all that had passed in eternal oblivion.

5. Cardinal Mazarine observed to Don Lewis de Haro, prime minister of Spain, that this gentle and humane conduct in France had prevented the troubles and re- volts of that kingdom from having any fatal consequences, and “that the king had not lost a foot of land by them to that day;” whereas “the inflexible severity of the Spaniards was the occasion that the subjects of that monarchy, whenever they threw off the mask, never returned to their obedience but by the force of arms; which sufficiently appears (says he) in the example of the Hollanders, who are in the peaceable possession of many provinces, that not an age ago were the patriots of the king of Spain.”

6. Leonidas the Lacedaemonian having, with 300 hired men only, disputed the pas of Thermopylae against the whole army of Xerxes; and being killed in that engagement, Xerxes, by the advice of Mardonius one of his generals, caused his dead body to be hung upon a gallows, making thereby the intended dishonour of his enemy his own immortal fame. But some time after, Xerxes being defeated, and Mardonius slain, one of the principal citizens of Argina came and addressed himself to Pausanius, desiring him to avenge the indignity that Mardonius and Xerxes had shown to Leonidas, by treating Mardonius’s body after the same manner. As a further motive for doing so, he added, that by thus satisfying the manes of those who were killed at Thermopylae, he would be sure to immortalize his own name throughout all Greece, and make his memory precious to the latest posterity.

“Carry thy base counsels elsewhere (replied Pausanius); thou must have a very wrong notion of true glory to imagine, that the way for me to acquire it is to resemble the Barbarians. If thee of the people of Argina is not to be purchased but by such a proceeding, I shall be content with preferring that of the Lacedemonians only, amongst whom the base and ungenerous pleasure of revenge is never put in competition with that of flowing clemency and moderation to their enemies, especially after their death. As for the souls of my departed countrymen, they are sufficiently avenged by the death of the many thousand Persians slain upon the spot in the late engagement.”

Clemens Romanus, bishop of Rome, where he is said to have been born; and to have been fellow-labourer with St Peter and St Paul. We have nothing remaining of his works that is clearly genuine, excepting one epistle, written to quiet some disturbances in the church of Corinth; which, next to holy writ, is esteemed one of the most valuable remains of ecclesiastical antiquity.

Clemens Alexandrinus, so called to distinguish him from the former, was an eminent father of the church, who flourished at the end of the second and beginning of the third centuries. He was the scholar of Pantaenus, and the instructor of Origen. The best edition of his works is that in 2 vols folio, published in 1725, by archbishop Potter.

Clement V. (pope) the first who made a public sale of indulgences. He transplanted the holy see to Avignon in France; greatly contributed to the supression of the knights templars; and was author of a compilation of the decrees of the general councils of Vienne, styled Clementines. He died in 1314.

Clement VII. (Julius de Medici), pope, memorable for his refusing to divorce Catherine of Aragon from Henry VIII.; and for the bull he published upon
Clement upon the king's marriage with Anne Boleyn; which according to the Romish authors, loft him England. He died in 1534.

Clement XIV. (Francis Laurentius Ganganelli), the late pope, was born at St Angelo in the duchy of Urbino, in October 1705; and chosen pope, though not yet a bishop, in 1769: at which time the see of Rome was involved in a most disagreeable and dangerous contest with the house of Bourbon. His reign was rendered troublesome by the collision of parties on the affairs of the Jesuits; and it is pretended that his latter days were embittered by the apprehensions of poison. Though this report was probably apocryphal, it is said that he often complained of the heavy burden which he was obliged to bear; and regretted, with great sensibility, the loss of that tranquillity which he enjoyed in his retirement when only a Franciscan. He was, however, fortunate in having an opportunity, by a single act, to distinguish a short administration of five years in such a manner as will ever prevent its linking into obscurity. His death was immediately attributed to poison, as if an old man from a suppression of urine, to which he was prone. It is said that those powers who had procured their elevation, to prevent the revival of a dangerous contest with the Jesuits; and it is reported that the malevolence of their enemies embellished it with circumstances. It even seems as if the ministers of those powers who had procured their dissolution did not think it beneath them to countenance the report; as if falsehood was necessary to prevent the revival of a body which had already funk, in its full strength, under the weight of real misconduct. The charge was the more ridiculous, as the pontiff had undergone a long and painful illness, which originally proceeded from a suppression of urine, to which he was subject; yet the report was propagated with the greatest industry: and though the French and Spanish ministers were present at the opening of his body, the most horrid circumstances were published relative to that operation. It was confidently told that the head fell off from the body, and that the spleen poisoned and killed the operators. It availed little that the operators showed themselves alive and in good health, and that the surgeons and physicians proved the falsehood of every part of the report. Clement XIV. appears to have been a man of a virtuous character, and possessed of considerable abilities. He died much regretted by his subjects.

Clementine, a term used among the Augustines, who apply it to a person who, after having been nine years a superior, ceases to be so, and becomes a private monk, under the command of a superior. The word has its rise hence, that pope Clement, by a bull, prohibited any superior among the Augustines from continuing above nine years in his office.

Clementines, in the canon law, are the constitutions of pope Clement V. and the canons of the councils of Vienne.

Clenard, (Nicholas) a celebrated grammarians in the 16th century, was born at Dieu; and having taught humanity at Louvain, travelled into France, Spain, Portugal, and Africa. He wrote in Latin, 1. Letters relating to his Travels, which are very curious and scarce. 2. A Greek Grammar, which has been revised and corrected by many grammarians; and other works. He died at Grenoble in 1542.

Cleobis and Biton, two youths, sons of Cydipp, the priests of Juno at Argos. When oxen could not be procured to draw their mother's chariot to the temple of Juno, they put themselves under the yoke, and drew it 45 stadia to the temple, amidst the acclamations of the multitude, who congratulated the mother on account of the piety of her sons. Cydipp intreated the gods to reward the piety of her sons with the best gift that could be granted to a mortal. They went to rest and awoke no more; and by this the gods showed that death is the only true happy event that can happen to a man. The Argives raised them flames at Delphi.

Cleobulus, son of Evagoras, and one of the Greek fages; he was valiant, a lover of learning, and an enemy to vice. Flourished about 690 years before Christ.

Cleombrotus, a king of Sparta, son of Anaxandrides. He was deterred from building a wall across the isthmus of Corinth against the approach of the Persians, by an eclipse of the sun. He died in the 75th Olympiad, and was succeeded by Philiarchus, son of Leonidas, a minor.

Cleomenes II. son of Panthias king of Sparta, after his brother Ageipolis I. He made war against the Boeotians; and lest he should be suspected of treacherous communications with Epaminondas, he gave that general battle at Lenæa, in a very disadvantageous place. He was killed in the engagement, and his army destroyed, in the year of Rome 382.

Cleombratius III. a son-in-law of Leonidas king of Sparta, who for a while usurped the kingdom after the expulsion of his father-in-law. When Leonidas was recalled, Cleombratius was banished, and his wife Chelonis who had accompanied her father, now accompanied her husband in his exile.

Clemens, in botany: A genus of the siliquoidea order, belonging to the tetradynamia class of plants; and in the natural method ranking under the 25th order, Putaminaceae. There are three neocalcariferous glansules, one at each sinus of the calyx except the lowest; the petals all rising upwards; the silique unilocular and bivalved. There are 15 species; all of them, except two, natives of warm climates. They are herbaceous plants rising from one to two feet high; and are adorned with flowers of various colours, as red, yellow, flesh colour, &c. They are propagated by seeds, and require no other care than what is common to other exotics which are natives of warm countries.

Cleomenes, king of Sparta, conquered the Argives, and freed Athens from the tyranny of the Pittides. By bribing the oracle he pronounced Demaratus, his colleague on the throne, illegitimate, because he refused to punish the people of Ægina, who had deferted the Greeks. He killed himself in a fit of madness.

Cleomenes II. succeeded his brother Ageipolis II. He reigned 34 years in the greatest tranquillity, and was father to Acrotatus and Cleonymus. He was succeeded by Areus I. son of Acrotatus.

Cleomenes III. succeeded his father Leonidas. He was of an enterprising spirit, and resolved to restore the ancient discipline of Lycurgus in its full force.
force. He killed the Ephori, and removed by poison his royal colleague Eurydamides, and made his own brother Euclides king, against the laws of the state, which forbade more than one of the same family to sit on the throne. He made war against the Ephori, and attempted to destroy the Achaean league. Aratus the general of the Achaeans, who suppos'd himself inferior to his enemy, called Antigonus to his assistance; and Cleomenes, when he had fought the unequal battle of Sellata, retired into Egypt to the court of Ptolemy Evergetes, where his wife and children had gone before him. Ptolemy received him with great cordiality; but his success, weak and unsatisfactory, soon expir'd his jealousy of this noble stranger, and imprisoned him. Cleomenes killed himself, and his body was flayed and exposed on a cross, 140 Olymp.

CLEON, the name of several noted men of antiquity. 1. Of an Athenian, who, though originally a tanner, became general of the armies of the state by his intrigues and eloquence. He took Thersitex in Thrace, and was killed at Amphipolis in a battle with Brasidas the Spartan general, Olymp. 59th. 2. A general of Messenia, who disputed with Artiodemos for the sovereignty. 3. A satyr. 4. A poet who wrote a poem on the Argonauts. 5. An orator of Halicarnassus who composed an oration for Lyfander, in which he intimated the propriety of making the kingdom of Sparta elective. 6. A Magnesian who wrote some comments, in which he speaks of portentous events, &c.

CLEONE, (anc. geog.) a town of Argolis, above Mycenae, on the road which leads from Argos to Corinth; standing on an eminence, on every side occupied by houses. In the forest near this town was slain by Hercules the huge lion (Sil. Italics, Seneca). Cleoneus the epithet; Cleoneum Sidus, the lion.—Another Cleone on Mount Athos in Chalcidice.

CLEOPATRA, the celebrated queen of Egypt, was daughter of Ptolemy Auletes. By her extraordinary beauty, she seduced the two renowned Roman generals, Julius Cæsar and Marc Antony; the latter of whom, it is thought, left the empire of Rome by his attachment to her. At length, Marc Antony being seduced by Octavius Cæsar, she tried the force of her declining charms upon the conqueror, but in vain; upon which declining in no measure from him, she committed her life, 36 years before Christ. According to some authors, she was the restorer of the Alexandrian library, to which she added that of Pergamos; and it is said, that she fled this philosophy to console her for the absence of Antony. With her death ended the family of the Ptolemies in Egypt, after it had reigned from the death of Alexander 294 years: for Egypt, after this, was reduced to a Roman province; in which dependence it remained till it was taken from them by the Saracens, A. D. 641.

CLEOPATRIS, (anc. geog.) a town of Egypt, on the Arabian Gulf. See ARSINOE. Now said to be Suez, situated at the bottom of the gulf of the Red Sea. E. Long. 24. 30. N. Lat. 30. 0.

CLEOSTRATUS, a celebrated astronomer born in Tenedos, was, according to Pliny, the first who discovered the signs of the Zodiac; others say, that he only discovered the signs Aries and Sagittarius. He also corrected the errors of the Grecian year about the 266th before Christ. Vol. V.

CLEPSYDRA, an instrument or machine serving to measure time by the fall of a certain quantity of water. The word comes from μετρητής, δόρδα, δόξα, ὕδωρ, “water;” though there have likewise been clepsydrae made with mercury.

The Egyptians, by this machine, measured the course of the sun. Tycho Brahe, in our day, made use of it to measure the motion of the stars, &c. and Dudley used the same contrivance in making all his maritime observations. The use of clepsydrae is very ancient: they were invented in Egypt under the Ptolemies; as were also lun-dials. Their use was chiefly in the winter; the sun-dials served in the summer. They had two great defects: the one, that the water ran out with a greater or less facility, as the air was more or less deposite; the other, that the water ran more readily at the beginning than towards the conclusion. M. Amonius has invented a clepsydra free from both these inconveniences; and which has these three grand advantages, of serving the ordinary purpose of clocks, of serving in navigation for the discovery of the longitude, and of measuring the motion of the arteries.

Construction of a CLEPSYDRA. To divide any cylindric vessel into parts to be emptied in each division of time; the time wherein the whole, and that wherein any part, is to be evacuated, being given. Suppose, \( v. \) gr. a cylindric vessel, whose charge of water flows out in twelve hours, were required to be divided into parts to be evacuated each hour. 1. As the part of time 1 is to the whole time 12; so is the same time 12 to a fourth proportional, 1. 2. Divide the altitude of the vessel into 144 equal parts: here the latitude will fall to the last hour; the three next above to the last part but one; the five next to the tenth hour, &c.; lastly, the 23 last to the first hour. For since the times increase in the series of the natural numbers 1, 2, 3, 4, 5, &c. and the altitudes, if the numeration be in retrograde order from the twelfth hour, increase in the series of the unequal numbers 1, 3, 5, 7, 9, &c. the altitude, computed from the twelfth hour, will be as the squares of the times 1, 4, 9, 16, 25, &c. therefore the square of the whole time 144 comprehends all the parts of the altitude of the vessel to be evacuated. But a third proportional, 144, is the square of 12, and consequently it is the number of equal parts into which the altitude is to be divided, to be distributed according to the series of the unequal numbers, through the equal intervals of hours. Since in lieu of parts of the same vessel, other less vessels equal thereunto may be subtiluted; the altitude of a vessel emptied in 12 or any space of time given, the altitude of another vessel to be emptied in a given time may be found; viz. by making the altitudes as the squares of the times. For a further description, with a figure, see HYDROSTATICS.

CLERC, (John le) a most celebrated writer and useful scholar, born at Geneva in 1617. After he had passed through the usual course of study at Geneva, and had lost his father in 1676, he went to France in 1678; but returning the year after, he was ordained with the general applause of all his examiners. In 1682, le Clerc visited England with a view to learning the language. He preached several times in the French churches.
Clerc. (John Le) called Chevalier, an eminent historical painter, was born at Nanci in 1687, but studied in Italy, where he resided for twenty years; and was a disciple of Carlo Vetetianico, with whom he worked a long time, and whose style he so effectually studied and imitated, that several of the pictures which were finished by le Clerc were taken for the work of Ve
tetianico. He was most highly esteemed at Venice for his extraordinary merit; and as a token of public re
dspect, he was made a knight of St. Mark. His freedom of hand was remarkable; he had a light pencil; and in his colouring he resembled his master. He died in 1736.

Clerc. (George Le) count de Buffon, a celebrated naturalist, was born at Montbard, in Burgundy, the 7th of September 1707; his father was a counsellor of the parliament of Dijon, and the son was destined for the law. He studied at Dijon; and his eager activity, his accurateness, penetration, and robust conjunction, fitted him to pursue benefices and pleasure with equal ardour. His early passion was for astronomy, and the young Le Clerc was never without Euclid in his pocket. At the age of twenty, he went with an English nobleman and his governor to Italy; but he overlooked the choicest remains of art, and, amidst the ruins of an elegant and luxurious people, he first felt the charms of natural history, whose zealous and fie-
culous admirer he afterwards proved. On his return to France, he fought, on some occasional quarrels, with an Englishman, whom he wounded, and was obliged to retire to Paris. He there translated Newton's Fluxions, from the Latin, and Halley's Statics from the English, into the French language. He afterwards came to England, at the age of twenty-five; and this journey concluded his travels: he laid there about three months. At the age of twenty-one, he succeeded to the estate of his mother, which was valued at about 300,000 livres (above 12,000 pounds Sterling); and he was one of those whose easy or affluent circumstances urge on literary pursuits, and clear the path of some of its thorns. Perhaps this was the period of his retirement to Montbard, where he spent much time, and where his leisure was little interrupted: while in the capital, his

The miracle of the feeding five thousand, a middling sized plate, lengthwise. In the first impressions, which are very rare, a town appears in the back-ground; in place of which a mountain is substituted in the common ones. 2. The elevation of the large stones used in building the front of the Louvre, a large plate, lengthwise. The first impressions are without the date 1677, which was afterwards added. 4. The academy of the sciences, a middling sized plate, lengthwise. The first impres-
sions are before the skeleton of the flag, and tears were added. The second impressions are before the shadow was enlarged at the bottom, towards the right hand side of the print. Both these impressions are very scarce. The first is rarely met with. This print was copied for Chamber's Dictionary. 5. The May of the Colsbels, a middling-sized plate, lengthwise. The first impression is before the woman was introduced, who covers the wheel of the coach. 6. The four con-
exes, large plates, lengthwise, representing the taking of Tournay, the taking of Dovay, the defeat of the comte de Marf, and the Switzerland alliance. 7. The battles of Alexander, from Le Brun, six small long plates, including the title, which represents the picture very at the Colsbels. The two impre-
sions of the tent of Darius, which plate makes part of this set, is distinguished by the shoulder of the woman, who is seated in the front, being without the shadow, which was afterwards added; for which reason they are called the prints with the naked shoulder. 8. The entry of Alexander into Babylon, a middling-sized plate, length-
wife. In the first impressions, the face of Alexander is seen in profile; in the second, it is a three quarter face, and therefore called the print with the head turned.
his office of intendant of the king's garden and cabinet engaged much of his time. He loved much company, and was partial to the fair; but he loved glory more. He spent 14 hours every day in study; and, when we examine the extent of his knowledge, and the number of his works, we wonder at his having executed so much even in this time. At five in the morning he retired to a pavilion in his vast gardens, and he was then inaccessible. This was, as prince Henry of Prussia called it, the cradle of natural history; but she was in different accommodation, and the walls were naked, an old writing-table, with pen, ink, and paper, and an elbow chair of black leather, were the only furniture of his study. His manuscripts were in a cabinet in another building, and he went occasionally from one to the other. The eras of Buffon's works are pretty well known. When each was finished, it was put aside, in order that he might forget it, and he then returned to it with the severity of a critic. He was anxious to have it periphrastic; and if those to whom he read his works hesitated a moment, he changed the passage. The works of others he read like Magliabechi, the titles, the contents, and the most interesting parts; but he read M. Neckar's Compte Rendu, and the Administration of the Finances, at length: he spoke of them also with no little enthusiasm. His favourite authors were Fenelon, Montesquieu, and Richardson.

M. de Buffon's conversation was undecorated, rarely animated, but sometimes very cheerful. He was exact in his drefs, particularly in dressing his hair. He fat long at table, and then seemed at his cafe. His conversation was at this time, unembarrassed, and his guests had frequently occasion to notice some happy turn of phrase, or some deep reflection. His complacency was very considerable: he loved praise, and even praised himself; but it was with so much frankness, and with so little contempt of others, that it was never disagreeable. Indeed, when we consider the extent of his reputation, the credit of his works, and the attention with which they were always received, we do not wonder that he was sensible of his own value. It would perhaps have displayed a stronger mind to have concealed it. His father lived to 93, and almost adored his son; his grandfather to 87; and the subject of the present article exceeded even 80. He died in April 1788. Fifty-six tons were found in his bladder; but if he had confined to the operation, he might probably have lived longer. One son remains; who near a high tower in the gardens of Montbard has placed a low column, with the following inscription:

Excelsa Turri
Humilis Columna,
Parenti fio
Fil. Buffon.

CLERGY, a general name given to the body of ecclesiastics of the Christian church, in contradistinction to the laity. See LAITY.

The distinction of Christians into clergy and laity, was derived from the Jewish church, and adopted into the Christian by the apostles themselves: whenever any number of converts was made, as soon as they were capable of being formed into a congregation or church, a bishop or presbyter, with a deacon, were ordained to minister to them. Of the bishops, priests, and deacons, the clergy originally consisted; but in the third, century, many inferior orders were appointed, as subfunvent of the office of deacon, such as ACOLYTHISTS, READERS, &c.

This venerable body of men being separate and set apart from the rest of the people, in order to attend the more closely to the service of Almighty God, have therefore large privileges allowed them by the municipal laws: and had formerly much greater, which were abridged at the time of the reformation, on account of the ill use which the popish clergy had endeavored to make of them. For, the laws having exempted them from almost every personal duty, they attempted a total exemption from every secular tie. But it is observed by Sir Edward Coke, that as the overflowing of waters doth many times make the river to lose its proper channel, so, in times past, ecclesiastical persons, seeking to extend their liberties beyond their due bounds, either loft, or enjoyed not, those which of right belonged to them. The personal exemptions do indeed for the most part continue: a clergyman cannot be compelled to serve on a jury, nor to appear at a court-leet, or view of frank-pledge, which almost every other person is obliged to do: but if a layman is summoned on a jury, and before the trial takes orders, he shall notwithstanding appear and be sworn. Neither can he be chosen to any temporal office, as bailiff, receve, constable, or the like; in regard of his own continual attendance on the sacred function. During his attendance on divine service, he is privileged from arrests in civil suits. In cases also of felony, a clerk in orders shall have the benefit of his clergy, without being branded in the hand; and may likewise have it more than once: in both which particulars he is distinguished from a layman. But, as they have their privileges, so they have also their difficulties, on account of their spiritual avocations. Clergymen are incapable of fitting in the house of commons; and by statute 21 Hen. VIII. c. 13, are not in general allowed to take any lands or tenants to farm, upon pain of 10l. per month, and total avoidance of the lease; nor, upon like pain, to keep any tap-house or brew-house: nor shall engage in any manner of trade, nor sell any merchandize, under forfeiture, of the treble value. Which prohibition is consonant to the canon law.

Benefit of Clergy, is an ancient privilege whereby one in orders claimed to be delivered to his ordinary to purge himself of felony.

After trial and conviction of a criminal, the judgment of the court regularly follows, unless suspended or arrested by some intervening circumstance; of which kind the principal is benefit of clergy: a title of no small consideration as well as use; and concerning which, therefore, it may not be improper to inquire, 1. Into its original, and the various mutations which this privilege of the clergy has sustained. 2. To what persons it is to be allowed at this day. 3. In what cases. 4. The consequences of allowing it.

1. Clergy, the privilegium clericum, or (in common speech) the benefit of clergy, had its original from the pious regard paid by Christian princes to the Church in its infant state, and the ill use which the popish ecclesiastics soon made of that pious regard. The exemp
tions which they granted to the church were principally of two kinds: 1. Exemptions of places consecrated to religious duties from criminal arrests; which was the foundation of sanitaries. 2. Exemption of the persons of clergymen from criminal process before the secular judge in a few particular cases; which was the true original and meaning of the privilegium clericale.

But the clergy increasing in wealth, power, honour, number, and interest, soon began to set up for themselves; and that which they obtained by the favour of the civil government, they now claimed as their inherent right, and as a right of the highest nature, indefeasible, and jure divino. By their canons, therefore, and constitutions, they endeavoured at, and where they met with easy princes, obtained, a vast extension of those exemptions; as well in regard to the crimes themselves, of which the lift became quite universal, as in regard to the persons exempted; among whom were at length comprehended, not only every little subordinate officer belonging to the church or clergy, but even many that were totally laymen.

In England, however, although the usurpations of the pope were very many and grievous, till Henry VIII. totally exterminated his supremacy, yet a total exemption of the clergy from secular jurisdiction could never be thoroughly effected, though often endeavoured by the clergy: and therefore, though the ancient privilegium clericale was in some capital cases, yet it was not universally allowed. And in those particular cases, the use was for the bishop or ordinary to demand his clerks to be remitted out of the king's courts as soon as they were indicted: concerning the allowance of which demand there was for many years a great uncertainty; till at length it was finally settled in the reign of Henry VI. that the prisoner should first be arraigned; and might either then claim his benefit of clergy by way of declinatory plea; or, after conviction by way of arrest of judgment. This latter way is most usually practised, as it is more to the satisfaction of the court to have the crime previously ascertained by confession or the verdict of a jury; and also it is more advantageous to the prisoner himself, who may possibly be acquitted, and to need not the benefit of the clergy at all.

Originally the law was held that no man should be admitted to the benefit of clergy, but such as had the habitum et tonsuram clericam. But, in process of time, a much wider and more comprehensive criterion was established: every one that could read (a great mark of learning in those days of ignorance and her sister superflition) being accounted a clerk, or clericus, and allowed the benefit of clerkship, though neither initiated in clerkship, nor trimmed with the holy tonsure. But when learning, by means of the invention of printing and other concurrent caues, began to be more generally disseminated than formerly; and reading was no longer a competent proof of clerkship, or being in holy orders; it was found that as many laymen as divines were admitted to the privilegium clericale; and therefore by statute 4 Henry VII. c. 13. a distinction was once more drawn between mere lay scholars and clerks that were really in orders. And, though it was thought reasonable still to mitigate the severity of the law with regard to the former, yet they were not put upon the same footing with actual clergy; being subjected to a slight degree of punishment, and not allowed to claim the clerical privilege more than once. Accordingly the statute directs, that no person, once admitted to the benefit of clergy shall be admitted thereto a second time, until he produces his orders: and in order to distinguish their persons, all laymen who are allowed this privilege, shall be burned with a hot-iron in the brawn of the left thumb. This distinction between learned laymen and real clerks in orders was abolished for a time by the statutes 28 Hen. VIII. c. 1. and 32 Hen. VIII. c. 3; but is held to have been virtually restored by statute 1 Edw. VI. c. 12. which statute also enacts, that lords of parliament and peers of the realm may have the benefit of their peerage, equivalent to that of clergy, for the first offence (although they cannot read, and without being burnt in the hand), for all offences then clergylike to commoners, and also for the crimes of horse-breaking, highway-robbery, horse-dealing, and robbing of churches.

After this burning, the laity, and before it the real clergy, were discharged from the sentence of the law in the king's courts, and delivered over to the ordinary, to be dealt with according to the ecclesiastical canons. Whereupon the ordinary, not satisfied with the proofs adduced in the profane secular court, let himself formally to make a purgation of the offender by a new canonical trial; although he had been previously convicted by his country, or perhaps by his own confession. This trial was held before the bishop in person, or his deputy; and by a jury of twelve clerks: And there, first, the party himself was required to make oath of his own innocence: next, there was to be the oath of twelve compurgators, who swore they believed he spoke the truth: then, witnesses were to be examined upon oath, but on behalf of the prisoner only: and, lastly, the jury were to bring in their verdict upon oath, which usually acquitted the prisoner: otherwise, if a clerk, he was degraded, or put to penance. A learned judge in the beginning of last century, remarks with much indignation the vast complication of perjury, and subornation of perjury in this solemn farce of a mock trial; the witnesses, the compurgators, and the jury, being all of them partakers in the guilt: the delinquent party also, though convicted in the clearest manner, and conscious of his own offence, yet was permitted, and almost compelled, to swear himself not guilty; nor was the good bishop himself, under whose countenance this scene was transacted, by any means exempt from a share of it. And yet, by this purgation, the party was restored to his credit, his liberty, his lands, and his capacity of purchasing after, and was entirely made a new and an innocent man.

This scandalous proliferation of oaths, and the forms of justice, in the almost constant acquittal of felonious clerks by purgation, was the occasion that, upon very heinous and notorious circumstances of guilt, temporal courts would not try the ordinary with the trial of the offender, but delivered over to him the convicted clerk, offere purgation faciendum in his situation the clerk convicted could not make purgation; but was to continue in prison during life, and was incapable
Accordingly the statute 18 Eliz. c. 7. enacts, that, for the avoiding such perjuries and abatements, after the offender has been allowed his clergy, he shall not be delivered to the ordinary as formerly; but, upon such allowance, and burning of the hand, he shall forthwith be enlarged and delivered out of prison; with proviso, that the judge may, if he thinks fit, continue the offender in gaol for any time not exceeding a year. And thus the law continued unaltered for above a century; except only, that the statute 21 Jac. I. c. 6, allowed, that women convicted of simple larcenies under the value of 10s. should (not properly have the benefit of clergy; for they were not called upon to read; but) be burned in the hand, whipped, or flogged, or imprisoned for any time not exceeding a year. And a similar indulgence by the statutes 5 and 4 Will. and Mary c. 9. and 4 and 5 Will. and Mary c. 24, was extended to women guilty of any clergyable felony whatever; who were allowed once to claim the benefit of the statute, in like manner as men might claim the benefit of clergy, and to be discharged upon being burned in the hand, and imprisoned for any time not exceeding a year. All women, all peers, and all male commoners who could read, were therefore discharged in such felonies absolutely, if clerks in orders; and for the first offence upon burning in the hand, if lay; yet all liable (except peers), if the judge gave occasion, to imprisonment not exceeding a year. And these men who could not read, if under the degree of peerage, were hanged.

Afterwards, indeed, it was considered, that education and learning were no extenuations of guilt, but quite the reverse: and that if the punishment of death for felony was too severe for those who had been liberally instructed, it was, à fortiori, too severe for the ignorant also. And thereupon, by statute 5 Anne, c. 6. it was enacted that the benefit of clergy should be granted to all those who were intituled to ask it, without requiring them to read by way of conditional merit. And, experience having shown that so universal a lenity was frequently inconvenient, and an encouragement to commit the lower degrees of felony; and that though capital punishments were too rigorous for these inferior offences, yet no punishment at all (or next to none, as branding or whipping), was as much too gentle; it was enacted by the same statute 5 Anne, c. 6, that when any person, is convicted of any theft or larceny, and burnt in the hand for the same, he shall, at the discretion of the judge, be committed to the house of correction or public work-house, to be there kept to hard labour for any time not less than six months, and not exceeding two years; with a power of inflicting a double confinement in case of the party's escape from the first. And it is also enacted by the statutes 4 Geo. I. c. 11. and 6. Geo. I. c. 23. that when any persons shall be convicted of any larceny, either grand or petit, or any felonious dealing or taking of money or goods and chattels, either from the person or the house of any other, or in any other manner, and who by the law shall be intitled to the benefit of clergy, and liable only to the penalties of burning in the hand, or whipping; the court, in their discretion, instead of such burning in the hand, or whipping, may direct such offenders to be transported to America for seven years; and if they return, or are seen at large in that kingdom within that time, it shall be felony without benefit of clergy.

In this state does the benefit of clergy at present stand; very considerably different from its original institution: the widows of the English legislature having, in the course of a long and laborious process, extracted, by a noble alchemy, rich medicines out of poisonous ingredients; and converted, by gradual mutations, what was at first an unreasonable exemption of particular popish ecclesiastics, into a merciful mitigation of the general law with respect to capital punishments.

From the whole of this detail, we may collect, that however in times of ignorance and superstition, that monstrosity in true policy may for a while subsist, of a body of men residing in a state, and yet independent of its laws: yet when learning and rational religion have a little enlightened mens minds, society can no longer endure an absurdity so gross, as must destroy its very fundamentals. For, by the original contract of government, the protection given by the community, the protection of individuals, is that of obedience to the united will of the community. This united will is declared in the laws of the land: and that united force is exerted in their due, and universal execution.

II. We are next to inquire, to what persons the benefit of clergy is to be allowed at this day: and this must chiefly be collected from what has been observed in the preceding article. For, upon the whole, we may pronounce, that all clerks in orders are, without any branding, and of course without any transportation (for that is only substituted in lieu of the other), to be admitted to this privilege, and immediately discharged, or at most confined for one year; and this as often as they offend. Again, all lords of parliament, and peers of the realm, by the statute 1 Edw. VI. c. 12. shall be discharged in all clergyable and other felonies provided for by the act without any burning in the hand, in the same manner as real clerks convielt: but this is only for the first offence. Lastly, all the commons of the realm, not in orders, whether male or female, shall, for the first offence, be discharged of the punishment of felonies, within the benefit of clergy, upon being burnt in the hand, and suffering discretionary imprisonment; or, in case of larceny, upon being transported for seven years, if the court shall think proper.

III. The third point to be considered is, for what crimes the privilegium clerico is, or benefit of clergy, is to be allowed. And it is to be observed, that neither in high treason, nor in petit treason, nor in any mere misdemeanors, it was indulged at the common law: and therefore we may lay it down as a rule, that it was allowable only in petit treason and capital felonies;
Clergy. felonies; which for the most part became legally intituled to this indulgence by the statute de cleris, 25 Edw. III. stat. 3. c. 4. which provides, that clerks convit for treason or felonies, touching other persons than the king himself or his royal majesty, shall have the privilege of holy church. But yet it was not allowed in all cases whatsoever: for in some it was denied even in common law, viz. in/idiato viarum, or lying in wait for one on the highway; depopulatio agriorum, or destroying and ravaging a country; combus-fatio hominum, or arson, that is, burning of houses; all which are a kind of hostile acts, and in some degree border upon treason. And farther, all these identical crimes, together with petit treason, and very many other acts of felony, are out of clerical jurisdiction by special provisions of parliament.

Upon the whole, we may observe the following rules. 1. That in all felonies, whether new created, or by common law, clergy is now allowable, unless taken away by act of parliament. 2. That where clergy is taken away from the principal, it is not of course taken away from the acco/ey, unless he be also particularly included in the words of the statute. 3. That when the benefit of clergy is taken away from the offence (as in case of murder, burglary, robbery, rape, and burglary), a principal in the second degree, being present, aiding and abetting the crime, is as well excluded from his clergy as he that is a principal in the first degree; but, 4. That where it is only taken away from the person committing the offence (as in the case of stabbing, or committing larceny in a dwelling-house), his aids and abettors are not excluded, through the tendernefs of the law which hath determined that such statutes shall not be taken literally.

IV. Lastly, We are to inquire what the consequences are to the party, of allowing him this benefit of clergy. We speak not of the branding, imprisonement, or transportation; which are rather concomitant conditions, than consequences, of receiving this indulgence. The consequences are such as affect his present interest, and future credit and capacity; having been once a felon, but now purged from that guilt by the privilege of clergy, which operates as a kind of statute pardon. And we may observe, 1. That, by his conviction, he forfeits all his goods to the king; which, being once vested in the crown, shall not afterwards be restored to the offender. 2. That, after conviction, and till he receives the judgment of the law by branding or the like, or else is pardoned by the king, he is, to all intents and purposes, a felon; and subjected to all the disabilities and other incidents of a felon. 3. That, after burning or pardon, he is discharged for ever of that, and all other felonies before committed, within the benefit of clergy; but not of felonies from which such benefit is excluded; and this by statutes 8 Eliz. c. 4. and 18. Eliz. c. 7. 4. That, by the burning, or pardon of it, he is restored to all capacities and credits, and the possession of his lands, as if he had never been convicted. 5. That what is said with regard to the advantages of commoners and laymen, subsequent to the burning in the hand, is equally applicable to all peers and clergymen, although never branded at all. For they have the same privileges, without any burning, to which others are intituled after it.

CLERK, (clericus) a word formerly used to signify a learned man, or man of letters. The word comes from the Greek κλέρος, used for clergy; but more properly signifying lot or heritages, in regard the lot and portion of clerks or ecclesiastics is to serve God. Accordingly clerus was at first used to signify those who had a particular attachment to the service of God. The origin of the expression is derived from the Old Testament, where the tribe of Levi is called the lot, heritages, κλέρος, and God is reciprocally called their portion; by reason that tribe was consecrated to the service of God, and lived on the offerings made to God, without any other settled provision as the rest had. Thus, Pasquier observes, the officers of the counts (comites) were anciently created under the title of clerks of accounts; and secretaries of state were called clerks of the secret. So clericus dominii regis, in the time of Edward I. was Englished, the king's secretary, or clerk of his council. The term was applied indifferently to all who made any profession of learning; or who knew how to manage the pen: though originally it was appropriated to ecclesiastics. As the nobility and gentry were usually brought up to the exercife of arms, there was none but the clergy left to cultivate the sciences: hence, as it was the clergy alone who made any profession of letters, a very learned man came to be called a great clerk, and a stupid ignorant man a bad clerk.

CLERK is also applied to such as by their course of life exercised their pens in any court or office; of which there are various kinds: thus, Clerk of the Bails, in England, an officer in the court of king's bench, whose business is to file all bail-pieces taken in that court, where he always attends. Clerk of the Check, an officer belonging to the king's court; so called, because he has the check and control of the yeomen that belong to the king, queen, or prince. He likewise, by himself or deputy, lets the watch in the court. There is also an officer in the navy of the same name, belonging to the king's yards. Clerk of the Crown, an officer in the king's bench, who frames, reads, and records all writs of parliament, with the names of the knights, citizens, and burgesses, are also returned into his office. He also makes out special pardons and writs of execution on bonds of statute-staple forfeited.

CLERK of the Deliveries of the Ordnance. See Ordnance.

CLERK of the Errors, in the court of common pleas, an officer who transcribes and certifies into the king's bench, the tenor of the record of the action on which the
the writ of error, made out by the curtilor, is brought there to be determined. In the king's bench, the clerk of the errors transcribes and certifies the records of causes, by bill, in that court, into the exchequer. And the builnifs of the clerk of the errors in the exchequer, is to transcribe the records certified thither out of the king's bench, and to prepare them for judgment in the exchequer-chamber.

**Clerk of the Exonias**, in the court of common pleas, keeps the exonias roll, or enters exonias: he also provides parchment, cuts it into rolls, marks the number on them, delivers out all the rolls to every officer, and receives them again when written. See **Exonias**.

**Clerk of the Exonius**, an officer in the exchequer, who every term receives the exonias out of the lord-treasurer's remembrancer's office, and writes them out to be levied for the crown.

**Clerk of the Green-cloth**, formerly an officer in chancery, but now abolished.

**Clerk of the Hamper, or Hamaper**, an officer in chancery, whose business is to receive all money due to the king for the fees of chancery, letters for the payment of perjuries, letters for the payment of perjuries, letters patent, commissions, and writs; also the fees due to the officers for enrolling and examining them.

**Clerk Comptroller of the King's Household**, an officer of the king's court, authorized to allow or disallow the charges of purveyors, messengers of the green-cloth, etc., to inspect and control all defects of any of the inferior officers; and to fit in the counting-house with the lord-warder and other officers of the household for regulating such matters.

**Clerk of the King's Silver**, an officer of the common pleas, to whom every fine is brought, after it has paid the office of the capias brevium; and who enters the effect of writs of covenant, into a book kept for that purpose, according to which all the fines of that term are recorded in the rolls of the court.

**Clerk of the Market**, an officer of the king's house, to whom is given the charge of the king's measures and weights, and the standards of those that ought to be used all over England.

**Clerk of the Nichils, or Nihil**, an officer of the exchequer, who makes a roll of all such facts as are nichilled by the sheriffs upon their exonias of green wax, and delivers them in to the remembrancer of the treasury, to have execution done upon them for the king. See **Nihil**.

**Clerk of the Ordnance. See **Ordnance**.

**Clerk of the Outwrits**, an officer of the common pleas, and deputy to the attorney-general, for making out all writs of capias ulterigabantur after outlawry, to which there must be the king's attorney's name.

**Clerk of the Paper-office**, an officer belonging to the king's bench, whose business is to make up the paper-books of special pleadings in that court.

**Clerk of the Peace**, an officer belonging to the felions of the peace, whose business is to read indictments, inroll the proceedings, and draw the process; he likewise certifies into the king's bench transcripts of indictments, outlawries, attainders, and convictions had before the justices of peace, within the time limited by statute, under a certain penalty. This office is in the gift of the afferre reiulfarum, and may be executed by deputy.

**Clerk of the Pells**, an officer that belongs to the exchequer, whose business is to enter every teller's bill into a parchment-roll called pells receptorum; and to make another roll of payments called pells extenuum.

**Clerk of the petty Bag**, an officer of the court of chancery, whereof there are three, the master of the rolls being the chief: their business is to record the return of all inquisitions out of every shire; to make out patents of c笑容ers, gaugers, comptrollers, &c.; liberates upon extent of statutes-deple; conge d' alires for bishops; summons of the nobility, clergy, and burgesses to parliament; and commissions directed to knights and others of every shire, for assessing subsidies and taxes.

**Clerk of the Pipe**, an officer of the exchequer, who having the accounts of all debts due to the king, delivered out of the remembrancer's office, charges them in a great roll folded up like a pipe. He writes out warrants to sheriffs, to levy the said debts on the goods and chattels of the debtors; and if they have no goods, then he draws them down to the treasurer's remembrancer to write effets against their lands.

**Clerk of the Pleas**, an officer of the exchequer, in whose office all the officers of the court, having special privilege, ought to sue or be sued in any action. In this office also actions at law may be prosecuted by other persons, but the plaintiff ought to be tenant or debtor to the king, or some way accountable to him. The under clerks are attorneys in all suits.

**Clerks of Privy-seal**, four officers that attend the lord privy seal, for writing and making out all things that are sent by warrant from the signet to the privy seal, and to be sealed the great seal; and likewise to make out privy seals, upon special occasions of his majesty's affairs, as for loan of money, or the like.

**Clerk of the Rolls**, an officer of the chancery, whose business is to make searches after, and copies of deeds, officers, &c.

**Clerk of the Signet**, an officer continually attending upon his majesty's principal secretary, who has the custody of the privy signet, as well for sealing the king's private letters as those grants which pass the king's hand by bill signed. There are four of these officers who have their diet at the secretary's table.

**Six Clerks**, officers in chancery next in degree below the twelve maisters, whose business is to inroll commissions, pardons, patents, warrants, &c., which pass the great seal. They were anciently clerks, and forfeited their places if they married. These are also attorneys for parties in suits depending in the court of chancery.

**Clerk of the Treasury**, an officer belonging to the court of common pleas, who has the charge of keeping the records of the court, makes out all records of nisipius, and likewise all exemplifications of records being in the treasury. He has the fees due for all searches; and has under him an under keeper, who always keeps one key of the treasury-door.

**Clerk of the Warrants**, an officer of the common pleas, whose business is to enter all warrants of attorney for plaintiffs and defendants in suit; and to inroll deeds of bargain and sale, that are acknowledged in court, or before a judge. His office is likewise to effect into the exchequer all fines, escheats, and amercements,
CLE

CLEVER, (Captain Charles) a celebrated English navigator, was bred up in the navy from his youth, and was present in several actions during the war of 1755. In that between the Bellona and Courageux he was in great danger; for having been stationed in the mizen-top on board the former, the mast was carried overboard by a shot, and he fell into the sea along with it: but, however, was taken up without having received any injury. When Commodore Byron made his first voyage round the world, Mr Clerke served on board his ship in quality of a midshipman; and was afterwards on the American station. In the year 1768, he failed round the world a second time in the Bellona, and died on the 22d of August 1778, in the 38th year of his age, the ship being then within view of the coast of Kamtschatka.

Clerke's Island lies on the western side of the American continent, in N. Lat. 63° 15', and E. Long. 190° 30'. It was discovered by Captain Cook in his last voyage, but a landing could not be effected. At a distance it appeared to be of considerable extent, and to have several hills connected with the low grounds in front, as small as to make it look like a group of islands. Near its eastern extremity is a little island remarkable for having three elevated rocks upon it. Both the large and small islands are uninhabited.

CLERMONT, a considerable, rich, and populous town of France, in Auvergne, with a bishop's seat. The cathedral, the public squares, and walks, are very fine. Here is a bridge naturally formed, as they say, by the throwing of dice, or little bones; and observing the points, or marks, turned up. The word comes from ἀρίστη, "lot," and μεταί, "divination." At Bura, a city of Achaia, was a temple and celebrated oracle of Hercules; where such as consulted the oracle, after praying to the idol, threw four dice, the points whereof being well scanned by the priest, he was supposed to draw an answer from them.

Something of this kind seems to have been practiced with regard to Jonah.

CLERVAUX, one of the most celebrated and finest abbeys of France, in Champagne, five miles from Bar-sur-Aube, and seated in a valley surrounded with woods and mountains. It is the chief of the Cistercian order. Here is a famous tun of St Bernard, which will hold 800 tuns of wine. Near this abbey is a small town.

CLESIDES, a Greek painter, about 276 years before Christ, in the reign of Antiochus I. He revenged the injuries he had received from queen Statonice by representing her in the arms of a fisherman. However indecent the painter might represent the queen, she was drawn with such personal beauty, that she preferred the piece and liberally rewarded the artist.

CLETHERA, in botany: A genus of the monogyne order, belonging to the decandria class of plants; and in the natural method ranking under the 18th order, Biornes. The calyx is quinquenariate; the petals five; the stigma tridif; the capsule trilocular and three-valved. There is but one species, viz., the Alnifolia. This is a native of Virginia and Carolina, where it grows in moist places, and near the sides of rivulets, rising near eight or ten feet high. The leaves are shaped like those of the alder-tree, but longer; these are placed alternately upon the branches: the flowers are produced in close spikes at the extremities of the branches; they are white, composed of five petals, and have ten stamens in each, nearly of the same length with the petals. This is hardy enough to bear the open air in Britain, and is one of the most beautiful flowering shrubs. Its seafon is commonly about the beginning of July; and, if the seafon is not very hot, there will be part of the spikes in beauty till the middle of September. This shrub will thrive best in moist land, and requires a sheltered situation, where it may be defended from strong winds, which frequently break off the branches where they are too much exposed to their violence. It is propagated by layers, but they are generally two years before they take root. It may also be propagated by suckers, which are sent out from the roots: if these are carefully taken off with fibres in the autumn, and planted in a nursery-bed, they will be strong enough in two years to transplant where they are to remain.

CLEVELAND, a district in the north riding of York.
CLEVELAND, (John) an English poet of some eminence in his time, who during the civil war under Charles I. engaged as a literary champion in the royal cause against the parliamentarians. He died in 1658, and in much extolled by his party. His works, which consist of poems, characters, orations, epistles, &c. were printed in octavo in 1677.

CLEVES, the duchy of, a province of the circle of Westphalia, in Germany. It is divided into two parts by the Rhine, and is about 40 miles in length from east to west, and 20 in breadth from north to south. It is a fine agreeable country, and pretty populous. The towns are, Cleves the capital, Calcar, Gennet, Santen, Orfoy, Barweck, and Greit. These lie on the left side the river. On the right, Duyburgh, Wefe, Rees, and Emmerick. There have been great contents about this duchy, but it now belongs to the king of Prussia.

CLEVES, a city of Germany, in the duchy of Cleves, of which it is the capital. It stands upon a pleasant hill, about three miles from the Rhine, with which it communicates, by means of a canal which is large enough for great barges. The castle stands upon a mountain, and, though old, is very agreeable. Calvinists, Lutherans, and Roman Catholics, are all tolerated in this city. E. Long. 5. 36. N. Lat. 51° 40.'

CLIENT, among the Romans, a citizen who put himself under the protection of some great man, who in respect of that relation was called patron.

This patron afflieted his client with his protection, interest, and goods; and the client gave his vote for his patron, when he sought any office for himself or his friends. Clients owed respect to their patrons, as they owed them their protection.

The right of patronage was appointed by Romulus, to unite the rich and poor together, in such a manner as that the one might live without contempt, and the other without envy; but the condition of a client, in course of time, became little else but a moderate slavery.

CLIENT is now used for a party in a law-suit, who has turned over his cause into the hands of a counsel- lor or solicitor.

CLIFFORTIA, in botany: A genus of the polyandria order, belonging to the dicotyledons of plants; and in the natural method ranking under the 38th order, Tricocce. The male calyx is triphyllous; no corolla; the stamina near 30 in number; the female calyx is triphyllous, superior to the receptacle of the fruit; no corolla; two styles; with a bilocular capsule; and a single seed. There are three species, all of them natives of Africa; so require to be kept in a green-house when cultivated in Britain. Their flowers make no great appearance; but the plants themselves are very ornamental evergreens. They grow to the height of four or five feet; and are propagated by cuttings, which must be young shoots of five or six inches length. If these are planted in pots in spring or summertime, and plunged in a hot bed, they will readily take root. They must be watered plentifully in summer, but very sparingly in winter.

CLIMACTERIC, among physicians, (from climacter, "a ladder"), a critical year in a person's life.

According to some, this is every seventh year; but others allow only those years produced by multiplying 7 by the odd number 3, 5, 7, and 9, to be climacteric. These years, they say, bring with them some remarkable change with respect to health, life, or fortune: the grand climacteric is the 63d year; but some, making two, add to this the 81st; the other remarkable climacterics are the 7th, 21st, 35, 49th, and 56th.

CLIMATE, or CLIME, in geography, a part of the surface of the earth, bounded by two circles parallel ro the equator; and of such a breadth, as that the longest day in the parallel nearer the pole exceeds the longest day in that next the equator by some certain spaces; viz. half an hour. The word comes from the Greek κλίμα, "inclination, an inclination.

The beginning of the climate, is a parallel circle wherein the day is the shortest. The end of the climate, is that wherein the day is the longest. The climates therefore are reckoned from the equator to the pole; and are so many bands, or zones, terminated by lines parallel to the equator: though, in strictness, there are several climates in the breadth of one zone. Each climate only differs from its contiguous ones, in that the longest day in summer is longer or shorter by half an hour in the one place than in the other. As the climates commence from the equator, the first climate at its beginning has its longest day precisely 12 hours long; at its end, 12 hours and an half: the second, which begins where the first ends, viz. at 12 hours and an half; and so of the rest, as far as the polar circles, where, what the geographers call hour-climates terminate, and month-climates commence. As an hour-climate is a space comprised between two parallels of the equator, in the first of which the longest day exceeds that in the latter by half an hour; so the month-climate is a space terminated between two circles parallel to the polar circles, whose longest day is longer or shorter than that of its contiguous one by a month or 10 days.

The ancients, who confined the climates to what they imagined the habitable parts of the earth, only allowed of seven. The first they made to pass through Meroe, the second through Sienna, the third through Alexandria, the fourth through Rhodes, the fifth through Rome, the sixth through Pontus, and the seventh through the mouth of the Boreas. The moderns, who have sailed further toward the poles, make 30 climates on each side; and, in regard the obliquity of the sphere makes a little difference in the length of the longest day, instead of half an hour, some of them only make the difference of climates a quarter.

Vulgarily the term climate is bestowed on any country or region differing from another either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants; without any regard to the length of the longest day. Albusdza, an Arabic author, distinguishes the first kind of climates by the
CLIMAX, or GRADATION, in rhetoric, a figure wherein the word or expression which ends the first member of a period begins the second, and so on; so that every member will make a distinct sentence, taking its rise from the next foregoing, till the argument and period be beautifully finished; as in the following gradation of Dr Tillotson: "After we have practised good actions a while, they become easy; and when they are easy, we begin to take pleasure in them; and when they please us, we do them frequently; and by frequency of acts, a thing grows into a habit; and confirmed habit is a kind of second nature; and so far as any thing is natural, so far it is necessary; and we can hardly do otherwise; nay, we do it many times when we do not think of it."

CLINCH, in the sea-language, that part of a cable which is bended about the ring of the anchor, and then seized or made fast.

CLINCHING, in the sea-language, a kind of flight caulking used at sea, in a prospect of foul weather, about the pots: it consists in driving a little oaken into their seams, to prevent the water coming in at them.

CLINIC, a term applied by the ancient church-historians to those who received baptism on their deathbed.

CLINIC Medicine, was particularly used for the method of visiting and treating sick persons in bed, for the more exact discovery of all the symptoms of their disease.

CLINIAS, a Pythagorean philosopher, and musician, in the 65th Olympiad. He was wont to affinge his passion, being very choleric, by his lyre.

CLINOPodium, field-basil: A genus of the gymnofermna order, belonging to the didynamia class of plants; and in the natural method ranking under the 41st order, Astersolus. The involucrum consists of many small bristles under the verticillus or whorl of flowers. There are six species, all of them herbaceous plants, growing from one to two feet high. They are remarkable only for their strong odour, being somewhat between marjoram and basil.

CLIO, in pagan mythology, the first of the muses, daughter of Jupiter and Mnemosyne. She presided over history. She is represented crowned with laurels, holding in one hand a trumpet, and a book in the other. Sometimes she holds a plectrum or quill with a lute. Her name signifies honour and reputation, fame, glory; and it was her office faithfully to record the actions of brave and illustrious heroes. She had Hyacintha by Pierius, son of Magnes.

CLIO, in zoology, a genus of insects belonging to the order of vermes mollusca. The body is oblong and fitted for swimming; and it has two membranaceous wings placed opposite to each other. The species are three, principally distinguished by the shape of their vagina, and are all natives of the ocean.

CLIPUS, in natural history, a name given to the flat depressed centronia, from their resembling a shield. See CENTRONIA.

CLISTHENES, a famous Athenian magistrate, the author of the mode of banishing ambitious citizens by ostracism, or writing their names upon a shell: the intention was patriotic, but it was abused like all other human institutions; some of the worthiest citizens of Athens being thus exiled. He died 510 years before Christ.

CLITOMACHUS, the philosopher, flourished about 140 years before Christ. He was born at Carthage; quitted his country at 40 years of age; and went to Athens, where he became the disciple and successor to Carneades. He composed many books, but they are all lost.

CLITORIA, in botany: A genus of the leguminous order, belonging to the diadelphia class of plants; and in the natural method ranking under the 32d order, Papilionaceae. The corolla is supine, or turned down-side up; with the vexillum or flag-crest very large, patent, and almost covering the alae or wing-petals. There are four species, all of them herbaceous perennials, or annuals, of the kidney-bean kind, growing naturally in both the Indies. The stalk is climbing, slender, and of the height of a man. The leaves are winged, placed alternately, and consist of two, three, or five pair of lobes, terminated by an odd one. The flowers, which are elegant, stand singly, each on its proper foot-stalk. They are very large, and generally of a deep blue, but sometimes of a white colour. From the fruit of this plant is distilled an eye-water. The beans reduced to powder, and taken in broth, to the quantity of two draachs, prove a gentle purge; and Grimmius remarks, in his Labor Ceyl. that the powder of the dried beans, being mixed with the milk of the cocoa nut, or with broth, and administered in quantity...
quantity from one to three drachms, not only mitigates colic pains, but is very useful, and much used in Ceylon, in all disorders of the stomach and bowels. These plants are propagated by seeds; and, in Britain, must be kept continually in a flower.

CLITORIS, in anatomy, is a part of the external pudenda, situated at the angle which the symphætic form with each other. Like the penis it has an erection, and it is thought to be the principal seat of venereal pleasure. The clitoris is of different sizes in different women; but in general it is small, and covered with the labia. The preternaturally enlarged clitoris is what constitutes an hermaphrodite. When the clitoris is too large, it may be so extirpated as to remove the unnecessary part; but this requires much care, for a farther extirpation subjects the patient to an involuntary discharge of urine.

CLITUMNUS, (anc. geog.) a river of Umbria, on this side the Apennine. According to Pliny, it was a fountain consisting of several veins, situated between Hifpellum and Spoletium; which soon after welled into a very large and navigable river, running from east to west into the Tinea, and both together into the Tiber. A river famous for its milk-white stocks and herds, (Virgil.) The god of the river was called Clitumnus.

CLITUS, brother to Alexander the Great's nurse, followed that prince in his conquests, and saved his life by cutting off the hand of Rosaces, which held an ax lifted up to kill him at the passage of the Granicus. Alexander, who had a great regard for him, some time after invited him to supper; when Clitus, at the end of the repast, being heated with wine, diminished the exploits of that prince, in order to magnify those of Philip his father. This so enraged Alexander, that he killed him with his own hand; but he was afterwards so afflicted at it, that he attempted his own life.

CLIVE, (Robert) lord, son of Richard Clive, Esq; of Styche near Drayton in Salop in England, was born in 1725. Toward the close of the war in 1741, he was sent as a writer in the East India service to Madras; but being fonder of the camp than the counting-house, he soon availed himself of an opportunity to exchange his pen for a pair of colours. He first distinguished himself at the siege of Pondicherry in 1748; acted under major Laurence at the taking of Devi Cotta in Tanjore, who wrote of his military talents in high terms; commanded a small party for the taking of Arcot, and afterwards defended that place against the French; and performed many other exploits, which, considering the remoteness of the scene of action, would require a long detail to render sufficiently intelligible. He was, however, in brief, looked upon and acknowledged as the man who first routed his countrymen to spirited action, and raised their reputation in the East: so that when he came over to England in 1752, he was presented, by the court of directors, with a rich sword set with diamonds, as an acknowledgment of past, and an incitement to future, services. Captain Clive returned to India in 1755, as governor of fort St David, with the rank of lieutenant-colonel in the king's troops; when as commander of the company's troops, he, in conjunction with admiral Watson, reduced Angria the pirate, and became master of Geria, his capital, with all his accumulated treasure. On the loss of Calcutta and the well-known barbarity of the foubah Surajah Dowla, they failed to Bengal; where they took fort William, in January 1757; and colonel Clive defeating the foubah's army soon after, accelerated a peace. Surajah Dowla's perfidy, however, soon produced fresh hostilities, which ended in his ruin; he being totally defeated by colonel Clive at the famous battle of Plassey. The next day the conqueror entered Muxadabad in triumph; and placed Jaffer Ally Cawn, one of the principal generals, on the throne: the deposed foubah was soon after taken, and privately put to death by Jaffer's son. Admiral Watson died at Calcutta; but colonel Clive commanded in Bengal the two succeeding years: he was honoured by the Mogul with the dignity of an Omrah of the empire; and was rewarded by the new foubah with a grant of lands, or a jaghire, producing 27,000l. a-year. In 1760, he returned to England, where he received the unanimous thanks of the company, was elected member of parliament for Shrewsbury, and was raised to an Irish peerage by the title of Lord Clive Baron of Plassey. In 1764, fresh disturbances taking place in Bengal, lord Clive was effectually the only man qualified to settle them, and was accordingly again appointed to that presidency; after being honoured with the order of the Bath, and with the rank of major-general. When he arrived in India he exceeded the most sanguine expectation, in restoring tranquility to the province without striking a blow, and fixed the highest ideas of the British power in the minds of the natives. He returned home in 1767; and, in 1772, when a parliamentary inquiry into the conduct of the East India company was agitated, he entered into an able justification of himself in a masterly speech in the house of commons. He died suddenly towards the close of the year 1774.

CLOACE, in antiquity, the common fewers of Rome, to carry off the dirt and soil of the city into the Tiber; justly reckoned among the grand works of the Romans. The first common sewer, called Cloaca Maxima, was built by Tarquinius, fone fay Prificus, others Superbus, of huge blocks of stone joined together without any cement, in the manner of the edifices of those early times; consisting of three rows of arches one above another, which at length conjoin and unite together; measuring in the clear 18 palms in height, and as many in width. Under these arches they rowed in boats; which made Pliny say that the city was inspended in air, and that they failed beneath the houses. Under these arches also were ways through which carts loaded with hay could pass with ease. It began in the Forum Romanum; measured 300 paces in length; and emptied itself between the temple of Vesta and the Pons Senatorius. There were as many principal fewers as there were hills. Pliny concludes their firmness and strength from their standing for so many ages the shocks of earthquakes, the fall of houses, and the vast loads and weights moved over them.

CLOACINA, the goddess of jakes and common fewers, among the Romans.
CLOCK, a machine constructed in such a manner, and regulated by the uniform motion of a pendulum, as to measure time, and all its subdivisions, with great exactness.

The invention of clocks with wheels is referred to Paciencia, archdeacon of Verona, who lived in the time of Lotharius, son of Louis the Debonnaire, on the credit of an epitaph quoted by Uglelli, and borrowed by him from Petavious. They were at first called nocturnal dials, to distinguish them from fun-dials, which showed the hour by the sun's shadow. Others ascribe the invention to Boethius, about the year 510. Mr Derham makes clock-work of a much older standing; and ranks Archimedes's sphere mentioned by Claudian, and that of Ptolemy's mentioned by Cicero, among the machines of this kind: not that either their form or use were the same with those of ours, but that they had their motion from some hidden weights or springs, with wheels, or pulleys, or some such clock-work principle. But be this as it will, it is certain the art of making clocks, such as are now in use, was either first invented, or at least retrieved, in Germany, about 200 years ago. The water clocks, or clepsydrae, and sun-dials, have both a much better claim to antiquity. The French annals mention one of the kind sent by Aaron, king of Persia, to Charlemagne, about the year 807, which, seemed to bear some resemblance to the modern clocks: it was of brass, and shewed the hours by twelve little balls of the same metal, which fell at the end of each hour, and in falling struck a bell and made it sound. There were also figures of 12 cavaliers, which at the end of each hour came forth at certain apertures or windows in the side of the clock, and hurled them again, &c.

The invention of pendulum-clocks is owing to the happy industry of the last age: the honour of it is disputed by Huygens and Galileo. The former, who has written a volume on the subject, declares it was first put in practice in the year 1657, and the description thereof printed in 1658. Becher de Nova Temporis dimitendi Theoria, anno 1680, contends for Galileo; and relates, though at second-hand, the whole history of the invention; adding, that one Trefler, clock-maker to the then father of the Grand Duke of Tuscany, made the first pendulum-clock at Florence, by direction of Galileo Galilei, a pattern of which was brought into Holland. The Academy de'l Cimento say expressly, that the application of the pendulum to the movement of a clock was first proposed by Galileo, and first put in practice by his son Vincenzo Galilei, in 1649. Be the inventor who he will, it is certain the invention never flourished till it came into Huygen's hands, who insists on it, that if ever Galileo thought of such a thing, he never brought it to any degree of perfection. The first pendulum-clock made in England was in the year 1662, by Mr Fromantil a Dutchman.

Of the general Mechanism of Clocks, and how they measure Time. The first figure of Plate CXXIX. is a profile of a clock: P is a weight that is suspended by a rope that winds about the cylinder or barrel C, which is fixed upon the axis a; the pivots b go into holes made in the plates TS, TS, in which they turn freely. These plates are made of brass or iron, and are connected by means of four pillars ZZ; and the whole together is called the frame. The weight P, if not restrained, would necessarily turn the barrel C with an uniform accelerated motion, in the same manner as if the weight was falling freely from a height. But the barrel is furnished with a ratchet wheel KK, on the right side of whose teeth strikes against the clock, which is fixed with a feerow to the wheel.

(a) A balance not unlike the fly of a kitchen-jack, was formerly used in place of the pendulum.
of the weight is communicated to the wheel DD, the
teachs of which act upon the teeth of the final wheel d
which turns upon the pivots ee. The communication
or action of one wheel with another is called the "pitching"; a small wheel like d is called a "pinion," and its teeth
are leaves of the pinion. Several things are requisite
to form a good pitching, the advantages of which are
obvious in all machinery where teeth and pinions are
employed. The teeth and pinion leaves should be of a
proper shape, and perfectly equal among themselves:
the size also of the pinion should be of a just proportion
to the wheel acting into it; and its place must be at a
certain distance from the wheel, beyond or within
which it will make a bad pitching.

The wheel EE is fixed upon the axis of the pinion
d; and the motion communicated to the wheel DD
by the weight is transmitted to the pinion d', consequen-
tially to the wheel E E, as likewise to the pinion e and wheel F F, which moves the pinion f upon
the axis of which the crown or balance wheel G H is
fixed. The pivots of the pinion f, play in holes of the
plates L M, which are fixed horizontally to the plates
TS. In a word, the motion begun by the weight is
transmitted from the wheel G H to the palettes I K,
and by means of the fork U X riveted on the pa-
lettes communicates motion to the pendulum A B,
which is suspended upon the hook A. The pendulum
A B describes, round the point A, an arc of a circle
alternately going and returning. If then the pendu-
um be once put in motion by a pull of the hand, the
weight of the pendulum at B will make it return upon
itself, and it will continue to go alternately backward
and forward till the resilience of the air upon the pen-
dulum, and the friction at the point of suspension A,
destroy the original impressed force. But as, at every
vibration of the pendulum, the teeth of the balance-
wheel G H act upon the palettes I K (the pivots
upon the axis of the pallets play in two holes of the
potence s i), that after one tooth H has communicated
motion to the palette K, that tooth escapes; then the
opposite tooth G acts upon the palette I, and escapes
in the same manner; and thus each tooth of the
wheel escapes the pallets I K, after having communi-
cated their motion to the pallets in such a manner
that the pendulum, instead of being flung, continues
to move.

The wheel E E revolves in an hour; the pivot c of
this wheel passes through the plate, and is continued
to r; upon the pivot is a wheel N N with a long fock-
et fastened in the centre; upon the extremity of this
socket r the minute-hand is fixed. The wheel N N
acts upon the wheel O; the pinion of which p acts
upon the wheel gg, fixed upon a socket which turns
along with the wheel N. This wheel gg makes its re-
volution in 12 hours, upon the socket of which the
hour-hand is fixed.

From the above description it is easy to see, 1. That
the weight p turns all the wheels, and at the same
time continues the motion of the pendulum. 2. That
the quickness of the motion of the wheels is determined
by that of the pendulum. 3. That the wheels point
out the parts of time divided by the uniform motion of
the pendulum.

When the cord upon which the weight is suspen-
ed is entirely run down from off the barrel, it is wound
up again by means of a key, which goes on the square
end of the barrel at Q, by turning it in a contrary di-
rection from that in which the weight descends. For
this purpose, the inclined side of the teeth of the wheel
R (fig. 2.) removes the click C, so that the ratchet-
wheel D is at rest; but as soon as the cord is wound up, the click falls in be-
tween the teeth of the wheel D, and the right side of
the teeth again act upon the end of the click, which
obliges the wheel D to turn along with the barrel;
and the spring A keeps the click between the teeth
of the ratchet-wheel R.

We shall now explain how time is measured by the
motion of the pendulum; and how the wheel E, upon
the axis of which the minute-hand is fixed, makes but
one precise revolution in an hour. The vibrations of
a pendulum are performed in a shorter or longer time
in proportion to the length of the pendulum itself. A
pendulum of 3 feet 6 French lines in length, makes
vibrations in an hour, or for one of the wheel
revolutions; for which reason it is called a second pendulum. But a pendulum of 9 inches
2 French lines makes 7200 vibrations in an hour, or
two vibrations in a second of time, and is called a half
second pendulum. Hence, in constructing a wheel
whose revolution must be performed in a given time,
the time of the vibrations of the pendulum which re-
gulates its motion must be considered. Supposing,
then, that the pendulum A B makes 7200 vibrations in
an hour, let us consider how the wheel E shall take up
an hour in making one revolution. This entirely
depends on the number of teeth in the wheels and
pinions. If the balance-wheel consists of 30 teeth,
it will turn once in the time that the pendu-
lum makes 60 vibrations; for at every turn of the
wheel, the same tooth acts once on the palette I, and
once on the palette K, which occasions two separate
vibrations in the pendulum: and the wheel having 30
teeth, it occasions 60, or 60 vibrations. Con-
sequently, this wheel must perform 120 revolutions
in an hour; because 60 vibrations, which it oc-
casions at every revolution, are contained 120 times
in 7200, the number of vibrations performed by the
pendulum in an hour. Now, in order to determine
the number of teeth for the wheels E F, and their pin-
ions e f; it must be remarked, that one revolution
of the wheel E must turn the pinion e as many times as
the number of teeth in the pinion is contained in the
number of teeth in the wheel. Thus, if the wheel E
contains 72 teeth, and the pinion e 6, the pinion will
make 12 revolutions in the time that the wheel makes
1; for each tooth of the wheel drives forward a tooth
of the pinion, and when the 6 teeth of the pinion are
moved, a complete revolution is performed; but the
wheel E has by that time only advanced 6 teeth, and
has still 66 to advance before its revolution be com-
pleted, which will occasion 11 more revolutions of the
pinion. For the same reason, the wheel F having
60 teeth, and the pinion f 6, the pinion will
make 10 revolutions while the wheel performs one.
Now, the wheel F being turned by the pinion e, makes
12 revolutions for one of the wheel E; and the pin-
ion f makes 10 revolutions for one of the wheel F;
consequently, the pinion f performs 10 times 12 or
Clock. 120 revolutions in the time the wheel E performs one. But the wheel G, which is turned by the pinion $f$, occasions 60 vibrations in the pendulum each time it turns round; consequently the wheel G occasions 60 times 120 or 7200 vibrations of the pendulum while the wheel E performs one revolution; but 7200 is the number of vibrations made by the pendulum in an hour, and consequently the wheel E performs but one revolution in an hour; and so of the rest.

From this reasoning, it is easy to discover how a clock may be made to go for any length of time without being wound up; 1. By increasing the number of teeth in the wheels; 2. By diminishing the number of teeth in the pinions; 3. By increasing the length of arc engraved. This plate turns round; and consequently the wheel G continues the same, the force which it communicates to the wheel G H will be diminished.

It only remains to take notice of the number of teeth in the wheels which turn the hour and minute hands.

The wheel E performs one revolution in an hour; the wheel N N, which is turned by the axis of the pocket, must likewise make one revolution in the same time; and the minute-hand is fixed to the socket of this wheel. The wheel N has 30 teeth, and acts upon the wheel O, which has likewise 30 teeth, and the same diameter; consequently the wheel O takes one hour to a revolution; now the wheel O carries the pinion $p$, which has 6 teeth, and which acts upon the wheel $gg$ of 72 teeth; consequently the pinion $p$ makes 12 revolutions while the wheel $gg$ makes one, and of course the wheel $gg$ takes 12 hours to one revolution; and upon the socket of this wheel the hour-hand is fixed. All that has been said here concerning the revolutions of the wheels, &c. is equally applicable to watches as to clocks.

The ingenious Dr Franklin has contrived a clock to show the hours, minutes, and seconds, with only three wheels and two pinions in the whole movement. The clock (fig. 5.) there is an opening, $a b c d$, below the centre; through which appears part of a flat plate, on which the 12 hours, with their divisions into quarters, are engraved. This plate turns round in 12 hours, and the index A points out the true hour, &c. B is the minute-hand, which goes round the large circle of 60 minutes whilst the plate $a b c d$ shifts its place one hour under the fixed index A. There is another opening $e f g$, through which the seconds are seen on a flat movable ring at the extremity of a hour-plate engraved on the dial-plate. A in fig. 6. is the great wheel of this clock, containing 120 teeth and turning round in 12 hours. The axis of this wheel bears the plate of hours, which may be moved forward through small holes drilled in the plate, without affecting the wheel-work. The great wheel A turns a pinion B of ten leaves round in an hour, and carries the minute-hand B on its axis round the dial-plate in the same time. On this axis is a wheel C of 120 teeth, turning round a pinion D of six leaves in three minutes; on the axis of which there is a wheel E of 90 teeth, that keeps a pendulum in motion, vibrating seconds by pallets, as in a common clock; when the pendulum-wheel has only 30 teeth, and goes round in a minute. In order to show the seconds by this clock, a thin plate must be divided into three times fixy, or 180 equal parts, and numbered 10, 20, 30, 40, 50, 60, three times successively; and fixed on the same axis with the wheel of 90 teeth, so as to turn round near the back of the dial-plate; and these divisions will show the seconds through the opening $e f g$, fig. 5. This clock will go a week without winding, and always show the precise hour; but this clock, as Mr Ferguson candidly acknowledges, has two disadvantages of which Dr Franklin’s clock is free; when the minute-hand B is adjusted, the hour-plate must also be set right by means of a pin; and the smallness of the teeth in the pendulum-wheel will cause the pendulum ball to describe but small arcs in its vibrations; and therefore the momentum of the ball will be less, and the times of the vibrations will be more affected by any unequal impulse of the pendulum-wheel on the pallets. Besides, the weight of the flat ring on which the seconds are engraved will load the pivots of the axis of the pendulum-wheel with a great deal of friction, which ought by all possible means to be avoided. To remedy this inconvenience, the second plate, might be omitted.

A clock similar to Dr Franklin’s was made in Lincolnsire about the end of last century or beginning of this; and is now in London in the possession of a grandon of the person who made it.

A clock, showing the apparent diurnal motions of the sun and moon, the age and phases of the moon, with the time of her coming to the meridian, and the times
Plate CLX. Plate CLX.

The dial-plate of this clock (fig. 7.) contains all the twenty-four hours of the day and night. S is the sun, which serves as an hour index, by going round the dial-plate in twenty-four hours; and M is the moon, which goes round in twenty-four hours fifty minutes and a half, the time of her going round in the heavens from one meridian to the same meridian again. The sun is fixed to a circular plate (fig. 8.), and carried round by the motion of that plate on which the twenty-four hours are engraved; and within them is a circle divided into twenty-nine and a half equal parts for the days of the moon's age, reckoning from new moon to new moon; and each day stands directly under the time, in the twenty-four hour circle of the moon's coming to the meridian; the XII under the sun standing for noon, and the opposite XII for midnight. The moon M is fixed to another circular plate (fig. 6.) of the same diameter with that which carries the sun, part of which may be seen through the opening, over which the small wires r and b pass in the moon-plate. The wire a shows the moon's age and time of her coming to the meridian, and b shows the time of high-water for that day in the sun-plate. The distance of these wires answers to the difference of time between the moon's coming to the meridian and high-water at the place for which the clock is made. At London their difference is two hours and a half. Above this, the moon M in twenty-four hours fifty minutes and a half; so that it will be twenty-nine days and a half, it is plain that the plate in twenty-four hours. The phases of the moon the hoop, and A, fig. 7. is a fixed plate N, supported by a wire A, fixed to the same plate, on which is an elliptic plate in twenty-four hours fifty minutes and a half very nearly. On the back of the wheel B is fixed an elliptical ring D, which, in its revolution, raises and lets down a lever EF, whose centre of motion is on a pin at F; and this, by the upright bar G, raises and lets down the tide-plate H twice in the time of the moon's revolving from the meridian to the meridian again; this plate moves between four rollers R, R, R, R. A clock of this kind was adapted by Mr. Ferguson to the movement of an old watch: the great wheel of a watch goes round in four hours; on the axis of this he fixed a wheel of twenty teeth, to turn a wheel of forty teeth on the axis of the pinion C; by which means that pinion was turned round in eight hours, the wheel A in twenty-four, and the wheel B in twenty-four hours fifty minutes and a half.

To this article we shall subjoin a brief account of two curious contrivances. The first, for giving motion to the parts of a clock by making it to descend along an inclined plane, is the invention of Mr. Maurice Wheeler; and the clock itself may be seen in Don Saltaro's coffee-house at Chelsea. DE, fig. 10, is the inclined plane on which the clock A B C descends; CXL, this consists externally of a hoop about an inch broad, and two slides or plates standing out beyond the hoop about one-eighth of an inch all round, with indented edges, that the clock may not slide, but turn round whilst it moves down. One of these plates is inscribed with the twenty-four hours, which pass successively under the index LP, fig. 11, which is always in a position perpendicular to the horizon, and shows the hour on the top of the machine: for this reason the lower edge of the index, or H, is lighter, that it may preponderate the other H P, and always keep a pendulous, with its point to the vertical hour, as the movement goes on. Instead of this index, an image may be fixed for ornament on the axis g, which with an erecting finger performs the office of an index. In order to describe the internal part or mechanism of this clock, let L E T Q be the external circumference of the hoop, and f f the same plate, on which is placed the train of wheel-work 1, 2, 3, 4, which is much the same as in other clocks, and is governed by a balance and regulator as in them. But there is no need of a spring and fusee in this clock; their effects being otherwise answered, as we shall see. In this machine the great wheel of t is placed in the centre, or upon the axis of the movement, and the other wheels and parts move to and fro, which would therefore prove a bias to the body of the clock, and cause it to move, even on an horizontal plane, for some short distance; this makes it necessary to fix a thin plate of lead at C, on the opposite part of the hoop, to rerove the equilibrium of the movement. This being done, the machine will abide at rest in any position on the horizontal plane.
Clock.

If that plane be changed into the inclined plane $DE$, it will touch it in the point $D$; but it cannot rest there, because the centre of gravity at $M$ acting in the direction $MI$, and the point $T$ having nothing to support it, must continually descend, and carry the body down the plane. But now if any weight $P$ be fixed on the other side of the machine, such as shall remove the centre of gravity from $M$ to the point $V$ in the line $LD$ which passes through the point $D$, it will then rest upon the inclined plane, as in the case of the rolling cylinder. If this weight $P$ be supposed not fixed, but suspended at the end of an arm, or wheel, which arm or lever is at the time fastened to a perpendicular wheel $I$, moving on the axis $M$ of the machine, which wheel by its teeth shall communicate with the train of wheels, &c. on the other side, and the power of the weight be just equal to the friction or resistance of the train, it will remain motionless as it did before when it was fixed; and consequently the clock also will be at rest on the inclined plane. But supposing the power of the weight $P$ to be superior to the resistance of the train, it will then put it into motion, and of course the clock likewise; which will then continue in a motion down the plane; while the weight $P$, its wheel $PM$, and the wheel $I$, all constantly retain the same position which they have at first when the clock begins to move. Hence it is easy to understand, that the weight $P$ may have such an intrinsic gravity, as shall cause it to act upon the train with any required force, so as to produce a motion in the machine of any required velocity; such, for instance, as shall carry it once round in twenty-four hours: then, if the diameters of the plates $ABC$ be four inches, it will describe the length of their circumference, viz. $12.56$ inches in one natural day; and therefore, if the plane be of sufficient breadth, such a clock may go several days, and would furnish a perpetual motion, if the plane were infinitely extended. Let $SD$ be drawn through $M$ perpendicular to the inclined plane in the point $D$; also let $LD$ be perpendicular to the horizontal line $HH$, passing thro' $D$; then is the angle $HDE=LD=DMT$; whence it follows that the greater the angle of the plane's elevation is, the greater will be the value $DT$; and consequently the further will the common centre of gravity be removed from $M$; therefore the power of $P$ will be augmented, and of course the motion of the whole machine accelerated. Thus it appears, that by duly adjusting the intrinsic weight of $P$, at first to produce a motion flowing the mean time as near as possible, the time may be afterwards corrected, or the clock made to go faster or slower by raising or depressing the plane, by means of the screw at $S$. The angle to which the plane is first raised is about ten degrees. The marquis of Worcester also did have contrived a watch that moved on a declivity. See farther, Phil. Trans. Abr. vol. i. p. 468, &c. or n° 161.

The other contrivance is that of M. de Gennes for making a clock ascend on an inclined plane. To this end let $ABC$ (fig. 12.) be the machine on the inclined plane $EDE$, and let it be kept at rest upon it, or in equilibrium by the weight $P$ at the end of the lever $PM$. The circular area $CF$ is one end of a spring barrel in the midst of the movement in which is included a spring as in a common watch. To this end of the barrel the arm or lever $PM$ is fixed upon the centre $M$; and thus, when the clock is wound up, the spring moves the barrel, and therefore the lever and weight $P$ in the situation $PM$. In doing this, the centre of gravity is constantly removed farther from the centre of the machine, and therefore it must determine the clock to move upwards, which it will continue to do as long as the spring is unbinding itself; and thus the weight and its lever $PM$ will preserve the situation they first have, and do the office of a chain and fusee. Phil. Trans. n° 143. or Abridg. vol. p. 467.

By flat 9 and to W. III. cap. 28. § 2. no person shall export, or endeavour to export out of England, any outward or inward box-case, or plate of metal, for clock or watch, without the movement in or with every such box, &c. made up fit for use, with the maker's name engraved thereon; nor shall any person make up any clock or watch without putting his name and place of abode or freedom, and no other name or place, on every clock or watch; on penalty of forfeiting every such box, case, and plate, clock and watch, not made up and engraved as aforesaid; and 20L. one moiety to the king, the other to those that shall sue for the same.

Clocks, portable, or pocket, commonly denominated Watches. See the article Watch.

Clock-Work, properly so called, is that part of the movement which strikes the hours, &c. on a bell; in contradistinction to that part of the movement of a clock or watch which is designed to measure and exhibit the time on a dial-plate, and which is termed Watch-work.

I. Of the Clock-part. The wheels composing this part are: The great or first wheel $H$; which is moved by the weight or spring at the barrel $G$; in sixteen or thirty-hour clocks, this has usually pins, and is called the pin-wheel; in eight-day pieces, the second wheel $I$ is commonly the pin-wheel, or striking-wheel, which is moved by the former. Next the striking-wheel is the detent-wheel, or hoop-wheel $K$, having a hoop almost round it, wherein is a vacancy at which the clock locks. The next is the third or fourth wheel, according to its distance from the first, called the warming-wheel $L$. The left is the flying pinion $Q$, with a fly or fan, to gather air, and so bridle the rapidity of the clock's motion. To these must be added the pinion of report; which drives round the locking-wheel, called also the count-wheel; ordinarily with eleven notches in it, unequally divided, to make the clock strike the hours.

Besides the wheels, to the clock part belongs the ratchet or ratch: a kind of wheel with twelve large fangs, running concentrical to the dial-wheel, and serving to lift up the detents every hour, and make the clock strike: the detents or stops, which are being lifted up and let fall, lock and unlock the clock in striking: the hammer, as $S$, which strikes the bell $R$; the hammer tails, as $T$, by which the striking pins draw back the hammers; latches, whereby the work is lifted up and unlocked; and lifting-pieces, as $P$, which lift up and unlock the detents.

The method of calculating the numbers of a piece of clock-work having something in it very entertaining, and at the same time very easy and useful, we shall give the readers the rules relating thereto: 1. Regard here needs only be had to the counting wheel, striking-
Clock.

striking-wheel, and detent-wheel, which move round in this proportion: the count-wheel commonly goes round once in 12 or 24 hours; the detent-wheel moves round every stroke the clock strikes, or sometimes but once in two strokes: wherefore it follows, that, 2. As many pins as are in the pin-wheel, so many turns hath the detent-wheel in one turn of the pin-wheel; or, which is the same, the pins of the pin-wheel are the quotients of that wheel divided by the pinion of the detent-wheel. But if the detent-wheel move but once round in two strokes of the clock, then the said quotient is but half the number of pins. 3. As many turns of the pin-wheel as are required to perform the strokes of 12 hours (which are 78), so many turns must the pin-wheel have to turn round the count-wheel once; or thus, the quotients of that wheel divided by the pinion of the pin-wheel, which is commonly done.

An example will make all plain: The locking-wheel being 48, the pin-wheel 78, the striking pins are 13, and fo of the rest. Note also, that 78 divided by 13 gives 6, the quotient of the pin-wheel. 4. To find how many strokes a clock strikes in one turn of the fufee or barrel: As the turns of the great wheel or fufee are to the days of the clock's continuance; so is the number of strokes in 24 hours, viz. 136, to the strokes of one turn of the fufee.

To find how many days a clock will go: As the strokes in 24 hours are to those in one turn of the fufee; so are the turns of the fufee to the days of the clock's going.

To find the number of turns of the fufee or barrel: As the strokes in one turn of the fufee are to those of 24 hours; so is the clock's continuance to the turns of the fufee or great wheel.

To find the number of leaves in the pinion of report on the axis of the great wheel: As the number of strokes in the clock's continuance is to the turns of the fufee; so are the strokes in 12 hours, viz. 78, to the quotient of the pinion of report fixed on the arbour of the great wheel.

To find the strokes in the clock's continuance: As 13 is to 78; so are the hours of the clock's continuance to the number of strokes in that time.

By means of the following table, clocks and watches may be so regulated as to measure true equal time.

The stars make 366 revolutions from 3 minutes, 56 seconds; by which quantity of time every star comes round sooner than it did on the day before.

Therefore if you mark the precise moment shown by a clock or watch when any star vanishes behind a chimney, or any other object, as fea tho' a small hole in a thin plate of metal, fixed in a window-dresser; and do this for several nights successively (as sup­pose twenty); if, at the end of that time, the star vanishes as much sooner than it did the first night, by the clock, as an­swers to the time denoted in the table for so many days, the clock goes true; if not, the difference between the clock and star be less than the table gives, the clock goes too fast; if greater, it goes too slow; and must be regulated accordingly, by letting down or raising up the ball of the pendulum, or any other object, by turning the screw so nut under the clock, till you find it keeps 57 57 true equal time.

Thus, supposing the star should disappear behind a chimney, any night when it is XII by the clock; and that, on the 20th night afterward, the same star should disappear when the time is 41 minutes 22 seconds past X by the clock; which being subtracted from 12 hours 0 min. 0 sec. leaves remaining 1 hour 18 minutes 28 seconds for the time the star is then faster than the clock: look in the table, and against 20, in the left hand column, you will find the acceler­ation of the star to be 1 hour 18 min. 28. sec. agreeing exactly with what the difference ought to be between the clock and star: which shows that the clock measures true equal time, and agrees with the mean solar time, as it ought to do.

II. Of the Watch-part of a clock or watch. This is that part of the movement which is designed to measure and exhibit the time on a dial-plate; in contradistinction to that part which contributes to the striking of the hour, &c.

The several members of the watch-part are, 1. The balance, consisting of the rim, which is its circular part; and the verge, which is its spindle; to which belong two palettes or leaves, that play in the teeth of the crown-wheel. 2. The pendulum, which is the strong piece in pocket-watches, whereon the lower pivot or the verge plays, and in the middle of which one pivot of the balance-wheel plays; the bottom of the pendulum is called the foot, the middle part the nole, and the upper part the shoulder. 3. The cock, which is the piece covering the balance. 4. The reg­ulator, or pendulum spring, which is the small spring, in the new pocket-watches, underneath the balance. 5. The pendulum (fig. 13); whose parts are, the verge x, palettes 5, 5, cocks yyy, the rod, the fork z, the flat a, the bob or great ball b, and the corrector or regu­lator 4, being a contrivance of Dr Derham for bringing the pendulum to its nice vibrations. 6. The wheels, which are the crown-wheel F in pocket­pieces, and swinging-wheel in pendulums; driving to drive the balance or pendulum. 7. The contra-wheel E, which is that next the crown-wheel, &c. and whose teeth...
Clock. teeth and hoop lie contrary to those of other wheels; whence the name. 8. The great, or first wheel C, which is that the fusee B, &c. immediately drives, by means of the chain or string of the spring-box or barrel A; after which are the second wheel D, third wheel, &c. Lastly, between the frame and dial-plate, is the pinion of report, which is that fixed on the arbour of the great wheel; and serves to drive the dial-wheel, so that serves to carry the hand.

For the illustration of this part of the work which lies concealed, let ABC (fig. 14.) represent the uppermost side of the frame plate, as it appears when detached from the dial-plate: the middle of this plate is perforated with a hole, receiving that end of the arbour of the centre wheel which carries the minute-hand; near the plate is fixed the pinion of report \( a b \) of 10 teeth; this drives a wheel \( e d \) of 40 teeth; this wheel carries a pinion \( ef \) of 12 teeth; and this again drives a wheel \( gh \) with 36 teeth.

As in the body of the watch the wheels every where divide the pinions; here, on the contrary, the pinions divide the wheels, and by that means diminish the motion, which is here necessary; for the hour-hand, which is carried on a socket fixed on the wheel \( gh \), is required to move but once round, while the pinion \( a b \) moves twelve times round. For this purpose the motion of the wheel \( c d \) is \( \frac{1}{12} \) of the pinion \( ah \).

Again, while the wheel \( cd \), or the pinion \( ef \), goes once round, it turns the wheel \( gh \) but \( \frac{1}{12} \) part round; consequently the motion of \( gh \) is but \( \frac{1}{12} \) of \( \frac{1}{12} \) of the motion of \( ah \); but \( \frac{1}{12} \) of \( \frac{1}{12} \) is \( \frac{1}{144} \); i.e. the hour-wheel \( gh \) moves once round in the time that the pinion of report, on the arbour of the centre or minute-wheel, makes 12 revolutions, as required. Hence the structure of that part of a clock or watch which shows the time may be easily understood.

The cylinder A (fig. 13.) put into motion by a weight or included spring moves the fusee B, and the great wheel C, to which it is fixed by the line or chord that goes round each, and answers to the chain of a watch.

The method of calculation is easily understood by the sequel of this article: for, suppose the great wheel C goes round once in 12 hours, then if it be a royal pendulum clock, swining seconds, we have \( 60 \times 60 \times 12 = 43200 \) seconds or beats in one turn of the great wheel. But because there are 60 swings or seconds in one minute, and the seconds are shown by an index on the end of the arbour of the swinging-wheel, in those clocks is in a horizontal position; therefore, it is necessary that the swinging-wheel \( F \) should have 20 teeth; whence \( \frac{20}{120} = \frac{1}{6} \), the number to be broken into quotients for finding the number of teeth for the other wheels and pinions.

In spring-clocks, the disposition of the wheels in the watch part is such as is here represented in the figure, where the crown-wheel \( F \) is in a horizontal position; the seconds not being shown there by an index, as is done in the large pendulum clocks. Whence in these clocks the wheels are disposed in a different manner, as represented in fig. 14, where C is the great wheel, and D the centre or minute-wheel, as before: but the contrate wheel \( E \) is placed on one side, and \( F \) the swinging-wheel is placed with its centre in the same perpendicular line \( GH \) with the minute-wheel, and with its plane perpendicular to the horizon, as are all the others. Thus the minute and hour hands turn on the end of the arbour of the minute-wheel at \( a \), and the second hand on the arbour of the swinging-wheel at \( b \).

Theory and calculation of the watch-part, as laid down by the Rev. Dr. Derham.-1. The same motion, it is evident, may be performed either by one wheel and one pinion, or many wheels and many pinions; provided the number of turns of all the wheels bears the proportion to all the pinions which that one wheel bears to its pinion; or, which is the same thing, if the number produced by multiplying all the wheels together, be to the number produced by multiplying all the pinions together, as that one wheel to that one pinion. Thus, suppose you had occasion for a wheel of 1440 teeth, with a pinion of 28 leaves; you make it into three wheels of 36, 8, and 5, and three pinions of 4, 7, and 1. For the three wheels, 36, 8, and 5, multiplied together, give 1440 for the wheels, and the three pinions 4, 7, and 1, multiplied together, give 28 for the pinions. Add, that it matters not in what order the wheels and pinions are, or which pinion runs in which wheel; only, for convenience sake, the biggest numbers are commonly put to drive the rest.

2. Two wheels and pinions of different numbers may perform the same motion. Thus, a wheel of 36 drives a pinion of 4; the same as a wheel of 45 a pinion of 5; or a wheel of 90 a pinion of 10; the turns of each being 9.

3. If, in breaking the train into parcels, any of the quotients should not be liked; or if any other two numbers, to be multiplied together, are desired to be varied; it may be done by this rule. Divide the two numbers by any other two numbers which will measure them; multiply the quotients by the alternate divisors; the product of these two last numbers found will be equal to the product of the two numbers first given.

Thus, if you would divide 36 times 8, divide thee by any two numbers which will evenly measure them: so 36 by 4 gives 9; and 8 by 4 gives 8; now, by the rule, 9 times 1 is 9, and 8 times 4 is 32; so that for 36X8, you have 32X9; each equal to 288. If you divide 36 by 6 and 8 by 2, and multiply as before, you have 24X12=36X8=288.

4. If a wheel and pinion fall out with cross numbers, too big to be cut in wheels, and yet not to be altered by these rules; in seeking for the pinion of report, find two numbers of the same, or a near proportion, by this rule: as either of the two given numbers is to the other, so is 360 to a fourth. Divide that fourth number, as also 360, by 4, 5, 6, 8, 9, 10, 12, 15 (each of which numbers exactly measures 360), or by any of those numbers that bring a quotient nearest to an integer. As suppose you had 147 for the wheel, and 170 for the pinion; which are too great to be cut into small wheels, and yet cannot be reduced into less, as having no other common measure but unity; say, as 170: 147:: 360: 311. Or, as 147: 170:: 360: 416. Divide the fourth number and 360 by one of the foregoing numbers: as 311 and 360 by 6, it gives 52 and 60; divide them by 8, you have 39 and 45: and if you divide 360 and 416 by 8,
Clock. 8, you have 45 and 52 exactly. Wherefore, instead of the two numbers 147 and 170, you may take 52 and 69, or 39 and 45, or 45 and 52, &c.

5. To come to practice in calculating a piece of watch-work: First pitch on the train or beats of the balance in an hour; as, whether a watch of about 20,000 beats (the usual train of a common 30 hour pocket-watch), or a slower of about 16,000 (the train of the new pendulum pocket-watches), or any other train. Next, resolve on the number of turns the fusee is intended to have, and the number of hours the piece is to go: suppose, e.g., 12 turns, and to go 30 hours, or 192 hours (i.e., 8 days), &c. Proceed now to find the beats of the balance or pendulum in one turn of the fusee; thus in numbers: 12: 16: 20000: 26666. Wherefore, 26666 are the beats in one turn of the fusee or great wheel, and are equal to the quotients of all the wheels unto the balance multiplied together. Now this number is to be broken into a convenient parcel of quotients; which is to be done thus: first, halve the number of beats, viz. 26666, and you have 13333; then pitch on the number of the crown-wheel, suppose 17, divide 13333 by 17, and you have 784 for the quotient (or turns) of the rest of the wheels and pinions; which, being too big for one or two quotients, may be broken into three. Choose therefore three numbers; which, when multiplied all together continually, will come nearest 784; as suppose 10, 9, and 9, multiplied continually, give 810, which is somewhat too much; therefore try again other numbers, 14, 9, 8: these, drawn one into another continually, produce 792; which is as near as can be, and is a convenient quotient. Having thus contrived the piece from the great wheel to the balance, but the numbers not falling out exactly, as you first supposed, correct the work thus: first, multiply 792, the product of all the quotients pitched upon, by 17 (the notches of the crown-wheel); the product is 13464, which is half the number of beats in one turn of the fusee; then find the true number of beats in an hour. Thus, 16: 12: 13464: 10008, which is half the beats in an hour. Then find what quotient is to be laid upon the pinion of report (by the rule given under that word). Thus, 16: 12: 12: 9, the quotient of the pinion of report. Having thus found your quotients, it is easy to determine how many of the wheels shall have, for choosing what numbers the pinions shall have, and multiplying the pinions by their quotients, the product is the number for the wheels. Thus, the number of the pinion of report is 4, and its quotient is 9; therefore the number for the dial-wheel must be 4×9, or 36: for the next pinion being 5, its quotient 11, therefore the great wheel must be 5×11=55; and so of the rest.

Such is the method of calculating the numbers of a 16 hour watch. Which watch may be made to go longer by lessening the train, and altering the pinion of report. Suppose you could conveniently slacken the train to 16000; then try, As 1: 16000: 10000: 12000: 12: 20: 4×9, or 36: so that this watch will go 20 hours. Then for the pinion of report, say (by the rule given under that word), as 20: 12: 12: 7. So that 7

is the quotient of the pinion of report. As to the numbers, the operation is the same as before, only the dial-wheel is 55 (11 is but 28; for its quotient is altered to 7). 45 (9)

If you would give numbers to a watch of 5) about 10,000 beats in an hour, to have 12

turns of the fusee, to go 170 hours, and 17 notches in the crown-wheel; the work

is the same, in a manner, as in the last example: and consequently thus: as 12: 170: 10000: 141666, which fourth number is the beats in one turn of the fusee; its half, 71808, being divided by 17, gives 4167 for the quotient: and because this number is too big for three quotients, therefore choose four, as 10, 8, 8, 61: whose product makes 71808, nearly half the true beats in one turn of the fusee. Then try, as 170: 12: 71808: 5069, which is the true train of your watch. And again, 170: 12: 12: 9, the denominator of which expresses the pinion of report, and the numerator is the number of the dial-wheel. But these numbers being too big to be cast in small wheels, they must be varied by the fourth rule above.

Then dividing 360, and either of these 24) 20 (12

two fourth proportionals (as directed by the rule), suppose by 15; you will have 40 or 15; then the numbers of the whole movement will stand as in the margin.

Such is the calculation of ordinary watches, to show the hour of the day: in such an hour, and seconds, the process is thus:

1. Having resolved on the beats in an hour; by dividing the designed train by 60, find the beats in a minute: and accordingly, find proper numbers for the crown-wheel and quotients, so as that the minute-wheel shall go round once in an hour, and the second wheel once in a minute.

Suppose, e.g., you shall choose a pendulum of seven inches, which vibrates 142 strokes in a minute, and 8520 in an hour. Half these sums are 71, and 4260. Now, the first work is to break this 71 into a good proportion, which will fall into one quotient, and the crown-wheel. Let the crown-wheel have 15 notches; then 71, divided by 15, gives nearly 5; so a crown-wheel of 15, and a wheel and pinion whose quotient is 5, will go round in a minute to carry a hand to show seconds. For a hand to go round in an hour to show minutes, because 8) 40 (5 there are 60 minutes in an hour, it is but breaking 60 into good quotients (suppose 10 and 6, or 8 and 7, &c.), and it is done. Thus, 4260 is broken as near as 8) 64 (8 can be into proper numbers. But since it 8) 60 (7, does not fall out exactly into the above-8) 40 (5 mentioned numbers, you must correct (as before directed), and find the true number of beats in an hour, by multiplying 15 by 5, which makes 75; and 75 by 60 makes 4500, which is half the true train. Then find the beats in one turn of the fusee; thus, 16: 192: 4500: 54000; which last is half the beats in one turn of the fusee. This

K 2 54000

Clock.
Clodia Clock, 54000 marches to provinces of Gabinillus and Achaia, Ligia, beleft, a native Magi, king of Egypt to fail in his regal power. Watches hours, so is the minute-wheel, which goes round in 24 hours. The fucene and first wheel, to go round in four hours. This wheel has 48 teeth, and it turns a pinion of 12 leaves, on whose axis is the second wheel, which goes round in one hour, and carries the minute hand. This wheel has 60 teeth, and it turns a pinion of 10 leaves; on whose axis is the third wheel of 60 teeth, turning a pinion of 6 leaves; on whose axis is the fourth (or contract) wheel, turning round in a minute, and carrying the small hand that shows the seconds, on a small circle on the dial-plate, divided into 60 parts: this contracte wheel has 48 teeth, and it turns a pinion of 6 leaves; on whose axis is the crown or balance-wheel of 15 teeth, which makes 30 beats in each revolution.

The crown-wheel goes 480 times round in an hour, and 30 times 480 make 14400, the number of beats in an hour. But one hour contains 3600 seconds; and 14400 divided by 3600 quotes 4, the required number of beats in a second.

The fucene must have 7½ turns, to let the chain go so many times round it. Then, as 7½ turns is to 4, so 7½ turns to 30 hours, the time the watch would go after it is wound up.

See further the articles Movement, Turn, &c. And for the history and particular constrution of Watches properly so called, see the article Watch.

Clodia Lex, de Cypro, was enacted by the tribune Clodius, in the year of Rome 607, to reduce Cyprus into a Roman province, and expulse Ptolemy king of Egypt to fail in his regal ornaments. It impowered Cato to go with the praetorian power and see the auction of the king's goods, and commisioned him to return the money to Rome. Another, de Magistratus, 695, by Clodius the tribune. It forbid the censors to put a stigma or mark of infamy upon any person who had not been actually accused and condemned by both the censors. Another; de Religion, by the same, 696, to deprive the priet of Cybele, a native of Paphns, of his office, and confine the priesthood upon Brotigonus, a Gallogrecian. Another, de Provincis, 695, which nominated the provinces of Syria, Babylon, and Persia, to the conful Gabinus, and Achaia, Thebalsy, Macedon, and Greece, to his colleague Piso, with proconfular power. It impowered them to defray the expences of their march from the public treasury. Another, 695, which required the same distribution of corn among the people gratis, as had been given them before at six asles and a triens the bushel. Another, 695, by the fame, de Judicis. It called to an account such as had executed a Roman citizen without a judgment of the people and all the formalities of a trial. Another, by the same, to pay no attention to the appearances of the heavens while any affair was before the people. Another, to make the power of the tribunes free in making and proposing laws. Another, to re-establish the companies of artists which had been instituted by Numa, but since his time abolished.

Clodius, (Publius) a Roman defcended of an illustrious family. He made himself famous for his licentiousness, avarice, and ambition. He committed incest with his three sisters, and introduced himself in women's clothes into the house of Julius Cæsar whilst Pompeia Cæsar's wife, of whom he was enamoured, was celebrating the mysteries of Ceres, where no man was permitted to appear. He was accused for this violation of human and divine laws; but he made himself tribune, and by that means screened himself from justice. He defended from a patrician into a plebeian family to become a tribune. He was such an enemy to Cato, that he made him go with praetorian power, in an expedition against Ptolemy king of Cyprus, that by the difficulty of the campaign he might ruin his reputation, and destroy his interest at Rome during his absence. Cato, however, by his uncommon successes frustrated the views of Clodius. He was also an inveterate enemy to Cicero, and by his influence he banished him from Rome, partly on pretence that he had punished with death and without trial the adherents of Catiline. He wreaked his vengeance upon Cicero's house, which he burnt, and set all his goods to sale; which, however, to his great mortification, no one offered to buy. In spite of Clodius, Cicero was recalled and all his goods restored to him. Clodius was sometime after murdered by Milo, whose defence Cato took upon himself.

Clouder, an episcopal town of Ireland, in the county of Tyrone, and province of Ulter. It sends two members to parliament. In a very early age an abbey of regular canons, dedicated to the Virgin Mary, was founded here. St Patrick is said to have presided over the church of Clouder; and having appointed St Kerren to be his successor, he resigned this government, and went to Armagh, where he founded his celebrated abbey. On the 20th of April 1396, a dreadful fire burnt to the ground the church, the two chapels, the abbey, the court of the bishops, and thirty-two other buildings, with all the facerdotal vestments, utensils, &c. belonging to the bishop's chapter and church. In the year 1603, on the 24th of July, whilst George Montgomery was bishop of Clouder, king James annexed this abbey and its revenues to that see. The fee (valued in the king's books at 350l per annum by extent returned 15th James 1) is reputed to be worth L.4000 annually. W. Long. 7° 30' N. Lat. 54° 16'.

Clouster (Claustrum) a habitation surrounded with walls, and inhabited by canons or religious, &c. In a more general sense, cloister is used for a monastery of religious of either sex. In a more restrained sense, cloister is used for the principal part of a regular
CLONMELL, the affize town of the county of Tipperary in Ireland, is situated on the river Suir, hath a barracks for two troops of horse, and is governed by a mayor, recorder, bailiffs, and town-clerk. The river is navigable from this town to Carrick and Waterford, and there is some trade carried on here in the woollen manufacture. There is a charter school here for forty children, when there are buildings on each of the four sides of the court.

In this condition it is carried to the fullery, to be scoured with urine, or a kind of potter's clay, well steeped in water, put along with the cloth in the trough wherein it is filled. The cloth being again cleared from the earth or urine, is returned to the former hands to have the greater filth, small straws, &c. taken off as before; then it is returned to the fuller to be beat and filled with hot water, wherein a suitable quantity of soap has been dissolved; after fulling, it is taken out to be smoothed or pulled by the lifters lengthwise, to take out the wrinkles, crevices &c.

The smoothing is repeated every two hours, till the fulling be finished, and the cloth brought to its proper breadth: after which it is washed in clear water, to purge it of the soap, and given wet to the carders to raise the hair or nap on the right side with the thistle or weed. After this preparation the cloth-worker takes the cloth, and gives it its first cut or shearing: then the carders resume it, and after wetting, give it as many more courses with the teasel, as the quality of the fluff requires, always observing to begin against the grain of the hair, and to end with it as also to brush the carded fibres in all directions, proceeding still with one sharper and sharper, as far as the sixth degree.

After these operations, the cloth being dried, is returned to the cloth-worker, who sheers it a second time, and returns it to the carders, who repeat their operation as before, till the nap be well ranged on the surface of the cloth, from one end of the piece to the other.

The cloth thus wove, scoured, napped, and thorned, is sent to the dyer; when dyed, it is washed in fair water, and the worker takes it again wet as it is, lays the cloth on the table, and then it is sent to the dyer to have it again dyed, and then mixed, spun, and wove of the colours intended, the process, except what relates to the colour, is mostly the same with that just represented.

Cloth made from Vegetable Filaments. See Bark and Filaments.

Incombustible Cloth. See Asbestos.

Clotho, the youngest of the three Parce, daughters of Jupiter and Themis. She was supposed to preside over the moment that we are born. She held the distaff in her hand and spun the thread of life, whence her name κοίλος, "to spin." She was represented wearing a crown with seven stars, and covered with a variegated robe.

Cloud, a collection of vopours suspended in the atmosphere.

That
Cloud.

That the clouds are formed from the aqueous vapours which before were so closely united with the atmosphere as to be invisible, is universally allowed: but it is no easy matter to account for the long continuance of some very opaque clouds without dissolving; or to give a reason why the vapours, when they have once begun to condenceed, do not at once, when they are formed, all fall to the ground in the form of rain or snow, &c. Under the article Barometer, No. 23, we have hinted at the general cause of the formation of clouds; namely, a separation of the latent heat from the water whereof the vapour is composed. The consequence of this separation, as is indenitely proved by Dr Black, must be the condensation of that vapour, in some degree at least; in such case, it will first appears a smoke, mist, or fog; which if interrupted between the sun and earth, will form a cloud; and the same causes continuing to act, the cloud will produce rain or snow. But though the separation of this latent heat in a certain degree is the immediate cause of the formation of clouds, the remote cause or the cloud produced in the atmosphere, whereby such a separation may be induced, are much more difficult to be discovered. In common observation, we see that vapour is most powerfully condensed by cold substances, such as metals, water, &c. But cold alone cannot in all cases cause the condensation of the atmospheric vapours, otherwise the nights behoved to be always cloudy or cloudy, owing to the vapours, raised throughout the day by the heat of the sun, being condensed by the superior coldness of the night. Great rains will happen in very warm weather, when the union of the vapours with the atmosphere, ought rather to be promoted than dissoluted, if cold was the only agent in their condensation. The frequency of the atmosphere, also, in the most fever hoefts, abundantly shows that some other cause besides mere heat or cold is concerned in the formation of clouds, and, condensation of the atmospheric vapours.

The electric fluid is now so generally admitted as an agent in all the great operations of nature, that it is no wonder to find the formation of clouds attributed to it. This hath accordingly been given by S. Bec- caria as the cause of the formation of all clouds whatsoever, whether of thunder, rain, hail, or snow. The first, he thinks, are produced by a very great power of electricity, and the others by one more moderate. But, though it is certain that all clouds, or even fogs and rain, are electrified in some degree, it still remains a question, whether the clouds are formed in consequence of the vapour whereof they are composed being first electrified, or whether they become electrified in consequence of its being first separated from the atmosphere, and in some measure condensed. This hath not yet, as far as we know, been ascertained by the experiments of Beccaria, or any other person; and indeed, notwithstanding the multitude of electrical discoveries that have lately been made, there seems to be little or no foundation for ascertaining it. Electricity is known to be in many cases a promoter of evaporation; but no experiments have yet been brought to prove, that electrified air parts with its moisture more readily than such as is not electrified; so that, till the properties of electrified air are farther investigated, it is impossible to lay down any rational theory of the formation of clouds upon this principle.

But whether the clouds are produced, i. e. the invisible vapours floating in the atmosphere confen- ded so as to become visible, by means of electricity or not, it is certain that they do contain the electric fluid in much more considerable and inconceivable quantities, and many very terrible and destructive phenomena have been occasioned by clouds very highly electrified. The most extraordinary instance of this kind perhaps on record happened in the island of Java in the East Indies in August 1772. On the 11th of that month, at midnight, a bright cloud was observed covering a mountain in the district called Cerberon, and at the same time several reports were heard like those of a gun. The people who dwelt upon the upper parts of the mountain not being able to fly fast enough, a great part of the cloud, almost three leagues in circumference, detached itself under them, and was seen at a distance rising and falling like the waves of the sea, and emitting globes of fire and smoke, that at night became as clear as day. The effects of it were astonishing; every thing was destroyed for seven leagues round; the houses were demolished; plantations were buried in the earth; and, 2140 people lost their lives, besides 1500 head of cattle, and a vast number of horses, goats, &c.

Another instance of a very destructive cloud, the elec-
dric qualities of which will at present scarcely be doubt- ed, is related by Mr Brydone, in his Tour through Malta. It appeared on the 29th of October 1757. About three quarters of an hour after midnight, there was seen to the south-west of the city of Melita, a great black cloud, which, as it approached, changed its colour, till at last it became like a flame of fire mixed with black smoke. A dreadful noise was heard on its approach, which alarmed the whole city. It passed over the port, and came first on an English ship, which in an instant was torn in pieces, and nothing left but the hulk; part of the masts, sails, and cordage, were carried to a considerable distance along with the cloud. The small boats and fellosques that fell in its way were all broken to pieces and sunk. The noise increased and became more frightful. A centinel terrified at its approach ran into his box; but both he and it were lifted up an carried into the sea, where he perished. It then traversed a considerable part of the city, and did in ruins almost every thing that stood in its way. Several houses were laid level with the ground, and it did not leave one sleetie in its passage. The bells of some of them, together with the spires, were carried to a considerable distance; the roofs of the churches demolished and beat down, &c. It went off at the north-east point of the city, and demolishing the light house, is said to have mounted up into the air with a frightful noise; and passed over the sea to Sicily, where it tore up some trees, and did other damage; but nothing considerable, as its fury had been most spent at Malta. The number of killed and wounded amounted to near 200; and the loss of shipping, &c. was very considerable.

The effects of thunder-forms, and the vast quantity of electricity contained in the clouds which produce these forms, are so well known, that it is superfluous to mention them. It appears, however, that even
Clouds are not so highly electrified as to produce their fatal effects on those who are immersed in them. It is only the discharge of part of their electricity upon such bodies as are either not electrified at all, or not so highly electrified as the cloud, that does all the mischief. We have, however, only the following instance of record, of any person's being immersed in the vicinity of young Mr. Jalabert, when travelling over one of these clouds. Professor Sauflure, and young Mr. Jalabert, when travelling over one of these clouds, were caught among clouds of this kind; and to their astonishment found their bodies so full of electrical fire, that spontaneous flashes darted from their fingers with a crackling noise, and the same kind of sensation as when strongly electrified by art.

The height of clouds in general is not great; the summits of very high mountains being commonly quite free from them, as Mr. Brydon experienced in his journey up Mount Etna: but those which are most highly electrified descend lowest, their height being often not above seven or eight hundred yards above the ground; nay, sometimes thunder-clouds appear actually to touch the ground with one of their edges: but the generality of clouds are suspended at the height of a mile, or little more, above the earth. Some, however, have imagined them to arise to a most incredible and extravagant height. Maignan of Thouloise, in his Treatise of Perspective, p. 593, gives an account of an exceedingly bright little cloud that appeared at midnight in the month of August, which spread itself almost as far as the zenith. He says that the same thing was also observed at Rome; and from thence concludes, that the cloud was a collection of vapours raised beyond the projection of the earth's shadow, and of consequence illuminated by the beams of the sun. This, however, can by no means be credited; and it is much more probable that this cloud owed its splendor to electricity, than to the refraction of the polar beams.

In the evenings after fun-fet, and mornings before sun-rise, we often observe the clouds tinged with beautiful colours. They are mostly red; sometimes orange, yellow, or purple; more rarely bluish; and seldom or ever green. The reason of this variety of colours, according to Sir Issac Newton, is the different size of the globules into which the vapours are condensed. This is controverted by Mr. Melville, who thinks that the clouds reflect the sun's light preciely as it is transmitted to them through the atmosphere. This reflects the most refrangible rays in the greatest quantity; and therefore ought to transmit the least refrangible ones, red, orange, and yellow, to the clouds, which accordingly appear most usually of those colours. In this opinion he was greatly confirmed by observing, when he was in Switzerland, that the snowiest summits of the Alps turned more and more reddish after sun-fet, in the same manner as the clouds; and he imagines, that the semitransparency of the clouds, and the obliquity of their situation, tend to make the colours in them much more rich and copious than those on the tops of snowiest mountains.

The motions of the clouds, though sometimes directed by the wind, are not always so; especially when thunder is about to ensue. In this case they seem to move very slowly, and often to be absolutely stationary for some time. The reason of this most probably is, that they are impelled by two opposite streams of air nearly of equal strength; by which means their velocity is greatly retarded. In such cases both the aerial currents seem to ascend to a very considerable height; for Meil. Charles and Roberts, when endeavouring to avoid a thunder-cloud in one of their aerial voyages, could find no alteration in the course of the current, though they ascended to the height of 4000 feet from the surface of the earth. In some cases the motions of the clouds evidently depend on their electricity, independent of any current of air whatever. Thus, in a calm and warm day, we often see small clouds meeting each other in opposite directions, and setting out from such short distances, that we cannot suppose any opposite winds to be the cause. These clouds, when they meet, instead of forming a larger one, become much lefs, and sometimes vanish altogether; a circumstance undoubtedly owing to the discharge of opposite elecrtricities into each other. This serves also to throw some light on the true cause of the formation of clouds; for if two clouds electrified, the one positively and the other negatively, destroy each other on contact; it follows, that any quantity of vapour suspended in the atmosphere, while it retains its natural quantity of electricity, remains invisible, but becomes a cloud when electrified either plus or minus. A difficulty, however, still occurs; viz., in what manner a small quantity of vapour surrounded by an immense ocean of the same kind of matter, can acquire either more or less electricity than that which surrounds it; and this indeed we seem not as yet to have any data to solve in a satisfactory manner.

The heights of the clouds are likewise undoubtedly owing to their electricity; for in those feasons in which a great commotion has been excited in the atmospheric electricity, we shall perceive the clouds assuming strange and whimsical shapes, which vary almost every moment. This, as well as the meeting of small clouds in the air, and vanishing upon contact, is an almost infaillable sign of thunder.

Besides the phenomena of thunder, rain, &c. the clouds are intimately connected with those of wind, and always assume a particular shape when a strong continued wind is about to ensue; though it is remarkable, that in the strongest winds we shall often observe them stationary. Sometimes also, on the approach of a cloud, we shall find a sudden and violent gust of wind arise; and at others, the wind, though violent before, shall cease on the approach of a cloud, and recover its strength as soon as the cloud is past. This connection of the clouds with wind is most remarkable in mountainous countries, where the peaks are sufficiently high to have their tops involved in clouds. A very remarkable mountain of this kind is met with at the Cape of Good Hope, from the clouds on whose tops, according to the relations of travellers, the winds blow forth as if they had been confined in a bag; and something similar has been observed of mountains in other parts of the world.

The uses of the clouds are evident; as from them proceeds the rain which refreshes the earth; and without which, according to the present system of nature, the whole surface of the earth must be a mere desert. They
They are likewise of great use as a screen interposed between the earth and the scorching rays of the sun, which are often so powerful as to destroy the grasses and other tender vegetables. In the more secret operations of nature also, where the electrical fluid is concerned, the clouds bear a principal share; and serve especially as a medium for conveying that fluid from the atmosphere into the earth, and from the earth into the atmosphere; in doing which, when electrified to a great degree, they sometimes produce very terrible effects; of which instances have already been given.

CLOVE, a term used in weights of wool. Seven pounds make a clove. In Essex in England, eight pounds of cheese and butter go to the clove.

Clove Jule-Flower. See Dianthus.

CLOVER-GRASS, in botany. See Trifolium; and Agriculture, no. 177, 179.

CLOUGH, or Draught, in commerce, an allowance of two pounds in every hundred weight for the turn of the scale, that the commodity may hold out weight when sold out by retail.

CLOVIO, (Giorgio Giulio) history and portrait painter, was born in Scelovia in 1498. Having in his early part of his youth applied himself to literature, his genius prompted him to pursue the art of painting for a profession; and at 18 years of age he went to Rome, where he spent three years to perfect his hand in drawing, and devoted himself entirely to painting in miniature. His knowledge of colouring was established by the instructions of Julio Romano, and his taste of composition and design was founded on the observation of his portraits and historical compositions, and his affinities he proceeded to such a degree of excellence in portrait as well as in history, that in the former he was accounted equal to Titian, and in the latter no inferior to Buonaroti. He died in 1578. His works are exceedingly valuable, and are at this day numbered among the curiosities of Rome. Vafari, who had seen the wonderful performances of Clovio with inexpressible astonishment, enumerates many of his portraits and historical compositions, and seems to be almost at a loss for language sufficiently expressive of their merit. He mentions two or three pictures on which the artist had bestowed the labour of nine years: but the principal picture represented Nimrod building the Tower of Babel; which was so exquisitely finished, and so perfect in all its parts, that it seemed quite incomprehensible how the eye or the pencil could execute it. He says it is impossible to imagine anything so admirably curious; whether one considers the elegance of the attitudes, the richness of the composition, the delicacy of the naked figures, the perspicuity of the objects, the tender distances, the scenery, the buildings, or other ornaments; for every part is beautiful and inimitable. He also takes notice of a single ant introduced in one of the pictures of this master; which, though exceedingly and incredibly small, is yet so perfect, that even the most minute member was as distinct as if it had been painted of the natural size.

CLOVIS I. was the real founder of the French monarchy; for he was the first conqueror of the several provinces of Gaul, possessed before his time by the Romans, Germans, and Goths. Thence he united to the then scanty dominions of France, removed the fest of government from Scetia to Paris, and made this the capital of his new kingdom. He died in 511, in the 46th year of his age and 31st of his reign. See (Hist. of France).

CLOTS, in gunnery, are thin plates of iron nailed on one part of the axle-tree of a gun-carriage which comes through the nave, and through which the linspur goes.

CLOYNE, a town of Ireland, in the county of Cork, and province of Munster, W. Long 8. o. N. Lat. 51. 40. It is but a small place, though an episcopal residence. A church was built, and a bishopric erected here, by St Colman, who died on the 4th of November 604; and in 707 an abbey was also founded here. In 1430, the bishopric was united to that of Cork; and the union continued till the 11th of November 1638, when Dr George Syngue was consecrated bishop of Cloyne; since which time this see has been governed by its own prelates, one of whom was the celebrated BERKELEY. This see is not taxed in the king's books; but is now reputed to be worth L.2500 a-year. The chapter of Cloyne is composed of a dean, chancellor, treasurers, and fourteen prebendaries. The diocese is divided into four rural deaneries, and the collegiate church of St. Mary of Youghal is united to the bishopric. The cathedral is a descent Gothic building. The nave is about 120 feet long; having lateral aisles, besides the crofs aisles, divided by Gothic arches, five on each side. In the choir there is an excellent organ. The bishop's palace, which was rebuilt at the beginning of the present century, is large and convenient. To the north-west of Cloyne is a reputed holy well, dedicated to St Colman, which is much frequented on the 24th of November, being the patron-day.

Clue of a Sail, the lower corner; and hence Clue-Garnets, are a sort of tackles fastened to the clout, or lower corners of the main-sail or fore-sail, to truss them up to the yard as occasion requires, which is usually termed closing up the sails.

Clue-Lines are for the same purpose as clue-garnets; only that the latter are confined to the courses, whereas the former are common to all the square sails. See these ropes as represented in the article Ship.

CUNIA, (anc. geog.) a principal town of the Iberian Spain, a Roman colony, with a conventus juridicus, on the Darius, to the north of Numantia. Now Codon del Conde.

CLUNIUM, (anc. geog.) a town of Corsica, near Basilia. Now St Catharine.

CLUNY, or CLOUNI, a celebrated abbey of Benedictine monks, in a city of that name; being the head or chief of the congregation denominated from them. It is situated in the Maconnois, a little province of France, on the river Grone; and was founded by William Duke of Berry and Aquitain; or, as others say, by the Abbot Bernon, supported by that Duke, in the year 910.

This abbey was anciently so very spacious and magnificent, that in 1245, after the holding of the first council of Lyons, Pope Innocent IV. went to Cluny, accompanied with the 2 patriarchs of Antioch and Constantinople, 12 Cardinals, 3 archbishops, 15 bishops, and a great number of abbots; who were all entertained,
Herrings. Clupea. tained, without one of the monks being put out of their place: tho’ S. Louis, Q. Blanche his mother, the Duke of Artois his brother, and his sifter, the Emperor of Constantinople, the sons of the kings of Aragon and CafTile, the Duke of Burgundy, 6 counts, and a great number of lords, with all their retinues, were there at the same time.

Cluny, at its first erection, was put under the immediate protection of the apostolic see; with express prohibition to all secular and ecclesiastic powers, to disturb the monks in the possession of their effects, or the election of their abbot. By this they pretended to be exempted from the jurisdiction of bishops; which at length gave the hint to other abbeys to imitate on the fame.

Cluny is the head of a very numerous and extensive congregation: in effe& it was the first congregation of divers monasteries united under one chief, so as only to constitute one body, or, as they call it, one order, that ever arose.

This order of monks was brought into England by William Earl of Warren, fon-in-law to William the Conqueror, who built a house for them at Lewes in Suflext about the year 1077. There were 27 priories and cells of this order in England, which were governed by foreigners, afterwards made denizens.

CLUPEA, or Herrings, in ichthyology, a genus belonging to the order of abdominales. The upper jaw is furnished with a serrated myrifiche; the branchiotege membrane has eight rays; a scaly serrated line runs along the belly from the head to the tail; and the belly-fins have frequently nine rays. There are 11 species, six.

1. The harenogus, or common herring, has no spots, and the under jaw is longer than the upper one. A herring dies immediately after it is taken out of the water: whence the proverb arises, As dead as a herring. The meat is everywhere in great esteem, being fat, soft, and delicate; especially if it is dressed as soon as caught, for then it is incomparably better than on the next day.

The herring was unknown to the ancients. Notwithstanding the words green and maquine are by translators rendered hale, the characters given to those fish are common to such numbers of different species as render it impossible to fix which they intended.

Herrings are found from the highest northern latitudes, yet known as low as the northern coasts of France; and except one instance, brought by Dod, of a few being once taken in the bay of Tangier, none are ever found more southerly. They are met with along the coasts of America, as low as Carolina. In Chesapeake-bay is an annual inundation of those fish, which cover the shore in such quantities as to become a nuisance. We find them again in the seas of Kamtchatka, and probably they reach Japan; for Kempfer mentions, in his account of the fish of that country, some that are congenorous. The great winter rendezvous of the herrings is within the arctic circle: there they continue for many months in order to recruit themselves after the fatigue of spawning: the fish within that space swarming with incoet food in a far greater degree than those of our warmer latitudes. This mighty army begins to put itself in motion in the spring: we distinguish this vast body by that name; for the word herring comes from the German her, ‘an army,’ to express their numbers. They begin to appear off the Shetland isles in April and May; there are only the forerunners of the grand shoal which comes in June: and their appearance is marked by certain signs, by the numbers of birds, such as gannets and others, which follow to prey on them; but when the main body approaches, its breadth and depth is such as to alter the appearance of the very ocean. It is divided into distinct columns of five or six miles in length, and three or four in breadth, and they drive the water before them with a kind of rippling: sometimes they sink for the space of ten or fifteen minutes, and then rise again to the surface; and in fine weather reflect a variety of splendid colours like a field of the most precious gems; in which, or rather in a much more valuable light, should this stupendous gift of Providence be considered by the inhabitants of the British isles.

The first check this army meets in its march southward is from the Shetland isles, which divide it into two parts: one wing takes to the east, the other to the western shores of Great Britain, and fill every bay and creek with their numbers; others pass on towards Yarmouth, the great and ancient mart of herrings: they then pass through the British Channel, and after that, in a manner disappear. Those which take towards the west, after offering themselves to the Hebrides, where the great stationary fishery is, proceed to the north of Ireland, where they meet with a second interruption, and are obliged to make a second division: the one takes to the western side, and is scarce perceived, being soon lost in the immensity of the Atlantic; but the other, that passes into the Irish sea, rejoices and feeds the inhabitants of most of the coasts that border on it. These brigades, as we may call them, which are thus separated from the greater columns, are often capricious in their motions, and do not show an invariable attachment to their haunts.

We were inclined to consider this partial migration in a moral light, we might reflect with veneration and awe on the mighty power which originally impressed on this most useful body of this creatures the instinct that directs and points out the course, that blest and enriches the Britifh islands, which exposes them, at certain and invariable times, to quit the vast polar deeps, and offer themselves to the expediting fleets. That benevolent Being has never been known, from the earliest account of time, once to withdraw this bleffing from the whole; though he often thinks proper to deny it to particulars, yet this partial failure (for which we see no natural reafon) should fill us with the most exalted and grateful ſense of his Providence for impressing such an invariable and general instinct on these fish towards a southward migration when the whole is to be benefited, and to withdraw it when only a minute part is to suffer.

This instinct was given them, that they might remove for the sake of depositing their spawn in warmer seas, that would mature and vivify it more alluredly than those of the frozen zone. It is not from defect of food that they set themselves in motion; for they come full of fat, and on their return are almost universally observed to be lean and miserable. What their food is near the Pole we are not yet informed; but
but in the British seas they feed much on the *enifius marinus*, a crustaceous insect, and sometimes on their own fry.

They are full of roe in the end of June, and continue in perfection till the beginning of winter, when they deposit their spawn. The young herring begin to approach the shores in July and August, and are then from half an inch to two inches long: those in Yorkshire are called *herring file*. Though we have no particular authority for it, yet as very few young herrings are found in the British seas during winter, it seems most certain that they must return to their parental haunts beneath the ice, to repair the vast destruction of their race during summer by men, fowl, and fish. Some of the old herrings continue on the British coast the whole year: the Scarborough fishermen never put down their nets but they catch a few: but the numbers that remain are not worth comparison with those that return. See *Herring-fishery*.

The Dutch are most extravagantly fond of this fish when it is pickled. A premium is given to the best that arrives from Holland in a laden of this fish. The Sevren file is sometimes caught in the Thames, though rarely, and called *alise* (no doubt *alise*, the French name) by the fishermen in that river. About the time of its appearance, especially in that month, it is taken twice or thrice in great numbers in the Severn, and again in the River Mere.

The Thames file has not frequent that river till the latter end of May or beginning of June and is esteemed a very course and inlipsoid sort of fish. The Severn file is sometimes caught in the Thames, though rarely, and called *alise* (no doubt *alise*, the French name) by the fishermen in that river. About the same time, and rather earlier, the variety called near Gloucester, the *twaiet*, makes its appearance; and is taken Twice de- in great numbers in the Severn, and is held in as a very delicate and excellent fish; vast quantities are annually taken in the rivers along the coast, and in these which fall into the Bay of Chesapeake, which are either used fresh or cured, and are much esteemed.

The Thames file has not frequent that river till the latter end of May or beginning of June and is esteemed a very course and inlipsoid sort of fish. The Severn file is sometimes caught in the Thames, though rarely, and called *alise* (no doubt *alise*, the French name) by the fishermen in that river. rium of antherae or glandise coalized, including the germen. The capsule is quinquangular, quinquavalved, and full of pulp. There are four species, all natives of America. The most remarkable is the Flava. This is pretty common in the British American islands, where the trees grow to the height of 20 feet, and shoot out many branches on every side, furnished with thick, round, succulent leaves placed opposite. The flowers are produced at the ends of the branches, each having a thick succulent cover. After the flowers are lost, they are succeeded by oval fruit. From every part of these trees there exudes a kind of turpentine, which is called in the West Indies, hog-gum; because they say, that when any of the wild hogs are wounded, they repair to these trees, and rub their wounded parts against the stem till they have anointed themselves with this turpentine, which heals their wounds. These plants are very tender, and in England must be kept constantly in a flore; and sparingly watered, especially in winter; for they naturally grow in those parts of the islands where it seldom rains, and consequently cannot bear much moisture. They may be propagated from cuttings, which must be laid to dry for a fortnight or three weeks, that the wounded parts may be healed over, otherwise they will rot. The best time for planting these cuttings is in July, that they may be well rooted before the cold weather comes on in autumn.

CLUSINA PALUS, (anc. geog.) a lake of Tuscany, extending north-west between Clusium and Arretium, and communicating with the Arnaus and Clasinus. Now Chiana Paluda.

CLUSINI, fontes, (Horace) bays in Tuscany, in the territory of Clusium, between this last to the north, and Acula to the south, at the distance of eight miles from each. Now Bagni di S. Casciana.

CLUSIUM, anciently called Camari, (Virgil, Lib.) a town of Tuscany, at the south end of the Palus Clusini, where it forms the Clasian; the royal residence of Porfeius, three days journey from Rome to the north, (Polybius). Clusinus the epithet. Clusini Victor the people. Now Chiusi. E. Long. 13. Lat. 43. — Clusium Novum, was a town of Tuscany, near the springs of the Tiber, in the territory of Arretium; where lies the Ager Clusinus; now called Castelnuovo Clusini Novi, the people, (Pliny).

CLUDIA, in botany: A genus of the gynandria order, belonging to the dicotyledonous plants; and in the natural method ranking under the 38th order, Tricocce. The male calyx is pentaphylous, the corolla pentapetalous: the calyx and corolla of the female as in the male; the styles are three, and the capsule is trilocular with a single seed. There are three species, all of them natives of warm climates. They are evergreen shrubby plants, rising fix or eight feet high, garnished with simple leaves, and greenish-white quinquangular flowers. They are propagated by cuttings in spring or summer, planting them in pots of light earth, plunged in a hot-bed. In Britain the plants must always be kept in a flore.

CLUFS, in botany: In his account of the medicinal plants of Jamaica, says that the clusia aetheria is the same as the cafcarilla and cleatheria of the shops. Other medical writers have supposed them to be distinct barks, and they are sold in the shops as different productions. Linnaeus's croton cafcarilla, Dr Wright observes, is the wild rosymary shrub of Jamaica, the bark of which has none of the felino qualities of the caf-

CLUVIER, (Philip) in Latin Cluviariotes, a celebrated geographer, born at Dantzic in 1580. He travelled into Poland, Germany, and the Netherlands, in order to study law; but, being at Leyden, Joseph Scaliger persuaded him to give way to his genius for geography. Cluviier followed his advice, and for this purpose visited the greatest part of the European states. He was well versed in many languages; and wherever he went, obtained illustrious friends and protectors. At his return to Leyden, he taught there with great applause; and died in 1623, aged 43. He wrote, 1. De tribus Rhenum abeatis. 2. Germania antiqua. 3. Sicilia antiqua. 4. Italia antiqua. 5. Introduction in universal Geographiam. All justly esteemed.

CLYDE, a river in Scotland, which, arising in Annandale, falls into the sea over against the Isle of Bute. Next to the Tay, it is the largest river in Scotland; and is navigable for small craft up to Glasgow. The canal, which joins the Forth, falls into it a little below that city. The cataract called the Frith of the Clyde, opposite to Lanark, is a great natural curiosity, and the first scene of the kind in Great Britain. This tremendous sheet of water for about a mile falls from rock to rock. At Stone-byres, the first fall is about 60 feet; the last, at Cory-Lynn, is over rock, not less than 100 feet high. At both these places this great body of water exhibits a grander and more interesting spectacle than imagination can possibly conceive.

At Cory-Lynn, the falls are seen to most advantage from a ruinous pavilion in a garden, placed in a lofty situation. The cataract is full in view, seen over the tops of trees and bushes, precipitating itself, for an amazing way, from rock to rock, with short interruptions, forming a rude slope of furious foam. The sides are bounded by vast rocks, clothed on their tops with trees: on the summit and very verge of one is a ruin tower, and in front a wood over-top by a verdant hill. A path conducts the traveller down to the beginning of the fall, into which projects a high rock, in floods insulated by the water, and from the top is a tremendous view of the furious stream. In the cliffs of this savage retreat the brave Wallace is said to have concealed himself, meditating revenge for his injured country.

On regaining the top, the walk is formed near the verge of the rocks; which on both sides are perfectly mural and equidistant, except where they overhang: the river is pent up between them at a distance far beneath; not running, but rather sliding along a honey bottom sloping the whole way. The summits of the rock are wooded; the sides smooth and naked; the strata narrow and regular, forming a stupendous natural masonry. After a walk of above half a mile on the edge of this great chasm, on a sudden appears the great and bold fall of Boniton, in a foaming sheet, far projecting into a hollow in which the water shows a violent agitation, and a wide extending mist arises from the surface. Above that is a second great fall; two lesser succeed: beyond them the river winds, grows more tranquil, and is seen for a considerable way, bounded
Clymene

bound on one side by wooded banks, on the other by rich and swelling fields.

The great fall of Stone-byers, first mentioned, has more of the horrible in it than any of the others, and is seen with more difficulty: it consists of two precipitous cataracts falling one above the other into a vast chasm, bounded by lofty rocks, forming a magnificent theatre to the view of those who take the pains to descend to the bottom. Between this and Cory-Lynn there is another fall called Dundaffin.

Clymenel, in fabulous history, the daughter of Oceanus: who, being beloved by Apollo, he had by her Phaeton, Lampatia, Egle, and Phebe. See Phae-ton.

Clypeola, treacle-mustard: A genus of the filiculofa order, belonging to the tetradynamia elafs of the 39th order, Silquifae. The filicula is emarginated, orbiculated, compressed plane, and deciduous. There are two species, both natives of France, Italy, and the warm parts of Europe, but hardy enough to bear the winters in Britain. One of them is an annual, the other a perennial plant; both are low and herbaceous, bearing spikes of white flowers. They are propagated by seeds, which should be sown in autumn, where they are to remain.

Clyssus, an extract prepared, not from one, but several bodies mixed together: and, among the moderns, the term is applied to several extracts prepared from the same body, and then mixed together.

Clyster, is a liquid remedy, to be injected chiefly at the anus into the larger intestines. It is usually administered by the bladder of a hog, sheep, or ox, perforated at each end, and having at one of the apertures an ivory pipe fastened with pack-thread. But the French, and sometimes the Dutch, use a pewter syringe, by which the liquor may be drawn in with more ease and expedition than in the bladder, and likewise more forcibly expelled into the large intestines. This remedy should never be administered either too hot or too cold, but tepid; for either of the former will be injurious to the bowels.

Clysters are sometimes used to nourish and support a patient who can swallow little or no aliment, by reason of some impediment in the organs of deglutition; in which case they may be made of broth, milk, ale, and decoctions, and taken with wine. The English have introduced a new kind of clyster, made of the smoke of tobacco, which has been used by several other nations, and appears to be of considerable efficacy when other clysters prove ineffectual, and particularly in the iliac pain, in the hernia incarcerata, and for the recovery of drowned persons.

Clytemnestra, in fabulous history, the daughter of Jupiter and Leda. She married Agamemnon; but while that prince was at the siege of Troy, she had an amorous intrigue with Ægillus, whom he engaged to murder Agamemnon at his return to his dominions. Her son Orestes, however, avenged the death of his father by killing Ægillus, with his mother Clytemnestra: but was afterwards haunted by the Furies as long as he lived.

Clytie, or Clytie, daughter of Oceanus and Tethys, beloved by Apollo. She was deserted by her lover, who paid his addresses to Leucothoe; and this so irritated her, that she discovered the whole intrigue to her rival’s father. Apollo defiried her the more for this: and she pined away, and was changed into a flower, commonly called a fun-flower, which still turns its head towards the sun in his course in token of her love.

Cneorum, widow-wail: A genus of the mono-gynia order, belonging to the triandra class of plants; and in the natural method ranking under the 38th order, Triocere. The clayxis is tridentate: there are three equal petals, and a tricolocous berry. There is but one species, a little evergreen and very ornamental shrub, adorned with simple leaves, and tripetalous flowers of a pale yellow colour. It is propagated from seeds, and requires no other care than to be kept free from weeds.

Cnicos, blessed-thistle: A genus of the polygynia equaills order, belonging to the syngeneia class of plants; and in the natural method ranking under the 49th order, Compositae. The clayxis is ovate, imbricated with fibious-striated leaves, and inclosed with bractea. The florets are equal. There are seven species, of which the only remarkable one is that used in medicine under the name of cardus benedictus. This is an annual plant cultivated in gardens: it flowers in June and July, and perfects it seed in autumn. For medical purposes the plants should be gathered when in flower, dried in the shade, and kept in a very dry airy place, to prevent its rotting or growing mouldy, which it is very apt to do. The leaves have a penetrating bitter taste, not very strong or durable, accompanied with an ungrateful flavour, which they are in a great measure freed from by keeping. Water extracts in a little time, even without heat, the lighter and more grateful parts of this plant; if the digestion is continued for some hours, the disagreeable parts are taken up; a strong decoction is very nauseous and offensive to the stomach. Rectified spirit gains a very pleasent bitter taste, which remains uninjured in the extract. The virtues of this plant are little known in the present practice. The nauseous decoction is sometimes used to provoke vomiting; and a strong infusion to promote the operation of other emetics. But this elegant bitter, when freed from the offensive parts of the herb, may be advantageously applied to other purposes. Dr Lewis informs us, that he has experienced excellent effects from a slight infusion of cardus in lots of appetites, where the stomach was injured by irregularties. A stronger infusion made in cold or warm water, if drunk freely, and the patient kept warm, occasions a plentiful sweat, and promotes all the secretions in general. The seeds of the plant are also considerable bitter, and have sometimes been used with the same intention as the leaves.

Cnidus, (anc. geog.) a Greek town of Caria; situated on a horn or promontory of a peninsula. It had in front a double port, and an island lying before it in form of a theatre, which being joined to the continent by mole or caufeways, made Cnidus a Dippo-lia or double town, (Strabo), because a great number of Cnidians inhabited the island. Pandænas mentions a bridge which joined the island to the continent.—Cnidis, the people: Cnidus, the epithet.—Cnidus Pri-nus, a principal divinity of the Cnidians, (Horace).
Her statue was executed by Praxiteles; and so exquisitely done, and so much admired, that people came from all parts to view it. (Pliny). Of this place was Eudoxus, the famous astronomer and geometer, who had here an observatory, (Sib. I.

CNOSSUS, or Cnosus, anciently called Carato, from a cognominal river running by it; a city of Crete, 23 miles to the east of Gortinia, (Pestinger). Here stood the sepulchre of Jupiter, the famous labyrinthis, and the palace of Minos, a very ancient king; here happened the adventure of Ariadne, his daughter with Theseus, called Gnofis, (Ovid). Its port-town was Hieraclea, on the east side of the island.

COACH, a vehicle for commodious travelling, suspended on leathers, and moved on wheels. In Britain, and throughout Europe, the coaches are drawn by horses, except in Spain, where they use mules. In France, and throughout Europe, the coaches are drawn by horses, except in Spain, where they use mules. In that country by a royal ordinance; on the duke d'Olivares, who found that a very important secret, whereon he had confided in his coach, had been overheard and revealed by his coachman; since that time the place of the Spanish coachman is the same with that of the French stage-coachman and English postilion, viz. on the first horse on the left.

The invention of coaches is owing to the French: yet coaches are not of any great antiquity, even in France, scarce reaching beyond the reign of their Francis I. Their use, at their first rise, was only for the country: and authors observe, as a thing very singular, that there were at first no more than two coaches in Paris; the one that of the queen, and the other that of Diana, natural daughter of Henry II. The first carrier, who had one was Jean de Laval de Bois Dauphin, whose enormous bulk disabled him from travelling on horseback. One may hence judge how much variety, luxury, and idleness, have grown upon our hands; these later days, there being many in the city no less than 15,000 coaches.

Coaches have had the face of all other inventions, to be brought by degrees to their perfection; at present they seem to want nothing, either with regard to ease or magnificence. Louis XIV. of France made several exemplary laws for restraining the excessive richness of coaches, prohibiting the use of gold, silver, &c. therein; but they have had the face to be neglected.

By the act 25 Geo. III. c. 47. former duties on coaches, &c. are repealed, and the following charged in lieu thereof, namely: For every coach, berlin, landau, chariot, calash, with four wheels, chair marine, calash with four wheels, and caravans, or by whatever name such carriages may be called, kept by any person for his own use, or to be let out to hire (except hackney coaches), shall be paid the yearly sum of £ 10. And for every calash, chair, chair, gig, or whiffkey, or by whatever name they are known or called, having two or three wheels, to be drawn by one or more horses, that shall be kept by any person for his own use, or to be let out to hire, the yearly sum of £ 5. 10s.

Every maker of coaches, chair, chariots, &c. must, from and after the fifth day of July 1785, taken out at the excise-office in London, or of their agents in the country, a licence to be renewed annually at least ten days before the expiration of the former, for which they must pay 20s. They must also pay 20s. duty for every four-wheeled carriage newly built for sale, and 10s. for every two-wheel carriage. These duties are also payable to the commissioners of the excise in town, or their agents in the country.

Coach-makers in Scotland are to take out their licences and pay the duties to the commissioners of excise in Edinburgh, or their agents in the country of that part of Great Britain.

Every coach-maker neglecting to take out a licence, and renewing the same annually, forfeits £ 10; and neglecting or refusing to settle every six weeks, in the manner particularly directed by the act, is a forfeiture of £ 20.

Hackney-Coaches, those exposed to hire, in the streets of London, and some other great cities, at rates fixed by authority.

One thousand hackney-coaches are allowed in London and Westminster; which are to be licensed by commissioners, and to pay a duty to the crown. They are all numbered, having their numbers engraved on tin plates fixed on the coach-doors. Their fares or rates are fixed by act of parliament; and by a late act have been increased in consequence of a new weekly tax.

Stage-Coches, are those appointed for the conveyance of travellers from one city or town to another. The masters of stage-coaches are not liable to an action for things lost by their coachmen, who have money given them to carry the goods, unless where such master takes a price for the same.

Persons keeping any coach, berlin, landau, or other carriage with four wheels, or any calash, chair, chair, or other carriage with two wheels, to be employed as public stage-coaches or carriages, for the purpose of conveying passengers for hire; and from different places in Britain, shall pay annually 6s. for a licence, and no person so licensed shall by virtue of one licence keep more than one carriage, under the penalty £ 10.

Mail-Coches in Britain under stage-coaches of a particular conformation to prevent overtures, and for a certain consideration carry his Majesty's mails, which are protected by a guard, and subject to the regulations of the post-office. They are pointed as to their time of arrival and departure, are restricted to four inside passengers, and from experience have proved very beneficial to the commerce and correspondence of Britain. John Palmer, Esq. who has the merit of the invention, and been indefatigable in bringing the establishment to a permanent footing, has been greatly patronized by government; and got, as the reward of his service, a handsome appointment in the general post-office London.

COACH, or Coach, is also a sort of chamber or apartment in a large ship of war near the stern. The floor of it is formed by the asafoot part of the quarter-deck, and the roof of it by the poop: it is generally the habitation of the captain.

COADUNATE, in botany, an order of plants in the fragmenta methodi naturalis of Linnaeus, in which he has the genera, viz. anonna, liroidendrum, magnolia, uvaria, michelia, thea.

COAGULATION, in chemistry, is performed by fix
COAL

COAGULUM is the same with what in English we call ☤runnet, or rather the curd formed thereby.

COAказать. For the exciting of intense heats, as for the melting of iron ore, and for operations where the acid and oily particles would be detrimental, as the drying of malt, fossil-coals are previously charred, or reduced to coals: that is, they are made to undergo an operation similar to that by which charcoal is made. By this operation coals are deprived of their phlegm, their acid liquor, and part of their fluid oil. Coals therefore, consist of the two most fixed constituent parts, the heavy oil and the earth, together with the acid concrete salt, which, though volatile, is dissolved by the oil and the earth.

COAL, among chemists, signifies any substance containing oil, which has been exposed to the fire in closed vessels, so that all its volatile principles are expelled, and that it can sustain a red heat without further decomposition. Coal is commonly solid, black, very dry, and considerabably hard. The specific character of perfect coal is its capacity of burning with access of air, while it becomes red-hot and sparkles, sometimes with a sensible flame which gives little light, with no smoke or foot capable of blackening white bodies.

Coal is capable of communicating its inflammable principle, either to the vitriolic acid with which it forms sulphur; or to the nitrous acid contained in nitre, which it inflames; or to metallic earths, which it reduces into metals. But the phlogiston cannot pass from coal to form these new combinations without the assistance of red-heat. Coal seems to be an unalterable compound in every instance but those mentioned, of burning in the open air, and of communicating its phlogiston to other bodies; for it may be exposed in closed vessels to the most violent and long continued fire without suffering the least decomposition. No disposition to fume, nor any diminution of weight can be perceived. It is a substance exceedingly fixed, and perhaps the most refractory in nature. It refists the action of the most powerful menstrua, liver of sulphur alone excepted. Coal is evidently a result of the decomposition of the compound bodies from which it is obtained. It consists of the greatest part of the earthy principle of these compound bodies, with which a part of the saline principles, and some of the phlogiston of the decomposed oil, are fixed and combined very intimately. Coal can never be formed but by the phlogiston of a body which has been in an oily state; hence it cannot be formed by sulphur, phosphorus, metals, nor by any other substance the phlogiston of which is not in an oily state. Also every oily matter treated with fire in closed vessels, furnishes true coal; so that whenever a charry residuum is left, we may be certain that the substance employed in the operation contained oil. Lastly, the inflammable principle of coal, although it proceeds from oil, certainly is not oil; but pure phlogiston; since coal added to vitriolic acid can form sulphur, to phosphoric acid can form phosphorus, &c. and since oil can produce some of these effects till it has been decomposed and reduced to the state of coal. Besides, the phenomena accompanying the burning of coal are different from those which happen when oily substances are burnt. The flame of charred coal is not so bright as that of oil, and produces no flame or foot.

All the phlogiston of coal is not burnt in the open air, particularly when the combustion is slow. One part of it exhaled without decomposition, and forms a vapour, or an invisible and insensible gas. This vapour (which is, or at least contains a great deal of, fixed air) is found to be very pungent, and to affect the animal system in such a manner as to occasion death in a very short time. For this reason it is dangerous to remain in a close place, where charcoal or any other part of coal is burnt. Persons struck by this vapour are stunned, faint, suffer a violent headache, and fall down senseless and motionless. The best method of recovering them is by exposure to the open air, and by making them swallow vinegar, and breathe its fumes.

Amongst coals, some differences are observable, which proceed from the difference of the bodies from which they are made: some coals, particularly, are more combustible than others. This combustibility seems to depend on the greater or less quantity of saline principle they contain; that is, the more of the saline principle it contains, the more easily it decomposes and burns. For example, coals made of plants and wood containing much saline matter capable of fixing it, the ashes of which contain much alkaline salt, burn vigorously and produce much heat; whereas the coals of animal matters, the saline principles of which are volatile, and cannot be fixed but in small quantity, and the ashes of which contain little or no salt, are scarcely at all combustible. For they not only do not kindle as easily as charcoal does, nor ever burn alone, but they cannot be reduced to ashes without very great trouble, even when the most effectual methods are used to facilitate the combustion. The coal of bullocks blood has been kept for six hours very red in a shallow crucible, surrounded with burning charcoal, and continually stirred all the time, that it might be totally exposed to the air; yet could it not be reduced to white, or even grey, ashes: it still remained very black, and full of phlogiston. The coals of pure oils, or of concrete oily substances and foot, which is a kind of coal raised during inflammation, are as difficultly reduced to ashes as animal coals. These coals contain very little saline matter; and their ashes yield no alkali. The coals which are so difficultly burnt, are also less capable of inflaming with nitre than others more combustible; and some of them even in a great measure resist the action of nitre.

COAL, in mineralogy, a kind of solid inflammable substance, supposed to be of a bituminous nature, and commonly used for fuel. Of this substance there are various species.

1. Pit-coal (Litanthran), is a black, solid, compact,
Coal. [ 88 ]

C O A

part, brittle masses, of moderate hardness, lamellated structure, more or less shining, but seldom capable of a good polish; and does not melt when heated. According to Kirwan, it consists of petrol or asphaltum, intimately mixed with a small portion of earth chiefly argillaceous; seldom calcareous; and frequently mixed easily to according to Kirwan, it with pyrites. A red tincture is extracted from it by spirit of wine, but caustic alkali attacks the bituminous part. From some sorts of it a varnish may be made by means of fat oils. Fixed alkali has never been found in any kind of it, nor sulphur, unless when it happens to be mixed with pyrites.—None of the various kinds are found to be electrics per se (a). The varieties of lithanthrax, enumerated by Cronstedt are, 1. With a small quantity of argillaceous earth and vitriolic acid. It is of a black colour, and shining texture: it burns, and is mostly consumed in the fire, but leaves, however, a small quantity of ashes. 2. Slaty coal. 2. Culm coal, called Olim, by the Swedes, has a greater portion of argillaceous earth and vitriolic acid, with a moderate proportion of petrol. It has the same appearance as the foregoing, though its texture is more dull: it burns with a flame, without being consumed, but leaves behind it a flag of the same bulk with the original volume of the coal. The following is Mr Kirwan’s description of it from the memoirs of the Stockholm academy. “Its fracture has a rougher section than the cannel coal; its specific gravity from 1300 to 1370. The bulk afforded by distillation, at first fixed air, then an acid liquor, afterwards inflammable air, and a light oil of the nature of petrol; then a volatile alkali; and lastly pitch-oil. The refoaner is nearly three quarters of the whole; and being slowly burnt, affords 13 per cent. of ashes, which consist mostly of argillaceous earth, and about three hundredth parts of them are magnetic. It is found in England, and among some aluminous ores in Sweden.”

3. Slate-coal contains such a quantity of argillaceous earth, that it looks like common slate; however, it burns by itself with a flame. M. Magellan is of opinion that this is the bituminous substance already described (see Clay, p. 51.) This schistus is of a dark bluish rusty colour; when thrown on the fire it burns with a lively flame, and almost as readily as the oily wood of dry olive tree, or lignum vitae; emitting the very disagreeable smell of petrol. Such large quantities of it are found near Purbeck in Dorsetshire, that the poorer part of the inhabitants are thence supplied with fuel. From the appearance of this flaty coal, Cronstedt has been induced to suppose that the earth of all kinds of coal is argillaceous, though it is not so easy to distinguish it after being burnt. The pit-coals, he says, contain more or less of the vitriolic acid; for which reason the smoke arising from them attacks silver in the same manner as sulphur does, let the coals be ever so free from marcasite, which, however, is often imbedded or mixed with them.

4. Cannel coal, (Amphelites) is of a dull black colour; breaks easily in all directions; and, if broken transversely, presents a smooth conchoidal surface. It burns with a bright lively flame, but is very apt to fly in pieces in the fire; however it is said to be entirely deprived of this property by immersion in water for some hours previous to its being used. It contains a considerable quantity of petrol in a less condensed state than other coals. Its specific gravity is about 1.770. This kind of coal, being of an uniform hard texture, is easily turned on a lathe, and takes a good polish. Hence it is used for making various toys, which appear almost as well as if made of the finest jet.

5. Kilkenny coal is the lightest of any; its specific gravity being only about 1.400. It contains the largest quantity of asphalum; burns with less smoke and flame, and more intensely, though more slowly, than the cannel-coal. The quantity of earth it contains does not exceed one-twentieth part of its weight; but this kind of coal is frequently mixed with pyrites. It is found in the county of Kilkenny, belonging to the province of Leinster in Ireland. The quality of it as burning without smoke, is proverbially used as an encomium on the county.

6. Sulphurous coal consists of the former kinds mixed with a very considerable portion of pyrites; whence it is apt to moulder and break when exposed to the air, after which water will act upon it. It contains yellow spots that look like metal; burns with a sulphurous smell, leaving behind it either flag or sulphurous ashes, or both. Its specific gravity is 1.500 or more.

7. Bovey coal, (Xylantrax) is of a brown or brownish black colour, and of a yellow laminar texture. Its lamina are frequently flexible when first dug, though they generally harden when exposed to

(a) “The varieties of this coal (says Mr Magellan) are very numerous according to the different substances with which it is mixed; but in regard to their economical uses, only two kinds are taken notice of by the British legislature, viz. culm and caking coals. The caking coals, in burning, throw an incipient fusion, so that their smallest pieces unite in the fire into one mass; by which means the smallest pieces, and even the mere dust of this kind, are almost equally valuable with the largest pieces. The other sort called cuim, does not fuse or unite in the fiercest fire; so that the small coal, being unfit for domestic purposes, can only be used in burning limestone.”

“It should be an easy matter for any person to distinguish culm from small caking coal, either by trying to make fire with it in a common grate, without interposing any other fuel between it; when if it kindles, it is a caking coal; if not, it is culm; Or by putting some of these small fragments of coal on an ignited iron shovel; if they melt and run together, they belong to the caking kinds; if not, they are culm. But it seems that coal merchants are now in the custom of calling culm the powdery parts of pit-coal, of whatsoever kind they may happen to be. The reason of this is, that there is a difference in the duty payable by culm and by caking coals. There never was any difficulty, however, on the subject; nor would there be any difficulty in collecting the tax, were it not for the insufferable ignorance and love of despotic oppression which generally pervades the underling officers of the revenue.”
the air. It consists of wood penetrated with petrol or bitumen, and frequently contains pyrites, alum, and vitriol. According to the German chemists its ashes contain a little fixed alkali; but Mr Mills differs from them on this subject. By distillation it yields a fetid liquor mixed with a volatile alkali and oil; part of which is soluble in spirit of wine, and part of a mineral nature, and insubstantial. It is found in almost all the countries of Europe.

There are the most considerable varieties of coals commonly known: but we must not imagine that each of them is to be met homogeneous in those places where they are found. On the contrary, the different qualities and proportions of their ingredients make a vast number of other varieties, fit for different purposes, according to the quality and quantity of those they contain. Thus, various kinds of coals are often found mixed with one another under ground; and some of the finer sorts sometimes run like veins between those of a coarser kind. Thus, M. Magellan observed in the fine coals employed in a curious manufactory at Birmingham, that they produced a much clearer flame than he had ever observed from common coal. On further inquiry, he found that these were picked out from the common coals of the country, through which they ran in veins, and were easily distinguished by the manufacturers, though they did not afford sufficient indications of a specific difference. The purpose to which they were applied was the moulding rods of transparent and coloured glafs into the shapes proper for common buttons: which they performed with astonishing expedition.

Fourcroy remarks, that this fossil bitumen, when heated in contact with a body in combustion, and having a free access of air, kindles the more slowly and with the greater difficulty in proportion as it is more woody and compact. When once kindled, it emits a strong and durable heat, and burns for a long time before it is consumed. The matter that is burned, and produces the flame, appears very dense, and seems united to some other substance which retards its destruction. On burning, it emits a particular strong smell, which is not at all sulphurous when the coal contains no pyrites. When the combustible, oily, and other volatile parts of the coal are distilled, if the combustion be then stopped, the remainder is found to be reduced to a true charred state, and is called coke. This substance is capable of exciting the most intense heat, for which purpose it is used in metallurgical works all over Britain.

It is well known (says M. Magellan), that the English method of burning pit-coal into coke has been a most profitable and happy acquisition for the smelting our ores, and, for many other metallurgical and chemical processes in this island. But the ingenious and advantageous undertaking of Lord Dunonald, by which he turns to a very considerable profit the mines of coals in his and other estates, building ovens of a proper construction for burning pit-coal into coke, and at the same time for collecting, in separate receptacles, the volatile alkali, oil, tar, and pitch, which were generally lost by the usual method, deserves to be noticed, as it affords a very remarkable instance of the great losses to mankind, for want of carefully attending to every result from great processes of art when made on a large scale. These ovens are so contrived, as to admit an under supply of air; and the coals, after being kindled, decompose themselves by a slow but incomplete combustion, which does not destroy the ingredients. The residuum left in the oven proves to be most excellent cinders or coaks; whilst the volatile parts, which otherwise would be diffipated in the air, are separated and condensed in reservoirs, or receptacles of capacious size, placed at proper distances beyond the reach of fire. Mon. Fanjas de St. Fond, who visited these works in a trip he made to Scotland, undertook to create a similar kind of oven in France; and it is rather singular, that he endeavours to establish a claim of having discovered the same processes before he saw them in Scotland; as if he did not reflect a greater honour on his industry, to carry back to his country some useful knowledge, than to return as ignorant as our English travellers," &c.

On subjecting pit-coal of any kind to distillation in close vessels, it first yields a phlegm or watery liquor; then an ethereal or volatile oil; afterwards a volatile alkali; and lastly, a thick and greasy oil; but it is remarkable, that, by rectifying this last oil, a transparent thin and light oil of a strong and warm viscid substance, which, being exposed to the air, becomes black like animal oils. From this and other observations, the general opinion is, that all coals, bitumens, and other oily substances found in the mineral kingdom, derive their origin from vegetables buried in the earth; since it is well known that only organized bodies have the power of producing oily and fat substances. "The amazing irregularities, gaps, and breaks (says M. Magellan) of the strata of coals, and of other fossil substances, evince that this globe has undergone the most violent convulsions by which its parts have been broken, detached and overturned in different ways, burying large tracts of their upper surfaces, with all the animal and vegetable productions there existing, at the time of those horrible catastrophes, whose epoch far precedes all human records. And it is easy to be conceived, that the various heaps and confederations of these vegetable and animal substances, remaining for ages and ages in the bowels of the earth, have obtained various conscriptions, and still produce those oily and bittersweet juices, which find way to gush out, leaving behind their thickest places on the same places where they are found, and in many others where the industry of mankind never will be able to penetrate."

COAL-MINE. See COALERY.—Maliciously setting fire to coal-mines is felony, by stat. 10. Geo. II. c. 32.

§ 6. Small COAL. A sort of charcoal prepared from the spruce and broadwood stripped off from the branches of coppice wood, sometimes bound in bairns for that purpose, and sometimes charred without binding, in which case it is called "coming it together."

COALERY, COALERY, or COLLIERY; a coal-History of work, or place where COALS are dug.

It is generally agreed, that cannel-coal * is the * See Ann. lapides ampullae of the Romans; though it seems to gelateria, have been used by them only for making toys, bracelet, &c. But of that common fuel which we denominate coals, the native Romans were entirely ignorant. It is certain that they are not, as some have imagined, the lapis obdianus of Fliny, about which there have been
The first public notice of the former is mentioned by Mr Hume to have been in the time of Henry III, who in the year 1272, granted a charter to the town of Newcastle, giving the inhabitants a licence to dig coals: and the first statute relating to this article was the 9 Henry V. c. 10. ordaining all keels in the port of Newcastle to be measured by commissiners, before carriage of coals, on pain of forfeiture. They were not brought into common use till the reign of Charles 1.

There are several other countries in Europe which possess considerable coal-mines; as France, Liege, Germany, and Sweden. Also on this side of the Atlantic ocean, there has been coal discovered, and wrought; in Newfoundland, Cape-Breton, Canada, also in Virginia and other parts of the United States. And although in America, wood, from its great plenty, is used in most of the manufactures, yet the coal is excellent, and will in time become an article of very great importance.

The inland coal-trade in Britain, that is, carrying coals from Newcastle, Sunderland, Blith, and other adjacent places in the north of England, as also from the frith of Edinburgh in Scotland, and other places thence to the city of London, and to the port-towns on the coast all the way, both north of Newcastle, and up the channel as high as Portsmouth, is a prodigious article, and employs abundance of shipping and seamen; in so much that, in a time of urgent necessity, the colliery navigation alone has been able to supply the government with a body of seamen for the royal navy, able to man a considerable fleet at a very
very short warning, and that without difficulty, when no other branch of trade would do the like. Likewise the Whitehaven coaling-yards, belonging to Sir James Lowther, furnishing several counties in Ireland with coals, and constantly employ upwards of 2000 seamen; which also is a noble nursery for the navy of Britain. And not only do the pit-coals sufficiently supply all the ports, but, by means of those ports and the navigable rivers, all the adjacent counties very far inland.

In short, coals, though not an exclusive, yet may, with propriety, be styled a peculiar blessing to Britain from their great plenty, their acknowledged excellence, and their being found in such places as are conveniently situated for exportation. Nor is there any danger of the export-trade being lessened even by the several duties that have been laid upon them; for the foreign consumption being found in necessity with regard to manufactures, and in economy where they are used for convenience (wood and turf being dearer than coals with the duty), there need be no fear of the markets declining. There is as little room to be alarmed from an apprehension of their being exhausted, as the present works are capable of supplying them for a long series of years, and there are many other mines ready to be opened when these shall fail. Besides, there are known to be coals in many parts of the three kingdoms, which hitherto they have not had encouragement to work.

Besides the value of this commodity as a convenience of life, as an article of commerce, and as giving rise to a nursery of seamen for the increase of the marine; other important advantages deserve to be noticed. Coals are in many regions, and in a very useful degree, useful to the landed interest; not only by raising exceedingly the real value, and of course the purchase, of those lands in which they are found, and those through which it is necessary to pass from the works to the places where they are embarked, but from the general improvements they have occasioned; so that many counties are now better cultivated than Northumberland, and the same effects they have had in a greater or less degree in other places. Thousands of laborious people are employed in and about the mines; thousands more in conveying them to the ports, and on board the ships; to say nothing of those that draw their subsistence from the carriage of them by land to supply families, &c.

There are also great numbers that live in a superior station; as stewards, directors, factors, agents, book-keepers, &c. To these we may add the extraordinary encouragement given to ingenious artists who have invented, and the numerous workmen continually employed about those several curious and costly machines which, for a variety of purposes in this business, are in continual use, and of course in continual wear: we may join to these the multitudes that obtain their living from the many manufactures in which they are employed, and which could not be carried on but by the help and cheapness of coals. Lastly, the produce of coals exported, which amounts to a very considerable sum, besides being profitable to the owners, merchants, and mariners, is so much clear gain to the nation.

It might be expected, that a trade so beneficial to individuals, and to the nation in general, and which has been gradually increasing for several centuries past, would have been advanced by this time to very great perfection, and reduced to a regular system. But, in one very essential respect, it is found to be quite otherwise. The art of working coal-mines in the most profitable manner is highly improved; but the fundamental of the art, that of searching for and discovering coal in any district of country where it has not yet been found, has never, that we know of, been treated in a systematic manner. The reader, therefore, will not be displeased to find this defect supplied in the course of the present article, together with a detail of all the other operations in the business of coaling.

The terrestrial matters, which compose the solid parts of the earth, are divided into strata, beds, or layers, the under surface of one bearing against or lying upon the upper surface of that below it, which last bears or lies on the next below in the same manner.

These strata consist of very different kinds of matter, such as free-stone, lime-stone, metal-stone or whinstone, coal, &c. as will be particularly specified in the sequel.

Some of these strata are of a considerable thickness, being often found from 100 to 200 feet or upwards, nearly of the same kind of matter from the superior to the inferior surface; and others are found of the leaf-thickness imaginable, one inch or less.

All these strata are divided or parted from each other laterally, either by their even, smooth, polished surfaces, with very thin lamina of soft or dusty matter between them, called the parting, which renders them easy to separate; or else only by the surfaces closely conjoined to each other, without any visible matter interposed between them; yet the different substances of each stratum is not in the least intermixed, though sometimes they adhere so strongly together, that it is very difficult to part or disjoint them: in this last case they are said to have a bad parting.

Besides this principal division or parting laterally, there are, in some strata, secondary divisions or partings also laterally, separating or approaching towards a separation, of the same stratum, into parts of different thicknesses, nearly parallel to each other, in the same manner as the principal partings divide the strata themselves into parts from each other: but these secondary ones are not so thick or visible, nor make so effectual a parting, as the principal ones do; and are only met with in such strata, as are not of an uniform hardness, texture, or colour, from the upper to the under surface.

There are other divisions or partings, called backs, in almost every stratum, which crosses the former lateral ones longitudinally, and cuts the whole stratum through its two surfaces into long rhomboidal figures. These again are crossed by others called cutters, running either in an oblique or perpendicular direction to the last mentioned backs, and also cut the stratum through its two surfaces. Both these backs, and cutters generally extend from the upper or superior stratum down through several of the lower ones; so that these backs and cutters, together with the lateral partings before mentioned, divide every stratum into innumerable cubic, prismatic, and rhomboidal figures, according to the thickness of the stratum, and the position and number of the backs and cutters. They
sometimes have a kind of thin partition of dusty or soft matter in them, and sometimes none, like the first mentioned partings; but the softer kind of strata generally have more backs and cutters than the harder kind, and they do not extend or penetrate through the others.

To explain this a little further, let A, B, C, D, E, F, G (fig. 1.) represent the principal partings mentioned before, and the upper and under surfaces of any stratum; then a, b, c, d, e, f, g will represent the secondary lateral partings nearly parallel to the principal ones: g, h, i, k, l, m, the longitudinal partings called backs; n, o, p, q, r, s, the cross partings called cutters, crossing the last mentioned ones either obliquely or perpendicular.

In all places where the strata lie regular, they are divided and subdivided in the manner abovementioned; and sometimes in this manner extend through a pretty large district of country: though it is often otherwise, for their regularity is frequently interrupted, and the strata broken and disordered, by sandy chafins, breaches, or fissures, which are differently denominated according to their various dimensions, and the matters with which they are filled, viz. dikes, hitches, and troubles, which shall be explained in order.

Dikes are the largest kind of fissures. They seem to be nothing but a crack or breach of the solid strata, occasioned by one part of them being broken away and fallen from the other. They generally run in a straight line for a considerable length, and penetrate from the surface to the greatest depth ever tried; in a direction sometimes perpendicular to the horizon, and sometimes obliquely: the same kind of strata are found lying upon each other in the same order, but the whole of them elevated or depressed, on the one side of the dike as on the other. These fissures are sometimes two or three feet wide, and sometimes many fathoms. If the fissure or dike be of any considerable width, it is generally filled with heterogeneous matter, different from that of the solid strata on each side of it. It is sometimes found filled with clay, gravel, or sand; sometimes with a confused mass of different kinds of stone lying edgeways; and at other times with a solid body of free-stone, or even whin-stone. When the fissure is of no great width, as suppose two or three feet only, it is then usually found filled with a confused mixture of the different matters which compose the adjoining strata, consolidated into one mass. If the dike runs or fringes north and south, and the same kind of strata are found on the east side of the dike, in a situation with respect to the horizon 10 or 20 fathoms lower than on the other side, it is then said to be a dip-dike or downcast-dike of 10 or 20 fathoms to the eastward; or counting from the east side, it is then said to be a rise-dike or upcast of so many fathoms westward. If the strata on one side are not much higher or lower with respect to the horizontal line, than those on the other, but only broken off and removed to a certain distance, it is then said to be a dike of so many fathoms thick; and from the matter contained between the two sides of the fissure or dike, it is denominated a clay-dike, stone-dike, &c.

A hitch is only a dike or fissure of a smaller degree, by which the strata on one side are not elevated or separated from those on the other side above one fathom. These hitches are denominated in the same manner as dikes, according to the number of feet they elevate or depress the strata.

There are dikes (though they are not often met with in the coal-countries) whose cavities are filled with spar, the ores of iron, lead, vitriol, or other metallic or mineral matters; and it is pretty well known, that all metallic veins are nothing else than what in the coal-countries are called dikes.

The strata are generally found lying upon each other in the same order on one side of the dike as on the other, as mentioned above, and nearly of the same thickness, appearing to have been originally a continuation of the same regular strata, and the dike only a break by some later accident, prependicular or obliquely down through them, by which one part is removed to a small distance, and depressed to a lower situation than the other. But this is not the only alteration made in the strata by dikes; for generally to a considerable distance on each side of the dike, all the strata are in a kind of shattered condition, very tender, easily pervious to water, and debased greatly in their quality, and their inclination to the horizon often altered.

Troubles may be denominated dikes of the smallest degree; for they are not a real breach, but only an approach towards it which has not taken a full effect. The strata are generally altered by a trouble from their regular site to a different position. When the regular course of the strata is nearly level, a trouble will cause a sudden and considerable ascent or descent: where they have, in their regular situation, a certain degree of ascent or descent, a trouble either increases it, or alters it to a contrary position: and a trouble has these effects upon the strata in common with dikes, that it greatly debases them from their original quality; the partings are separated; the backs and cutters disjoined, and their regularity disordered, the original cubic and prismatic figures, of which the strata were composed, are broken, and the diminution filled with heterogeneous matter; and the whole strata are reduced to a tender and more friable state.

The strata are seldom or never found to lie in a true horizontal situation; but generally have an inclination or descent, called the dip, to some particular part of the horizon. If this inclination be to the east or west of the strata, it is called an east dip, and a west rise; and according to the point of the compass to which the dip inclines, it is denominated, and the ascent or rife is to the contrary point. This inclination or dip of the strata is found to hold every where. In some places, it varies very little from the level; in others, very considerably; and in some so much, as to be nearly in a perpendicular direction; but whatever degree of inclination the strata have to the horizon, if not interrupted by dikes, hitches, or troubles, they are always found to lie in the first regular manner mentioned. They generally continue upon one uniform dip until they are broken or disordered by a dike, hitch, or trouble, by which the dip is often altered, sometimes to a different part of the horizon, and often to an opposite point; so that on one side of a dike, hitch, or trouble, if the strata have an east dip, on the other side they may have an east rife, which is a west dip; and in general, any considerable alteration in the dip is never
met with, but what is occasioned by the circumstances last mentioned.

To illustrate what has been said, see fig. 2, where $a b c d$, &c. represents a course of strata lying upon each other, having a certain inclination to the horizon. $A B$, is a downcast-dike, which depresseth the strata obliquely to $e f h$, &c. lying upon each other in the same order, but altered in their inclination to the horizon. $C D$ represents a clay or free-dike, where the strata are never elevated nor depressed, but only broken off and removed to a certain distance. $E F$, represents a hith, which breaks off and depresseth the strata only a little, but alters their inclination to the horizon. $G H$, represents a trouble, where the strata on one side are not entirely broken off from those on the other, but only in a crushed and irregular fashion.

As some particular strata are found at some times to increase, and at other times to diminish, in their thicknesses, whilst others remain the same, consequently they cannot be all parallel; yet this increase and diminution in their thicknesses comes on very gradually.

The strata are not found dipping in the earth according to their specific gravities: for we often find strata of very dense matter near the surface; and perhaps at 50 or even 100 fathoms beneath, we meet with strata of not half the specific gravity of the first. A stratum of iron ore is very often found above one of coal, though the former has twice the gravity of the latter; and, in short, there is such an absolute uncertainty in forming any judgment of the disposition of the strata from their specific gravities, that it cannot in the least be relied upon.

It has been imagined by many, that hills and valleys are occasioned by those breaches in the strata before mentioned called dikes: but this is contradicted by experience. If it was so, we should meet with dikes at the skirts of the hills, and by the sides of valleys, and the sea-shore; but instead of that, we generally find the strata lying as uniformly regular under hills and valleys, and beneath the bottoms of the seas (as far as has been yet tried), as in the most campaign countries. It may happen, indeed, that a dike is met with in some of these places; but that being only a calcarious matter, can never be admitted as a general cause. Whatever irregularities are occasioned in the solid strata by dikes, or other breaches, are commonly covered over and evened by those beds of gravel, clay, sand, or soil, which lie uppermost, and form the outward surface of the earth. Wherever those softer matters have been carried off, or removed by accidents, as on the tops of hills and the sides of valleys, there the solid strata are exposed, and the dip and rife and other circumstances of them may be examined; but no certain conclusions can be drawn, merely from the unequivalency and inequalities of the outward surface.

The preceding observations, upon the general disposition of the solid strata, are equally applicable to the strata of coal, as to those of stone or other matter.

We shall next give an account of the several strata connected with coal, and of stone and other matters, which are usually connected with coal, and are found to have a particular affinity with it: and, for the sake of distinction, shall arrange them into six principal classes, which will include all the varieties of strata that have been found to occur in all those districts of country both in Scotland and England where coal abounds.

1. Of Whin-flone. The strata of what is denominated whin-flone are the hardest of all others; the angular pieces of it will cut glass; it is of a very coarse texture, and when broke across the grain exhibits the appearance of large grains of sand half vitrified; it can scarcely be wrought, or broke in pieces, by common tools without the assistance of gun-powder; each stratum is commonly homogeneous in substance and colour, and cracked in the rock to a great depth. The most common colours of these strata are black or dark blue, yet there are others of it ash-coloured and light brown. Their thicknesses in all the coal countries is but inconsiderable, from six or five feet down to a few inches; and it is only in a few places they are met with of these thicknesses. In the air it decays a little, leaving a brown powder; and in the fire it cracks, and turns reddish brown. Lime-flone, and what is called bastard lime-flone, is sometimes, though rarely, met with in coalseries. It is a well known flone; but from its resemblance in hardness and colour is often mistaken for a kind of whin. Sometimes, particularly in hilly countries, the solid matter next the surface is found to be a kind of soft or rotten whin; but it may be noted, that this is only a mass of heterogeneous matter dipping upon the regular strata; and that beneath this, all the strata are generally found in a regular order as where this heterogeneous matter does not occur.

2. Of Poht-flone.] This is a free flone of the hardest kind, and next to the lime-flone with respect to hardness and solidity. It is of a very fine texture; and when broken appears as if composed of the finest sand. It is commonly found in a homogeneous mass, though variegated in colour; and, from its hardness, is not liable to injury from being exposed to the weather. Of this kind of flone there are four varieties, which may be distinguished by their colour: the most common is white poft, which in appearance is like Portland flone, but considerably harder; it is sometimes variegated with streaks or spots of brown, red, or black.

Grey poft is also very common; it appears like a mixture of fine black and white sand: it is often variegated with brown and black streaks; the last mentioned appear like small clouds composed of particles of coal.

Brown or yellow poft is often met with of different degrees of colour; most commonly of the colour of light ochre or yellow sand: it is as hard as the red, and sometimes variegated with white and black streaks.

Red poft is generally of a dull red colour: this is but rarely met with; it is often streaked with white or black.

All these lie in strata of different thicknesses; but commonly thicker than any other strata whatever: they are separated from each other, and from other kinds of strata, by partings of coal, sand, or soft matter of different colours which are very distinguishable.

3. Of Sand-flone. This is a free flone of a coarser texture than poft, and not so hard; is so lax as to be easily pervious to water; when broke, is apparently of a coarse sandy substance; is friable and moulders to sand.
COA

Coalery, land when exposed to the wind and rain; has frequently white shining splangles in it, and pebbles or other small stones inclosed in its mass. Of this, there are two kinds commonly met with, distinguished by their colours, grey and brown, which are of different shades, lighter or darker in proportion to the mixture of white in them. It is most generally found in strata of considerable thickness, without many separate partings; and sometimes, though rarely, it is subdivided into layers as thin as the common grey slate. It has generally has so and soft partings.

4. Of Metal-flone. This is a tolerable hard stratum, being in point of hardnes next to sand-flone; generally solid, compact, of considerable weight, and of an argillaceous substance, containing many nodules or balls of iron ore, and yellow or white pyrites; its partings, or the surfaces of its strata, are hard, polished, and smooth as glass. When broke, it has a dull dully apppearance (though of a fine texture), like hard dried clay mixed with particles of coal. Though hard in the mine or quarry, when exposed to the fresh air it falls into very small pieces. The most usual colour of this stone is black; but there are several other lighter colours, down to a light brown or grey. It is easily distinguished from free-flone by its texture and colour, as well as by its other characteristics. It lies in strata of various thicknesses, though seldom so thick as the two last mentioned kinds of flone.

5. Of Sliver.] This stratum is more frequently met with in coaleries than any other. There are many varieties of it, both in hardnes and colour; but they all agree in one general characteristic. The black colour is most common; it is called by the miners black sliver, black mottle, or bleas. It is softer than metal-flone, and in the mine is rather a tough than a hard substance, is not of a solid or compact matter, being easily separable, by the multitude of its partings, &c., into very small parts, and readily absorbing water. The substance of this stratum is a decomposed bole, commonly divided into thin lamina of unequal thicknesses, which break into long small pieces when struck with force; and, on examination, they appear to be small irregular rhombohides: each of these small pieces has a polished glassy surface; and, when broke, the grain, appears of a dry, leafy, or laminated texture, like exceeding fine clay; it is very friable; feels to the touch like an unctuous substance; and dissolves in air or water to a fine powdery black clay. There are almost constantly found inclosed in its strata lumps or nodules of iron ore; often real beds of the same.

There are other colours of this stratum besides black. The brown or dun sliver is very frequently met with; it agrees with the above description in every thing but colour. Grey sliver is also very common: it seems to be only a mixture of the black and dun; and by the different degrees of mixture of these colours others are produced. It lies in strata sometimes of considerable thickness, at other times not exceeding a few feet: they are commonly parted from each other by lamina of spar, coal, or soft matter.

6. Of Coal.] Referring the reader, for the scientific division of coals, to AMPHITES, LITHANTHRAX, and the preceding articles, we shall here consider them as distinguishable into three kinds, according to their degrees of inflammability.

1. The least inflammable kinds are those known by the name of Welsh coal, which is found in Wales; Kilkenny coal, which is found near Kilkenny in Ireland; and kind or dead coal, which is found in many parts of Scotland and England. This coal takes a considerable degree of heat to kindle it, but when once thoroughly ignited will burn a long time; it remains in the fire in separate pieces with flicking together or caking; it produces neither flame nor smoke, and makes no cinder, but burns to a white fowy flag; it makes a hot glowing fire like charcoal or cinders; and emits effluvia of a suffocating nature which renders it unfit for burning in dwelling-houses, its chief use being amongst malleys, dyers, &c., for drying their commodities.

2. Of open burning coal, soon kindles, making a hot pleasant fire, but is soon consumed: it produces both flame and smoke in abundance; and lies open in the fire, and does not cake together so as to form cinders, its surface burning to ashes before it is thoroughly calcined in the midst; from this it has its name of an open burning coal: it burns to white or brown ashes very light. Of this kind are cannel-coal, jet, parrot splint, and most of the coals in Scotland.

3. Of close burning coal, kindles very quickly, makes a very hot fire, melts and runs together like bitumen, the very smallest lump making the finest cinders, which being thoroughly burnt are porous and light as a pumice stone, and when broke are of a shining lead colour; it makes a more durable fire than any other coal, and finally burns to brown or reddish coloured heavy ashes. Of this kind are the Newcastle and several other of the English coals, and the finity coals of Scotland. The open burning and the close burning coal mixed together, make a more profitable fire for domestic uses than either of them separate.

In all those districts of country where coal is found, there are generally several strata of it; perhaps all the different kinds above mentioned will be found in some, and only one of the kinds in others: yet this one kind may be divided into many different seams or strata, by beds of sliver or other kinds of matter interposing, so as to give it the appearance of so many separate strata.

All these strata above described, with their several varieties, do not lie or bear upon each other in the same order in which they are described, nor in any certain or variable order. Though there be found the same kinds of strata, in one coalery or district as in another, yet they may be of very different thicknesses. In some places there are most of the hard kinds, in others most of the softer; and in any one district it rarely happens that all the various kinds are found; for some kinds, perhaps, occur only once or twice, whilst others occur ten or twenty times before we reach the principal stratum of coal.

In order to explain this, suppose the strata in the Plate pit at A (fig. 3.) lie in the order a, b, c, d, &c.; they may be so much altered in their thicknesses, by reason of some of them increasing and others diminishing, at the distance of B, that they may be found there of very different thicknesses; or if they are examined in a pit at D, by reason of its lower situation, and the strata

CXLII. COA
Coalery. strata there not being a continuation of those in the other places, they may be very different both in their order and thicknesses, and yet of the same kinds.

Though they be thus found very different in one coalery or district from what they are found to be in another, with respect to their thicknesses, and the order in which they lie upon each other, yet we never meet with a stratum of any kind of matter but what belongs to some of those above described.

To illustrate how the various strata lie in some places, and how often the same stratum may occur between the surface and the coal, we shall give the following example. The numbers in the left hand column refer to the classes of strata before described, to which each belongs. The second column contains the names of the strata; and the four numeral columns to the right hand, express the thickness of each stratum, in fathoms, yards, feet, and inches.

Total Fathoms: 25

In this instance the species of sandstone only occurs twice, poft five times, whilst the shiver occurs no lefs than nine times.

To apply the foregoing observations to practice.

Suppose it was required to examine whether there was coal in a piece of ground adjoining to, or in the neighbourhood of, other coalleries.

In the first place, it is proper to be informed, at some of the adjacent coalleries, of the number and kinds of strata; the order in which they lie upon each other; to what point of the horizon, and in what quantity they dip; if any dikes, hitches, or troubles, and the course they stretch. Having learnt these circumstances, search in the ground under examination where the strata are exposed to view, and compare these with the other. If they be of the same kinds, and nearly correspond in order and thickness, and be lying in a regular manner, and agree by computation with the dip and rife, it may safely be concluded the coal is there; and the depth of it may be judged from the depth of the coal in the other coallery, below any particular stratum which is visible in this.

If the solid strata are not expos'd to view, neither in the hills nor valleys of the ground under examination, then search in the adjoining grounds; and if the same kind of strata are found there as in the adjacent coallery, and there is reason, from the dip and other circumstances, to believe that they stretch through the ground to be examined: it may then be concluded that the coal is there, as well as the other strata.

Suppose a coallery is on the side of a hill at A, fig. 3. Plate and you would search for a coal at B, on the other side of the hill, but in a much lower situation; by observing the several strata, lying above the coal at A, and the point to which they dip, which is directly towards B (if clear of dikes), you may expect to find the same kind of strata on the other side of the hill, but much lower down. Accordingly, if some of the strata are visible in the face of the precipice C, they may be compared with some of those in the pit at A. Or, if they are not to be seen there, by searching in the opposite hill, they may perhaps be discovered at the place F; where, if they be found in the manner before mentioned, and there be reason to believe they extend regularly from the first place to this, it is more than probable the coal, as well as these strata, will be found in the intermediate ground.

If the ground to be examined lie more to the rife Rule 5d. of the coal, as at E, which being supposed to be on a flat, perhaps the solid strata there may be wholly covered by the gravel, clay, &c. of the outward surface lying upon them: In this case, by measuring the horizontal distance and the descent of ground from A to E, and computing the quantity of ascent or rife of the coal in that distance: by comparing these together, it may be judged at what depth the coal will be found there, allowing that it lie regular. Thus, suppose the coal at A 80 yards deep, the distance from A to E 500 yards, and that the coal rises 1 yard in 10 yards of horizontal distance.

Then, from the depth of the pit 80
Deduct the descent of ground from A to E, suppose - - - - 24

This remainder would be the depth, if the coal was level - - - - 56

But as the coal rises 1 yard in 10 feet, then deduct what it rises in 500 yards, which is 50

And the remainder is the depth of that coal at E - - - - 6 Yards.

Or suppose that the place at B is 500 yards the contrary way, or to the full dip of the coal at A; if a view of the solid strata cannot be obtained, then by proceeding in the same manner as before, the depth of the coal at that place may be compared. Thus,

To the depth of the coal at the pit A 80
Add the descent or inclination of the coal in 500 yards, which, as before, is 50

This sum would be the depth, if the ground was level - - - - 130

But as the ground descends towards B, deduct the quantity of that, which suppose - - - - 80

Remains the depth of the coal at B 50 Yards.
If the place to be examined be either to the full dip nor full rife, but in some proportion towards either, the same method may be pursued, computing how much the coal rises or dips in a certain distance in that direction.

If there is known to be a dike in the workings of the pit at A, which elevates or depresses the strata towards the place under examination, then the quantity of the elevation or depression must be accordingly added to or deducted from the computed depth of the coal at that place. Suppose there is an upcast dike of 10 fathoms or 20 yards towards B, then deduct 20 from 30, the depth before computed; there will remain 10 yards or 15 fathoms for the depth of the coal at B.

But it often happens that coal is to be searched for, in a part of the country, at such a considerable distance from all other coalerties, that by reason of the intervention of hills, valleys, unknown dike, &c. the connection or relation of the strata with those of any other coalert cannot be traced by the methods last mentioned; in which case a more extensive view must be taken of all circumstances than was necessary in the former; and a few general rules founded on the foregoing observations, and on conclusions drawn from them, will greatly assist in determining sometimes with a great degree of probability, and sometimes with absolute certainty, whether coal be in any particular district of country or not.

**Rule 5th.**

The first proper step to be taken in such a case, is to take a general view of that district of country intended to be searched, in order to judge, from the outward appearance or face of the country, which particular part of the whole is the most likely to contain those kind of strata favourable to the production of coal: and consequently such particular part being found, is the most advisable to be begun with in the examination.

Though the appearance of the outward surface gives no certain or infallible rule to judge of the kinds of strata lying beneath, yet it gives a probable one; for it is generally found, that a chain of mountains or hills rising to a great height, and very steep on the sides, are commonly composed of strata much harder and of different kinds from those before described wherein coal is found to lie, and therefore unfavourable to the production of coal; and the mountainous situations are also more subject to dikes and troubles than the lower grounds: so that if the solid strata composing them gave even favourable symptoms of coal, yet the last circumstance would render the quality bad, and the quantity precarious. And, on the whole, it may be observed, that mountainous situations are found more favourable to the production of metals than of coal. It is likewise generally found that those districts abounding with valleys, moderately rising hills, and interposed with plains, sometimes of considerable extent, do more commonly contain coal, and those kinds of strata favourable to its production, than either the mountainous or champaign countries; and a country so situate as this last described, especially if at some considerable distance from the mountains, ought to be the first part appoinuted for particular examination. Plains, or level grounds of great extent, generally situated by the sides of rivers, or between such moderate rising grounds as last described, are also very favourable to the production of coal, if the solid strata, and other circumstances in the higher grounds adjoining, be conformable; for it will scarcely be found, in such a situation, that the strata are favourable in the rising grounds, on both sides of the plain, and not in the space between them. Though plains be so favourable, in such circumstances, to the production of coal, yet it is often more difficult to be discovered in such a situation, than in that before described; because the clay, soil, and other lax matter, brought off the higher grounds by rains and other accidents, have generally covered the surfaces of such plains to a considerable depth, which prevents the exploration of the solid strata there, unless they be exposed to view by digging, quarrying, or some such operation.

That part of the district being fixed upon which abounds with moderate hills and valleys as properest to begin the examination at, the first step to be taken is to examine all places where the solid strata are exposed to view (which are called the edges of the strata), as in precipices, hollows, &c. tracing them as accurately and gradually as the circumstances will allow, from the uppermost stratum or highest part of the ground to the very undermost: and if they appear to be of the kinds before described, it will be proper to note in a memorandum book their different thicknesses, the order in which they lie upon each other, the point of the horizon to which they dip or incline, and the quantity of that inclination; and whether they lie in a regular state. This should be done in every part of the ground where they can be seen: observing at the same time, that if a stratum can be found in one place, which has a connection with some other in a second place, and if this other has a connection with another in a third place, &c.; then, from these separate connections, the joint correspondence of the whole may be traced, and the strata, which in some places are covered, may be known by their correspondence with those which are exposed to view.

If by this means the crops of all the strata cannot be seen (which is often the case), and if no coal be discovered by its crop appearing at the surface; yet if the strata that have been viewed consist of those kinds before described, and are found lying in a regular order, it is sufficiently probable that coal may be in that part of the district, although it be concealed from sight by the surface of earth or other matter. Therefore, at the same time that the crops of the strata are under examination, it will be proper to take notice of all such springs of water as seem to be of a mineral nature, particularly those known by the name of iron water, which bear a mud or sediment of the colour of rust of iron, having a strong astringent taste. Springs of this kind proceed originally from those strata which contain beds or balls of iron-ore; but by reason of the tenacity of the matter of those strata, the water only diffuses itself slowly from them, descending into some more porous or open stratum below, where, gathering in a body, it runs out to the surface in small streams or rills. The stratum of coal is the most general reservoir of this water; for the iron-flone being lodged in different kinds of flaver, and the coal commonly
Rule 7th.

If the stratum of coal is not exposed to view, or cannot be discovered by the first method of searching for the crop, although the appearance of the other strata be very favourable, and afford a strong probability of coal being there; and if the last-mentioned method of judging of the particular place where the crop of the coal may lie, by the springs of water issuing from it, would, from the deficiency of those springs or other circumstances, be thought equivocal, and not give a satisfactory indication of the coal; then a further search may be made in all places where the outward surface, or the stratum of clay or earth, is turned up by ploughing, ditching, or digging, particularly in the lower grounds, in hollows, and by the sides of streams. These places should be strictly examined, to see if any pieces of coal be intermixed with the substance of the superior clay strata; if any such be found, and if they be pretty numerous and in detached pieces, of a firm substance, the angles perfect or not much worn, and the texture of the coal distinguishable, it may be concluded, that the stratum of coal to which they originally did belong is at no great distance, but in a situation higher with respect to the horizon; and if there be also found along with the pieces of coal other mineral matter, such as pieces of fliver or freestone, this is a concurrent proof, that it has come from a small distance. Though the two fore-mentioned methods should only have produced a strong probability, yet if this last mentioned place, where the pieces of coal, &c. are found in the clay, be in a situation lower than the springs; when this circumstance is joined to the other two, it amounts to little less than a moral certainty of the stratum of coal being a very little above the level of the springs. But if, on the contrary, these pieces of coal are found more sparingly intermixed in the superior stratum, and if the angles are much fretted or worn off, and very little of other kinds of mineral matter connected with them; it may then be concluded, that they have come from a stratum of coal situated at a greater distance than in the former case, and by a strict search and an accurate comparison of other circumstances, that particular place may be discovered with as much certainty as the other.

After the place is thus discovered, where the stratum of coal is expected to lie concealed, the next proper step to be taken, is to begin digging a pit or hole there perpendicularly down to find the coal. If the coal has no solid strata above and beneath it, but be found only embodied in the clay or other lax matter, it will not be there of its full thickness, nor so hard and pure as in its perfect state when enclosed between two solid strata, the uppermost called the roof, and the undermost called the pavement, of the coal: in such situation therefore it becomes necessary, either to dig a new pit, or to work a mine forward until the stratum of coal be found between the solid roof and pavement, after which it need not be expected to increase much in its thickness: yet as it goes deeper or farther to the dip, it most likely will improve in its quality, for that part of the stratum of coal which lies near the surface, or only at a small depth, is often debased by a mixture of earth and muddy other impurities, washed down from the surface, through the backs and cutters, by the rains; whilst the other part of the stratum which lies at a greater depth is preferred pure, by the other solid strata above it intercepting all the mud washed from the surface.

The above methods of investigation admit of many different cases, according to the greater or less number of favourable circumstances attending each of the modes of inquiry; and the result accordingly admits every degree of probability, from the most distant, even up to absolute certainty. In some situations, the coal will be discovered by one method alone; in others, by a comparison of certain circumstances attending each method; whilst in some others, all the circumstances that can be collected only lead to a certain degree of probability.

In the last case, where the evidence is only probable, it will be more advisable to proceed in the search by boring a hole through the solid strata (in the manner hereafter described), than by digging or sinking a pit, it being both cheaper and more expeditious; and in every case, which does not amount to an absolute certainty, this operation is necessary, to ascertain the real existence of the coal in that place.

We shall now suppose that having examined a certain district, situated within a few miles of the sea or some navigable river, that all the circumstances which offer only amount to a probability of the coal being there, and that boring is necessary to ascertain it; we shall therefore describe the operation of boring to the coal; then the method of clearing it from water, commonly called winning it; and all the subsequent operations of working the coal and raising it to the surface, leading it to the river or harbour, and finally putting it on board the ships.

Suppose that the ground, A, B, C, D, fig. 4, has been examined, and from the appearance of the strata for the where coal.
The purposes for which boring is used are numerous, and some of them of the utmost importance in coaleries. In coaleries of great extent, although the coal be known to extend through the whole grounds, yet accidental turns, and other alterations in the dip, to which the coal is liable, render the boring of three or more holes necessary, to determine exactly to what point of the horizon it dips or inclines, before any capital operation for the winning of it can be undertaken; because a very small error in this may occasion the loss of a great part of the coal, or at least incur a double expense in recovering it.

Suppose A, B, C, D, fig. 5, to be part of an extensive field of coal, intended to be won or laid dry by a fire-engine; according to the course of the dip in adjoining coaleries, the point C is the place at which the engine should be erected, because the coal dips in direction of the line AC, consequently the level line would be in the direction CD; but this ought not to be trusted to. Admit two holes, 1, 2, be bored to the coal in the direction of the supposed dip, at 200 yards distance from each other, and a third hole 3 at 200 yards distance from each of them: suppose the coal is found, at the hole 1, to be 10 fathoms deep; at the hole 2, 10 fathoms deeper; but at the hole 3, only 8 fathoms deeper than at 1. Then to find the true level line and dip of the coal, say, As 10 fathoms the dip from 1 to 2, is to 200 yards the distance, so is 8 fathoms, the dip from 1 to 3, 160 yards, the distance from one on the line 1 2, to a the point upon a level with the hole 3. Again say, As 8 fathoms, the dip from 1 to 3, is to 200 yards the distance, so is 10 fathoms, the dip from 1 to 2, to 160 yards, the distance from 1, in direction of the line 1 2, to a, the point upon a level with the hole 2. Then let fall the perpendicular e, which will be the true direction of the dip of the coal, instead of the supposed line AC; and by drawing ED, and EF, parallel to the other lines, the angle D, and no other place, is the deepest part of the coal, and the place where the engine should be erected. If it had been erected at the angle, C, the level line would have gone in the direction 1 e, by which means about one-third part of the field of coal would have been below the level of the engine, and perhaps lost, without another engine was erected at D.

Boring not only shows the depth at which the coal lies, but its exact thickness; its hardness; its quality, whether close burning or open burning, and whether any soil mixture in it or not; also the thickness, hardness, and other circumstances of all the strata bored through; and from the quantity of water met with in the boring, some judgment may be formed of the size of an engine capable of drawing it, where an engine is necessary. When holes are to be bored for these purposes, they may be fixed (as near as can be guessed) in such a situation from each other, as to suit the places where pits are afterwards to be sunk; by which means most of the expenses may be saved, as these pits would otherwise require to be bored, when sinking, to discharge their water into the mine below. There are many other uses to which boring is applied, as will be explained hereafter.

For these reasons, boring is greatly practised in England, and is brought to great perfection; and as the operation is generally entrusted to a man of integrity, who makes it his profession, the accounts given by him of the thickness and other circumstances of the strata, are the most accurate imaginable, and are trusted to with the greatest confidence; for as very few gentlemen choose to take a lease of a new coalery which has not been sufficiently explored by boring, it is necessary the accounts should be faithful, being the only rule to guide the landlord in letting his coal, and the tenant in taking it. In Scotland it is not so generally practised; nor are there any men of character who are professed borers, that operation being commonly left to any common workman; whence it happens that it never has been in any esteem, the accounts given by them being so imperfect and equivocal as not to merit any confidence.

The tools or instruments used in boring are very simple. The boring rods are made of iron from 3 to 4 feet long, and about one inch and a half square, with a screw at each end, by which they are screwed together, and other rods added as the hole increases in depth. The chisel is about 18 inches long, and two and a half broad at the end, which being screwed on at the lower end of the rods, and a piece timber put through an eye at the upper end, they are prepared for work. The operation is performed by lifting them up a little, and letting them fall again, at the same time turning them a little round; by a continuance of which motions, a round hole is fretted or worn through the hardest strata. When the chisel is blunt, it is taken out, and a scooped instrument, called a wimble, put on in its stead; by which the dust or pulverized matter which was worn off the stratum in the last operation is brought up. By this substance, the borers know exactly the nature of the stratum they
they are boring in; and by any alteration in the working of the rods (which they are sensible of by handling them), they perceive the least variation of the strata. The principal part of the art depends upon keeping the whole clean, and observing every variation of the strata with care and attention.

The established price of boring in England is 5 s. per fathom for the first five fathoms; 10 s. per fathom for the next five fathoms; and 15 s. per fathom for the next five fathoms; and so continually increasing 5 s. per fathom at the end of every five fathoms; the bore finding all kinds of boring instruments, and taking his chance of the hardness of strata, except above one foot in thickness of whin occur, when the former price ceases, and he is paid per day.

It is exceedingly uncommon to meet with a stratum of coal which is naturally dry, or whose subterranean springs or feeders of water are so very small as to require no other means than the labour of men to draw off or conduct them away: for it most commonly happens, that the stratum of coal, and the other strata adjacent, abound so much in feeders of water, that, before access can be had to the coal, some other methods must be pursued to drain or conduct away these feeders; therefore, after the deepest part of the coal is discovered, the next consideration is of the best method of draining it, or, in the miner's language, of winning the coal.

If the coal lies in such an elevated situation, that a part of it can be drained by a level brought up from the lower grounds, then that will be the most natural method; but whether it be the most proper or not, depends upon certain circumstances. If the situation of the ground be such, that the level would be of a great length, or have to come through very hard strata, and the quantity of coal it would drain, or the profits expected to be produced by that coal, should be inadequate to the expense of carrying it up; in such case some other method of winning might be more proper. Or suppose, in another case, it be found, that a level can be had to a colliery, which will cost L. 2000, and require two years to bring it up to the coal, whereas it will drain 50 acres of coal when completed; yet if it be found that a fire-engine, or some other machine, can be erected on that colliery, for the same fum of money, in one year, which will drain 50 acres of the same coal, then this last would be a more proper method than the level; because four years profit would be received by this method before any could come in by the other; and after the 30 acres drained by the level is all wrought, a machine of some kind would nevertheless be necessary to drain the remaining 20 acres: so that erecting a machine at first would be on all accounts the most advisable.

Where a level can be drove, in a reasonable time, and at an adequate expense, to drain a sufficient tract of coal, it is then the most eligible method of winning; because the charge of upholding it is generally less than that of upholding fire-engines or other machines.

If a level is judged proper after consideration of every necessary circumstance, it may be begun at the place appointed in the manner of an open ditch, about three feet wide, and carried forward until it be about six or seven feet deep from the surface, taking care to secure the bottom and sides by timber-work or building; after which it may be continued in the manner of a mine about three feet wide, and three feet and a half high, through the solid strata, taking care all along to keep the bottom upon a level, and to secure the roof, sides, and bottom, by timber or building, in all places where the strata are not strong enough to support the incumbent weight, or where they are liable to decay by their exposure to the fresh air. If the mine has to go a very long way before it reach the coal, it may be necessary to sink a small pit, for the convenience of taking out the stones and rubbish produced in working the mine, as well as to supply fresh air to the workmen; and if the air should afterwards turn damp, then square wooden pipes made of deals closely jointed (commonly called air-boxes), may be fixed in the upper part of the mine, from the pit-bottom all the way to the end of the mine, which will cause a sufficient circulation of fresh air for the workmen; perhaps in a great length it will be found proper to sink another or more pits upon the mine, and by proceeding in this manner it may be carried forward until it arrive at the coal; and after driving a mine in the coal a few yards to one side, the first coal-pit may be sunk.

If a level is found impracticable, or for particular reasons unadvisable; then a fire-engine, or some other machine, will be necessary, which should be fixed upon the deepest part of the coal, or at least so far towards the dip as will drain a sufficient extent of coal, to continue for the time intended to work the colliery: and whether a fire-engine, or any other machine, is used, it will be of great advantage to have a partial level brought up to the engine-pit, if the situation of the ground will admit it at a small charge, in order to receive and convey away the water without drawing it so high as to the surface: for if the pit was 30 fathoms deep to the coal, and if there was a partial level, which received the water five fathoms only below the surface, the engine by this means would be enabled to draw 1-6th part more water than without it; and if there were any feeders of water in the pit above this level, they might be conveyed into it, where they would be discharged without being drawn by the engine.

The engine-pit may be from seven to nine feet wide; and whether it be circular, oval, or of any other form, is not very material, provided it be sufficiently strong, though a circular form is most generally approved. If any feeders of water are met with a few fathoms from the surface, it will be proper to make a circular or spiral cutting about one foot deep, and a little hollowed in the bottom, round the circumference of the pit, in order to receive and conduct the water down without flying over the pit and incommoding the workmen. If the strata are of so tender or friable a nature as not to bear this operation, or if the water leaks through them, then it will be necessary to insert in the forementioned cutting a circular piece of timber called a crib, hollowed in the same manner to collect the water; and a second may be inserted two or three yards below the first, with a sloping nitch down the wall or side of the pit, to convey the water from the former into it; proceeding by some of these methods until the pit is 15 or 20 fathoms; at which place it would be proper to fix a cistern.
cistern or reservoir, for the first or upper set of pumps to stand in; for if the pit be 30 fathoms as suppos'd, it would be too great a length for the pumps to be all in one set from bottom to top; therefore, if any extraordinary feeders are met with, between 15 and 20 fathoms deep, it would be best to fix the cistern where it may receive them, and prevent their descending to the bottom; observing that the upper set of pumps be so much larger than the lower one, as the additional feeders may require; or if there are no additional feeders, it ought then to be a little smaller.

After the upper cistern is fixed, the operation may be purified by the other set of pumps in much the same manner as has been described, until the pit is sunk to the coal; which being done, it would be proper to sink it fix or eight feet deeper, and to work some coal out from the dip side of the pit, to make room for a large quantity of water to collect, without incommoding the coal-pits when the engine is not working.

It would exceed the proper bounds of this article, to enumerate all the accidents to which engine-pits are liable in sinking; we shall therefore only recite a few which seem important.

If a quicksand happen to lie above the solid strata, next the surface, it may be got through by digging the pit of such a width as at the top (allowing for the natural slope or running of the sand) as to have the proper size of the pit on the uppermost solid stratum; where fixing a wooden frame or tube as the timber-work of the pit, and covering it round on the outside with wrought clay up to the top, the sand may again be thrown into the excavation round the tube, and levelled with the surface.

If the quicksand should happen to lie at a considerable depth between the clay and solid strata, then a strong tube of timber closely jointed and shod with iron, of such a diameter as the pit will admit, may be let down into it; and by fixing a great weight upon the top, and by working out the sand, it may be made to sink gradually, until it come to the rock or other solid stratum below; and when all the sand is got out, if it be lightly calcined and secured it will be sufficient.

It sometimes happens, that a stratum of soft matter, lying between two hard solid ones, produces so large a quantity of water as greatly to inconvenience the operations. In such a case, a frame-work of plank, strengthened with cribs and closely calked, will stop both the whole or the greatest part of it, provided the two strata which include it are of a close texture; or let an excavation of about two feet be made in the soft stratum, quite round the circumference of the pit; and let that be filled close up between the hard strata, with pieces of dry fir-timber about ten inches square inserted endwise, and afterwards as many wooden wedges driven in to them as they can be made to receive; if this be well finished, little or no water will find a passage through it.

It rarely happens that any suffocating damp or foul air is met with in an engine-pit; the falling of water, and the working of the pumps, generally carrying a sufficient circulation of fresh air. But that kind of combustible vapour, or inflammable air, which will catch fire at a candle is often met with. It proceeds from the cuttings, backings, and cutters, of the solid strata, exhaling from some in an insensible manner, whilst from others it blows with as great impetuosity as a pair of bellows. When this inflammable air is permitted to accumulate, it becomes dangerous by taking fire, and burning or destroying the workmen, and sometimes by its explosion will blow the timber out of the pit, and do considerable damage. If a considerable supply of fresh air is forced down the pit by air-boxes and a ventilator, or by dividing the pit into two by a close partition of deals from top to bottom, or by any other means, it will be driven out, or so weakened, that it will be of no dangerous consequence: or when the inflammable air is very strong, it may be safely carried off by making a close sheathing or lining of thin deals quite round the circumference of the pit, from the top of the solid strata to the bottom, and lengthening it as the pit is sunk, leaving a small vacancy behind the sheathing; when the combustible matter, which exhales from the strata, being confined behind these deals, may be vented by one or two small leaden pipes carried from the sheathing to the surface; so that very little of it can transpire into the area of the pit. If a candle be applied to the orifice of the pipe to the surface, the inflammable air will instantly take fire, and continue burning like an oil-lamp until it be extinguished by some external cause. Upon the whole, every method should be used to make the pit as strong in every part, and to keep it as dry as possible; and whenever any accident happens, it should be as expeditiously and thoroughly repaired as possible, before any other operation be proceeded in, left an additional one follow, which would more than double the difficulty of repairing it.

The first operations, after sinking the engine-pit, are
Of working the coal; the next consideration should be of the best method of working it. The most general practice in Scotland is to excavate and take away a part only of the stratum of coal in the first working of the pit, leaving the other part as pillars for supporting the roof; and after the coal is wrought in this manner to such a distance from the pit as intended, then these pillars, or so many of them as can be got, are taken out by a second working, and the roof and other solid strata above permitted to fall down and fill up the excavation. The quantity of coal wrought away, and the size of the pillars left in the first working, is proportioned to the hardness and strength of the coal and other strata adjacent, compared with the incumbent weight of the superior strata.

The same mode of working is pursued in most parts of England, differing only as the circumstances of the coalery
Coaler. **Coalery may require:** for the English coal, particularly in the northern counties, being of a fine tender texture, and of the clove-burning kind, and also the roof and pavement of the coal in general not so strong as in Scotland; they are obliged to leave a larger proportion of coal in the pillars for supporting the roof, during the first time of working; and, in the second working, as many of these pillars are wrought away as can be got with safety.

The Scots coal in general being very hard, and of the open-burning kind, it is necessary to work it in such a manner as to produce as many great coals as possible, which is best effected by taking away as high a proportion of the coal as circumstances will allow in the first working; on the contrary, the English coal being very tender cannot possibly be wrought large, nor is it of much importance how small they are, being of so rich a quality; so that a larger proportion may be left in pillars in the coal than could with propriety be done in the other; and, when all circumstances are considered, each method seems well adapted to the different purposes intended.

The ancient method of working was, to work away as much of the coal as could be got with safety at one working only: by which means the pillars were left so small as to be crushed by the weight of the superior strata, and entirely lost. As great quantities of coals were lost by this method, it is now generally exploded, and the former adopted in its place; by which a much larger quantity of coal is obtained from the same extent of ground, and at a much less expense in the end.

The exact proportion of coal proper to be wrought away, and to be left in pillars at the first working, may be judged of by a comparison of the circumstances before mentioned. If the roof and pavement are both strong, as well as the coal, and the pit about 30 fathoms deep, then two-thirds, or probably three-fourths, may be taken away at the first working, and one-third or one-fourth left in pillars. If both roof and pavement be soft or tender, then a larger proportion must be left in pillars, probably one-third or near one-half; and in all cases the hardness or strength of the coal must be considered. If tender, it will require a larger pillar than hard coal; because, by being exposed to the air after the first working, a part of it will moulder and fall off, by which it will lose much of its solidity and resistance.

The proportion to be wrought away and left in pillars being determined, the next proper step is to fix upon such dimensions of the pillars to be left, and of the excavations from which the coal is to be taken away, as may produce that proportion. In order to form a just idea of which, see a plan of part of a pit's workings (fig. 6.), supposing to be at the depth of 30 fathoms, and the coal having a moderate rife. A, represents the engine-pit; B, the coal-pit; A a B, the mine from the former to the latter; B C, the first working or excavation made from the coal-pit, common in coal of coal the pillars for supporting, nine feet wide; b b b b, &c. the workings called rooms, turned off at right angles from the others, of the width of 12 feet; c c c, &c. the workings called throughers or thirplings, 9 feet wide, wrought through at right angles from one room to another; d d d, &c. the pillars of coal left at the first working for supporting the roof, 18 feet long and 12 feet broad; D D, two large pillars of coal near the pit-bottom, 15 or 20 yards long, and 10 or 15 broad, to support the pit, and prevent its being damaged by the roof falling in; e e, the level mine wrought in the coal from the engine-pit bottom, 4 or five feet wide; f f, &c. large pillars of coal left next the level, to secure it from any damage by the roof falling in; g g, a dike which depresseth the coal, 1 fathom; h h, &c. large pillars and barriers of coal left unwrought, adjoining to the dike where the roof is tender, to prevent its falling down. The coal taken out by the first working in this pit is supposed to be one-third of the whole; and allowing the rooms 12 feet wide, and the thirlings 9 feet wide, then the pillars will require to be 12 feet wide and 18 feet long; for if one pillar be in a certain proportion to its adjoining room and thirling, the whole number of pillars will be in the same proportion to the whole number of rooms and thirlings in the pit. Suppose A B C D, (fig. 7.), to be a pillar of coal 18 feet long and 12 feet broad, its area will be 216 square feet; A C H E, the adjoining thirling, 12 feet by 9 feet, and its area 108 square feet; B A E F G, the adjoining room 27 feet long and 12 feet broad, and its area 324 square feet; which added to 108 gives 432 square feet, or two-thirds wrought, and 216 square feet left, or one-third of the whole area F G H D.

It is proper to observe, that in the prosecution of the workings, the rooms to the right of the winning headway should be opposite to the pillars on the left; and the first, third, and fifth pillars, or the second, fourth, and sixth, adjoining the said headway, should be of such a length as to overlay the adjoining thirlings; as, in the plan, the pillar 2 overlays the thirlings 1 and 3; and the pillar 4, overlays the thirlings 3 and 5; this will effectually support the roof of the main road B C, and will bring the other pillars into their regular order, by which means each pillar will be opposite to two thirlings. Also a larger proportion of coal than common should be left in all places which are intended to be kept open after the second working; such as the pit-bottoms, air-courts, roads, and water-courts, or where the roof is tender, as it generally is near dikes, hitches, and troubles; and if the roof should be difficult for a considerable space, it will perhaps be found proper to leave a few inches of coal adhering to the roof, which, together with a few props of timber fixed under it, may support it effectually for a long time. The level mine e e, and the winning headway B C, should be wrought forward a considerable length before the other rooms, in order to be drove through any dikes that might interfere; otherwise the progress of the workings might probably be stopped a considerable time, waiting until a course of new rooms were procured on the other side of the dike. Suppose the dike g g, fig. 6., to depress the coal fix feet or one fathom, and that it rises in the same manner on the under side of the dike as it does on the upper side, its proper cure would be to work or drive a level mine through the strata of stone from the engine-level at e, over the dike, until it intersects the coal at i; and from thence to drive a new level mine in the coal at i i, and a new winning headway i k. In order to gain a new set of places,
to supply fresh air to this new operation, a small mine might be driven from the room h, and a hole sunk down upon the level room i i; therefore, if the level mine was not drove so far forward as to have all these operations completed before the rooms and other workings were intercepted by the dike, the working of the pit might cease until these new places were ready.

If there be two or three strata or seams of coal in the same pit (as there often are) having only a stratum of a few feet thick lying between them, it is then material to observe, that every pillar in the second seam below one in the first, and every pillar in the third seam below one in the second; and in such a situation the upper stratum of coal ought to be first wrought, or else all the three together; for it would be unsafe to work the lower one first, lest the roof should break, and damage those lying above.

It sometimes becomes necessary to work the coal lying to the dip of the engine of the level; which coal is consequently drowned with water, and must therefore be drained by some means before it can be wrought. If the quantity of water proceeding from it be inconsiderable, it may then be drained by small pumps laid upon the pavement of the coal, and wrought by men or horses, to raise the water up to the level of the engine-pit bottom: or if the feeders of the water be more considerable, and the situation be suitable, the working rod of these pumps might be connected with those in the engine-pit; by which means the water would be raised up to the level: but if the quantity of water be very great; or if, from other circumstances, these methods may not be applicable; then the engine-pit may be sunk as deep below the coal as may be necessary, and a level stone mine driven from its bottom to the dip of the strata, until it interfets the stratum of coal, from whence anew level mine might be worked, which would effectually drain it. Suppose A B, fig. 8. to be a section of the engine-pit; B C, the coal drained by the engine; B D, the coal to the dip of the engine intended to be drained; then if the engine-pit be sunk deeper to E, a stone mine may be wrought in the direction E D, until it interfets the coal at D, by which the water will have a free passage to the engine, and the coal will be drained.

If there be another stratum of coal lying at such a depth below the first as the engine-pit is intended to be sunk to, the upper seam may in some situations be conveniently drained, by driving a mine in the lower seam of coal from E to F, and another in the upper one from B to D; and by boring a hole from D to F, the water will descend to F, and, filling the mine EF, rise up to the engine-pit bottom at E, which is upon a level with D.

Whenever it is judged necessary to work the pillars, regard must be had to the nature of the roof. If the roof be tender, a narrow room may be wrought through the pillar from one end to the other, leaving only a shelf of coal on each side for supporting the roof of the time of working. Suppose A B C D, fig. 7. to be a pillar of coal 12 feet long and 12 feet broad: if the roof is not strong, the room 1, 2, 3, 4, of eight feet wide, may be wrought up through that pillar, leaving a shelf of two feet thick on each side; and if it can be sufficiently done, a part of these shelves may also be wrought away, by working two places through them as at 5 and 6. By this means very little of the coal will be lost; for two-thirds of the whole being obtained by the first working, and above two-thirds of the pillar by the second working, the loss upon the whole would not exceed one-tenth: but it may be observed, that some pillars will not produce so great a proportion, and perhaps others cannot be wrought at all; so that, upon the whole, there may be about one-eighth, one-seventh, or one-sixth part of the coal lost. If the roof be hard and strong, then as much coal may be wrought off each side and each end of the pillar as can be done with safety, leaving only a small piece standing in the middle; and when the roof is very strong, some times several pillars may be taken entirely off, without any loss of coal: and in general this last method is attended with less loss, and produces larger coals, than the former. In all cases it is proper to begin working those pillars first which lie farthest from the pit bottom, and to proceed working them regularly away towards the pit; but if there be a great number of pillars to the dip of the pit, it is the safest method to work these after those to the rife of the pit are begun with safety.

There is no great difference in the weight of different kinds of coals, the lightest being about 74 pounds avoirdupois, and the heaviest about 79 pounds the cubic foot; but the most usual weight is 75 pounds the foot, which is 18 hundred weight and 9 pounds the cubic yard. The statute chaldron is 53 hundred weight; or when measured is as follows: 268.8 cubic inches to the Winchester gallon; 47 gallons to the peck, about 3 pounds weight; 8 coal pecks to the bushel, about 247 pounds; and 24 bolls to the chaldron, of 52 hundred weight. If one coal measuring exactly a cubic yard (nearly equal to 5 bolls) be broken into pieces of a moderate size, it will measure seven coal bolls and a half. If broken very small, it will measure 6 bolls; which shows, that the proportion of the weight to the measure depends upon the size of the coals; therefore accounting by weight is the most rational method.

A Table of the weight and quantity of coal contained in one acre Scots measure, allowing one-sixth part to be lost below ground, in seams of the following thicknesses.

We shall next mention some of the various methods of bringing the coals from the rooms and other workings to the pit-bottom. Where the stratum of coal is of a sufficient thickness, and has a moderate rise and dip, the coals are most advantageously brought out by horses, who draw out the coals in a tub or basket placed
Coalery. ed upon a pledge: a horse by this means will bring out
from four to eight hundred weight of coals at once,
according to the quantity of the acent or deficient. In
some coaleries they have access to the workings by a
mine made for them; floping down from the surface of
the earth to the coal; and where that convenience is
wanting, they are bound into a net, and lowered down
the pit. If the coal be not of such a height as to ad-
mit horses, and has a moderate rise like the lat, then
men are employed to bring out the coals: they usually
draw a basket of four or five hundred weight of coals,
fixed upon a small four-wheeled carriage. There are
some situations in which neither horses nor men can be
properly used; particularly, where the coal has a great
degree of deficient, or where many dikes occur; in such a
cave the coals are best brought out by women called
bearers, who carry them in a kind of bucket upon their
backs, usually a hundred, or a hundred weight and a
half at once.

When the coals are brought to the pit-bottom, the
buckets are then hooked on to a chain, and drawn up
the pit by a rope to the surface, which is best ef-
cected by a machine called a gin, wrought by horses. There
are other kinds of gins for drawing coals, some wrought
by water, others by the vibrating lever of a fire-engine;
better of these last is only convenient in some par-
ticular situations, those wrought by horses being in
most general use. After the coals are got to the sur-
fase, they are drawn a small distance from the pit, and
laid in separate heaps: the largest coals in one heap,
the smaller pieces called chews in another, and the
cull or pan-coal in a separate place.

Flames. Of flutches

There is an accident of a very dangerous nature to
dom, under which all coaleries are liable, and which has
been the ruin of severall: it is called a flutb, or a flut. When
the pillars of coal are left so small as to fall, or yield
under the weight of the superior strata; or when the
pavement of the coal is so soft as to permit the pillars
at to sink in it, which sometimes happens by the great
weight that lies upon them; in either case the solid
stratum above the coal breaks and falls in, crushes the
pillar to pieces, and cloathes up a great extent of the
workings, or probably the whole face of the coalery.
As such an accident seldom comes on suddenly, if it be perceived
in the beginning, it may sometimes be stoped by building
large pillars of stone amongst the coal pillars; but if
it has already made some progres, then the best
method is to work away as many of the coal pillars ad-
joining to the cruch as may be sufficient to let the roof
fall freely down; and if it makes a breach of the solid
strata from the coal up to the surface, it will very pro-
bably prevent the cruch from proceeding any farther in
that part of the coalery. If the cruch begins in the rife
part of the coalery, it is more difficult to stop it from
proceeding to the dip, than it is to stop it from going
to the rife when it begins in a contrary part.

Foul air.

Another circumstance proper to be taken notice of
is the foil or adulterated air so often troublesome in
coaleries. Of this there are two kinds: the black
damp or flyer, which is of a suffocating nature, and
the inflammable or combustible damp. Without stay-
ing to inquire, in this place, into the origin and effects
of these dams, it may be sufficient to observe, that,
in whatever part of any coalery a confant supply or
a circulation of freth air is wanting, there come of
these dams exist, accumulate in a body, and become
noxious or fatal; and whenever there is a good cir-
culation of freth air, they cannot accumulate, being mixed
and carryed away by the stream of air as it
as they generate and exhale from the strata. Upon
these principles are founded the several methods of
ventilating a coalery. Suppose the workings of the
pits A and B (fig. 6.) to be obnoxious to the inflammable Plate
damps; if the communication were open betwixt the CXL.

pit A, the air which went down the pit A would
proceed immediately along the mine a, and ascend out
of the pit B; for it naturally takes the nearest direc-
tion: so that the air in all the workings would be flag-
nant; and they would be utterly ineffectible from
the accumulation of the combustible damp. In order to
expel this, the air must be made to circulate through
all the different rooms by means of collateral air
courses made in this manner: The paillage or mine a
must be clofed up or flopped by a partition of deals, or
by a wall built with bricks or stones, to prevent the air
pafling that way. This building is called a flopping.
There must also be foppings made in the thrilings 11, 11, &c.
twixt the pillars f1, f2, &c. which will di-
rect the air up the mine e, until it arrive at the
innermost thrilling 2, which is to be left open for its pa-
fage. There must also be foppings made at the fide of the mine a, &c. see, and on both sides of the main head-
way BC at bb, &c. then returning to the innermost thril-
ing 2, proceed to the third row of pillars, and build
up the thrilings 2 2, &c. leaving open the thrilling 3
for a paillage for the air; and proceed on to the
fifth row of pillars, build up in the fame manner the
foppings 3 3, &c. leaving open 4 for an air-courfe:
and by proceeding in this manner to flop up the thril-
ings or paffages in ebery other row of pillars, the cur-
cent of freth air will circulate through and ventilate
the whole workings, in the direction pointed to by the small
arrows in the plan, clearing away all the damp and
noxious vapours that may generate. When it is arrived at
C, it is conducted across the main headway, and car-
rried through the other part of the pit's workings in
the fame manner, until it return through nn to the pit B,
where it ascend, and as the rooms advance farther,
other foppings are regularly made.

In one of the foppings, on the fide of the main
headway, ther must be doors to admit a paillage for
the bringing out of the coals from the rooms to the pit,
as at 5 5: these doors must be constantly flut, except
at the time of pafling through them.

There are other methods of difposing the foppings
so as to ventilate the pit; but none which will fo ef-
ectually difperfe the dams as that described above.
If the dams are not very abundant, then the foppings 1 1, &c.
in the level mine, and the others at bb, &c. in the main headway, without any others,
may perhaps be sufficient to keep the pit clear. If at
any time the circulation of the freth air is not brisk
enough, then a large lamp of fire may be placed at the
bottom of the pit B, which, by rareifying the air there,
will make a quicker circulation.

Most of the larger coaleries in Britain tend their coals of leading
to the ships for the coaling trade or exportation; and, as the
and ship quantity is generally very large, it would take a greater
number of carts than could conveniently be obtained at
time to carry them; besides the considerable expence of
COALLIER, a vessel employed to carry coals from one port to another; chiefly from the northern parts of England to the capital, and more southerly parts, as well as to foreign markets. This trade is known to be an excellent nursery for feamen; although they are often found, from the constitution of their climate, not to be so well calculated for southern navigation.

COAMINGS, in ship-building, are those planks, or that frame, forming a border round the hatches, which raise them up higher than the rest of the deck. Loop-holes for muskets to shoot out at, are often made in the coamings, in order to clear the deck of the enemy when the ship is boarded.

COANE, among the Greeks, a name given to a peculiar species of tutti or tutch, which was always found in a tubular form. It had its name from στοιχ., a word used to express a sort of cylindric tube, into which the melted brass was received from the furnace, and in which it was suffered to cool. In cooling, it always deposited a sort of encrustation on the sides of the vessel or tube, and this was the tunic called coane.

COAST, a sea-flore, or the country adjoining to the edge of the sea. Dr Campbell, in his political survey of Great Britain, considers an extensive sea-coast as of great advantage to any kingdom; and consequently that that island hath many conveniences resulting from the extent of its coasts, superior to other kingdoms which are much larger. The chief advantages arising from an extensive sea-coast are, that thus there is a convenient opportunity for exportation and importation to or from all parts of the kingdom. Thus, a number of cities are formed on the coasts; by this means the internal parts are improved, &c.

The extent of the sea-coasts of Aradus, he looks upon as the genuine source of wealth and splendour to the ancient inhabitants of that peninsula; the same was the instrument of the greatness of ancient Egypt, of Phcenicia, &c. In short, according to him, no country or city can for any length of time be flourishing unless it hath a considerable connexion with the sea.

COALESCE, the union or growing together of two bodies before separate. It is principally applied to some bones in the body, which are separate during infancy, but afterwards grow together; or to some morbid union of parts, which should naturally be distinct from each other. Thus there is a coalescence of the sides of the vulva, anus, and naries; of the eye-lids, fingers, toes, and many other parts.

COALLIER, the vessel used for conveying coals from two to three tons at a time, when in a cart not above half a run could be drawn.

The first thing to be done in making a waggon-way is to level the ground in such a manner as to take all sudden ascents and descents: to effect which, it is sometimes necessary to cut through hills, and to raise an embankment to carry the road through hollows. The road should be formed about 12 feet wide; and no part should have a greater descent than one yard perpendicular in 10 of a horizontal line, nor a greater ascent than one yard in 30. After the road is formed, pieces of timber, about six feet long and six inches diameter, called sleepers, are laid across it, being 18 or 24 inches distant from each other. Upon these sleepers other pieces of timber, called rails, of four or five inches square, are laid in a lateral direction, four feet distant from each other, for the waggon wheels to run upon; which being firmly pinned to the sleepers, the road may then be filled with gravel and finished.

The waggon wheels have four wheels, either made of solid wood or of cast iron. The body of the carriage is longer and wider at the top than at the bottom; and usually has a kind of trap-door at the bottom, which, being loofed, permits the coals to run out without any trouble. The size of a waggon to carry 50 hundred weight of coals is as follows:

Where the pits are situated at some considerable distance from the harbour, it becomes necessary to have a foare-house near the wharfing place, where the coals may be lodged, until the lighter or ships are ready to take them in. The waggon-way should be made into the foare-house, at such a height from the ground, as to permit the coals to run from the waggon wheels down a spout into the vessels; or else to fall down into the foare-house, as occasion may require.

This kind of foare-house is well adapted to dispatch and saving expense: for a waggon-load of coals may be delivered either into the foare-house or vessels instinctly with very little trouble: and if the coals were exposed to the effects of the sun and rain, they would be greatly injured in their quality; but being lodged under cover of the foare-house, they are preferred.

COALESCEENCE, the union or growing together of two bodies before separate. It is principally applied to some bones in the body, which are separate during infancy, but afterwards grow together; or to some morbid union of parts, which should naturally be distinct from each other. Thus there is a coalescence of the sides of the vulva, anus, and naries; of the eye-lids, fingers, toes, and many other parts.
COAT, or COAT OF ARMS, in heraldry, a habit worn by the ancient knights over their arms both in war and tournaments, and still borne by heralds at arms. It was a kind of fur-coat, reaching as low as the navel, open at the sides, with short sleeves, sometimes turned with ermine and hair, upon which were applied the armories of the knights embroidered in gold and silver, and enamelled with beaten tin coloured black, green, red, and blue; whence the rules never apply colour on colour, nor metal on metal. The coats of arms were frequently open, and diversified with bands and fillets of several colours, alternately placed, as we still see cloths scarlet, watered, &c. Hence they were called devises, as being divided and composed of several pieces sewed together; whence the words fail, pale, chevron, bend, fessels, fesse, &c., which have since become honourable pieces, or ordinaries of the shield. See Cross, Bend, Chevron, &c.

Coats of arms and banners were never allowed to be worn by any but knights and ancient nobles.

COAT, in anatomy. See INTESTINE and Eye.

COAT OF Mail, a kind of armour made in form of a shirt; consisting of iron rings woven together with metal. See Mail.

COATI, in zoology, a synonomy of a species of Verruca, and Ursus.

COATMUNDI, a variety of the above.

COATING, among Chemists. See Chemistry, 

COATING of Vials, Plates of Glass, &c. among electicians, is usually performed by covering the outside of the vial with tinfoil, brass or gold-leat, &c. and filling its inside with loose pieces of brass-leaf, by which means it becomes capable of being charged. See Electricity.

COATZONTECOXCHITL, or Flower with the niper’s head, in botany, a Mexican flower of incomparable beauty. It is composed of five petals or leaves, purple in the innermost part, white in the middle, the red, red, but elegantly stained with yellow and white spots. The plant which bears it has leaves resembling those of the iris, but longer and larger; its trunk is small and thin; this flower was one of the most esteemed amongst the Mexicans. The Lincean academicians of Rome, who commented on and published the History of Hernandez in 1651, and saw the paintings of this flower, with its colours, executed in Mexico, conceived such an idea of its beauty, that they adopted it as the emblem of their very learned academy, denominating it Fior di Lino. See Plate CXLIII.

COBALTI, one of the ferrimetal, according to Crofts, of a whilith-grey colour, nearly resembling fine hardened steel, and of the specific gravity of 6,600; but according to others, of a bluith grey, or reddish white colour, and of the specific gravity of 7,500. It is as difficult of fusion as copper, or even gold; and when well purified, scarcely yields to iron itself in this respect. When slowly cooled, it crystallizes, forming on its surface small bundles of needles, or needle-formed prisms, laid on one another, and united into bundles; greatly resembling, according to Mongez, a mass of shaken balsafires. In order to succeed in this crystallization, it is sufficient to melt the cobalt in a crucible till it furners a kind of ebullition: and, after having...
Cobalt, when calcined along with the calx of arsenic in a gentle heat, affumes a red colour. The fame is naturally produced by way of efflorescence, and is then called the bloom or flowers of cobalt. When cobalt and arsenic are melted in a strong fire, they burn with a blue flame. It does not mix either with mercury by any means hitherto known, nor will it form any union with bismuth without the addition of some mordant. It is easily soluble in spirit of nitre, and the solution either in this or any other acid is of a red colour; and it is observable that the colour of the acid solutions of this semimetal, instead of fading by dilution with water, becomes more vivid. It is precipitated of a pale red colour from its solutions by acid of sugar, which has the greatest attraction for it; though acid of ferreol likewise precipitates it.

Crenfated, in speaking of this semimetal, makes mention of native cobalt; but other mineralogists affirm, that it has never been found perfectly pure in the bowels of the earth. What passes for such, is said by Kirwan to be mineralized by arsenic. That called the green cobalt ore comes nearest to the purity of the native semimetal, but always holds some quantity of arsenic and iron. It is found in Sweden, Saxony, Norway, and England, particularly at Mendip hills in Somersetshire, and in Cornwall, where Dr Lewis says it has lately been dug up in large quantities. Here it is sometimes found in conjunction with bismuth, and sometimes without it, resembling very much in appearance the Saxon ores from Schneberg in Mihiia, and produces the finest blue colours by proper management. An arsenificated grey cobalt ore has also been found at Chatelaudren in France.

This kind of ore is solid, heavy, and compact, sometimes dull and sometimes of a bright appearance, crystallized frequently in a tabular and sometimes in a dendritical form; being generally hard enough to strike fire with steel, when an arsenical snell is perceived. It grows black in the fire, is soluble with effervescence in the nitros acids, from which it may be precipitated by the marine, and affords the Sympathetic Inc. mentioned under the article Chemistry, N° 822. This and the blue colour communicated by it to glasses are indeed the two characteristics by which the ores of cobalt are distinguished from other arsenical ores.

The most common ore of cobalt is that called the black or vitreous ore, and Kobalt Muth or Schlacken Kobalt by the Germans. It is found in a loose powdery form, sometimes resembling lamp-black, sometimes of a grey colour, in which state it is called cobalt oboe; but when in scoriform half vitrified masses, it obtains the name of vitreous or glassy ore. When this kind of ore contains any sulphur or arsenic, they are only mechanically mixed with it. A small portion of copper, however, is sometimes found in it. It is frequently embodied in stones or bands of a black colour; sometimes it is contained in argillaceous earths of a blue or green colour. Tale, chalk, and gypsum, impregnated with it, are called by the same name; and by fome, smelted cobalt.

Cobalt mineralized by the arsenical acid, is found either loose and pure, or mixed with chalk or gypsum, or indurated and crystallized in tetrahedral crystals. It is also found in a fatalectical form. It melts easily, and then becomes blue. It frequently invets other cobaltic ores; and is found sometimes in stone and sand. From the experiments of Bergman it appears, that the arsenical acid, and not the calx of arsenic, enters into this combination; for cobalt is never red but when united to an acid. Flowers of cobalt, mineralized by arsenic without any silver, and intermixed with galena, have also been discovered in France.

The flowers or efflorescence of cobalt are often found of a red colour, like other earths, spread very thin on the cobalt ores; and is, when of a pale colour erroneously called flowers of bismuth. A white cobalt earth or ochre is said to have been found, and examined by a celebrated mineralogist, who found it to resemble the cobalt flowers in every respect except the colour; and indeed it is possible that in these flowers the colour might by length of time, or some other accident, have lost their colour. The indurated flowers of cobalt are commonly crystallized in form of deep red semitransparent rays or radiations. It is found at Schneberg in Saxony.

Cobalt, mineralized by sulphurated iron, is of a colour nearly resembling tin or silver. It is sometimes found in large masses, sometimes in grains crystallized of a dull white colour, and frequently has the appearance of waf-pickle. It has no mixture of arsenic. By calcination it becomes black and not red, which distinguishes it from the pyrites; and it contains no telle sulphur, that none can be extracted from it. When dissolved in aqua regia the solution is yellow, but becomes green when boiling hot; which alternation, says Kirwan, is peculiar to marine cobalt. A coarse grained kind of this ore, found in Sweden, becomes fliny in the fire, and sticks to the iron rods employed in flirring it while calcining. The fluffy kind contains a large quantity of iron, and affords a very beautiful colour as well as the former.

Cobalt mineralized by sulphur, arsenic, and iron, has a great resemblance to the harder kinds of grey cobalt ore, formerly mentioned; but it is never hard enough to strike fire with steel, and sometimes may even be scraped with a knife. The most shining kinds of this and the former species are called cobalt glints.

The great consumption of cobalt is for the permanent blue colour which it communicates to glases and enamels, either upon metals, porcelains, or earthen wares of any kind. It is the same blue prepared in a very cheap way by the Dutch, chiefly from the coarse glases or blue glases of cobalt, and called azur de Holland by the French, and which is employed by hundredes.
Cobalt

Cobalt, in Europe. The loache is found in several small rivers in Britain, keeping at the bottom on the gravel; and is, on that account, in some places called the *groundling*:

It is frequent in the stream near Amebury in Wiltshire, where the sportmen, through frolic, swallow it down alive in a glass of white-wine.

Coble, a boat used in the turbot fishery, twenty feet six inches long, and five feet broad. It is about one ton burden, rowed with three pair of oars, and admirably constructed for encountering a mountainous sea.

Coblenz, an ancient, handsome, and strong town of Germany, in the electorate of Trier or Treves, seated at the confluence of the rivers Rhine and Moselle, in a fertile country, with mountains covered with vineyards. It is the usual residence of the elector of Trier, to whom Treves, a town of about six thousand inhabitants, was added by the sale of the bishopric of Metz, in 1480. Coblenz is a bridge of twelve arches, built for the convenience of the inhabitants of Coblenz and the adjacent places. A ferry machine is constantly going from the city to the other side of the Rhine, where there is a little town and very strong castle built on an eminence, named the rock of honour. This machine is erected on two boats, in the form of a large square gallery, encompassed with balustrades; and carries a tall flagstaff, on which are displayed the arms of the elector of Treves. It is put in motion by the ferry-man's pulling a rope, which is fixed to a standard on each side the river. The castle appears to be almost inaccessible to an enemy, and entirely commands the city of Coblenz. The archbishop's palace stands at the foot of this rock, and the arsenal at a little distance. E. Long. 7. 18. N. Lat. 50. 24.

COBÓB, the name of a dill among the Moors. It is made of several pieces of mutton wrapped up in the cawl, and afterwards roasted in it; the poorer people, instead of the meat, use the heart, liver, and other parts of the entrails, and make a good dill, though not equal to the former.

COBOOSE, in sea-language, is derived from the Dutch *kabouis*, and denotes a sort of box, resembling a ferry-box, used to cover the chimneys of some merchant-ships. It generally stands against the hawse side, on the fore-part of the quarter deck. It is called in the West Indies *cobre vega*.

COBURG, a town of Germany in the circle of Franconia, and capital of a territory of the same name, with a famous college, a fort, and a castle. This town with its principality, belongs to the house of Saxony, and the inhabitants are Protestants. It is seated on the river Ilch, E. Long. 11. 5. N. Lat. 50. 20.

COBWEB, in physiology, the fine net-work which spiders spin out of their own bowels, in order to catch their prey. See Aranea.

Coccceia, a genus of flies belonging to the order of abdominales. The eyes are in the upper part of the head; the branchiolegge membrane has from four to five rays; and the body is nearly of an equal thickness throughout. The species are five; three of which are natives of Europe. The loache is found in several small rivers in Britain, keeping at the bottom on the gravel; and is, on that account, in some places called the *groundling*:

It is frequent in the stream near Amebury in Wiltshire, where the sportmen, through frolic, swallow it down alive in a glass of white-wine.

Coble, a boat used in the turbot fishery, twenty feet six inches long, and five feet broad. It is about one ton burden, rowed with three pair of oars, and admirably constructed for encountering a mountainous sea.

Cobletz.
The insect in its perfect state receives the impressions of the air that gives its elytra a greater degree of confidence. It seldom flies, and cannot keep long on the wing. Of all the different larvae of the coccinella, the most curious is the white hedgehog, a name given it by M. de Reaumur on account of the singularity of its figure, and the tufts of hair which render it remarkable. It seeks its food on the leaves of trees. After a fortnight, it settles on one spot, and without parting with its fur, turns to a chrysalis; three weeks after which, it becomes a coccinella. The slough appears nowise impaired by its transformation. M. de Reaumur has observed it on a plum-tree. It is likewise found upon the rosette of the hedgehog, a species of Coccus, in gardens.

When the coccinella first arrive at the state of perfection, the colours of their elytra are very pale, nearly bordering upon white or cream colour; and the elytra are very soft and tender, but soon grow hard, and change to very lively brilliant colours. Their eggs are of an oval form, and of the colour of amber.

**Coccolobo**, in botany: A genus of the tri-nyphia order, belonging to the octandria class of plants; and in the natural method ranking under the 12th order, Holarceae. The calyx is quinquepartite and colour; there is no corolla; the berry is formed of the sex of that dog-grass, little nuts, of a white cottony substance, in which she deposits her eggs. The small threads of her tail are scarce perceptible.

3. The coccus cacti, a native of the warmer parts of America, is the famous cochineal animal, so highly valued in every part of the world for the incomparable beauty of its red colour, which it readily communicates to wool and silk, but with much more difficulty to linen and cotton. This insect, like all others, is of two sexes, but exceedingly dissimilar in their appearance. The female, which alone is valuable for its colour, is ill-shaped, tardy, and stupid: its eyes, mouth, and antennae, are fixed to deep, and are so concealed in the folds of the skin, that it is impossible to distinguish them without a microscope. The male is very scarce and is sufficient for 300 females or more: it is active, small, and slender, in comparison with the female; its neck is narrower than the head, and still narrower than the rest of the body. Its thorax is of an elliptic form, a little longer than the neck and head put together, and flattened below; its antennae are jointed, and out of each joint issue long slender hairs that are disposed in pairs in each side. It has fix feet, each formed of distinct parts. From the posterior extremity of its body two large hairs or bristles are extended, which are four or five times the length of the insect. It bears about the size of the head, the upper part of the thorax, which falls like the wings of common flies when it walks or rests. These wings, which are of an oblong form, are suddenly diminished in breadth where they are connected to the body. They are strengthened by two oblong muscles, one of which extends itself on the outside all round the wing; and the other, which is internal and parallel to the former, seems interrupted towards the summit of the wings. The male is of a bright red; the female of a deeper colour. They are bred on a plant known in Oaxaca in New Spain, and all those parts where it abounds, by the name of nopal, or nopalfece, the Indian fig-tree. See Cactus, xii. 2.

The cochineal was formerly imagined to be a fruit or seed of some particular plant; an error which probably arose from an ignorance of the manner in which it is propagated; but at present every one is convinced of its being an insect, agreeably to its name, signifying a wood-louse, which generally breeds in damp places, especially in gardens. These insects, by rolling themselves up, form a little ball something less than a pea; and in some places are known by the name of bagulias de San Antonio, i.e. St Anthony's little.
Cocccus. little cows: and such is the figure of the cochineal, except that it has not the faculty of rolling itself up; and its magniture, when at its full growth, does not exceed that of a tick common in dogs and other animals.

The juice of the plant on which these insects breed, is their sole nourishment, and becomes converted into their substance; when, instead of being thin and watery, and to all outward appearance of little or no use, it is rendered of a most beautiful crimson colour. The plant is in May or June in its most vigorous state, and at this most favourable season the eggs are deposited among the leaves. In the short space of two months, from an animalcula, the insect grows up to the size aforesaid: but its infant state is exposed to a variety of dangers; the violent blasts of the north wind sweep away the eggs from the foliage of the plant; and, what is equally fatal to their tender constitutions, flowers, foals, and frosts, often attack them, and destroy the leaves, leaving the careful cultivator this only resource, namely, that of the worms, &c. which are taken to be lost; though there is no danger of it, where they are at hand. The plantations of nopals: for that unless constant care is taken to fright the birds away from the plantation, and to clear the ground of those various kinds of vermin which multiply so fast in it, the owner will be greatly disappointed in his expectations.

When the insects are at their full growth, they are gathered and put into pots of earthen ware; but much attention is requisite to prevent them from getting out, as in that case great numbers of them would be lost; though there is no danger of it, where they are at liberty on the nopal leaves, those being their natural habitation, and where they enjoy a plenty of delicious food: for though they often remove from one leaf to another, they never quit the plant; nor is it uncommon to see the leaves entirely covered with them, especially when they are arrived at maturity. When they have been confined some time in these pots, they are killed and put in bags. The Indians have three different methods of killing these insects: one by hot water, another by fire, and a third by the rays of the sun: and to these are owing the several gradations of the colour, which in some is dark, and in others bright; but all require a certain degree of heat. Those therefore who use hot water are very careful to give it the requisite heat, and that the quantity of water be proportioned to the number of insects. The method of killing the creatures by fire is to put them on shovels into an oven moderately heated for that intention; the fine quality of the cochineal depending on its not being over dried at the time of killing the insects: and it must be owned, that among the several ways made use of to destroy this valuable creature, that is the ray of the sun seems to bid fair for performing it in the most perfect manner.

Besides the precaution requisite in killing the cochineal, in order to preserve its quality, it is equally necessary to know when it is in a proper state for being removed from the leaves of the nopal; but as experience only can teach the cultivator this necessary criterion, no fixed rule can be laid down. Accordingly, in those provinces where the cultivation of these insects is chiefly carried on, those gathered by Indians of one village differ from those gathered in another; and even those gathered by one person in the same village, are often different from those gathered by another; every individual adhering to his own method.

The cochineal-insect may, in some circumstances, be compared to the silk-worm, particularly in the manner of depositing its eggs. The insects defined for this purpose are taken at a proper time of their growth, and put into a box well closed, and lined with a coarse cloth that none of them be loft; and in this confinement they lay their eggs and die. The box is kept close till the time of placing the eggs on the nopal, when, if any motion is perceived, it is a sufficient indication that the animalcula has life, though the egg is so minute as hardly to be perceived; and this is the feed placed on the foliage of the nopal, and the quantity contained in the shell of a hen's egg is sufficient for covering a whole plant. It is remarkable that this insect does not, or at least in any visible manner, injure the plant, but extracts its nourishment from the most succulent juice, which it sucks by means of its proboscis through the fine teguments of the leaves.

The principal countries where the cochineal insects are bred, are Oaxaca, Tlaxcala, Chulula, Nueva Galicia, and Chiapa, in the kingdom of New Spain; and Hambato, Loja, and Tucuman in Peru: but it is only in Oaxaca that they are gathered in large quantities, and form a branch of commerce, the cultivation of these little creatures being there the chief employment of the Indians.

Though the cochineal belongs to the animal kingdom, of all others the most liable to corruption, yet it never spoils. Without any other care than merely that of keeping in a box, it has been preferred for ages. In drying, it loses about two thirds of its weight. When dried, it is forced into large entire grains, and small or broken ones: the first are called by the Spaniards grana, the latter granillas. In trade, four sorts are distinguished, Mallorquina, Campobanes, Tetrafochale, and Spailher, of which the first is accounted the best, and the last the worst. The three first are named from the places where they are produced; the latter from its being found wild without any culture.

In medicine, cochineal has been strongly recommended as a sudorific, cardiac and alexipharmac; but practitioners have never observed any considerable effects from it. Its principal consumption is among dyers. See the article Dyening.

4. The coccus illicis, or that forming the kermes grains, inhabits the queen coccifera of the southern parts of Europe. Mr Hellot of the French Academty of Sciences, in his Art of Dyening, chap. 12. says it is found in the woods of Vauvert, Vendeman, and Narbonne: but more abundantly in Spain, towards Alcant and Valencia. It not only abounds in Valencia, but also in Murcia, Jaen, Cordova, Seville, Eftremadura, la Mancha, Serranias de Cuenca, and other places.
In Xixona and Tierra de Relleu, there is a district called De la Granja, where the people of Valencia first began to gather it, whose example was followed all over Spain. It has some years produced 30,000 dollars (3000 l.) to the inhabitants of Xixona.

Both ancients and moderns seem to have had very confused notions concerning the origin and nature of the kermes; some considering it as a fruit, without a just knowledge of the tree which produced it; others taking it for an excrecence formed by the puncture of a particular fly, the fame as the common gall observed upon oaks. Tournefort was of this number. Count Marigli, and Dr Nifole a physician of Montpellier, made experiments and observations, with a view of further discoveries; but did not perfectly succeed.

Two other physicians at Aix in Provence, Dr Emeric and Dr Garidel, applied themselves about the same time, and with greater success; having finally discovered that the kermes is in reality nothing else but the body of an insect transformed into a grain, berry, or husk, according to the course of nature.

The progress of this transformation must be considered at three different seasons. In the first stage, at the beginning of March, an animalcule, no larger than a grain of millet, scarce able to crawl, is perceived on the branches of the tree, where it fixes itself, and soon becomes immovable; at this period it grows the moh, appears to swell and thrive with the fulness it draws in by degrees. This state of rest seems to have deceived the curious observer, it then resembling an excrecence of the bark; during this period of its growth, it appears to be covered with a down, extending over its whole frame like a net, and adhering to the bark; its figure is convex, not unlike a small floe; in such parts as are not quite hidden by this soft garment, many bright specks are perceived of a gold colour, as well as stripes running across the body from one space to another. At the second stage, in April, its growth is completed; its shape is then round, and about the size of a pea: it has then acquired more strength, and its down is changed into dust, and seems to be nothing but a husk or a capsule, full of a reddish juice not unlike discoloured blood. Its third state is towards the end of May, a little sooner or later, according to the warming of the air; it appears quite free from the husk, and replenishes with small eggs, less than the seed of a poppy. These are properly ranged under the belly of the insect, progressively placed in the neft of down that covers its body, which it withdraws in proportion to the number of eggs; after this work is performed, it soon dies, though it still adheres to its position, rendering a further service to its progeny, and shielding them from the inclemency of the weather, or the hostile attacks of an enemy. In a good season they multiply exceedingly, having from 1800 to 2000 eggs, which produce the same number of animalcules. When observed with the microscope in July or August, we find, that what appeared as dust, are to many eggs or open capsules, as white as snow, out of each of which issues a gold-coloured animalcule, of the shape of a cockroach, with two horns, six feet, and a forked tail. In Languedoc and Provence the poor are employed to gather the kermes, the women letting their nails grow for that purpose, in order to pick them off with greater facility.

The custom of lopping off the boughs is very injurious, as by this means they destroy the next year’s harvest. Some women will gather two or three pounds a-day; the great point being to know the places where they are most likely to be found in any quantity, and to gather them early with the morning-dew, as the leaves are more pliable and tender at that time than after they have been dried and parched by the rays of the sun: strong dew will occasionally make them fall from the trees sooner than usual: when the proper season passes, they fall off of themselves, and become food for birds, particularly doves. Sometimes there will be a second production, which is commonly of a less size with a fainter tinge. The first is generally found adhering to the bark, as well as on the branches and stalks; the second is principally on the leaves, as the worms choose that part where the nutritious juice prevails itself the longest, is most abundant, and can be most easily devoured in the short time that remains of their existence, the bark being then drier and harder than the leaves.

Those who buy the kermes to send to foreign parts, spread it on linen; taking care to sprinkle it with vinegar, to kill the worms that are within, which produces a red dust, which in Spain is separated from the husk. Then they let it dry, passing it through a sack, and make it up into bags. In the middle of each, its proportion of red dust, put in a little leather bag, also belongs to the buyer; and then it is ready for exportation, being always in demand on the African coast. The people of Hinojos, Bonares Villalba, and other parts of the kingdom of Seville, dry it on mat in the sun, stirring it about, and separating the red dust, which is the finest part, and being mixed with vinegar goes by the name of pastel. The same is done with the husks; but these have but half the value of the dust. The kermes of Spain is preferred on the coast of Barbary, on account of its goodness. The people of Tunis mix it with that of Tertua, for dyeing those scarlet caps so much used in the Levant. The Tunilians export every year above 150,000 dozen of these caps, which yields to the Day a revenue of 150,000 hard dollars (33,750 l.) per annum for duties; so that, exclusive of the uses and advantages of kermes in medicine, it appears to be a very valuable branch of commerce in Spain.

5. The coccus lacca, or gum-lac animal, is a native of the East Indies. The head and trunk form one uniform oval, compressed, red body, of the shape and magnitude of a very small louse, consisting of twelve transverse rings. The back is carinate; the belly flat; the antennae half the length of the body, filiform, truncated, and diverging, ending off two, often three, delicate, diverging hairs, longer than the antennae; the mouth and eyes could not be seen with the naked eye. The tail is a little white point, ending off two horizontal hairs as long as the body. It has three pair of limbs, half the length of the insect.

This is its description in that state in which it falls forth from the womb of the parent in the months of November and December. They traverse the branches of the trees upon which they were produced for some time, and then fix themselves upon the succulent extremities of the young branches. By the middle of January they are all fixed in their proper situa-
Coccus.

The limbs, antennæ, and face of the tail are no longer to be seen around their edges they are environed with a spidery subpellucid liquid, which seems to glue them to the branch; it is the gradual accumulation of this liquid, which forms a complete cell for each insect, and is what is called gum lacca. About the middle of March the cells are completely formed, and the insect is in appearance an oval, smooth, red-bag, without life, about the size of a small cantharid insect, emerged at the obtuse end, full of a beautiful red liquid. In October and November we find about 20 or 30 oval eggs, or rather young grubs, within the red fluid of the mother. When this fluid is all expended, the young insects pierce a hole through the back of their mother, and walk off one by one, leaving their exuviae behind, which is that white membranous substance found in the empty cells of the flick lacer.

The insects are the inhabitants of four trees: 1. Ficus religiosa, Linnæus; 2. Ficus indica, Linnæus; 3. Pláto, Hortus Malabaricus; and 4. Rhamnus jujuba, Linnæus.

The insects generally fix themselves to clove together, and in such numbers, that scarcely one in fix can have room to complete her cell; the others die, and are eaten up by various insects. The extreme branches appear as if they were covered with a red dust, and their sap is so much exhausted, that they wither and produce no fruit, the leaves drop off, or turn to a dirty black colour. These insects are transplanted by birds; if they perch upon these branches, they must carry off a number of the insects upon their feet to the next tree; they rest upon. It is worth observing, that these fig-trees when wounded drop a milky juice, which instantly coagulates into a viscid ropey substance, which, hardened in the open air, is similar to the cell of the coccus lacca. The natives boil this milk with oils into a bird-lime, which will catch peacocks or the largest birds.

A red medicinal gum is procured by incision from the plano tree, similar to the gum lacca, that it may readily be taken for the same substance. Hence it is probable, that these insects have little trouble in animizing the sap of these trees in the formation of their cells. The gum lacca is rarely seen upon the Rhamnus jujuba; and it is inferior to what is found upon the other trees. The gum lacca of this country is principally found upon uncultivated mountains, and in both sides the Ganges, where bountiful nature has produced it in such abundance, that was the consumption ten times greater the markets might be supplied by this minute insect. The only trouble in procuring the lac is in breaking down the branches, and carrying them to market. The present price in Dacca is about twelve shillings the hundred pounds weight, although it is brought from the distant country of Affan. The best lac is of a deep red colour. If it is pale, and pierced at top, the value diminishes, because the insect have left their cells, and consequently they can be of no use as a dye or colour, but probably they are better for varnishes.

This insect, and its cell, have gone under the various names of gum lacca, lac; loc. tree. In Bengal, la; and by the English it is distinguished into four kinds, differently denominated: for which, and their several ues, see the article LACCA.

In the figure, a represents the insect in its birth; b ditto, big with young; both the natural size. c The embryo before birth enclosed in its membrane; d The coccus, with two hairs from each antenna; e Ditto, with three hairs from each antenna; these three figures are magnified.

6. Coccus Polonicus, an insect which may properly enough be called the cochineal of the northern part of the world. As the cochineal loves only the hot climates, this creature affects only the cold ones. It is collected for the use of dyers: but the crops of it are much smaller, more difficultly made, and the drug itself greatly inferior to the true cochineal. It is commonly known by the name of coccus I'olonicus, or the scarlet grain of Poland. That country is indeed the place where it is gathered in the greatest abundance; but it is not the only one where it is found. It is to be met with in many of the northern countries; and possibly may be found in some of the more temperate ones, where it is not yet known; as it is very much hid by nature from the eyes of common observers. It is found affixed to the root of a plant, and usually to plants of that species from whence called polygynus cochineal: though authors have informed us of the same berry, as it is often called, being found at the roots of the mouse-ear, rupture-wort, pimpernel, and pellitory of the wall; and that it is in no other than sandy places that it is found at the roots of those plants.

Breynius, in 1731, printed at Dantzick a very curious account of this production, which proves it incontestably to be an animal. Towards the end of June the coccus is in a fit state for being gathered. Every one of the creatures is then nearly of a spherical form, and of a nice violet colour. Some of them, however, are not larger than poppy seeds, and others of the size of a pepper corn; and each of them is lodged, either in part or entirely, in a sort of cup like that of an acorn. More than half the surface of the body of the animal is covered by this cup. The outside of the covering is rough, and of a blackish brown; but the inside is smooth, polished, and shining. On some plants they find only one or two of these, and on others more than forty; and these are sometimes placed near the origin of the stalks of the plants.

Breynius began his observations on the animals in this state; several of them being put into vessels of glass; and by the 24th of July, there was produced from every one of them a hexapod, or six-legged worm, with two antennae on its head. Several of these were kept a night, and showed no inclination to eat any thing. They run about, however, very swiftly for some time; but then began to be more quiet, drew up their bodies shorter, and ceased to run about any longer. They were now of a purple colour; but in this state, though they did not walk about, they were subject to various contortions. At length, when they were become wholly motionless, their bodies became covered with a fine down; this was white, and formed them a perfect covering, which was sometimes of a spherical, and sometimes of an irregular figure; it was always, however, very elegant; and the downy matter plainly enough transpired out of the animal's body. The creatures
creatures remained in this state of rest, and covered with this down, for five or six days; but at the end of that time, every one of them laid more than 150 eggs. These eggs were deposited upon the paper on which the animals were placed, and were enveloped in some measure by a downy matter. When the creatures had laid all their eggs, they died; and after the 24th of August there came from every egg a small infect, which to the eye scarce seemed any other than a red point; it might, however, be observed very plainly to move about. These young animals lived about a month, wholly without sustenance. Mr Brey­nius was induced at first to believe, that these animals came to be in a state to produce perfect eggs, without any congress with the male; but farther observations convinced him of the error of this opinion. He saw afterwards a sort of very small flies with two white wings bordered with red, produced from several of the coccis. These flies are plainly of the same kind with the male gall-insects.

It has before been observed, that these coccis differ in size. The flies are produced by the small ones not bigger than a poppy seed; the others produce the worms before described: and one observation of Mr Brey­nius's affords a plain proof that these flies are the male infects of the species; since all those of the females, which had been a day or two accompanied by these flies, quickly covered themselves with down and began to lay their eggs; whereas those which had not this commerce with the flies remained in the same state, or else got only a very thin and slight covering of down, and never laid any eggs. The manner of this creature's life, however, from its being hatched, to its being found in the shape of a berry at the roots of the plants, is yet unknown: and how they assume the shape of a ball lodged in a cup, must require a nice observation to discover.

The proper time for gathering this insect, as we have already observed, is about the end of June, when it is quite full of a purple juice. Those who gather it have a hollow spade with a short handle; then, taking hold of the plant with one hand, they raise it out of the ground with the tool held in the other; after which they very quickly and dexterously detach the insect, and replace the plant in the ground, where it again takes root. The coccus is then separated from the earth by means of a sieve; and in order to prevent them from turning into worms, they sprinkle them with very cold water or vinegar. Lastly, they are killed by exposure to the sun, or keeping them for some time in a warm place; but this must be done with caution, as too hafty drying would spoil the colour. Sometimes they separate the insects from the vegetation with their fingers, and form them into balls: but by this operation the price is greatly increased.

We are informed by Bernard de Bemith, from whom this account is taken, that the harvest of coccus was farmed out to the Jews by some Polish lords, who had possessions in the Ukraine, that it was used by them, as well as the Turks and Armenians, for dyeing not only wood and silk, but the tails and manes of their horses; that by its means the Turkish women dyed the tips of their fingers of a beautiful carnation; and that it was formerly used by the Dutch along with an equal quantity of cochineal, the coccus being pur-

chased at a very dear rate; that beautiful paints may be prepared from this insect and pounded chalk, &c. All this, however, M. Macquer supposes to have been exaggerated, as he never could produce with it any other than lilach, flesh-colour, or crimson; and he found it, moreover, vastly more expensive than cochineal, as not yielding one-fifth part of the colour. Hence this drug is almost entirely fallen into disuse, being scarce known in any of the European cities remarkable for having good dyes.

COCCYGÆUS MUSCULUS. See Anatomy, Table of the muscles.

COCCYX, or COCCYGS OF. See Anatomy, no. 35.

COCHIN, a Dutch settlement on the coast of Malabar in N. Lat. 9°. 58. E. Long. 75°. 38.—The town is not unpleasant, though it lies far short of their settlement at Columbo in the island of Ceylon. The fortification is irregular, but strong enough to resist any of the Indian powers, and has 40 or 50 cannon facing the sea. The people in this town and the country adjacent are subject to a strange disorder of the legs called Cochins or elephant legs, in which the swollen limb is sometimes of such an enormous bulk as to have greatly the appearance both in shape and size of the leg of an elephant. According to Mr Ives, this disorder seems to be merely an oedematous swelling, occasioned by an impoverished state of the blood and juices. The persons afflicted with this distemper very seldom apply to European surgeons, and thus are rarely, if ever, cured. Indeed, our author observes, that their application would probably be of little avail, as the only thing that could be prescribed would be an alteration from the poorest to the most cordial and nutritious diet; and the Indians are so incalculably wedded to their own customs, that they would sooner die than break through them. Of this he says there were several instances in their long passage to Bengal, during which some of the Sepoys perished for want of food, rather than save themselves by partaking of the ship's provender after their own had been expended. Most of those afflicted with this disorder we speak of, are unable to call any assistance, being the very poorest of the people, who live entirely upon a kind of fish called Sardines, without being able to purchase even the smallest quantity of rice to eat along with it; their drink is also mere water, unless they sometimes procure a draught of the simple unfermented juice called toddy. Cochins is the principal place from whence the Dutch import their pepper into Europe.

COCHIN-CHINA, a kingdom of Asia, bounded on the north by Tonquin; on the east, by the sea of China; on the south, by the Indian ocean; and on the west, by Cambodia, and a ridge of mountains inhabited by a savage people called Kamois, who live independent of any government. Little of the history of this kingdom is known. M. le Poulle, a French traveller informs us, that about half a century before the French first arrived in these distant regions, a prince of Tonquin, as he fled from his sovereign, by whom he was pursued as a rebel, had with his soldiers and adherents crossed the river, which serves as a barrier between Tonquin and Cochinchina. The fugitives, who were warlike and civilized men, soon expelled the feattered inhabitants, who wandered about without any sociey
C O C

Cylicy or form of government, and founded a new kingdom, which soon grew rich and populous. During the reigns of the first six kings, no nation could be happier than the Cochin-Chinese. Their monarchs governed them as a father does his family, establishing no laws but those of nature, to which they themselves were the first to pay obedience. They honoured and encouraged agriculture, as the most useful employment of mankind; and required from their subjects only a small annual free gift to defray the expense of their defensive war against the Tonquinese, who were their enemies. This imposition was regulated, by way of poll-tax, with the greatest equity. Every man, able to till the ground, paid into the prince a small sum proportioned to the strength of his constitution, and the vigour of his arm; and nothing more.

Cochin-China continued happy under these princes for more than a century; but the discovery of gold mines put a stop to the above mild regulations. Luxury immediately took place. The prince began to despise the simple habitation of his subjects, and caused a fair palace to be built a league in circumference, surrounded with a wall of brick in the model of that of Pekin, and defended by 1600 pieces of cannon. Not content with this, he would needs have a winter palace, an autumn palace, and a summer palace. The old taxes were by no means sufficient to defray these expenses; new ones were devised; and oppression and tyranny every where took place. His courtiers, to flatter their prince, gave him the title of the king of heaven, which he continues to assume. When speaking of his subjects, he stylesthem his children, but by no means behaves as if he was their father: for our author informs us, that he has seen whole villages newly abandoned by their inhabitants, who were harassed with toil and insupportable expeditions; the necessary consequence of which was, that their lands returned to their former uncultivated state.

M. le Poivre represents the Cochin-Chinese as gentle, hospitable, frugal, and industrious. There is not a beggar in the country; and robbery and murder are absolutely unknown. A stranger may wander over the kingdom from one end to the other (the capital excepted) without meeting with the slightest interference. He will be everywhere received with the most eager curiosity, but at the same time with the greatest benevolence. A Cochin-Chinese traveller, who has not money sufficient to defray his expenses at an inn, enters the first house of the town or village he arrives at, and waiting the hour of dinner, takes part with the family; and goes away when he thinks proper, without speaking a word, or any person's putting to him a single question.

The country of Cochin-China is much of the same temperature with that of Tonquin, though rather milder, as lying nearer the sea. Like Tonquin, it is annually overflowed, and consequently fruitful in rice, which requires no other manure than the mud left by the inundations. They have sugar-canes, and the same kinds of fruits common to other parts of India. The country produces no grapes, and therefore they drink liquor brewed from rice. They have vast woods of mulberry-trees, which run up as tall as our hemp. Their silk is stronger than that of China, but not so fine. They have the best timber in the world, particularly a sort which abounds in the mountains, and is called the in corruptible tree; because it never rots under earth or water, and it is so cold that it serves for anchors. There are two kinds, black and red. The trees are very tall, straight, and so big that two men can scarce fathom them. They have also on the mountains of the Kemois a tree of the most fragrant scent, which is supposed to be the same with lignum aloes. This, being reckoned the best product of the country is engrossed by the king, and is sold from five to ten ducats per pound. It is highly valued both in China and Japan, where the logs of it are sold for 200 ducats a pound, to make pillows for the king and nobility; and among those Indians which continue to burn their dead, great quantities of it are used in the funeral piles. The young trees called aquila, or eagle wood, are every one's property, which makes the old ones called calamba so scarce and dear. They have oak and large pines, for the building of ships; so that this country is of the same use to China that Norway is to Britain. In general, they have the same kind of trees and plants that are to be met with in Tonquin, they have mines of gold, as well as diamonds; but the last they do not value so highly as pearl. They also esteem their coral and amber very much. In all the provinces there are great granaries filled with rice, in some of which that grain is kept upwards of 30 years. One of the greatest rarities in these parts, especially in grand entertainments, is a ragout made of the estable birds' nests, which some are found only in Cochin-China, and two in four islands that lie south of its coast. See Birds-Nests.

The merchants of Cambodia, Tonquin, China, Malacca, Manila, Japan, and Malaca, trade to Cochin-China with plate, which they exchange for the commodities of the country. The Portuguese are the most favoured here of any Europeans. The Cochin-Chinese themselves, nor being inclined to travel, seldom fall out of fight of their own shore, but purchase many trifles from foreigners at great rates, particularly combs, needles, bracelets, glass pendants, &c. They are very fond of our hats, caps, girdles, shirts, and other clothes; and, above all, set a great value on coral. The country is said to be the largest in the world, as well as the most populous. The people of this country have a great affinity with those of Tonquin, with whom they have a common origin, and from whom they differ very little in their manner of living, as well as in their manners and customs, all of which they have in a great measure borrowed from the Chinese. The principal exports of the country are silk, sugar, ebony, and calamba wood; gold in dust or in bars, which is sold for only ten times its weight in silver; and copper and porcelain brought from China and Japan. From this country also are exported the birds' nests esteemed such a delicacy at the table. They are found in four islands situated near the coasts of Cochin-China, to the eastward of which are five other smaller ones, where are found prodigious numbers of turtles, the flesh of which is so delicate that the Tonquinese and people of Cochin-China frequently fight desperate battles,
in order to take them from one another.—The commodities which fell most readily in this country are, salt petre, sulphur, lead, fine cloths, and barred or flowered china. Pearls, amber, and coral, were formerly in great request, but at present only the two last are saleable; and even these will not answer unless the beads of coral be round, well polished, and of a beautiful red colour; the amber must also be extremely clear, the beads of an equal size, and not larger than an hazel nut.

The only money current in Cochin-China is that of Japan, which is paid and received by weight. The money of the country is of copper, and as large as our halfpenny. There is an odd number of holes in the middle by which the pieces may be strung like beads. Three hundred of these are put on one side, and as many on the other, which in Cochin China pass for a thousand; because in 600 are found ten times 60, which make a century among almost all the people of the east. There is, however, scarce any country in which merchants are more apt to be deceived with regard to the value of money than Cochin-China, owing to the pieces being unequal in figure and quality, and the difficulty of determining their value, which is regulated only by a few characters stamped upon them. The dealers must therefore be at pains to have honest and skilful people to ascertain the value of the pieces they receive; otherwise they run a great risk of being deceived in their value, as the Cochin-Chinese make a great merit of being able to cheat an European.

European merchants complain, according to M. Grolier, unjustly of the demands made in Cochin-China for entrance, clearance, and anchorage. The duties indeed are very trifling, amounting only, even those of the customs-house, to 4 per cent; but nothing can be removed from a ship which arrives there until she has first been inspected, when the customs officers unload her, weigh and count the smallest pieces, and generally take what they look upon to be most valuable, in order to send it to the king. The monarch takes what he thinks proper and returns the value of the goods. The rulers are afraid to keep part of the goods also, without paying any thing for them. Thus the ordinary goods, which, had they been accompanied with the more valuable part of the cargo, would have found a ready market, can now scarcely be disposed of; though our author is of opinion, that the matter is not altogether without remedy. When the Dutch sent to this country, vessels loaded with cloths, lead, and salt petre, their cargoes were suffered to remain entire, because they had taken the precaution to pay every year a certain sum for each vessel that entered. Other nations, by endeavouring to avoid the payment of this duty, entirely destroy the commerce, on which people of Cochin-China, however, for some years past have been much more moderate in their demands; and whatever their exactions may be, they are far less exorbitant than those of the Tonquinese.

M. Grolier observes, that a false report has gained ground in Europe, that when a trading vessel happens to run aground in Cochin-China, or to be driven into any of its harbours by fires of weather, the king seizes the cargo if the ruler be broken. He assuages us, however, that, so far from this being the case, a vessel in distress is much safer on the coasts of Cochin-China than almost anywhere else. Barks are immediately sent to the relief of the crew, and people employed to drag the sea with nets in order to recover the goods that are lost; and in short neither labour nor expences are spared to put the ship in the best condition possible. Only two things can hurt the trade of foreigners at Cochin-China, one of which may be easily avoided. This regards the clearing out of vessels. Thus, while the matter is waiting on the evening before his departure, or on the day fixed for sailing, in order to receive his dispatches, it often happens that he loses his voyage, which may prove the ruin of a trader. For this reason, care must be taken to solicit a clearance a month before, by which means one is always certain of obtaining it, and departing on the day appointed. The other difficulty is occasioned by the necessity of selling goods on credit, which are seldom paid at the stipulated time. This, however, is contrary to the inclination of the prince; for every merchant who can convey to him an account of these unjust delays, is sure to be paid, and sometimes even with interest.

COCHINEAL, or COCHINEEL, a drug used by the dyers, &c. for giving red colours, especially crimsons and scarlets, and for making carmine; and likewise in medicine as a cardiac, cordial, sudorific, aperient opium, and febrifuge.

The cochineal, in the state in which it is brought to us, is in small bodies of an irregular figure, usually convex, and ridged and furred on one side, and concave on the other. The colour of the beet is a purplish grey, powdered over with a fort of white dust. All that the world knew of it for a long time was, that it was gathered from certain plants in Mexico; and therefore it was naturally supposed to be a feed, till in the year 1692 Father Plumier gave Pomet an account of its being an animal. And this, though then disregarded, has been confirmed by subsequent observations. Indeed, to determine the point, we have now the means in our own hands, even in this part of the world.—We need only mollify and soak in water or in vinegar, a number of cochineals till they are swelled and diffused, to know that every one is the more or less perfect body of an insect; the most imperfect and mutilated specimens always show the rings of the body; and from observing others, it will be easy to find the number and disposition of the legs; parts, or even whole ones, being left on several, and often complete pairs. In this way the legs, antennae, and proboscis, may be discovered. See COCCUS above.

M. Macquer observes, that the cochineal of Sylvestre is gathered in the woods of Old and New Mexico. The insect lives, grows, and multiplies on the uncultivated opiums which grow there in great abundance. It is there exposed to the inclemencies of the weather, and dies naturally. The colour is more durable than that of the common cochineal, but less bright: but there is no advantage in using it; for, though cheaper, a greater quantity is requisite.

COCHLEA, the shell-snail, in zoology. See HELIX.

COCHLEA, in Anatomy. See ANATOMY, p. 765, col. 18.
SOURY-GRASS: A genus of the filiculae order, belonging to the tetradyomia class of plants; and in the natural method ranking under the 39th order, Siliculoidae. The filicula is emarginated, serrated, and thorny; with the valves gibbons and obtuse. There are six species; the most remarkable of which are, 1. The angelica, or garden soury-grass, grows naturally on the sea-shore, in the north of England and in Holland; but is cultivated for use in the gardens near London. It has a thorny root, from which arise many round succulent leaves, which are hollowed like a spoon; the stalks rise from six inches to a foot high; these are brittle, and garnished with leaves which are oblong and nutated. The flowers are produced in clusters at the end of the branches, consisting of four small white petals which are placed in the form of a cross; and are succeeded by short, roundish, swelling, seed-vessels, having two cells divided by a thin partition. In each of these are lodged four or five roundish seeds. 2. The armazas, or horse-radish, is so well known as to need no description.

The first is propagated by seeds, which are to be sown in July, in a moist spot of ground; and when the plants are come up, they should be thinned, so as to be left at about six inches distance each way. The plants that are taken out may be transplanted into other borders. In the spring these plants will be fit for use; those that are left will run up to seed in May, and perfect their seeds in June. If the seeds are sown in the spring, they seldom grow well. The horse-radish is propagated by cuttings or buds from the sides of the old roots. The best reason for this work is in October or February; the former for dry lands, the latter for moat.

**Ufes.** Soury-grass is a pungent stimulating medicine; capable of dissolving vitrified juices, opening obstructions of the viscera and the more distant glands, and promoting the more fluid secretions. It is particularly celebrated in fevers, and is the principal herb employed in these disorders in the northern countries. Horse-radish root has a quick pungent smell, and a penetrating acid taste; it nevertheless contains in certain vessels a sweet juice, which sometimes exudes on the surface. By drying it loses all its acrimony, becoming first sweetish, and then almost insipid: if kept in a cool place in sand, it retains its qualities for a considerable time. The medical effects of it are to stimulate the foeds, attenuate the juices, and promote the fluid secretions; it seems to extend its action through the whole habit, and to affect the minute parts; it has frequently done service in some kinds of fevers, and other chronic disorders proceeding from a viscidity of the juices or obstructions of the excretory ducts. Sydenham recommends it likewise in dropsies, particularly those which follow intermittent fevers. Both water and rectified spirit extract the virtues of this root by infusion, and elevate them in distillations; along with the aqueous fluid an effential oil rises, puffing the whole taste and pungency of the horse-radish.

**COCHLITES,** in natural history, an appellation given to the petrified shells of the cochleae or finals.

**COCHINTUM** (anc. geog.), a promontory of the Brutii, reckoned the longest in Italy: and which Holteius and Voelius have restored to Ovid, reading Cocintia for Corintia, Metam. XV. v. 704—Cochintum, also a town, 22 miles to the south of Sicyonia, almost on the spot where Stius now stands; from which the opposite promontory Cocalia is commonly called Cape de Stivo.

**COCK,** in zoology, the English name of the males of gallinaceous birds, but more especially used for the common dunghill cock. See **Phasius.**

Black Cock. See **Tetrao.**

Cock's Wood. See **Scarcabacus.**

Cock-Paddle, Lump-fish, or Sea-owl. See **Cyclonius.**

Cock-Fish, a sort of theatre upon which game-cocks fight.

It must appear astonishing to every reflecting mind, that a mode of diversion so cruel and inhuman as that of cock-fighting should so generally prevail, that not only the ancients, barbarians, Greeks, and Romans, should have adopted it; but that a practice so savage and heathenish should be continued by Christians of all ages, and even purged in these better and more enlightened times.

The ancient Greeks and Romans, as is well known, were wont to call all the nations in the world barbarians; yet certainly, if we consider the many instances of cruelty practised among them, there was very little reason for the distinction. Human sacrifices were common both to them and the barbarians; and with them the expulsing of infants, the combats of men with wild beasts, and of men with men in the gladiatorial feats, were spectacles of delight and festivity.

The islanders of Delos, it seems, were great lovers of cock-fighting; and Tanagra a city in Boeotia, the isle of Rhodes, Chalcis in Euboea, and the country of Media, were famous for their generous and magnanimous race of chickens. The kingdom of Persia was probably included in the left, from whence this kind of poultry was first brought into Greece; and if one may judge of the rest from the fowls of Rhodes and Media, the excellency of the broods at that time consisted in their weight and largeness (as the fowls of those countries were heavy and bulky), and of the nature of what our sportmen call thakoban or rounders. The Greeks, moreover, had some method of preparing the birds for battle, by feeding; as may be collected from Columella.

It should seem, that at first cock-fighting was partly a religious, and partly a political institution at Athens; and was there continued for the purpose of improving the feeds of valour in the minds of their youth; but was afterwards abused and perverted both here and in the other parts of Greece to a common pastime, without any moral, political, or religious intention, and as it is now followed and practised among us.

At Rome, as the Romans were prone to imitate the Greeks, we may expect to find them following their example in this mode of diversion, and in the worst way, viz., without any good or laudable motives; since, when they took and brought it to Rome, the Greeks had forgotten everything that was commendable in it, and had already perverted it to a low and unmeaning sport. Signior Hyam thinks the Romans borrowed the pastime from Dardanus in Asia; but there is little reason...
of many other males, he will scratch and provide for them with an affinity almost equal to that of the hen; and his generosity is so great, that, on finding a hoard of meat, he will chuckle the hens together, and without touching one bit himself will relinquish the whole of it to them. He was called the brave-foreword, by many of the ancients; he was highly esteemed in some countries, and in others was even held sacred, in much that one cannot but regret that a creature so useful and noble, should, by a strange fatality, be erroneously abused by us. It is true, our | cock-pit|, or the massacre of Shrove Tuesday, is now in a declining way; and, in a few years, it is to be hoped will be totally disused: but the cock-pit still continues a pro-\hush| to the humanity of Englishmen, and to their religion; the purest, the tenderest, and most compassionate, of all others, not excepting even the Brach-mannic.

It is unknown when the pitched battle first entered England; but it was probably brought thither by the Romans. The bird was here before Caesar's arrival; but no notice of his fighting occurs earlier than the time of William Fitz-Stephen, who wrote the life of archbishop Becket, some time in the reign of Henry II, and describes the cocking as a sport of School-boys on Shrove Tuesday. From this time at least the diversion, however absurd, and even impious, was continued amongst them. It was followed, though disapproved and prohibited by Edward III; also in the reign of Henry VIII; and A.D. 1569. It has by some been called a royal diversion; and, as every one knows, the cock-pit at Whitehall was erected by a crowned head, for the more magnificent celebration of it. There was another pit in Drury-lane, and another at Jermyn-street. It was prohibited, however, by one of Oliver's acts, March 51, 1664. What aggravates the reproach and disgrace upon Englishmen, are those species of fighting which are called the battle-royal and the Welsh-main, known nowhere in the world but there: neither in China, nor in Persia, nor in Maccab, nor among the savage tribes in America. These are feats so bloody as almost to be too shocking to relate; and yet, as many may not be acquainted with the horrible nature of them, it may be proper for the excitement of our aversion and detestation to describe them in a few words. In the former, two birds, or a pair of cockes, are pitted, and when they have flanghunger one another for the diversion, the bird to be esteemed the victor, and carries away the prize. The Welsh-main consists, we will suppose of 16 pair of cocks; of these, the 16 conquerors are pitted a second time; the 8 conquerors of these are pitted a third time; the 4 conquerors the fourth time; and lastly, the two conquerors of these are pitted the fifth time; so that [incredible barbarity!] 32 cocks are sure to be slain inhumanly murdered for the sport and pleasure, the noise and nonence, the prose curzing and sneering, of those who have the effrontery to call themselves, with all these bloody doings, with all this impiety about them, Christian! may, what with many is a superior and distinct character, men of benevolence and morality. But let the morality and benevolence of such be appropriated from the following instance recorded as authentic in the obituary of the Gentleman's
C COCK [117] COC

Coc-Kfit, Gentleman's Magazine for April 1789. "Died, April 4, at Tottenham, John Arde(of, early. as was very agreeable. This favour naturally wrought a goad opinion of her genius, ripened apace, and the fame, in her infancy a Protestant, but being a sprightly, ingenious, and beautiful child, she was particularly cared for by some considerable families among the Papists. This favour naturally wrought a good opinion of such friends; and entering into an intimacy with them as she grew up, she became an easy conquest to their faith, in which she continued many years. In the meantime her genius ripened space, and first proofs of her talents for poetry, even before she had passed her childhood. In her twelfth year she produced a tragedy called Agnes de Caffro, which was acted in 1695. This performance, and some verses addressed to Mr Congreve upon his Mourning Bride in 1697, brought her into the acquaintance of that gentleman. Thus encouraged in her first attempt, her Muse brought upon the stage three plays more, before the death of Mr Dryden in 1701, to whose memory she joined with several other ladies in paying a tribute of verse. However, poetry and dramatic writing was not the most distinguished of Miss Trotter's talents; she had a remarkable philosophic turn, and equal to such researches. Mr Locke's Essay on Human Understanding came out during this interval; that famous philosopher had drefled out logic and metaphysics in such a new mode as was very agreeable to the taste of the sex in general, and particularly engaged the attention and admiration of our young authors. She had begun to project a defence of the Essay against some remarks of Dr Burnet of the Charter-house, which was finished so early as the beginning of December 1701. She had but lately passed the 22nd year of her age; and the masterly way in which the piece was drawn, must needs have given singular pleasure to her great champion, who accordingly expressed his satisfaction by a present of books to his fair defendress. Philosophy sojourns in the neighbourhood of religion; these philosophic verses would naturally fit a thoughtful mind to that fellow; and taking into her consideration the tenets of her present faith, she began to discover their indefensible grounds; she therefore resolved to remove it, and published a vindication of her change in 1707; and returning to the established church of Scotland, she changed her condition likewise the next year, 1708; and was married to Mr Cockburne, a learned divine of that church. The duties of a wife and mother called Mrs Cockburne from her books and pen many years; and domestic cares engaging her attention, we hear nothing of her as a writer till 1726, when her zeal for Mr Locke's opinions drew her again into public light. She exercised her pen afterwards as occasion offered; and in 1739 she entered into the controversy concerning the foundation of moral duty and obligation. In that controversy she wrote two treatises, the first of which she transmitted in manuscript to Mr afterwards Dr Warburton, the late bishop of Gloucester, who published it, with a preface of his own, in 1747. Mrs Cockburne survived this publication two years only. She died in 1749, and was interred at Long Hordley, near her husband, who died the year before her, with this short sentence upon the tomb, 'Let their works praise them in the gates.' Prov. xxx. 31. Her Works were collected and published in 1751, in two volumes 8vo, with an account of her life prefixed.—This collection is incomplete; it contains but the proof of the author's genius. But her abilities as a writer will not be seen without attending to the peculiar circumstances in which her writings were produced: her early youth, for instance, when she wrote some; her very advanced age, and ill state of health, when she drew upon others; the uneasy situation of her fortune during the whole course of her life; and an interval of near 20 years, in the vigour of it, spent in the cares of a family, without the least leisure for reading or contemplation; after which, with a mind so long dispirited and encumbered, refining her mind, she insensibly recovered its energy and vigour, and, in the hour of relaxation from domestic employments, purged to the utmost limits some of the deepest researches the human understanding is capable of. Her character is that of a most uncommon lady, no less celebrated for her beauty in her younger years, than for her genius and accomplishments. She was small of stature, but had a remarkable liveliness in her eyes, and a delicacy of complexion which continued to her death.

Cockermouth, a town of Cumberland in England, situated in W. Long. 3. 12. N. Lat. 54. 35. It is a large town irregularly built, with broad streets. It is washed by the Derwent on the western side; divided in two by the Cocker; and the parts are connected by a stone-bridge of one single arch. The number of inhabitants is between three and four thousand; the manufactures are stockings, worsted fleecings, and hats; the last exported from Glasgow to the West Indies. It is a borough-town, and the right of voting is vested by burgess tenure in certain houses; this is also the town where the county elections are made. —Here is a castle seated on an artificial mount on a bank above the Derwent. It has a square building and strengthened with several square towers: on each side...
Cock. side of the inner gate are two deep dungeons capable of holding 50 persons in either; they are vauted at
top, and have only a small opening in order to lower
through it the unhappy prisoners into this dire prison;
and on the outside of each is a narrow slit with a slope
from it, down which were the provisions allotted
for the wretched inhabitants. This caffle was found-
ated by Waldof, first lord of Alldale, and son of God-
or, page of Earl of Northumberland, contemporary with
William the Conqueror. Waldof resid ed first at Pap-
castle, which he afterwards demolished; and with the
materials built that at Cockermouth, where he and his
family long resided; but several arms over the gate-
way, which Cambden says are those of the Multons,
Hamfranville's, Lucies, and Piercyes, evince it to have
belonged in latter times to those families. It appears
that it was first granted by Edward II. to Anthony
de Lucie, son of Thomas de Muliton, who had asum-
med that name, because his mother was daughter
co-heiress to Richard de Lucie; and afterwards, by
marriages, this caffle and its honours descended to the
Hamfranville's, and finally to the Piercyes. In 1659,
it was garrisoned for the king; and being besieged and
taken by the rebels, was burned, and twice after-
wards repaired.-Cockermouth is now in the posses-
sion of the Lowther family, who have here a great
property in coal-works. The town sends two mem-
bers to parliament.

Cocket. COCKET, is a feal belonging to the king's caffle-
house, or rather a feroll of parchement sealed and de-
ivered by the officers of the caffles to merchants, as a
warrant that their merchandises are caffomed.

It is also ufed for the office where goods transporte
d were first entered, and paid their caffon, and had a
cocket or certificate of discharge.

Cockle. COCKLE, in ichthyology. See Cardium.

Cockle, or Shille, in mineralogy, a species of flones
of the garnet kind, belonging to the Gleecey sands.
It is called Schoerlus by Bergman, Lapis corneus crestifi-
Iatus by Wallerius and Stearnus; crestis columnaribus
by Linnaeus. It is hard and heavy, shooting into cry-
flals of a prismatic figure, principally of a black or
green colour. The name cockle for these kinds of
flones is old Cornish word; but is sometimes also
applied to very different subsances. The term shire
is adopted from the Germans. The English miner-
al name of call has alfo been used by some authors as fa-
nomous with cockle; and these are even confounded
together at the mines; but the call, definitively speak-
ing, is the fame with the substance called wolfram
by the Germans.

The specific gravity of these flones is between 3000
and 3300, though always in proportion to their dif-
terfoldities. They crack in the fire, and are very
difficult to be fused; refilling both microcofmic falt
and mineral alkali. They cannot totally be difolved
in aqua-fortis; but the difolved part is precipitated
in a gelatinous form on the addition of an alkali. On
a chemical analysis they are found to contain fihiceous
earth, argil, calcareous earth, and iron; which laft is
found in a much greater quantity when they are op-
paque than when transparent. According to Berg-
man, one contains 15 parts of fihiceous earth, 39 of
argilaceous, and fix of pure calcareous earth; but fome
contain ten or twelve of magnesia. In Britain they
are chiefly found in Cornwall, about the tin mines, and
some fine cryftallized kinds have been brought from
Scotland. The varieties are,

1. The Schoerlus martialis, or cockle mixed with
iron. It is of a green colour, and found in moft of
the Swedish iron mines. It is coarse, and without any
derminite figure.

2. The flatus, or parry cockle, is found in some
places of a deep green colour, whence authors have
called it the mother of emeralds. Its specific charac-
ter is, that it always breaks in a cubic or romboidal
form. In some parts of Sweden it is found of a pale
green, white, or black colour, and of a brown colour
in Welfmoreland in England. It frequently occurs in
the fealy lime-flones, and its colour changes from a
depth green to white, in proportion as it contains more
or lefs iron.

3. Fibrous cockle refembles threads of glafs. These
are either parallel, or like rays from a centre, in which
laft cafe it is called fanned cockle. Its colours are black,
green, white, blackish green, and light green; all
which are to be met with in Sweden. In Welfman-
land it is found along with a filed-grained lead ore;
and here the whole is called gram-re-malm, or cockle,
from its reminence to the branches of that tree.
Cromfiedt observes, that the figure of this subsance
has caufed it to be sometimes confounded with the
aefbif, and that to this species belong most of the
substances called imperfect aefbif. The fliated cockle,
compared with the aefbif, is of a fhining and angular
surface, though this fometimes requires the aid of
a magnifying glafs to discover it; always somewhat tran-
parent; and is pretty easily vitrified before the blow-
pipe, without being confumed as the pure aefbif firm
be.

4. Cryftallized cockle is found of black, deep-green,
light-green, and reddifh-brown in Sweden, and in feve-
ral other European countries. Near Basf in Switzerland
is found, though very rarely, a ftone called tauaffifm,
belonging to this variety. It is of a reddifh-brown
colour, and confis of two hexagonal cryftals of cockle
grown together in the form of a crofs, which is worn
by the Roman Catholics as an amulet, and called by
them lapis crucifer, or the crofs-stone. This form,
however, is not peculiar to the cockle, for both Wer-
ner and Bergman mention cryftals of mountain-cryftal
joined together in the fame manner.

This variety was lately found by M. Fichtel on the
Carpathian mountains, cryftallized in prisms, and em-
bodyed in lime-fone. It effervesces flightly with acids,
and contains 61.6 of filex, 21.6 of calcareous earth,
6.6 of argil, 5 of magnesia, 1.6 of iron, and three
of water. The reddifh-brown prismatic fhiril from Ve-
fusius contains 48 of filex, 40 of argil, five of cafls,
one of magnesia, and five of iron. Other kinds, how-
ever, have afforded 50 per cent. of fihiceous earth, 30
of argilaceous, one or two of magnesia, and 18 or
20 of iron. The white fort probably contains lefs iron,
but all become reddifh by calcination. Cronfiedt in-
forms us that he has heard of lead being melted out of a
kind of cockle from Rodbeck's Eng at Umea in Lap-
land; and he alfo thinks it very probable, that fome of
the cockles found in the English tin mines may contain
tin. Some cryftals of cockles are more fubtle than any
fort of flone whatever; these are always glafy and le-
mittransparent.
COC

Cockney. The precise figure of the cockle, that always prifmatical, is uncertain. What from Yxio, at Nys kopparberg, is quadrangular; the French kind has nine fides or planes, and the sautfein is hexagonal.

COCKNEY, a very ancient nickname for a citizen of London. Ray says, an interpretation of it is, A young person coaxed or coquered, made a wanton, or neftee-ock, delicately bred and brought up, so as when arrived at man's estate to be unable to bear the least hardship. Another, A person ignorant of the terms of country economy, such as a young citizen, who having been ridiculed for calling the neighing of a horse laughing, and told that it was called neighing, next morning, on hearing the cock crow, to show instruction was not thrown away upon him, exclaimed to his former instructor, How that cock neighs! whence the citizens of London have ever since been called cockneighs, or cockneys. Whatever may be the origin of this term, we at least learn from the following verities, attributed to Hugh Bagot earl of Norfolk, that it was in use in the time of king Henry II.

COCO.

PLATE I.

COCO.

COCOY, or Cockon, an officer on board a man of war, who hath the care of the boat, or bough, and all things belonging to it. He is to be always ready with his boat's gang or crew, and to man the boat on all occasions. He fits in the stern of the boat, and fleets: and hath a whistle to call and encourage his men.

COCKLES, (Pub. Hor.) a celebrated Roman, who alone opposed the whole army of Porfenna at the head of a bridge, while his companions behind him were cutting off the communication with the other shore. When the bridge was destroyed, Cockles, thro' wounded by the darts of the enemy, leapt into the Tiber, and swam across it with his arms. A brazen statue was raised to him in the temple of Vulcan, by the confult Publicola, for his eminent services.

COCOA, in botany. See Cocos.

COCONATO, a town of Piedmont in Italy, famous for being the birth-place of Columbus, who first discovered America; E. Long in N. N. Lat. 44. 50.

COCOS, in botany: a genus belonging to the natural order of Palmæ. The calyx of the male is triradiate; the corolla tripetalous, with six stamina. The calyx of the female quinquepartite; the corolla tripetalous; the stigmata three, and the plum choridious. There is only one species known, which is cultivated in both the Indies, and is of the greatest use to the inhabitants. It is supposed to be a native of the Maldive and some desert islands in the East Indies; and from thence to have been transported to all the warm parts of America; for it is not found in any of the inland parts, nor any where far distant from settlements. The tree frequently rises 60 feet high.

The body of the trunk, which generally leans to one side, occasioned as it is supposed, by the great weight of nuts it sustains when young, is the exact shape of an apothecary's large iron pestle, being of an equal thickness at top and at bottom, but somewhat smaller in the middle; its colour is of a pale brown throughout, and the bark smooth. The leaves or branches are often 14 or 15 feet long, about 20 in number, winged, of a yellow colour, straight and tapering. The pinnas or partial leaves are green, often three feet long next the trunk, but diminishing in length towards the extremity of the branches. The branches are fetten at top by brown stringy threads that grow out of the side, of the size of ordinary pack-thread, and are interwoven like a web. The nuts hang at the top of the trunk, in clusters of a dozen each. Each nut, next the stem, has three holes closely stopped: one of them being wider, and more easily penetrated than the rest. When the kernel begins to grow, it incults the infide of the nut in a blister, jelly-like substance; this grows harder, the inclosed liquid, distilled into the nut from the roots, become somewhat acid; and the kernel, as the nut ripens, becomes still more fold; and at length lines the whole inside of the nut for above a quarter of an inch thick, being as white as snow, and of the flavour of an almond. The quantity of liquor in a full grown nut is frequently a pint and upwards. The hulky tegument of the nut consists of strong, tough, stringy filaments, which, when removed from the fruit resemble coarse oskham, and may perhaps be conveniently enough used as such. The shells of these nuts, being tipped with silver, are frequently used for drinking bowls. The bark of the tree may be wrought into cordage, and the leaves into baskets, brooms, hampocks in form of nets, mats, sacks, and other useful utensils. The liquor contained in the shell is a most cooling wholesome beverage in those sultry climates, and the white kernel a most agreeable food. The Maldive cocoa-nut is esteemed, by the inhabitants of these islands, as a powerful antidote against the bites of serpents and other poisons. The cocoa-nut tree is propagated by planting the nuts; which, in six weeks or two months time, will come up, provided they are fresh and thoroughly ripe; but this is what few of them are when brought into this country; for they always gather them before they are ripe, that they may keep during their passage. The best way, therefore, would be to gather such nuts as are thoroughly ripe in their native country, and plant them in a tub of dry sand, in order to keep them from the vermin during their passage. Here they will frequently sprout, which will be an advantage, as they may then be immediately planted in pots of earth, and plunged in the bark-strew.
COCTION, a general term for all alterations made in bodies by the application of fire or heat.

COCYTUS, one of the rivers of hell, according to the theology of the poets. It has its name from lamentation, from groaning and lamenting. Hence Milton,—Cocyts nam’d of lamentation loud,

Heard on the rueful stream.

It was a branch of the river Styx; and flowed, according to Horace, with a dull and languid stream.

COD, in ichnology. See GADUS and FISHERY.

Cod is also a term used, in some parts of England, for a pod. See Pod.

Cod-Cape, a promontory on the coast of New England, near the entrance of Boston harbour. W. Long. 69° 50’. N. Lat. 42° 0.’

CODDY-MODDY, the English name of a species of Laurus.

CODE (codex), a collection of the laws and constitutions of the Roman emperors, made by the order of Justinian. The word comes from the Latin codex, a paper book; so called a codicinus, or codicibus armatorum, the trunks of trees; the bark whereof being stripped off, served the ancients to write their books on.

The code is accounted the second volume of the civil law, and contains twelve books; the matter of which is nearly the same with that of the digests, especially the first eight books: but the style is neither so pure, nor the method so accurate, as that of the digests; and it determines matters of daily use, whereas the digests discuss the more abstract and subtle questions of the law, giving the various opinions of the ancient lawyers. Although Justinian’s code is distinguished by the appellation of code, by way of emulation, yet there were codes before his time; such were, 1. The Gregorian code, and Hermogenian code; collections of the Roman laws, made by two famous lawyers, Gregorius and Hermogenes, which included the constitutions of the emperors from Adrian to Diocletian and Maximinus. 2. The Theodosian code, comprised in 16 books, formed out of the constitutions of the emperors from Constanstine the Great to Theodosius the younger: this was observed almost over all the west, till it was abrogated by the Justinian code.

There are also several later codes, particularly the ancient Gothic, and those of the French kings; as the code of Euride, code-Lewis, code-Henry, code-Marshande, code des Eaux, &c; and the present king of Prussia has lately published a code, which comprises the laws of his kingdom in a small volume.

CODEX, in antiquity, denotes a book or tablet on which the ancients wrote. See Codex.

Codex also denoted a kind of punishment by means of a log or block of wood, to which slaves who had offended were tied fast, and obliged to drag it along with them; and sometimes they fasten it closely bound.

CODIA, among botanists, signifies the head of any plant, but more particularly a poppy head; whence its syrup is called diascodiam.

CODIA, in botany: A genus of the diginna order, belonging to the decandria class of plants. The calyx is tetraphyllous, with small oblong horizontal leaves; the corolla consists of four very small linear petals; the flamina are eight filaments twice as long as the calyx; the stamens are roundish.

CODICIL, is a writing, by way of supplement to a will, when any thing is omitted that the testator would have added, or wants to be explained, altered, or recalled.

CODLIN, an apple useful in the kitchen, being the most proper for baking.

CODLING, a appellation given to the cod-fillet: when young. See GADUS.

CODON (genus), in antiquity, a cymbal, or rather little brafs bell, resembling the head of a poppy. They were fastened to the trappings and bridles of horses.

CODON, in botany: A genus of the monogynia order, belonging to the decandria class of plants. The calyx is decempartite, with the segments alternately long and short; the corolla campanulate, with the limb decempartite and equal; the stamens decempartite, of ten scales inserted into the heels of the flamina; the seed-capsule bicellular; the seeds hairy, roundish, in a dry coloured pulp.

CODRINGTON, (Christopher), a brave English officer, and not less distinguished for his learning and benevolence; was born at Barbadoes in the year 1668, and educated at Oxford; after which he betook himself to the army; and, by his merit and courage, soon recommending himself to the favour of king William, was made a captain in the first regiment of foot-guards. He was at the siege of Namur in 1695; and, upon the conclusion of the peace of Ryswick, was made captain-general and governor in chief of the Leeward and Caribbee islands. However, in 1701, several articles were exhibited against him to the house of commons in England; to which he published a distinct and particular answer, and was honourably acquitted of all imputations. In 1703, he showed great bravery at the attack of Gaudaloupe; but at last he resigned his government, and lived a studious retired life; for a few years before his death, he chiefly applied himself to church-history and metaphysics. He died at Barbadoes, on the 7th of April 1710, and was buried there the day following; but his body was afterwards brought over to England, and interred, on the 19th of June 1716, in the chapel of All-Souls College, Oxford. By his will, he bequeathed his plantations in Barbadoes, and part of the island of Barbuda, to the society for propagating the gospel in foreign parts; and left a noble legacy to All-Souls College, of which he had been a fellow. This legacy consisted of his library, which was valued at 6000/.; and 10,000/. to be laid out, 6000 in building a library, and 4000 in furnishing it with books. He wrote some of the poems in the Muse Anglicana, printed at London in 1741.

CODRUS, the 17th and last king of Athens, son of Melanthus. When the Heraclidae made war against Athens, the oracle said that the victory would be granted to that nation whose king was killed in battle. The Heraclidae upon this gave strict orders to spare the life of Codrus; but the patriotic king disdained himself and attacked one of the enemy, by whom he was killed. The Athenians obtained the victory, and Codrus was deferently called the father of his country. He reigned 21 years, about 2153 years before the Christian era. To pay more honour to his memory, the Athenians made a resolution that no man after Codrus should reign in Athens under the name of king.

COECUM,
COELOM, or BLIND-GUT. See Anatomy, p. 93.
Dr Mafgrave gives us an account, in the Philosophical Translations, of the coecum of a dog being cut out without any prejudice to the animal. Mr. Giles gives another of the coecum of a lady being dissected, so as to form a tumour that held almost fix pints of a thin, greyish, almost liquid substance, from which she died. And Mr. Knowler a third, of a boy's coecum being vastly extended and studded with cherry-stones, which like-wise proved mortal.

COEFFICIENTS, in algebra, are such numbers or known quantities as are put before letters or quantities, whether known or unknown, and into which they are suppos'd to be multiplied. Thus, in $3x$, $a_x$, or $b_x$, $3$, $a$, and $b$ are the coefficients of $x$; and in $6a$, $9b$, and $9$, are the coefficients of $a$ and $b$. See Algebra.

COELIAC ARTERY, in anatomy, that artery which fisses from the aorta, just below the diaphragm. See Anatomy, p. 123.

COELIOBRIGA (anc. geog.), a town of the Bracari in the province of the Palatine, and on the north the valley through which the rivulet of the Aventine to the south, on the east the Sabines, (Dionysius Halicarnassus). Called also Coelius Seminatrix, or Coelius, from the oak growing on it; and Angelus, by Tibrius (Tacitus, Suetonius). To the east it had the city walls, on the south the Coelius, to the west the Palatine, and on the north the Eurialus.

COELIUS, a part of mount Coelius to the south, called Minor Coelius (Marzial); having the city walls on the east, the Aventine to the south, on the west the Palatine, and on the north the Eurialus.

COELON, one of the seven hills of Rome; so called from Coelus, a Tuscan captain, who came to the assistance of Romulus against the Sabines, (Dionysius Halicarnassus). Called also Querquulentus, or Querucentarius, from the oaks growing on it; and Augustus, by Tibrius (Tacitus, Suetonius). To the east it had the city walls, on the south the Coelius, to the west the Palatine, and on the north the Eurialus.

COELUS (Heaven), in Pagan mythology, the son of Ethe or Dies or Air and Day. According to Vol. V., Hefiod, he married Terra or the Earth: on whom he Coemeteries were built. See CEMETERY.

COENOBITE, a religious who lives in a convent, or in community, under a certain rule, in opposition to anachoret, or hermit, who lives in solitude. The word comes from the Greek συνόπτος, συνόπτον; and σύνων, "life". Caifian makes this difference between a convent and a monastery, that the latter may be applied to the residence of a single religious or recluse; whereas the convent implies coenobites, or numbers of religious living in common. Fleury speaks of three kinds of monks in Egypt: anachoret, who live in solitude; coenobites, who continue to live in community; and paraklesites, who are a kind of monks-errant, that stroll from place to place. He refers the institution of coenobites to the times of the apostles, and makes it a kind of imitation of the ordinary lives of the faithful at Jerusalem. Though St Pachomius is ordinarily owned the inventor of the coenobite life, as being the first who gave a rule to any community.

COENOBIVUM, συνόπτον, the state of living in a society, or community, in which all things are common. Pythagoras is thought to be the author or first instigator of this kind of life; his disciples, though hundreds in number, being obliged to give up all their private estates, in order to be annexed to the joint stock of the whole. The Effenians among the Jews and Platonists have been said to have lived in the same manner. Many of the Christians also have thought this the most perfect kind of society, as being that in which Christ and his apostles chose to live.

COESFELDT, a town of Germany, in Westphalia, and in the territories of the bishop of Munster, where he often resides. It is near the river Barkel, E. Long. 64. 2. N. Lat. 51. 58.

COEVERDEN, one of the strongest towns in the United Provinces, in Overgiefel, fortified by the famous Cohorn. It was taken by the bishop of Munster, 1673; and the Dutch retook it the same year. It is surrounded by a moats. E. Long. 6. 41. N. Lat. 52. 40.

COFFEA, the Coffee-tree: A genus of the monogynia order, belonging to the pantandra clafs of plants; and in the natural method ranking under the 47th order, Stellata. The corolla is funnel-shaped; the flamina above the tube; the berry inferior, ditterous; the seeds arilled, or having a proper exterior covering dropping off of its own accord. There is but one species, supposed to be a native of Arabia Felix. It seldom rises more than 16 or 18 feet in height; the main stem grows upright, and is covered with a light brown bark; the branches are produced hori-
Coffee. horizontally and opposite, crossing each other at every joint; so that every side of the tree is fully garnished with them, and they form a sort of pyramid. The leaves also stand opposite; and when fully grown are about four or five inches long, and two broad in the middle, decreasing toward each end, the borders are waved, and the surface is of a lucid green. The flowers are produced in clusters at the root of the leaves, sitting close to the branches; they are tubulous, and spread open at the top, where they are divided into five parts; they are of a pure white, and have a very grateful odour, but are of short duration. The fruit, which is the only useful part, resembles a cherry. It grows in clusters, and is ranged along the branches under the axille of the leaves, of the same green as the laurel, but something longer. When it comes to be of a deep red, it is gathered for the mill, in order to be manufactured into those coffee-beans now so generally known. The mill is composed of two wooden rollers furnished with iron plates 18 inches long, and 10 or 12 in diameter. These moveable rollers are made to approach a third which is fixed, and which they call the chops. Above the rollers is a hopper, in which they put the coffee, from whence it falls between the form of the rollers and divided into two parts, as may be seen by the appearance of the coffee-tree. The plants which the coffee is cultivated in Arabia, Peru, the East Indies, the Isle of Bourbon, and several parts of America. It is also raised in botanic gardens in several parts of Europe. Prince Eugene's garden at Vienna produced more coffee than was sufficient for his own consumption. It delights particularly in hills and mountains, where its root is almost always dry, and its head frequently watered with gentle showers. It prefers a western aspect, and ploughed ground with an appearance of grass. The plants should be placed at eight feet distance from each other, and in holes twelve or fifteen inches deep. If left to themselves, they would rise to the height of 16 or 18 feet, as already observed: but they are generally planted to five, for the convenience of gathering their fruit with the greater ease. Thus drawn, they extend their branches so, that they cover the whole space round about them. They begin to yield fruit the third year, but are not in full bearing till the fifth. With the same infirmities that most other trees are subject to, these are likewise in danger of being destroyed by a worm or by the scourging rays of the sun. The hills where the coffee-trees are found have generally a gravelly or chalky bottom. In the last, it languishes for some time and then dies: in the former, its roots, which seldom fail of striking between stones, obtain nourishment, and keep the tree alive and fruitful for 30 years. This is nearly the period for plants of the coffee-tree. The proprietor, at the end of this period, not only finds himself without trees, but has his land reduced, that it is not fit for any kind of culture; and unless he is so situated, that he can break up a spot of virgin land, to make himself amends for that which is totally exhausted by the coffee-trees, his loss is irreparable.

The coffee produced in Arabia is found so greatly to excel that raised in the American plantations or elsewhere, that the cultivation of the tree is now but seldom practiced in any of the British colonies. Large plantations of this kind were formerly made in some of them; and it was proposed to the parliament to give a proper encouragement for cultivating this commodity there, so as to enable the planters to under sell the importers from Arabia. Accordingly, there was an abatement of the duty payable on all coffee imported from the colonies in America, which at that time was supposed to be for that encouragement for this kind of commerce; but the inferiority of the American coffee to the Arabian hath almost ruined the project. Mr Miller proposes some improvements in the method of cultivation. According to him, the trees are planted in too moist a soil, and the berries, are gathered too soon. They ought, he says, to be permitted to remain on the trees till their skins are shrivelled, and they fall from the trees when shaken. This will indeed greatly diminish their weight, but the value of the commodity will thereby be increased to more than double of that which is gathered sooner. In Arabia, they always shake the berries off the trees, spreading cloths to receive them, and only take such as readily fall at each time. Another cause may be the method of drying the berries. They are, he observes, very apt to imbibe moisture, or the flavour of anything placed near them. A bottle of rum placed in a cloet, in which a canvas of coffee-berries closely stopped was standing on a shelf at a considerable distance, in a few days so impregnated the berries as to render them very disagreeable; the same hath also happened by a bottle of spirit of wine standing in the same cloet with coffee and tea, both which were in a few days spoiled by it. Some years ago, a coffee-ship from India had a few bags of pepper put on board, the flavour of which was imbibed by the coffee, and the whole cargo spoiled. For these reasons, Mr Miller directs that coffee-berries should never be brought over in ships freighted with rum, nor left on board in the houses where ftagars are bottled or rum distilled. When they are fully ripe, they should be shaken off when the trees are perfectly dry, and spread upon cloths in the sun to dry, carrying them every evening, under
Coffee. under cover, to prevent the dew or rain from falling on them. When perfectly dry, they should have their outer skins beaten off, and then be carefully packed up in cloths or bags three or four times double.

The coffee-tree, as we have already observed, is sometimes cultivated in European gardens; but for this it requires the affiance of a stove. It makes a fine appearance at all seasons of the year (being an evergreen), but especially when in flower, and when the berries are red, which is generally in the winter, so that they continue a long time in that state. It is propagated from the berries; but they must be planted immediately when gathered from the tree, for they lose their vegetative quality in a very short time; when sent abroad by the post, they have constantly failed in those that have been a fortnight on their journey; so that where these trees are defined, the young plants must be sent, if it be at any distance from the place where they grow. The fresh berries may be planted in small pots, and plunged into a hot-bed of tanners bark. If the bed be of a proper temperature, the young plants will appear in a month or five weeks time; and in six weeks more, they will be ready for transplanting into several pots. During summer, they must be frequently watered, but not too much, otherwise the roots will be apt to rot. The first sign of the plants being disordered is their leaves sweated out a clammy juice; after which they are over-run with insects, that cannot be destroyed till the plants have recovered their health; so that on the first appearance of these insects, the trees should be removed into fresh earth, and all possible care taken to recover them. The disorders incident to them, generally proceed either from their having been put into large pots, or from the earth about them being too stiff or over-watered. The most proper soil for them is that of a kitchen-garden, which is naturally loamy, and not subject to bind, especially if it has constantly been well wrought and dunged.

Coffee also denotes a kind of drink, prepared from those berries; very familiar in Europe for three hundred years, and among the Turks for 170.

Its original is not well known. Some ascribe it to the prior of a monastery, who being informed by a goat-herd, that his cattle sometimes browsing on the tree would wake and cafer all night, became curious to prove its virtue; accordingly, he first tried it on his monks, to prevent their sleeping at matins. Others, from the same author, refer the invention of coffee to the Persians; from whom it was learned in the 16th century by Gemaleddin, muft of Aden, a city near the mouth of the Red Sea; and who having tried its virtues himself, and found that it dilated the flames which opposed the head, inspired joy, opened the bowels, and prevented sleep, without being incommoded by it, recommended it first to his deviates, with whom he used to spend the night in prayer. Their example brought coffee into vogue at Aden; the profectors of the law for study, artificians to work, travellers to walk in the night, in fine every body at Aden drank coffee. Hence it passed to Mecca; where first the devotees, then the rest of the people, took it. From Arabia Felix it passed to Cairo. In 1511, Kabie Beg prohibited it, from a persuasion that it inebriated, and inclined to things forbidden. But Sultan Caiun immediately after took off the prohibition; and coffee advanced from Egypt to Syria and Constantinople. The derixes claimed against it from the Alcoran, which declares, that coal is not of the number of things created by God for food. Accordingly, the muti ordered the coffee-houses to be shut; but his successor, declaring coffee not to be coal, they were again opened. During the war in Candia, the assemblies of new-monks making free with state affairs, the grand vizir Cuproli suppressed the coffee-houses at Constantinople: which impression, though still on foot, does not prevent the public use of the liquor there. Thenvoren, the traveller, was the first who brought it into France; and a Greek servant, named Fejuas, brought it into England by Mr. Dan. Edwards, a Turkey merchant, in 1652, to make his coffee, first let up the profession of coffee-man, and introduced the drink into that island.

The word coffee is originally Arabic: the Turks pronounce it cahief, and the Arabians cahah; which some authors maintain to be a general name for any thing that takes away the appetite, others for any thing that makes them feel. Others again for any thing that gives strength and vigour. The Mahometans have observed, distinguished three kinds of cahah. The first is wine, or any liquor that inebriates; the second is made of the pods that contain the coffee-berry; this they call the Sultan's coffee, from their having first introduced it on account of its heating less than the berry, as well as its keeping the bowels open: the third is that made with the berry itself, which alone is used in Europe, the pods being found improper for transportation. Some Europeans who imported the pods called them the flower of the coffee-tree. The deep brown colour of the liquor occasioned its being called Surup of the Indian mulberry, under which specious name it first gained ground in Europe.

The preparation of coffee consists in roasting, or giving it a just degree of torrefaction on an earthen or metallic plate, till it have acquired a browny hue equally deep on all sides. It is then ground in a mill, as much as serves the present occasion. A proper quantity of water is next boiled, and the ground coffee put into it. After it has just boiled, it is taken from the fire, and the decoction having stood a while to settle and fine, they pour or decant it into dishes. The ordinary method of roasting coffee amongst us is in a tin cylindrical box full of holes, through the middle whereof runs a spit; under this is a semicircular hearth, wherein is a large charcoal-fire: by help of a jack the spit runs swift, and so roasts the berry being now and then taken up to be shaken. When the oil rises, and it is grown of a dark brown colour, it is emptied into two receivers made with large hoops, whose bottoms are iron plates: there the coffee is shaken and left till almost cold; and if it look bright and oily, it is a sign it is well done.

Very different accounts have been given of the medicinal qualities of this berry. To determine its real effects on the human body, Dr Percival has made severals experiments, the result of which he gives in the following words: "From these observations we may infer that coffee is slightly astringent, and antiseptic; Vol. II. that it moderates alimentary fermentation, and is p. 127, powerfully sedative. Its action on the nervous system Q. 2
probably depends on the oil it contains; which receives its flavour, and is rendered mildly empyreumatic, by the process of roasting. Neumann obtained by distillation from one pound of coffee, five ounces five drachms and a half of water, six ounces and half a drachm of thick febird oil, and four ounces and two drachms of a caput mortuum. And it is well known, that rye, torrefact with a few almonds, which furnish the necessary proportion of oil, is now frequently employed as a substitute for these berries.

"The medicinal qualities of coffee seem to be derived from the grateful fermentation which it produces in the stomach, and from the digestive powers it excerts on the vitaria. Hence it affift digestion, and relieves the headache; and is taken in large quantities, with peculiar propriety, by the Turks and Arabians; because it counteracts the narcotic effects of opium, to the use of which those nations are much addicted.

"In delicate habits, it often occasions watchfulness, and many of those complaints which are denominated nervous. It has been even suspected of producing palsy; and from my own observation, I should apprehend, not entirely without foundation. Slare affirms that he became paralytic by the too liberal use of coffee, and that his disorder was removed by abstinence from that liquor.

"The following curious and important observation is extracted from a letter with which I was honoured by Sir John Pringle, in April 1773: "On reading your letter concerning coffee, one quality occurred to me which I have observed of that liquor, confirming what you have said of its sedative virtues. It is the best abater of the paroxysms of the periodic asthma that I have seen. The coffee ought to be of the best Mocco, newly burnt, and made very strong immediately after grinding it. I have commonly ordered an ounce for one dish: which is to be repeated fresh after the interval of a quarter or half an hour; and which I direct to be taken without milk or sugar. The medicine in general is mentioned by Muffgrave, in his treatise De arithritide anomaia: but I first heard of it from a physician in this place, who having once practised it in Litchfield, had been informed by the old people of that place, that Sir John Pleyter, during the latter year of his life, kept free from, or at least lived easy under, his asthma, from the use of very strong coffee. This discovery it seems, he made after the publication of his book upon that disease. Since the receipt of that letter, I have frequently directed coffee in the asthma with great success."

COFFER, in architecture, a square depreçature or finking in each interval between the modillions of the Corinthian cornice: ordinarily filled up with a rofe, sometimes with a pomegranate, or other enrichment.

COFFER, in fortification, denotes a hollow lodgment, at- thrath a dry moist, from 6 to 7 feet deep, and from 16 to 18 broad: the upper part made of pieces of timber raised two feet above the level of the moist; which little elevation has hurdles laden with earth for its covering: and serves as a parapet with embrasures: the coffers is nearly the same with the caponiere, excepting that this last is sometimes made beyond the counterfcarp on the glacis; and the coffers always in the moist taking up its whole breadth, which the caponiere does not. It differs from the traverse and gallery, in that these latter are made by the besiegers, and the coffers by the besieged. The besieged generally make use of coffers to repulse the besiegers when they endeavour to pass the ditch. To save themselves from the fire of these coffers, the besiegers throw up the earth on that side towards the coffers.

COFFERER of the KING'S HOUSEHOLD, in Britain, a principal officer in the court, next under the comptroller. He was likewise a white-staff officer, and always a member of the privy council. He had a special charge and oversight of the other officers of the household. He paid the wages of the king's servants below stairs, and for provisions as directed by the board of green cloth. This office is now suprzeded, and the business of it is transferred by the lord steward, and paymaster of the household. He had L. 100 a-year wages, and L. 400 a-year board-wages.

COFFIN, in which dead bodies are put into the ground.

The sepulchral honours paid to the manes of departed friends in ancient times, demand attention, and are extremely curious. Their being put into a coffin has been particularly considered as a mark of the highest distinction. With us the poorest people have their coffins. If the relations cannot afford them the parith is at the expense. On the contrary, in the cast they are not at all made use of in our times: Turks and Christians, as Thevenot affures us, agree in this. The ancient Jews seem to have buried their dead in the same manner: neither was the body of our Lord, it should seem, put into a coffin; nor that of Elihah, 2 Kings xiii. 21, whose bones were touched by the corpse that was let down a little after into his sepulchre. However, that they were anciently made use of in Egypt, all agree; and antique coffins of bone and fycamore wood, are still to be seen in that country; not to mention those said to be made of a kind of pafleboard; formed by folding or gleaning cloth together a great many times, curiously plaited, and then painted with hieroglyphics. Its being an ancient Egyptian custom, and not practised in the neighbouring countries, were, doubtless, the cause that the modern historians express our ladies of Joseph, that he was not only embalmed, but put into a coffin too; both being manuscripts peculiar to the Egyptians.

Bishop Patrick, in his commentary on this passage, takes notice of these Egyptian coffins of sycamore wood, and of pallet-board; but he doth not mention the contrary usage in the neighbouring countries which was requisite, one might suppose, in order fully to illustrate the place: but even this perhaps would not have conveyed the whole idea of the sacred author. Maillet apprehends that all were not enclosed in coffins who were laid in the Egyptian repositories of the dead: that it was an honour appropriated to persons of figure: for after having given an account of several riches found in those chambers of death, he adds, "But it must not be imagined that p. 281. all inclosed in coffins, and placed in niches. The greatest part were simply embalmed and swathed after that manner which every one hath some notion of; after which they laid them one by the side of another without any ceremony. Some were even laid in
**C O N S I D E R A T I O N .** Considered references the cognate, Coffin in these tombs without any embalming at all; or such

Cognate, a flight one, that there remains nothing of them in the linen in which they were wrapped, but the bones, and their half rotten. It is probable, that each considerable family had one of these burial-places to themselves; that the nitches were designed for the bodies of the heads of the families; and that those of their domestics or slaves had no other care taken of them than the laying them on the ground, after having been embalmed, or even without that; which, without doubt, was also all that was done even to the heads of families of less distinction. After this he gives an account of a way of burial, practiced anciently in that country, which had been but lately discovered; and which consisted in placing the bodies, after they were washed, upon a layer of charcoal, and covering them with a mat, under a depth of sand of seven or eight feet.

That coffins then were not universally used in Egypt, is undoubted from these accounts; and probably they were only persons of distinction who were buried in them. It is also reasonable to believe, that in times so remote as that of Joseph, they might be much less common than afterwards; and consequently, that Joseph’s being put in a coffin in Egypt might be mentioned with a design to express the great honours which the Egyptians did him at his death, as well as in life, being interred after the most sumptuous manner of the Egyptians, embalmed, and put into a coffin. Agreeably to this, the Sepulchric version, which was made for Egyptians, seems to represent coffins as a mark of grandeur.

It is no objection to this account, that the widow of Nain’s son is represented as carried forth to be buried in a σπήλαιον, or “on a bier:” for the present inhabitants of the Levant, who are well known to lay their dead bodies in the earth unclothed, carry them frequently out to burial in a kind of coffin. So Dr Ruffel, in particular, decries the bier used for the Turks at Aleppo, as a kind of coffin much in the form of ours, only that the lid rises with a ledge in the middle. Christians, indeed, as he tells us, are carried to the grave on an open bier; but as the most common kind of bier resembles our coffins, that used by the people of Nain might very possibly be of the same kind; in which case the word σπήλαιον was very proper.

**COGGLE, or Cog,** a small fishing-boat upon the coasts of Yorkshire: and cogs (cognes) are a kind of little ships or vessels used in the rivers Oxne and Humber; (Stat. 23. H. VIII. c. 13.) Preparati cogontbus, galeis, & laps navibus, &c. (Matt. Paris. ann. 1066.) And hence the cogmen, boatmen, and fishermen, who after shipwreck or loss by fire travelled and wandered about to defraud the people by begging and stealing, until they were restrained by proper laws.

**COGITION, a term used by some for the act of thinking.**

**COGNAC, a town of France in Angoumois, with a castle, where Francis I. was born.** It is seated on the river Charante, in a very pleasant country, abounding in wine, and remarkable for excellent brandy. W. Long. c. 10. N. Lat. 45. 42.

**COGNATE, in Scots law, any male relation thro’ the mother.**

**COGNATION, in the civil law, a term for that cognation line of consanguinity which is between males and females, both descended from the same father; as agreed for the line of parentage between males only descended from the same flock.**

**COGNITIO, an ancient and strong town of Caramania in Turkey in Asia, and the residence of a beglerbeg.** It is seated in a pleasant country, abounding in corn, fruits, pulses, and cattle. Here are slippery trees that weigh 30 pounds. E. Long. 32. 36. N. Lat. 37. 56.

**COGNITIONIS CAUSA, in Scots law.** When a creditor charges the heir of his debtor to enter, in order to constitute the debt against him, and the heir renounces the succession, the creditor can obtain no decree of constitution of that debt against the heir, but only a decree subjoining the hardus pacis, or the effete which belonged to the debtor, to his diligence; and this is called a decree cognitionis causa.

**COGNIZANCE, or CONNOISANCE, in English law, has divers significations.** Sometimes it is an acknowledgment of a fine, or confession of something done; sometimes the hearing of a matter judicially, as to take cognizance of a cause; and sometimes a particular jurisdiction, as cognizance of pleas is an authority to call a cause or plea out of another court, which no person can do but the king, except he can show a charter for it. The cognizance is a privilege granted to a city or a town to hold plea of all contracts, &c. within the liberty; and if any one is impeached for such matters in the courts at Westminster, the mayor, &c. of such franchise may demand cognizance of the plea, and that it may be determined before them.

**COGNIZANCE is also used for a badge on a waterman’s or serving-man’s sleeve, which is commonly the giver’s crest, whereby he is distinguished to belong to this or that nobleman or gentleman.**

**COGS. See COGLE.**

**COHABITATION, denotes the state of a man and a woman who live together without being legally married.** By the common law of Scotland, cohabitation for year and day, or a complete twelve-month, is deemed equivalent to matrimony.

**CO-HEIR, one who possesses a share of an inheritance, to be divided among several.**

**COHESION, one of the four species of attraction, denoting that force by which the parts of bodies adhere or stick together.**

This power was first confidered by Sir Isaac New-

**1. Confidered as one of the properties essential to all matter, and by Sir Isaac Newton as an essential property of matter.**

**2. His account is as follows: It seems probable, that God in the ori-

**beginning formed matter in solid, malleable, impermeable, indivisible particles; of such sizes, figures, and other properties, and in such proportion to space, as most

**conduced to the end for which he formed them; and that these primitive particles being solid, are incomparably harder than any porous bodies composed of them; even so very hard as never to wear or break in pieces; no ordinary power being able to divide what God himself made one at the first creation. While the
the particles continue entire, they may compose bodies of one and the same nature and texture in all ages; but should they wear away, or break in pieces, the nature of all things depending on them would be changed. Water and earth composed of old worn particles and fragments of particles, would not now be of the same nature with water and earth composed of entire particles in the beginning. And therefore, that nature may be lasting, the changes of corporeal things are to be placed in the various separations and new associations and motions of these permanent particles; compound bodies being apt to break, not in the midst of solid particles, but where these particles are laid together, and touch in a few points." It seems farther, "That these particles have not only a vis inertia, accompanied with such passible laws of motion as naturally result from that force; but also that they are moved by certain active principles, such as that of gravity, and that with equal force and the cohesion of bodies. These principles are to be considered not as occult qualities, fitted to refute itself from the specific forms of things, but as general laws of nature by which the things themselves are formed: their truth appearing to us by phenomena, though their cause is not yet discovered."  

The general law of nature, by which all the different bodies in the universe are composed, according to Sir Isaac Newton, is that of attraction: i.e., "Every particle of matter has an active force, or a tendency to every other particle; which power is strongest in the point of contact, and suddenly decreases, incomprehensible, that acts no more at the least sensible distance; and at a greater distance is converted into a repellent force, whereby the parts fly from each other. On this principle of attraction may we account for the cohesion of bodies, otherwise inexplicable."

"The smallest particles may cohere by the strongest of particles, and attractions, and compose bigger particles of weaker virtue; and many of these may cohere, and compose bigger particles, whose virtue is still less; and so on for divers succeditions, until the progression end of the biggest particles, on which the operations in chemistry, and the colours of natural bodies, depend; and which, by cohering, compose bodies of a feasible magnitude."

If the body is compact, and bends or yields inward to pressure without any sliding of its parts, it is hard and elastic; returning to its figure with a force arising from the mutual attraction of its parts. If the parts slide from one another, the body is malleable or soft. If they slip easily, and are of a fit size to be agitated by heat, and the heat is great enough to keep them in agitation, the body is fluid; and if it be apt to stick to things, it is humid; and the drops of every fluid affect a round figure by the mutual attractions of their parts, as the globe of the earth and sea affect a round figure from the mutual attraction and gravity of its parts.

"Since metals dissolved in acids attract but a small quantity of the acid, their attractive force reaches but to small distances; but not so as in which where a

power provided.
Nor we observe it elementary fire. In support of this it hath been urged, that more than an hour before there is any visible action of the electric fluid; and so on any other hypothesis, should make the same observation. This scheme of the immateriality of matter, as it may be called, or rather the mutual penetration of matter, first occurred to Mr. Michell on reading Baxter on the immateriality of the soul. He found that this author's idea of matter was, that it consisted as it were of bricks cemented together with immaterial mortar. These bricks, if he would be consistent with his own reasoning, were again composed of Ley's bricks, cemented likewise by an immaterial mortar; and so on ad infinitum. This putting Mr. Michell upon the consideration of the several appearances of nature, he began to perceive that the bricks were so covered with this immaterial mortar, that if they had any existence at all, it could not possibly be perceived; every effect being produced, in nine instances of ten certainly, and probably in the tenth also, by this immaterial, spiritual, and penetrable mortar. Instead therefore of placing the world upon the giant, the giant upon the tortoise, and the tortoise upon he could not tell what, he placed the world at once upon itself.

Other philosophers have supposed the powers both of gravitation and cohesion to be material, and to be only a different action of the electrical fluid, or elementary fire. In support of this it hath been urged, that before we have recourse to a spiritual and immaterial power as the cause of any natural phenomenon, we ought to be well assured that there is no material substance with which we are acquainted, that is capable of producing such effects. In the present case, we are so far from having such assurance, that the contrary is manifest to our senses. One instance of this is in the experiment with the Magdeburg hemispheres, as they are called. These are two hollow hemispheres of brass, exactly fitted to one another, so as to form one globe when joined together, without admitting any air at the joining. In this state, if the air within is exhausted by means of a pump, they will cohere with each other, if they are five or six inches in diameter, as to require a weight of some hundreds of pounds to separate them. The pressure of the atmosphere, we see, is in this case capable of producing a very strong cohesion; and if there is in nature any fluid more penetrating, as well as more powerful in its effects, than the air we breathe, it is possible that what is called the attraction of cohesion may be found how or other to be an effect of the action of that fluid. Such a fluid as this is the element of fire. Its action is such as to penetrate all bodies whatever; and in the state in which it is commonly called fire, it acts according to the quantity of solid matter contained in the body. In this state, it is capable of dissolving the strongest coherences observed in nature: but whatever is capable of dissolving any cohesion, must necessarily be endowed with greater power than that by which the cohesion is caused. Fire, therefore, being able to dissolve coherences, must also be capable of causing them, provided its power is exerted for that purpose. Nor will it seem at all strange that this fluid should act in two such opposite ways, when we consider the different appearances which it produces. These are three, viz. fire or heat, in which it continues, destroys, and dissolves: light, in which it seems deprived of all defractive or dissolvent power, and to be the most mild, quiet, and placid being in nature. The third state of this element is, when it becomes what is called the electric fluid; and then it attracts, repels, and moves bodies in a vast variety of ways, without either burning or rendering them visible by its light. In this state it is not less powerful than in either of the other two; for a violent shock of electricity will displace and tear in pieces the most heavy and solid bodies. The seeming capricious nature of this fluid, however, probably renders it less suspected as the cause of cohesion, than it otherwise would be, were the attractions so far as it is manifest, which we observe it to occasion. But here we must observe, that the fluid has an existence in all bodies before the experiments are tried which make its effects visible to us, and was acting in them according to its settled and established laws. While acting in this manner it was perfectly invisible; and all we can do is, to produce some little infringement of these regular laws according to which it commonly acts. In some cases, however, the electrical attractions produced by art are found to be pretty permanent and strong. Thus, Mr. Symmer, in some experiments with silk flossings, found their attraction to be strong, that it required upwards of 15 pounds weight to separate them from each other; and this attraction would continue for more than an hour. In plates of glass, too, he observed a remarkable cohesion when electrified. In the Philosophical Transactions for 1777, we find this hypothesis taken notice of, and in some measure adopted, by Mr. Henry. "Some gentlemen (says he) have supposed that the electric matter is the cause of the cohesion of the particles of bodies. If the electric matter be, as I suspect, a real elementary fire inherent in all bodies, that opinion may probably be well founded; and perhaps the folding of metals, and the coagulation of iron, by fire, may be considered as strong proofs of the truth of their hypothesis.

On this last hypothesis we must observe, that if the electric, or any other fluid, is supposed to be the cause of the attraction of cohesion universally, the particles of that fluid must be definite of all cohesion between themselves; otherwise we should be at as great a loss to account for the cohesion of these particles, as for that of terrestrial matter. Philosophers, indeed, do not suppose any cohesion between the particles of the electric fluid themselves; it is generally believed that the particles of this fluid are repulsive of one another, though attracted by all other matter. If this is a fact, we cannot suppose the electric fluid to be the cause of cohesion. The probability or improbability of the hypothesis just mentioned must greatly depend on its being ascertained whether the particles of the electric fluid do really repel one another, and attract all other kinds of matter, or not; but for this we must refer to the article ELECTRICITY.

COHOBATION, in chemistry, an operation by
Cohom which the same liquor is frequently distilled from the same body, either with an intention to dissolve this body, or to produce some change upon it. This is one of those operations which the ancient chemists practiced with great patience and zeal, and which are now neglected. To make this operation easier, and to prevent the trouble of frequently changing the vessels, a particular kind of alembic, called a pelican, was invented. This vessel was made in the form of a cucurbit with an alembic-head, but had two spouts communicating with the body. As the vapour rose up into the head, it was gradually condensed, and ran down the spouts into the body of the pelican, from whence it was again distilled; and so on. This vessel is represented Plate CXXIV. fig. 6.

COHORN (N.) the greatest engineer Holland has produced. Among his other works, which are esteemed master-pieces of skill, he fortified Bergen-op-zoom; which, to the fairprize of all Europe, was taken by the French in 1747. He wrote a treatise on fortification; and died in 1704.

COHORT, in Roman antiquity, the name of part of the Roman legion, comprehending about 600 men. There were ten cohorts in a legion, the first of which exceeded all the rest both in dignity and number of men. When the army was ranged in order of battle, the first cohort took up the right of the first line; the rest followed in their natural order: so that the third was in the centre of the first line of the legion, and the fifth on the left; the second between the first and third; and the fourth between the third and fifth: the five remaining cohorts formed a second line in their natural order.

COIF, the badge of a sergeant at law, who is called sergeant of the coif, from the lawn coif they wear under their caps, when seated in the court. See Tonsure.

COILING, on shipboard, implies a sort of serpentine winding of a cable or other rope, that it may occupy a small space in the ship. Each of the windings of this sort is called a fake; and one range of fakes upon the same line is called a tier. There are generally from five to seven fakes in a tier; and three or four tiers in the whole length of a cable. This, however, depends on the extent of the fakes. The smaller ropes employed in the fakes are coiled upon cleats at sea, to prevent their being entangled among one another in traversing, contracting, or extending the fakes.

COILON, in the ancient Grecian theatres, the same with the caves of the Romans.

COIMBRA, a handsome, large, and celebrated town of Portugal, capital of the province of Beira, with a bishop's see, and a famous university. The cathedral and the fountains are very magnificent. It is seated in a very pleasant country adjoining in vineyards, olive-trees, and fruits. It stands on a mountain, by the side of the river Mondego. W. Long. 8. 57. N. Lat. 40. 10.

COIN, a piece of metal converted into money by the impressing of certain marks or figures thereon.

COIN differs from Money as the species from the genus. Money is any matter, whether metal, wood, leather, glafs, horn, paper, fruits, shells, or kernels, which have currency as a medium in Commerce. Coin is a particular species, always made of metal, and struck according to a certain process called Coining.

The precise epocha of the invention of money is too ancient for our annals; and, if we might argue from the necessity and obviousness of the thing, must be nearly coeval with the world.

Whether coins be of equal antiquity, may admit of some doubt; especially as most of the ancient writers are so frequent and express in their mention of leather-moneys, paper-moneys, wooden-moneys, &c. Some, however, notwithstanding this are of opinion, that the first moneys were of metal: the reasons they give, are the firmness, neatness, cleanliness, durability, and universality of metals; which, however, do rather conclude they ought to have been so, than that they actually were so.

In effect, the very commodities themselves were the first moneys, i.e. were current for one another by way of exchange; and it was the difficulty of cutting or dividing certain commodities, and the impossibility of doing it without great loss, that first put men on the expedient of a general medium. See Exchange.

Indeed, thus much may be paid in behalf of coins, that, on this view, it was natural for men to have their first recourse to metals; as being almost the only things whose goodness and as it were integrity, is not diminished by partition; besides the advantages above expressed, and the conveniences of melting and returning them into a mass of any size or weight.

It was probably, then, this property of metals which first accustomed people, who trafficked together, to account them in lieu of quantities of other merchandizes in their exchanges, and at length to substitute them wholly in their stead; and thus arose money: as it was their own property to prefer any mark or impression a long time, which confirmed them in the right; and thus was the first rife of coins.

In the first ages, each person cut his metal into pieces of different sizes and forms, according to the quantity to be given for any merchandise; or according to the demand of the seller, or the quantity fluxus between them. To this end, they went to market loaded with metal in proportion to the purchase to be made, and furnished with instruments for portioning it, and scales for dealing it out, according as occasion required. By degrees, it was found more commodious to have pieces ready weighed; and as there were different weights required according to the value of the different wares, all those of the same weight began to be distinguished with the same mark or figure: thus were coins carried one step further. At length the growing commerce of money beginning to be disturbed with frauds, both in the weights and the matter, the public authority interposed; and hence the first flamps or impressions of money; to which succeeded the names of the moniers; and at length the effigy of the prince, the date, legend, and other precautions to prevent the alterations of the species; and thus were coins completed.

Modern Coins. In England the current species of gold are the guinea, half-guinea, Jacobus, laureat, angel, and rofe-noble: the four last of which are now seldom to be met with; having been most of them con-
The silver coins are the crown, half-crown, shilling, and sixpence. Copper coins are the half-penny and farthing.

In Scotland, by the articles of the Union, it is appointed that all the coins be reduced to the English, and the same accounts observed throughout. Till then the Scots had their pounds, shillings, and pence, as in England; but their pound was but 20 pence English, and the others in proportion: accordingly, their mark was 13 1/2 Scots. Scots, current in England at 13 1/2 d. their noble in proportion. Besides they had their turner—pence and half-pence; their penny, of that of England: besides base money of achises, babees, and plucks. The bodle ½ of the penny, ½ of the achiton, ½ of the babee, and ½ of the pluck.

In Ireland, the coins are as in England, viz. shillings, pence, &c. with this difference, that their shilling is but equal to 11 ½ d. Sterling: whence their pound is only 18s. 5½ d.

But, for a view of all the coins presently current in the four quarters of the globe, with their values and proportions, see the table injoined to the article Money.

In many places the coins are current for coins; particularly a small white kind dug out of the ground in the Maldives, and some parts of America, called in the Indies couries, or coris, on the coast of Africa bonges, and in America porceâlains; which it takes a vast number to be equivalent in value to a penny. Of zim­bis, another kind of shell current, particularly in the kingdoms of Angola and Congo, two thousand make what the negroes call a macoute; which is no real money; for of this there is none in this part of Africa but a manner of reckoning: thus, two Flemish knives they esteem a macoute; a copper-bason two pounds weight, and 12 inches diameter, they reckon three macoutes; a fuzie 10, &c.

In some places fruits are current for coins. Of these there are three forts used: two in America, particularly among the Mexicans, which are the cacao and maize; the other in the East Indies, viz. almonds brought thither from Lar, and growing in the deserts of Arabia. Of cacao 15 are esteemed equivalent to a Spanish rial, or seven pence sterling. Maize has ceased to be a common money since the discovery of America by the Europeans. Almonds are chiefly used where the couries are not current. As the year proves more or less favourable to this fruit, the value of the money is higher or lower. In a common year 40 almonds are set against a cacoa, or half-penny sterling; which brings each almond to 1/24 of a farthing.

Ancient Coins are those chiefly which have been current among the Jews, Greeks, and Romans. Their values and proportions are as follows:

Note: Of these the drachma, didrachm, &c. were of silver, the rest for the most part of brass. The other parts, as tridrachm, triobolus, &c. were sometimes coined.

Note also: The drachma is here, with the generality of authors, supposed equal to the denarius; though there is reason to believe that the drachma was somewhat the weightier. See Drachma and Denarius.
Coin, or Coinage, the art of making money, as performed either by the hammer or mill.

Formerly the fabric of coins was different from what it is at present. They cut a large plate of metal into several little squares, the corners of which were cut off with sheers. After having shaped these pieces, so as to render them perfectly conformable, in point of weight, to the standard piece, they took each piece in hand again, to make it exactly round by a gentle hammering. This was called a planchet, and was fit for immediate coinage. Then engravers prepared, as they still do, a couple of freely-moved, or speakable, figures, in form of the figures, that are engraved on the faces of coins, and which afterwards obtained, whereby the aures were cut off with sheers. After having shaped these pieces, they took each one between the two dyes, brought near each other with one blow, forces the two surfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which serves to laminate lead, gives a sufficient notion of that which serves to flatten gold and silver laminæ between rollers of a lesser size.

The principal pieces of the machine (fig. 1.), to stamp coins on the edge, are two steel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thickens of one of the laminæ, and the other half on the thickness of the other; and these two laminæ are straight, although the planchet marked with them be circular.

When they stamp a planchet, they first put it between the two laminæ, as that the edge of the upper laminæ upon that of the lower, and the other moveable, the former ended in a square prism, that it might be introduced into the square hole of the block, which, being fixed very fast, kept the dye as steady as any vice could have done. The planchet of metal was horizontally laid upon this inferior mass, to receive the stamp of it on one side, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved surface resting upon the planchet, had at its opposite extremity a flat square, and larger surface, upon which they gave several heavy blows, with a hammer of an enormous size, till the double stamp was sufficiently, in relievo, impressed on each side of the planchet. This being finished, was immediately succeeded by another, and they thus became a standard coin, which had the degree of fineness of the weight and mark determined by the judgment of the inspectors, to make it good current money. The strong tempering which was and is still given to the two dyes, rendering them capable of bearing those repeated blows. Coining has been considerably improved and rendered expeditious, by several ingenious machines, and by a wise application of the fittest physical experiments to the methods of filing, dyeing, and stamping the different metals.

The three finest instruments the mint-man uses, are the laminating engine; the machine for making the impressions on the edges of coins; and the mill.

After they have taken the laminæ, or plates of metal, out of the mould in which they are cast, they do not beat them on the anvil, as was formerly done, but they make them pass and repass between the several rollers of the laminating engine, which being gradually brought closer and closer to each other, presently give the laminæ its uniform and exact thickness. Instead of dividing the laminæ into small squares, they cut them off quite entire, and then boiled and made clean, they arrive, at last, at the machine (fig. 1.), which marks them upon the edge; and finally, the mill (fig. 2.), which, squeezing each of them singly between the two dyes, brought near each other with one blow, forces the two surfaces or fields of the piece to fill exactly all the vacancies of the two figures engraved hollow. The engine which serves to laminate lead, gives a sufficient notion of that which serves to flatten gold and silver laminæ between rollers of a lesser size.

The principal pieces of the machine (fig. 1.), to stamp coins on the edge, are two steel laminæ, about a line thick. One half of the legend, or of the ring, is engraved on the thickness of one of the laminæ, and the other half on the thickness of the other; and these two laminæ are straight, although the planchet marked with them be circular.

When they stamp a planchet, they first put it between the two laminæ, as that the edge of the upper laminæ upon that of the lower, and the other moveable, the former ended in a square prism, that it might be introduced into the square hole of the block, which, being fixed very fast, kept the dye as steady as any vice could have done. The planchet of metal was horizontally laid upon this inferior mass, to receive the stamp of it on one side, and that of the upper dye, wherewith it was covered, on the other. This moveable dye, having its round engraved surface resting upon the planchet, had at its opposite extremity a flat square, and larger surface, upon which they gave several heavy blows, with a hammer of an enormous size, till the double stamp was sufficiently, in relievo, impressed on each side of the planchet. This being finished, was immediately succeeded by another, and they thus became a standard coin, which had the degree of fineness of the weight and mark determined by the judgment of the inspectors, to make it good current money. The strong tempering which was and is still given to the two dyes, rendering them capable of bearing those repeated blows. Coining has been considerably improved and rendered expeditious, by several ingenious machines, and by a wise application of the fittest physical experiments to the methods of filing, dyeing, and stamping the different metals.

The planchet thus stamped and coined, goes through a final examination of the mint wardens, from whose hands it goes into the world.

In the Coining of Medals, the process is the same, in effect, with that of money: the principal difference consisting in this, that money having but a small relief, receives its impression at a single stroke of the chisel; whereas for medals the height of their relief makes it necessary that the stroke be repeated several times: to this end the piece is taken out from between the dies, heated, and returned again; which process, in medallions and large medals, is repeated fifteen or twenty times before the full impression be given: care must be taken, every time the planchet is removed, to take off the superfluous metal flattered beyond the circumference with a file. Medallions, and medals of high relief, are usually first cast in sand, by reason of the difficulty of stamping them in the press, where they are put only to perfect them: in regard the sand does not leave them clear, smooth, and accurate enough. Therefore we may see that medals receive their form and impression by degrees, whereas money receives them all at once.

British Coineage, both by the beauty of the engraving, and by the invention of the impressions on the edges, that admirable expedient for preventing the alteration of the species, is carried to the utmost perfection.

It was only in the reign of king William III. that the hammer-money ceased to be current in England, where till then it was struck in that manner, as in other nations. Before the hammer species was called in, the English money was in a wretched condition, having been filed and clipped by natives as well as foreigners, in so much that it was scarce left of half the value: the retrieving this dittrefled state of the English money is looked upon as one of the glories of king William's reign.

The British coining is now wholly performed in the Tower of London, where there is a corporation for it under the title of the mint. Formerly there were here, as there are still in other countries, the rights of coining and brassing: but since the eighteenth year of king Charles II. there is nothing taken either for the coining or for the expenses of coining: so that weight is returned for weight to any person who carries their gold and silver to the Tower.

The species coined in Great Britain are esteemed contraband goods, and not to be exported. All foreign species are allowed to be sent out of the realm, as well as gold and silver in bars, ingots, dust, &c.

Barbary Coineage, particularly that of Fez and Tunis, is under no proper regulations as every goldsmith, Jew, or even private person, undertakes it at pleasure; which practice renders their money exceeding bad, and their commerce very unsafe.

Muscovite Coineage. In Muscovy there is no other coin struck but silver, and that only in the cities of Muscov, Novagrod, Twere, and Plekow, to which may be added Peterburgh. The coinage of each of these cities is let out to farm, and makes part of the royal revenue.

Perfan Coineage. All the money made in Persia is struck with a hammer, as is that of the rest of Asia; and the same may be underfoot of America, and the coast of Africa, and even Muscovy: the king's duty, in Persia, is seven and a half per cent, for all the money coined, which are lately reduced to silver and copper, there being no gold coin there except a kind of medals, at the accidence of a new fopli.

Spanish Coineage is esteemed one of the best perfect in Europe. It is settled at Seville and Segovia, the only cities where gold and silver are struck.

COIR, or, as the Germans call it, CHUR, a large and handsome town of Switzerland, and capital of the country of the Grisons, with a bishop's see, whose prelate has the right of coining money. It is divided into two parts; the left of which is of the Roman Catholic religion, and the greatest of the Protestant. It is governed by its own laws, and leated in a plain, abounding in vineyards and game, on the river Pfeu­fare, half a mile from the Rhine E. Long. 9. 27 N. Lat. 46. 50.

COITION, the intercourse between male and female in the act of generation.

It is observed that frogs are forty days in the act of coition. Bartholin, &c. relate, that butterflies make 150 vibrations of the wings in one act of coition.

COIX,JOBS' TEARS: A genus of the triandria order, belonging to the monoeia clafs of plants; and in the natural method ranking under the 4th order, Gramine. The male flowers grow in spikes remote from one another; the calyx is a biforous, beardlefs glume. The calyx of the female is a biforous glume; the corolla a beardlefs glume; the style bipartite; the seed covered with the calyx oifified. Of this there is but one species, a native of the Archipelago islands, and frequently cultivated in Spain and Portugal, and also in the West Indies. It is an annual plant, rising from a fibrous root, with two or three jointed flanks, to the height of two feet, with fingle, long, narrow leaves at each joint, reftembling thofe of the reed; at the base of the leaves come out the spikes of flowers flanding on short foot-flanks; the seeds greatly resembfe thofe of gromwell; whilfe the plant has by fome writers been called lithofpermum. This plant may be propagated in Britain by seeds brought from Portugal, and sown on a hot-bed; after which the young plants are to be removed into a warm border, and planted at the distance of two feet at leaft from each other. They need require no other care than to be kept free from weeds. In Spain and Portugal the poor people gather the seeds of this plant, in times of scarcity, and make a coarse kind of bread of them. The seeds are inclofed in small capsulfs about the bignefs of an English pea, and of different colours. These are frung upon filk, and ufed instead of bracelets by fome of the poorer folk in the West Indies, but especially by the negroes.

COKE, or COKE (Sir Edward), lord chief justice of the king's bench in the reign of James I. was descended from an ancient family in Norfolk, and born at Milham in 1549. When he was a student in the Inner-Temple, the first occasion of his distinguishing himself was the stating the cafe of a cook belonging to the Temple to exactly, that all the house, who were puzzled with it, admired him and his pleading, and the whole bench took notice of him. After his marriage with a lady of great fortune, preferments flowed in upon him. The cities of Norfolk and Coventry chose him for their recorder; the county of Norfolk, for

COLE. one of their knights in parliament; and the house of commons, for their speaker, in the 35th year of queen Elizabeth. The queen appointed him solicitor-general in 1592, and attorney-general the next year. In 1603, he was knighted by king James I.; and in November the same year, upon the trial of Sir Walter Raleigh, &c. at Winchelsea, he treated that gentleman with a feverity of language hardly to be paralleled. June 27, he was appointed lord chief justice of the common pleas; and in 1613, lord chief justice of the king's bench, and sworn one of the privy council. In 1615, he was very vigorous in the discovery and prosecution of the persons employed in poifoning Sir Thomas Overbury in the Tower in 1612. His content not long after with the lord chancellor Egerton, with some other cafes, haifened the ruin of his interest at court: so that he was sequestered from the council-table and the office of lord chief justice. In 1621, he vigorously maintained in the house of commons, that no proclamation is of any force against the parliament. The same year, being looked upon as one of the great incendiaries in the house of commons, he was removed from the council of state with disgrace; the king saying, that “he was the fittest instrument for a tyrant that ever was in England”: he was also committed to the Tower, and his papers were feized. Upon the calling of a new parliament in 1625, the court-party, to prevent his being elected a member, got him appointed sheriff of Buckinghamshire; to avoid the office, if possible, he drew up exceptions against the oath of a sheriff, but was obliged to undertake the office. In 1629, he spoke vigorously upon grievances; and made a speech in which he affirmed, that “the duke of Buckingham was the cause of all our miseries.” While he lay upon his deathbed, his papers and laft will were feized by an order of council. He died in 1634, and published many works: the most remarkable are his Institutes of the laws of England; the first part of which is only a translation and comment of Sir Thomas Littleton, one of the chief justices of the common pleas in the reign of Edward IV.

COLAPIS, Coloms (anc. geog.), a river of Lemburnia, which after a winding north-east course, falls into the Savus, at the Influa Segelica. Now the Cuip, the boundary of the Alps, running through Croatia into the Save. Colopiani, the people living on it (Pliny).

COLARASIS, or Colobrasians, a set of Christians in the second century; so called from their leader Colarus, a disciple of Valentine; who, with Marcus, another disciple of the same master, maintained the whole plentitude, and perfection, of truth and religion, to be contained in the Greek alphabet; and thought upon this account that Jesus Christ was called the alpha et omega. This sect was a branch of the Valentinians. See also Marcobrians.

COLBERG, a strong, handsome sea-port town of Germany, in Pomerania, belonging to the king of Prussia. It is remarkable for its salt works; and is feated at the mouth of the river Persant, on the Baltic sea, 60 miles north-east of Sestin, and 30 north-east of Camin. E. Long. 15. 57. N. Lat. 54. 18.

COLBERT (John Baptiste), marquis of Segnelay, one of the greatest statesmen that France ever had, was born at Paris in 1619; and descended from a family that lived at Rheims in Champagne, no way considerable for its splendor and antiquity. His grandfather is said to have been a wine-merchant, and his father at first followed the same occupation; but afterwards traded in cloth, and at last in silk. Our Colbert was instructed in the arts of merchandize; and afterwards became clerk to a notary. In 1648, his relation John Baptist Colbert, lord of S. Pouange, preferred him to the service of Michael Le Tellier, secretary of state, whose father he had married; and here he discovered such diligence, and exactness in executing all the commissions that were entrusted to his care, that he quickly grew distinguished. One day his master sent him to cardinal Mazarine, who was then at Sedan, with a letter written by the queen mother; and ordered him to bring it back, after that minister had seen it. Colbert carried the letter, and would not return without it, though the cardinal treated him roughly, used several arts to deceive him, and obliged him to wait for it several days. Some time after, the cardinal returning to court, and wanting one to write his agenda or memoranda, desired Le Tellier to furnish him with a person fit for that employment: and Colbert being preferred to him, the cardinal had some remembrance of him, and desired to know where he had seen him. Colbert was afraid of putting him in mind of Sedan, left the remembrance of his impompancy, in demanding the queen's letter, should renew the cardinal's anger. But his eminency was so far from hating him for his faithfulness to his late master, that he received him on condition, that he should serve him with the like zeal and fidelity.

COLBERT applied himself wholly to the advancement of his master's interests, and gave him so many marks of his diligence and skill, that afterwards he made him his intendant. He accommodated himself so dexterously to the inclinations of that minister, by retrenching his superfluous expenses, that he was entrusted with the management of that gainful trade of selling benefices and governments. It was by Colbert's counsel, that the cardinal obliged the governors of frontier places to maintain their garrisons with the contributions they exacted; with which advice his eminency was extremely pleased. He was sent to Rome, to negotiate the reconciliation of cardinal de Rets, for which the Pope had showed some concern; and to persuade his holiness to confer to the ducamatering of Caffo, according to the treaty concluded with his predecessor Urban VIII. Upon the whole, Mazarine had so high an opinion of Colbert's abilities, and withal such a regard for his faithful services, that at his death, which happened in 1661, he earnestly recommended him to Louis XIV. as the proper person to regulate the finances, which at that time were in much need of reformation. Louis accepted the recommendation, and made Colbert intendant of the finances. He applied himself to their regulation, and succeeded: though it procured him many enemies, and some affronts. France is also obliged.
Colbert, obliged to this minister for establishing at that time her trade with the East and West Indies, a great design, and from which she has reaped innumerable advantages.

In 1664, he became superintendent of the buildings; and for that time applied himself so earnestly to the enlarging and adorning of the royal edifices, that they are at present so many master-pieces of architecture: witness the palace of the Tuileries, the Louvre, St Germain, Fontainebleau, and Chambord. As for Verailles, it may be said that he raised it from the ground. It was formerly a dog-kennel, where Louis XIII. kept his hunting furniture: it is now a palace fit for the greatest monarch. But royal palaces were not Colbert's only care: he formed several designs for increasing the beauty and convenience of the capital city, and he did it with great magnificence and grandeur.

The public was obliged to this same minister for the establishment of the academy for painting and sculpture in 1664. The king's painters and sculptors, with other skilful professors of those arts, being prosecuted at law by the master-Painters at Paris, joined together and began to form a society, under the name of the Royal Academy for Sculpture and Painting. Their design was to keep public exercises, for the sake of improving those fine arts, and advancing them to the highest degree of perfection. They put themselves under the protection of Mazarine, and chose Seguier their vice-protector, and after Mazarine's death, choose Seguier their protector, and Colbert their vice-protector. It was at his solicitation that they were finally established by a patent, containing new privileges, in 1664. Colbert, being made protector after the death Seguier, thought it an historian should be appointed, whose business it should be to collect all curious and useful observations that should be made at their conferences. This was accordingly done; and his majesty was pleased to settle on him a salary of 200 livres. To Colbert also the lovers of naval knowledge are obliged for the erection of the Academy of Sciences: for the making of which the more useful, he caused to be erected, in 1667, the royal observatory at Paris, which was first inhabited by Caffini. But these are not the only obligations France has to that minister: he owes to him all the advantages she receives by the union of the two seas; a prodigious work, begun in 1666 and finished in 1680. Colbert was also very intent upon matters of a more private nature, such as regarded the order, decency, and well-being of society. He undertook to reform the courts of justice, and to put a stop to the usurpation of noble titles, which it seemed was then very common in France. In the former of those attempts he failed, in the latter he succeeded.

In 1669, he was made secretary of state, and entrusted with the management of affairs relating to the sea; and his performances in this province were answerable to the confidence his majesty reposed in him. He suppressed several offices, which were chargeable, but useless: and in the mean time perceiving the king's zeal for the extirpation of heresy, he shut up the chamber instituted by the edicts of Paris and Roan. He proposed severally new regulations concerning criminal courts; and was extremely severe with the parliament of Tholouf for obstructing the measures he took to carry the same execution. His main design in reforming the tedious methods of proceeding at law, was to give the people more leisure to apply themselves to trading; for the advancement of which he procured an edict, to erect a general insurance-office at Paris, for merchants, &c. In 1672, he was made minister of state: for how busied ever he was in the regulation of public affairs, yet he never neglected his own or his family's interest and grandeur, or missed any opportunity of advancing either. He had been married many years, had sons and daughters grown up; all of whom, as occasion served, he took care to marry to great persons. For though he had no reason to doubt of his master's favour, yet he wisely secured his fortune by powerful alliances. However, business was certainly Colbert's natural turn; and he not only loved it, but was very impatient to be interrupted in it, as the following anecdote may serve to show. A lady of great quality was one day urging him, when he was in the height of his power, to do her some piece of service: and perceiving him inattentive and inflexible, threw herself at his feet, in the presence of above 100 persons, crying, "I beg your greatnees, in the name of God, to grant me this favour." Upon which Colbert, kneeling down over against her, replied, in the same mournful tone, "I conjure you, madam, in the name of God, not to disturb me."

This great minister died of the stone, September 6, 1683, in his 65th year: leaving behind him six sons and three daughters. He was of a middle stature, rather lean than fat. His mien, was low and dejected, his air gloomy, and his aspect stern. He slept little, and was very sober. Though naturally severe and moody, he knew how to act the lover, and had mistresses. He was of a slow conception, but spoke judiciously of every thing after he had once comprehended it. He understood business perfectly well, and he pursued it with unwearied application. Thus he filled the most important places with high reputation and credit; and his influence diffused itself through every part of the government. He restored the finances, the navy, the commerce: and he erected those various works of art, which have ever since been monuments of his taste and magnificence. He was a lover of learning, though he never applied to it himself; and therefore conferred donations and pensions upon scholars in other countries, while he established and protected academies in his own. He invited into France painters, statuary, mathematicians, and artists of all kinds, who were any way eminent: thus giving new life to the sciences, and making them flourish, as they did exceedingly. Upon the whole, he was a wise, active, generous, spirited minister; ever attentive to the interests of his master, the happiness of the people, the progress of arts and manufactures, and his desire to do every thing that could advance the credit and interest of his country. He was a pattern for all ministers of state; and every nation may with themselves be pleased with a Colbert.

COLCHESTER, the capital of the county of Essex in England. It is by some thought to be the place mentioned by Antoninus under the name of Colonia, different from Colonla Camboduni, and by the Saxons called Caer Colun. It is a beautiful, populous, and pleasant town, extended on the brow of a hill from eal
Colchis, Colchicum

east to west, and adorned with 10 churches. It had formerly strong walls and a castle, but now there are scarce any remains of either. This place is said to have given birth to Fl. Julia Helen, mother to Constantine the Great, and daughter to king Coeus, to much celebrated for her piety and zeal and propagating the Christian religion. Here, and in the neighbouring towns, is a great manufacture of bays and fays. It is also famous for its oysters; in pickling and barrelling which, the inhabitants excel. The rendering navigable the river Coln, on which the town stands, has greatly promoted its trade and manufactures. The town had formerly an abbey whose abbots was mitred and fat in parliament. In the time of the civil wars it was besieged by the parliament's troops and reduced by famine. It was formerly a corporation, but lately lost its charter for some misdemeanour; however, it still sends two members to parliament. E. Long. 1. 2. N. Lat. 35° 55'.

COLOCHI (Arrian, Ptolemy), a town of the Hither India; thought to be Cochin, on the coast of Malabar; now a factory and strong fort of the Dutch. E. Long. 75° o. N. Lat. 10° o.

COLCHICUM, MEADOW-SAFFRON: A genus of the trigynia order, belonging to the alexandria class of plants; and in the natural method ranking under the ninth order, Spathacetae. The corolla is sexpartite, with its tube radicated, or having its root in the ground; there are three capsules, connected and inflated. There are three species, all of them bulbous-rooted, low, perennials, posessing the singular property of their leaves appearing at one time, and their flowers at another; the former rising long and narrow from the root in the spring, and decaying in June; the flowers, which are monopetalous, long, tubular, erect, and six-parted, rise naked from the root in autumn, not more than four or five inches high. Their colours afford a beautiful variety; being purple, variegated purple, white, red, rofe-coloured, yellow, &c. with simple and double flowers. They are all hardy plants, infomuch that they will flower though the roots happen to lie out of the ground; but by this they are much weakened. They are propagated by offsets from the roots, of which they are very prolific. There are to be taken up and divided at the decay of the leaf in the summer, planting the whole again before the middle of August. They are to be placed at nine inches distance from one another, and three inches deep in the ground.

The root of this plant is poisonous. When young and full of sap, its taste is very acrid; but when old, mealy and faint. Two drachms of it killed a large dog in 2 hours, operating violently by foool, vomit, and urine. One grain of it swallowed by a healthy man, produced heats in the stomac, and soon after flushing heats in different parts of the body, with frequent shiverings, followed by colicky pains; after which an itching in the loins and urinary passages was perceived; then came on a continual inclination to make water several times in the day, quick pulse, thirst, and other disagreeable symptoms. Notwithstanding these effects, however, an infusion of the roots in vinegar, formed into a syrup with honey or sugar, proves a safe and powerful pectoral and diuretic, and is often of service in dropsies, &c. The virtues of colchicum seem much to resemble those of ignilis. The hermodacyl of the shops is said to be the root of the variegatum, a species of this genus.

COLCHIS, a country of Asia, at the south of Asia Minor, north of Armenia, and west of Iberia. It is famous for the expedition of the Argonauts, and as the birth-place of Medea. It was fruitful in poisonous herbs, and produced excellent flax. The inhabitants were originally Egyptians, who settled there when Scrofis king of Egypt extended his conquests in the north.

COLOCTHAR, the substance remaining after the distillation or calcination of martial virtil by a violent fire. See CHEMISTRY, N° 621.

COLD, in a relative sense, signifies the sensation which accompanies a transition of the fine vessel of the human body from an expanded to a more contracted state. In an absolute sense, it signifies the cause of this transition; or, in general, the cause of the contraction of every substance, whether solid or fluid, in nature.

The arguments concerning the substance of cold in Cold tend the abstract, are discussed under the article CHEMISTRY, to which we must at present refer the reader. In that article it is observed, that cold naturally tends to make bodies electric which are not so naturally, and to increase the electric properties of those which are; and in confirmation of the hypothesis there advanced, it may be observed, that all bodies do not transmit cold equally well; but that the best conductors of electricity, viz. metals, are likewise the best conductors of cold. We may also add, that when the cold has been carried to such an extent as to render any body an electric body, it then ceases to conduct the cold as well as formerly. This is exemplified in the practice of the Laplanders and Siberians, where the cold in winter is extremely severe. In order to exclude it from their habitations the more effectually, they cut pieces of ice, which in the winter time were always electric in these countries, and put them into their windows; which they find to be much more effectual in keeping out the cold than any other substance.

Cold as well as heat, may be produced artificially, Why cold though we have no method of making cold increase itself as heat will do. The reason of this easily appears from what is said on the subject of cold under the article CHEMISTRY: for if this consists in a partial cessation of motion in the elementary fluid, it is plain, that where we may partly put an end to this motion in a very small part of it; yet that of the surrounding atmosphere extending for an immense way farther than we can extend our influence, will quickly counteract our operations, and reduce the bodies to the same temperature they were of before. Though there are therefore some liquids, which by mixture will produce considerable degrees of cold; yet being left to the action of the surrounding warm atmosphere, the heat is quickly communicated from it to them, and the effect is lost in the mixture cools. The case is very different with heat; for this fluid, of itself naturally very much inclined to motion, no sooner finds an opportunity of exerting its action, than vast quantities of what was formerly at rest rush from all quarters to the place

where
The bodies of the feline class. In a paper of the Philosophical Transactions, Mr. Geoffroy gives an account of some remarkable experiments with regard to the production of cold. Four ounces of sal ammoniac dissolved in a pint of water, made his thermometer descend two inches and three quarters in less than fifteen minutes. An ounce of the same salt put into four or five ounces of distilled water, made the thermometer descend two inches and a quarter. Half an ounce of sal ammoniac mixed with three ounces of spirit of niter, made the thermometer descend two inches and five lines; but on using spirit of vitriol instead of niter, it sunk two lines and six lines. In this last experiment it was remarked, that the vapours raised from the mixture had a considerable degree of heat, though the liquid itself was so extremely cold. Four ounces of saltpetre mixed with a pint of water, sunk the thermometer one inch three lines; but a like quantity of sea-falt sunk it only two lines. Acids always produced heat, even common salt with its own spirit. Volatile alkaline salts produced cold in proportion to their purity, but fixed alkalies heat.

The greatest degree of cold produced by the mixture of salts and aqueous fluids was that shown by M. Homberg; who gives the following receipt for making the experiment: “Take a pound of corrosive sublimate, and as much sal ammoniac; powder them separately, and mix the powders very exactly; put the mixture into a vial, pouring upon it a pint and a half of distilled vinegar, shaking all well together.” This composition grows so cold, that a man can scarce hold it in his hands in summer; and it happened, as M. Homberg was making the experiment, that the subject froze. The same thing once happened to M. Geoffroy in making an experiment with sal ammoniac and water, but it never was in his power to make it succeed a second time.

If, instead of making these experiments, however, with fluid water, we take it in its congealed state of ice, or rather snow, degrees of cold will be produced vastly superior to any we have yet mentioned. A mixture of snow and common salt sinks Fahrenheit’s thermometer to 0; potash and powdered ice sink it eight degrees farther; two affusions of spirit of salt on pounded ice sink it below 14° below 0; but by repeated affusions of spirit of niter Mr. Homberg sank it to 40° below 0. This is the ultimate degree of cold which the mercurial thermometer will measure: because the mercury itself begins then to congeal; and therefore we must afterwards have recourse to spirit of wine, naphtha, or some other fluid which will not congeal. The greatest degree of cold hitherto producible by artificial means has been 80° below 0; which was done at Hudson’s Bay by means of snow and vitriolic acid, the thermometer standing naturally at 20° below 0. Greater degrees of cold than this have indeed been supposed. Mr. Martin, in his Treatise on Heat, relates, that at Kirenga in Siberia, the mercurial thermometer sunk to 110° below 0; and Professor Brown at Petersburg, when he made the first experiment of congealing quicksilver, fixed the point of congelation at 350° below 0; but Dr. Black, as soon as the experiment was made known in Britain, observed, that in all probability the point of congelation was far above this. His reasons for supposing this to be the case were, that the mercury descended regularly only to a certain point, after which it would descend suddenly and by starks 100 degrees at a time, this, he conjectured, might proceed from the irregular contraction of the metal after it was congealed; and he observed, that there was one thermometer employed in the experiment which was not frozen, and which did not descend so low by a great many degrees. Experience has since verified his conjecture; and it is now generally known, that 40° below 0 is the freezing point of quicksilver.

Since the discovery of the possibility of producing cold by artificial means, various experiments have been made on the efficacy of feline substances in this way; all of which, when properly applied, are found to have a considerable degree of power. Dr. Boerhaave found, that both sal ammoniac and niter, when well dried in a crucible, and reduced to fine powder, will produce a greater degree of cold than if they had not been treated in this manner. His experiments were repeated by Mr. Walker apothecary to the Redcliffe Infirmary in Oxford with the same result: but he found, that his thermometer sunk 32° by means of a solution of sal ammoniac; when Boerhaave’s, with the same, fell only 28°. Niter sunk it 19°. On mixing the two salts together, he found that the power of producing cold was considerably increased. By equal parts of these salts, he cooled some water to 22°, the thermometer standing at 47° in the open air. Adding to this some powder of the same kind, and immersing two small phials in the mixture, one containing boiled and the other unboiled water, he soon found them both frozen, the unboiled freezing first.

Having observed that Glauber’s salt, when it retains the water of crystallization, produces cold during its solution, he tried its power when mixed with the other salts, and thus sunk the thermometer from 65° to 19°; and he was able to freeze water when the thermometer stood as high as 70°. And, lastly, by first cooling the salts in water in one mixture, and then making another of the cooled thermometers, he was able to sink the thermometer 64°. Thus he froze a mixture of spirit of wine and water in the proportion of seven of the latter to one of the former; and by adding a quantity of cooled materials to the mixture in which this water was frozen, the thermometer sunk to -4, or 69°. Spirit of niter diluted with water reduced the thermometer to -3; and thus, by the addition of sal ammoniac, to -15. Nitrous ammoniac reduced it from 50° to 15°; but the cold was not augmented by the addition of sal ammoniac or niter.

The most remarkable experiment, however, was this: Mr. Walker put some of the spirit of niter poured on Glauber’s salt, the effect of freezing the salt of which was found to be similar to that of the quicksilver. Some spirit poured on ice or snow; and the addition of sal ammoniac increased the cold still more intense. The proportions of these ingredients recommended by Mr. Walker are concentrated nitrous acid two parts by weight, water one part; of this mixture cooled to the temperature of the atmosphere 18 ounces, of Glauber’s salt 2 pounds and an half avoirdupois, and of sal ammoniac 12 ounces. On adding the Glauber’s salt to the
the nitrous acid, the thermometer fell from 30° to 1°, or 29 degrees; and on the addition of the sal ammoniac, to — 8°. Thus Mr Walker was able to freeze quicksilver without either ice or snow, when the thermometer stood at 45°. For the experiments we procured of different fixes, that one might be put within the other. The largest of these pans was placed in a vessel still larger, in which the materials for the second frigoric mixture were thinly spread in order to be cooled; the second pan, containing the liquor, went, the vitriolic acid properly diluted, was placed in the largest pan; the third pan, containing the froth for the third mixture, was immersed in the liquor of the second pan; and the liquor for the third mixture was put into wide-mouthed phials, which were immersed in the second pan likewise, and floated round the third pan; the fourth pan, which was the smallest of all, containing its cooling materials, was placed in the midst of the salts of the third pan. The materials for the first and second mixtures consisted of dilute vitriolic acid and Glauber's salt; the third and fourth of dilute nitrous acid, Glauber's salt, and sal ammoniac, in the proportions above mentioned. The pans being adjusted in the manner already mentioned, the materials of the first and largest pan were mixed: this reduced the thermometer to 10°, and cooled the liquor in the second pan to 20°; and the froth for the second mixture, which were placed underneath in the large vessel, nearly as much. The second mixture was then made with the materials thus cooled, and the thermometer was reduced to 3°. The ingredients of the second mixture, by immersion in this, were cooled to 10°; and, when mixed, reduced the thermometer to — 15°. The materials for the fourth mixture were cooled by immersion in this mixture to about — 12°. On mixture they sunk the mercury very rapidly, and seemingly below — 40°, though the froth occasioned by the ebullition of the materials prevented any accurate observation. The reason why this last mixture reduced the thermometer more than the third, though both were of the same materials, and the latter of a lower temperature, was supposed to have proceeded from the circumstance, that the fourth pan had not another immersed in it to give it heat, and partly because the materials were reduced to a finer powder.

The experiments were repeated with many variations; but only one mixture appeared to Dr Beddoes, by whom the account was communicated to the Royal Society, to be applicable to any useful purpose. This is oil of vitriol diluted with about an equal quantity of water; which, by diffusing Glauber's salt, produces about 46° of cold, and by the addition of sal ammoniac becomes more intense by a few degrees. At one time, when Mr Walker was trying a mixture of two parts of oil of vitriol and one of water, he perceived, that at the temperature of 24° the mixture coagulated as if frozen, and the thermometer became stationary; but on adding more Glauber's salt, it fell again in a short time: but less cold was produced than when this circumstance did not occur, and when the acid was weaker. The same appearance of coagulation took place with other proportions of acid and water, and with other temperatures.

It is observable, that this effect of Glauber's salt in producing cold took place only when it was posessed of its water of crystallization; and thus the mineral alkali also augmented the cold of some of the mixtures: but when the water of crystallization was diffipated, neither of them had any effect of this kind. "This circumstance (says Dr Beddoes) leads us in some measure to the theory of the phenomenon. Water undoubtedly exists in a solid state in crystals; it must therefore, as in other cases, absorb a determinate quantity of fire before it can return to its liquid state. On this depends the difference between Glauber's salt and mineral alkali in its different states of crystallization and efflorescence. The same circumstance, too, enables us to understand the great effect of Glauber's salt, which, as far as I understand, has the greatest quantity of water of crystallization." On this the reviewers remark, that "if in summer the water brought from a deep well is at 54°, in this cheap and easy way it might be reduced to 10°; and wine placed in it would be chilled."

These excessive degrees of cold occur naturally in many parts of the globe in the winter-time. It is true, the inhabitants of temperate climates are little acquainted with them: yet in the winter of 1780, Mr Wilton of Glasgow observed, that a thermometer laid on the snow sunk to 25° below o; but this was only for a short time; and in general the atmosphere there does not admit of very great degrees of cold for any length of time. Dr Derham, however, in the year 1708, observed in England, that the mercury stood within one-tenth of an inch of its station when plunged into a mixture of snow and salt. In 1732, the thermometer at Petersburg stood at 28° below o; and in 1737, when the French academicians wintered at the north polar circle, or near it, the thermometer sunk to 33° below o; and in the Asiatic and American continents, still greater degrees of cold are very common.

The effects of these extreme degrees of cold are very surprising. Trees are burst, rocks rent, and rivers and lakes frozen, several feet deep; metallic substances blister the skin like red-hot iron: the air, when drawn in by respiration, hurts the lungs, and excites cough: even the effects of a great measure seem to cease; and it is observed, that those who are kept for a considerable time before a strong fire, will still freeze water when thrown upon them. When the French mathematicians wintered at Tornes in Lapland, the external air, when suddenly admitted into their rooms, converted the moisture of the air into whirls of snow; their breaths seemed to be rent when they breathed it, and the contact of it was intolerable to their bodies; and the spirit of wine, which had not been highly rectified, burst some of their thermometers by the congelation of the aqueous part.

Extreme cold very often proves fatal to animals in the countries where the winters are very severe; and thus 7500 Swedes perished at once in attempting to pass the mountains which divide Norway from Sweden. It is not necessary, indeed, that the cold, in order to prove fatal to the human life, should be so very intense as has been just mentioned. There is only requisite a degree somewhat below 32° of Fahrenheit, accompanied with snow or hail, from which shelter cannot be obtained. The snow which falls upon the clothes, or the uncovered parts of the body, then melts, and by a continual evaporation carries off the animal heat to such
such a degree, that a sufficient quantity is not left for the support of life. In such cases, the person first feels himself extremely chill and uneasy; he begins to turn little gloomy, walking orifices to keep himself warm; and at last turns slowly, sits down to refresh himself with sleep, but wakes no more. An instance of this was seen many years ago at Terra del Fuego, where Dr. Solander, with some others, having taken an excursion up the country, the cold was so intense, that one of their number died. The Doctor himself, though he had warned his companions of the danger of sleeping in that situation, yet could not be prevented from making that dangerous experiment himself; and though he was awakened with all possible expedition, his body was so much shrunk in bulk, that his shoes fell off his feet, and it was with the utmost difficulty that he was recovered.

In those parts of the world where vast masses of ice are produced, the accumulation of it, by absorbing the heat of the atmosphere, occasions an absolute sterility in the adjacent countries, as is particularly the case with the island of Iceland; where the vast collections of ice floating out from the Northern Ocean, and stop on the coast, are sometimes several years in thawing. Indeed, where great quantities of ice are collected, it would seem to have a power like fire, both augmenting its own cold and that of the adjacent bodies. An instance of this is related under the article Evaporation, in Mr. Wedgewood's experiment, where the true cause of this phenomenon is also pointed out.

COLD, in medicine. See Medicine-Index.

COLD, in farriery. See there, § 3.

COLDENIA, in botany: A genius of the tetragony order, belonging to the teradaeria class of plants; and in the natural method ranked among those of the order of which is dombrif. The calyx is tetraphyllous; the corolla funnel-shaped; the styles four; the seeds two and biloaral. There is but one species, native of India. It is an annual plant, whose branches trail on the ground, extending about six inches from the root. They are adorned with small blue flowers growing in clusters, which come out from the wings of the leaves. They are propagated by seeds sown on a hot-bed; when the plants come up, they may be removed each into a separate pot, and plunged into a hot-bed of tanner's bark, where they are to remain conffantly.

COLDINGHAM, supposed to be the Colonia of Polemy, and called by Bede the city Coldana and of Colud (Coldum), situated on the borders of Scotland, about two miles from Eymouth, was a place famous many ages ago for its convenant. This was the oldest nunnery in Scotland, for here the virgin-wife Etheldreda took the veil in 670; but by the ancient name Coludum it should seem that it had been before inhabited by the religiously called Coldeess. In 870 it was destroyed by the Danes, but its name rendered immortal by the heroism of its nuns; who, to preserve themselves involatlive from those invaders, cut off their lips and noses; and thus rendering themselves objects of horror, were, with their abbe Bbba, burnt in the monastery by the disappointed savages. After this it lay deserted till the year 1098, when king Edgar founded on its site a priory of the canons in honour of St. Camber, and bequeathed it on the monks of Durham.

Mr. Pennant's description of the black, joylees,

COLIURE, a small, but ancient and strong town of France, in Rouillon, seated at the foot of the Pyrenean mountains, with a small harbour. E. Long. 3. 10. N. Lat. 43. 24.

COLIR, an officer in China, who may properly be called an inspector, having an eye over what passes in every court or tribunal of the empire. In order to render him impartial, he is kept independent, by having his post for life. The power of the collars is such, that they make even the princes of the blood tremble.

COLISEUM, or COLISIUM, in the ancient architectural, an oval amphithatre, built at Rome by Vespasian, in the place where stood the bason of Nero's gilded house. The word is formed from colossum, on account of the colossal of Nero that stood near it; or, according to Nardini, from the Italian colosso. In this were placed statues, representing all the provinces of the empire; in the middle whereof stood that of Rome, holding a golden apple in her hand. The same term, colosseum, is also given to another amphithatre of the emperor Severus. In thebes colosse were represented games, and combats of men and wild beasts; but there are now little remaining of either of them, time and war having reduced them to ruins.

COLITES, in natural history, a name given by some writers to a kind of pebble, found in the shape of the human penis and testes, and that either separately or both together.

COLLAERT (Adrian), an eminent engraver who flourished about 1530, was born at Antwerp. After having learned in his own country the first principles of engraving, he went to Italy, where he resided some time in Rome, where he resided some time; and was also an excellent artificer. He drew and engraved works, exclusively or both together.

In 1555 of engraving, he went to Italy, where he resided some time; and was also an excellent artificer. He drew and engraved works, exclusively or both together.

COLLAERT (Hans or John), son to the foregoing, was also an excellent artist. He drew and engraved exactly in the style of his father; and was in every respect equal to him in merit. He must have been very old when he died; for his prints are dated from 1555 to 1622. He assisted his father in all his great works, and engraved besides a prodigious number of plates of various subjects. One of his best prints is Majesty striking the rock, a large print, lengthwise, from Lambert Lombard. A great number of small figures are introduced into this print; and they are admirably well executed: the heads are fine, and the drawing very correct.

COLLAR, in Roman antiquity, a sort of chain put generally round the neck of slaves that had run away, after they were taken, with an inscription round it, intimating their being defectors, and requiring their being restored to their proper owners, &c.

Collar, in a more modern sense, an ornament consisting of a chain of gold, enamelled, frequently fet with ciphers or other devices, with the badge of the order hanging at the bottom, worn by the knights of several military orders over their shoulders, on the mantle, and its figure drawn round their armories.

Thus, the collar of the order of the garter consists of S. S. with roses enamelled red, within a garter enamelled blue, and the George at the bottom.

Lord Mayor's Collar is more usually called chain. See Chain.

Knights of the Collar, a military order in the republic of Venice, called also the order of St. Mark, or the medal. It is the doge and the senate that confer this order; the knights bear no particular habit, only the collar, which the doge puts around their neck, with a medal, wherein it represented the winged lion of the republic.

Collar of a Draught-horse, a part of harness made of leather and canvas, and stuffed with straw or wool, to be put about the horse's neck.

Collarage, a tax or fine laid for the collars of wine-drawing horses.

Collateral, any thing, place, country, &c. situated by the side of another.

Collateral, in genealogy, those relations which proceed from the same flock, but not in the same line of ascendants or descendants, but being, as it were, aside of each other. Thus, uncles, aunts, nephews, nieces, and cousins, are collaterals, or in the same collateral line: those in a higher degree, and nearer the common root, represent a kind of patrony with regard to those more remote. See Consanguinity.

Collateral Succession. When a defunct, for want of heirs descended of himself, is succeeded in his estate by a brother or sister, or their descendants, the estate is said to have gone to collateral heirs.

Collatia (anc. geog.), a town of the Sabines; thought to be distant between four or five miles out of Rome to the east, situated on an eminence (Virgil). Of this place was Tarquinius Collatinius, married to Lucretia, ravished by Sextus Tarquinius (Livy); situated on this or on the left side of the Anio (Pliny). Extant in Cicero's time, but in Strabo's day only a village; now no trace remains of it.—Another supposed Collatia of Apulia, near mount Garganus; because Pliny mentions the Collatini in Apulia, and Frontinus the Ager Collatinius.

Collatina Porta, a gate of Rome, at the Collis Hortulorum, afterwards called Pinciana, from the Pincii, a noble family. Its name Collatina is from Collatia, to the right of which was the Via Collatina, which led to that town.

Collina, a gate of Rome at the Collis Quirinales, not far from the temple of Venus Erycina (Ovid); called also Salana, because the Sabines carried their falt through it (Tacitus). Now Salata.

Collation, in the canon law, the giving or bestowing of a benefice on a clergyman by a bishop, who has it in his own gift or patronage. It differs from institution in this, that institution is performed by the bishop, upon the presentation of another; and collation is his own act of presentation: and it differs from a common presentation, as it is the giving of the church to the person, and presentation, is the giving or offering of the person to the church. But collation supplies the place of presentation and institution; and amounts to the same as institution where the bishop is both patron and ordinary. Anciently the right of presentation to the churches was in the bishop; and now if the patron neglects to present to a church, then this right returns to the bishop by collation; if the bishop neglects to collate within six months...
COL [140] COL

Collation after the elapse of the patron, then the archbishop hath a right to do it; and if the archbishop neglects, then it devolves to the king; the one as superior, to supply the defects of bishops, the other as suprence, to supply all defects of government.

Collation, in common law, the comparison or presentation of a copy to its original, to see whether or not it be conformable; or the report or act of the officer who made the comparison. A collated act is equivalent to its original, provided all the parties concerned were present at the collation.

Collation, in Scots law, that right which an heir has of throwing the whole inheritable and moveable estates of the deceased into one mass, and sharing it equally with the others in the same degree of kinred, when he thinks such there will be more than the value of the heritage to which he had an exclusive title.

Collation is also used among the Romanists for the meal or repast made on a fast-day, in lieu of a supper. Only fruits are allowed in a collation: F. Lobineau observes, that anciently there was not allowed even bread in the collations in Lent, nor anything beside a few comfits and dried herbs and fruits; which custom, he adds, obtained till the year 1453. Cardinal Humbert observes further, that in the middle of the 11th century there were no collations at all allowed in the Latin church in the time of Lent; and that the custom of collations was borrowed from the Greeks, who themselves did not take it up until about the 11th century. Collation is also properly used for a repast between meals, particularly between dinner and supper. The word collation, in this sense, Du Cange derives from colectatio, "conference," and maintains, that originally collation was only a conference, or conversation on subjects of piety, held on fast-days in monasteries; but that, by degrees, the custom was introduced of bringing in a few refreshments; and that by the excises to which those sober repasts were at length carried, the name of the abuse was retained, but that of the thing lost.

Collation of Seals, denotes one seal set on the same label, on the reverse of another.

Colleage, a partner or associate in the same office or magistrature. See Aesct.

Collect, collection, a voluntary gathering of money, for some pious or charitable purpose. Some say, the name collected, or collection, was used, by reason those gatherings were anciently made on the days of collects, and in collects, i.e. in assemblies of Christians; but, more probably, quia colligitur pecunia.

Collect is sometimes also used for a tax, or imposition, raised by a prince for any pious design. Thus, histories say, that in 1166, the king of England, coming into Normandy, appointed a collect for the relief of the holy land, at the desire and after the example of the king of France. See Croisade.

Collect, in the liturgy of the church of England, and in those of the Romanists, denotes a prayer accommodated to any particular day, occasion, or the like. See Liturgy, and Mass.

In the general, all the prayers in each office are called collects; either because the priest speaks in the name of the whole assembly, whose sentiments and desires he sums up by the word orimus, "let us pray," as is observed by pope Innocent III. or, because those prayers are offered when the people are assembled together, which is the opinion of Fulminus on Tertullian. The congregation itself is in some ancient authors called collect. The popes Gelasius and Gregory are said to have been the first who established collects. Defense, a doctor of the faculty of Paris, has an express treatise on collects, their origin, antiquity, authors, &c. Collective, among grammarians, a term applied to a noun expressing a multitude, though itself be only singular; as an army, company, troop, &c. called collective noun.

Collector, in general, denotes a person who gets or brings together things formerly dispersed and separated. Hence, Collector, in matters of civil policy, is a person appointed by the commissioners of any duty, the inhabitants of a parish, &c. to raise or gather any kind of tax.

Collector, among botanists, one who gets together as many plants as he can, without studying botany in a scientific manner.

Collegatory, in the civil law, a person who has a legacy left him in common with one or more other persons.

College, an assemblage of several bodies or societies, or of several persons into one society.

College, among the Romans, served indifferently for those employed in the offices of religion, government, the liberal and even mechanical arts and trades; so that, with them, the word signified what we call a corporation or company.

In the Roman empire, there were not only the college of augurs, and the college of capitolini, i.e. of those who had the superintendence of the capitoline games; but also colleges of artisans, collegia artificum; college of carpenters, fabricorum, or fabrorum signariorum; of potters, sigillorum; of founders, avarium; the college of locksmiths, fabrorum ferrarium; of engineers of the army, signarium; of butchers, lanarium; of dandrophors, dandrophorum; of centonaries, centenarium; of makers of military caques, segariorium; of tent-makers, tabernaclarium; of bakers, pistorium; of musicians, tibicarium, &c. Plutarch observes, that it was Numa who first divided the people into colleges; which he did to the end that each confuting the interest of his college, whereby they were divided from the citizens of the other colleges, they might not enter into any general conspiracy against the public repose.

Each of these colleges had distinct meeting-places or halls; and likewise, in imitation of the flate, a treasury and common chef, a registre, and one to represent them upon public occasions, and acts of government. These colleges had the privilege of manumitting slaves, of being legisates, and making by-laws for their own body, provided they did not clash with those of the government.

There are various colleges on foot among the moderns, founded on the model of those of the ancients. Such are the three colleges of the empire, viz. College of Electors, or their Deputies, assembled in the diet of Ratibon.

College of Princes; the body of princes, or their deputies, at the diet of Ratibon.

College of Cistes, is, in like manner, the body of deputies which the imperial cities send to the diet.

College of Cardinals, or the Sacred College; a body
College.

College is also used for a public place endowed with certain revenues, where the several parts of learning are taught.

An assembly of several of these colleges constitute an universit.y. The erection of colleges, in Britain, is part of the royal prerogative, and not to be done without the king's licence.

The establishment of colleges or universities is a remarkable period in literary history. The schools in cathedrals and monasteries confined themselves chiefly to the teaching of grammar. There were only one or two masters employed in that office. But, in colleges, professors are appointed to teach all the different parts of science. The first obscure mention of academical degrees in the university of Paris (from which the other universities in Europe have borrowed most of their customs and institutions), occurs A.D. 1215.

College of Civilians, commonly called Doctors Common; a college founded by Dr Harvey, dean of the arches, for the professors of the civil law residing in London: where usually, likewise, resides the judge of the arches court of Canterbury, judge of the admiralty, of the prerogative court, &c. with other civilians; who all live, as to diet and lodging, in a collegiate manner, commoning together; whence the appellation of Doctors Common. Their house being consumed in the great fire, they all refided at Exeter-house in the Strand till 1672; when their former house was rebuilt, at their own expense, in a very splendid manner. To this college belong 34 professors, who make themselves parties for their clients, manage their causes, &c.

College of Physicians, a corporation of physicians in London, who, by several charters and acts of parliament of Henry VIII. and his successors, have certain privileges, whereby no man, though a graduate in physic of any university, may, without licence under the said college-fest, practice physic in or within seven miles of London; with power to administer oaths, fine and imprison offenders in that and several other particulars; to search the apothecaries shops, &c. in and about London, to see if their drugs, &c. be wholesome, and their compositions according to the form prescribed by the said college in their dispensatory. By the said charter they are also freed from all troublesome offices, as to serve on juries, to be constable, keep watch, provide arms, &c.

The society had anciently a college in Knight-rider-street, the gift of Dr Linacre physician to king Henry VIII. Since that time they have had a house built them by the famous Dr Harvey in 1652, at the end of Amen-corner, which he endowed with his whole inheritance in his lifetime; but this being burnt in the great fire in 1666, a new one was erected, at the expense of the fellows, in Warwick-lane, with a noble library, given partly by the marquis of Dorchester, and partly by Sir Theodore Mayerne.

Of this college there are at present a president, four censors, eight electors, a registrar, and a treasurer, chosen annually in October; the censors have, by charter, power to survey, govern, and arrest, all physicians, or others practising physic, in or within seven miles of London; and to fine, amerce, and imprison them, at discretion. The number of fellows was anciently thirty, till king Charles II. increased their number to forty; and king James II. giving them a new charter, allowed the number of fellows to be enlarged so as not to exceed fourscore; referring to himself and successors the power of placing and displacing any of them for the future.

The college is not very rigorous in asserting their privileges; there being a great number of physicians, some of very good abilities, who practise in London, &c. without their licence, and are consulted at by the colleges; yet by law, if any person not expressly allowed to practise, take on him the cure of any disease, and the patient die under his hand, it is deemed felony in the practitioner. In 1666, the college made a subcription, to the number of forty-two of their members, to set on foot a dispensatory for the relief of the sick poor; since that they have erected two other dispensatories.

Edinburgh College of Physicians was erected on the 29th November 1661. The design of this institution was to prevent the abuses daily committed by foreign and illiterate impoters, quacks, &c. For by reason of his majesty, at the time aforesaid, granted letters patent to erect into a body corporate and politic, certain physicians in Edinburgh and their successors, by the title of "the President and Royal College of Physicians at Edinburgh," with power to choose annually a council of seven, one whereof to be president: these are to elect a treasurer, clerk, and other officers; to have a common seal; to fine and be fined; to make laws for promoting the art of physic, and regulating the practice thereof, within the city of Edinburgh, town of Leith, and districts of the Canongate, Warr­port, Pleasance, and Potter-row; through all which the jurisdiction of the college extends. Throughout this jurisdiction, no person is allowed to practice physic, without a warrant from the college, under the penalty of L. 5 Sterling the first month, to be doubled monthly afterwards while the offence is continued; one-half the money arising from such fines to go to the poor, the other to the use of the college. They are also empowered to punish all licentiates in physic within the aforesaid bounds, for faults committed against the institutions of the college; and to fine them of sums not exceeding 40s. On such occasions, however, they must have one of the bailies of the city to sit in judgment along with them, otherwise their sentence will not be valid. They are also empowered to search and inspect all medicines within their jurisdiction, and throw out into the street all such as are bad or unwelcome. That they may the better attend their patients, they are exempted from watching, warding, and serving on juries. They are, however, restrained from erecting schools for teaching the art of physic, or conferring degrees on any person qualified for the office of a physician; but are obliged to license all such as have taken their degrees in any other university, and to admit as honorary members all the professors of physic in the rest of the universities of Scotland. These privileges and immunities are not, however, to interfere with the rights and privileges of the apothecary-surgeons, in their practice of curing wounds, contusions, fractures, and other external operations.

Edinburgh College of Surgeons. This is but a very late
College, late institution, by which the surgeons of Edinburgh are incorporated into a Royal College, and authorized to carry into execution a scheme for making provision for their widows and children, &c. They have also the privilege of examining, and licensing, if found qualified, all practitioners in surgery within certain bounds.

College of Justice, the supreme civil court of Scotland; otherwise called Court of Session, or, of Council and Session. See Law, Part III. No. 2., c. 4.

Sion College, or the college of the London clergy; which has been a religious house time out of mind, sometimes under the denomination of a priory, sometimes under that of a hospital; at its dissolution under 31st Henry VIII. it was called Elgin's Spital, from the name of its founder, a merchant, in 1530. At present it is a composition of both, viz. a college for the clergy of London, who were incorporated in 1630, in pursuance to the will of Dr White, under the name of the President and Fellows of Sion College; and an hospital for ten poor men and as many women. The officers of the corporation are the president, two deans, and four suffrals; who are annually chosen from among the rectors and vicars of London; and are subject to the visitation of the bishop. They have a good library, built and stocked by Mr Simpson, furnished by several other benefactors, chiefly for the clergy of the city, without excluding other students on certain terms; and a hall, with chambers for students, generally occupied by the ministers of the neighbouring parishes.

Greatham College, or College of Philosophy; a college founded by Sir Thomas Greatham, and endowed with the revenue of the Royal Exchange: one moiety of this endowment the founder bequeathed to the mayor and aldermen of London and their successors, in trust, that they should find four able persons to read, within the college, divinity, geometry, astronomy, and music: who are chosen by a committee of the common council, consisting of the lord mayor and three aldermen and eight commoners, and allowed each, annually, L. 50 per annum. The other moiety he left to the company of mercers, to find three more able persons, chosen by a committee of that company, consisting of the master and three wardens, during their office, and eight of the court of suffrals, to read law, phyic, and rhetoric, in the same terms; with this limitation, that the several lecturers should read in term-time, every day in the week except Sundays; in the morning in Latin, in the afternoon the fame in English: but that in music to be read only in English. By 8th George III. cap. 32. the building appropriated to this college was taken down, and the excise-office crested in its room. Each of the professors is allowed L. 50 per annum, in lieu of the apartments, &c. relinquished by them in the college, and is permitted to marry, notwithstanding the resubscription of Sir Thomas Greatham's will. The lecturers are now read in a room over the Royal Exchange; and the city and mercers company are required to provide a proper place for this purpose.

In this college formerly met the Royal Society, that noble academy, instituted by king Charles II. and celebrated throughout the world for their improvements in natural knowledge. See their history and policy under Society.

College de Propaganda Fide, was founded at Rome in 1622 by Gregory XV. and enriched with ample revenues. It consists of thirteen cardinals, two priest, and a secretary; and was designed for the propagation and maintenance of the Romish religion in all parts of the world. The funds of this college have been very considerably augmented by Urban VIII. and many private donations. Millionaires are supplied by this institution, together with a variety of books suited to their several appointments. Seminaries for their instruction are supported by it, and a number of charitable establishments connected with and conducive to the main object of its institution.

Another college of the same denomination was established by Urban VIII. in 1627, in consequence of the liberality of John Baptist Viles, a Spanish nobleman. This is set apart for the instruction of those who are designed for the foreign missions. It was at first committed to the care of three canons of the patriarchal churches; but ever since the year 1641 it is under the same government with the former institution.

College of Heralds, commonly called the Heralds Office; a corporation founded by charter of king Richard III. who granted them several privileges, as to be free from subsidies, tolls, offices, &c. They had a second charter from king Henry VI.; and a house built near Doctors' Commons, by the earl of Derby, in the reign of king Henry VII. was given them by the duke of Norfolk, in the reign of queen Mary, which house is now rebuilt. This college is subordinate to the earl-marshals of England. They are assistans to him in his court of chivalry, usually held in the common-hall of the college, where they sit in their rich coats of his majesty's arms. See Herald.

College of Heralds in Scotland, consists of Lyon king at arms, six heralds, and six pursuivants, and a number of meiengers. See Lyon.

Collegians, Collegiani, Collegiants, a religious sect formed among the Arminians and Anabaptists in Holland, about the beginning of the seventeenth century; so called because of their colleges, or meeting, twice every week; where every one, males excepted, has the same liberty of expounding the scripture, praying, &c. They are said to be all either Arians or Socinians: they never communicate in the college, but meet twice a year from all parts of Holland at Rhenishbergh, whence they are also called Rhenishberghers, a village twomiles from Leyden, where they communicate together; admitting every one that prescribes himself, professing his faith in the divinity of the holy scriptures, and resolution to live suitably to their precepts and doctrines, without regard to his sect or opinion. They have no particular ministers, but each officiates as he is disposed. They never baptize without dipping.

Collegiate, or Collagial, churches, are those which have no bishop's see, yet have the ancient retinue of the bishop, the canons and prebends. Such are Westminster, Ripon, Windfor, &c, governed by deans and chapters.

Of these collegiate churches there are two kinds: some of royal, and others of ecclesiastical foundation; each of them, in matters of divine service, regulated in the same manner as the cathedrals. There are even some collegiate churches that have the episcopal rights.
rights. Some of these churches were ancienly abbeys, which in time were seculariz'd. The church of St Peter's, Westminister, was ancienly a cathedral; but the revenues of the monastery being by act of parliament, Elizabeth, vested in the dean and chapter, it commenced a collegiate church. In several cases the (styling it cathedrall, instead of collegiate, church of Westminister, has occasioned error in the pleadings.

COLLET, among jewellers, denotes the horizontal face or plane at the bottom of brilliants. See Brilliant.

Collet, in glass-making, is that part of glass vessels which sticks to the iron instrument wherewith the metal was taken out of the melting-pot: these are afterwards used for making green glasses.

COLLETS, in pharmacy, denote much the same with Agglutinants or Vulgar Radiers.

COLLIER (Jeremy), a learned English non-juring divine, born in 1624, and bred a book-seller at Cambridge. He had first the small rectory of Ampthor, near St. Edmund's Bury in Suffolk; which in six years he resigned, to come to London, in 1683, where he was made lecturer of Gray's Inn: but the change of government that followed, soon rendered the public exercise of his function impracticable. He was committed to Newgate for writing against the revolution; and again, for carrying on a correspondence which that change of events made treasonable; but was released both times, without trial, by the intervention of friends. It is observable that he carried his scruples so far, as to prefer confinement to the tacit acknowledgment of the jurisdiction of the court by accepting his liberty upon bail. Suitable to these principles, he next acted a very extraordinary part with two other clergymen of his own way of thinking, at the execution of Sir John Friend and Sir William Perkins for the affillation plot; by giving them solemn abolution, and by imposition of hands: abscinding for which, he continued under an outlawry to the day of his death in 1726. These proceedings having put a check to his activity, he employed his retired hours rather more usefully in literary works. In 1698, he attempted to reform our theatrical entertainments, by publishing his "Scripture of the immorality and profaneness of the English stage"; which engaged him in a controversy with the wits of the time: but as Mr Collier defended his censures not only with wit, but with learning and reason, it is allowed that the decorum observed, for the most part, by succeeding dramatic writers, has been owing to his animadversions. He next undertook a translation of Merton's great Historical and Geographical Dictionary; a work of extraordinary labour, and which appeared in 4 vols. folio. After this he published "An Ecclesiastical History of Great Britain, chiefly of England," in 2 vols. folio; which is allowed to be written with great judgment, and even with impartiality. He was besides engaged in several controversies, which his conduct and writings gave rise to, not material to mention. In queen Anne's reign, Mr Collier was tempted, by offers of considerable preferment, to a submission; but as he was a non-juror upon principle, he could not be brought to listen to any terms.

COLLIER, of Coallier. See Coallier.

COALLIER, COALEY, or COALLIERS. See Collier.

COLLINS (Anthony), a polemical writer, born at Heften near Hounslow in the country of Middlesex in 1670, was the son of Henry Collins, a gentleman of about L. 1500 a year. He was first bred at Eton college, and then went to king's-college Cambridge, where he had for his tutor Mr Francis Hare, afterwards bishop of Chichester. He was afterwards a student of the Temple; but not relishing the law, soon abandoned that study. He was an ingenious man, and author of several curious books. His first remarkable piece was published in 1707, "An Essay concerning the use of reason in propositions, the evidence whereof depends on human testimony." In 1702, he entered into the controversy between Mr Clark and Dr Dodwell, concerning the immortality of the soul. In 1713, he published his discourse on free-thinking; which made a prodigious noise. In 1715, he retired into the county of Essex, and acted as a judge of peace and deputy lieutenant for the same county, as he had done before for that of Middlesex and liberty of Westminster. The same year, he published a "Philosophical Essay concerning human liberty." In 1718, he was chosen treasurer of the county of Essex; and this office he discharged with great honour. In 1724, he published his "Historical and critical Essay on the 39 articles." Soon after, he published his "Discourse of the grounds and reasons of the Christian religion," to which is prefixed, "An Apology for free debate and liberty of writing," which piece was immediately attacked by a great number of writings. In 1726, appeared his "Scheme of literary prophecy considered, in a view of the controversy occasioned by a late book entitled, A discourse of the grounds, &c." In this discourse, he mentions a MS. dissertation of his to show the Sibylline oracles to be a forgery made in the times of the primitive Christians, who, for that reason, were called Sibyllists by the Pagans; but it never appeared in print. His scheme of literary prophecy was replied to by several writers; and particularly by Dr John Rogers in his "Necessity of divine revelation asserted." In answer to which, our author wrote "A letter to the Reverend Dr Rogers, on occasion, &c." His health began to decline some years before his death, and he was very much afflicted with the stone, which at last put an end to his life at his house in Harley-square in 1729. He was interred in Oxford chapel, where a monument was erected to him, with an epitaph in Latin. His curious library was open to all men of letters, to whom he readily communicated all the assistance in his power; he even furnished his antagonists with books to confute himself, and directed them how to give their arguments all the force of which they were capable. He was remarkably averse to all indecency and obscurity of discourse; and was, independent of his scepticism, a sincerely good man.

COLLINS (John), an eminent accountant and mathematician, born in 1624, and bred a book-seller at Oxford. Besides several treatises on practical subjects, he communicated some curious papers to the Royal Society, of which he was a member, which are to be found in the early numbers of the Philosophical Transactions.
actions: and was the chief promoter of many other scientific publications in his time. He died in 1683; and about 25 years after, all his papers coming into the hands of the learned William Jones, Esq: F. R. S. it appeared that Mr Collins held a constant correspondence for many years with all the eminent mathematicians; and that many of the late discoveries in physical knowledge, if not actually made by him, were yet brought forth by his endeavours.

Collins (William), an admirable poet, was born at Chichefter, about the year 1724. He received his classical education at Winchelsea; after which he studied at New college, in Oxford, was admitted a commoner of King's college in the same university, and was at length elected a demy of Magdalen college. While at Oxford, he applied himself to the study of poetry, and published his Oriental Eclogues; after which he came to London. He was naturally possessed of an ear for all the varieties of harmony and modulation; his heart was susceptible of the finest feelings of tenderness and humanity, and was particularly carried away by that high enthusiasm which gives to nature its strongest colouring; and he was at once capable of soothing the ear with the melody of his numbers, of influencing the passions by the force of the passions, and of gratifying the fancy by the luxury of description. With these powers, he attempted lyric poetry; and in 1746, published his Odes, descriptive and allegorical; but the fate of this work being not at all answerable to its merit, he burnt the remaining copies in indignation. Being a man of a liberal spirit and a small fortune, his pecuniary resources were unhappily soon exhausted; and his life became a miserable example of necessity, indolence, and idleness. He projected books which he was well able to execute; and became in idea a historian, a critic, and a dramatic poet; but wanted the means and encouragement to carry these ideas into execution. Day succeeded day, for the support of which he had made no provision; and he was obliged to flit, either by the repeated contributions of a friend, or the generosity of a casual acquaintance. His spirits became oppressed, and he sunk into a full denpance. While in this gloomy state of mind, his uncle colonel Martin died, and left him a considerable fortune. But this came too late for enjoyment; he had been so long harassed by anxiety and distress, that he fell into a nervous disorder, which at length reduced the finest understanding to the most deplorable childhoods. In the first stages of this disorder, he endeavoured to relieve himself by travelling, and passed into France; but the growing malady obliged him to return; and having continued, with short intervals, in this pitiable state till the year 1756, he died in the arms of his sister. The ingenious Mr Langhorne has published his poetical works, with memoirs of the author, in one volume duodecimo.

Collinson (Peter), an eminent naturalist and antiquarian, defender of an ancient family, was born on the paternal estate called Bugal-Hall, or, Height of Bugal, near Windermere lake, in the parish of Staveley, about ten miles from Kendal in Westmoreland. In his youth he discovered his attachment to natural history. He began early to make a collection of dried specimens of plants, and had access to the best gardens at that time in the neighbourhood of London. He became early acquainted with the most eminent naturalists of his time; the Drs Derham, Woodward, Dale, Lloyd, and Sloane, were amongst his friends. Among the great variety of articles which form that superb collection, now (by the wise disposition of Sir Hans and the munificence of parliament) the British Museum, small was the number of those with fidelity Mr Collinson was not well acquainted; he being one of those few who visited Sir Hans at all times familiarly; their inclination and pursuits in respect to natural history being the same, a firm friendship had early been established between them. Peter Collinson was elected a fellow of the Royal Society on the 12th of December 1728; and perhaps was one of the most diligent and useful members, not only in supplying them with many curious observations himself, but in promoting and preferring a most extensive correspondence with learned and ingenious foreigners, in all countries on every useful subject. Besides his attention to natural history, he minutely every striking hint that occurred either in reading or conversation; and from this source he derived much information as there were very few men of learning and ingenuity who were not of his acquaintance at home; and most foreigners of eminence in natural history, or in arts and sciences, were recommended to his notice and friendship. His diligence and economy of time was such, that though he never appeared to be in a hurry, he maintained an extensive correspondence with great punctuality; acquainting the learned and ingenious in distant parts of the globe with the discoveries and improvements in natural history in that country, and receiving the like information from the most eminent persons in almost every other. His correspondence with the ingenious Calwallader Colcen, Esq; of New York, and the justly celebrated Dr Franklin of Philadelphia, furnish instances of the benefit resulting from his attention to all improvements. The latter of these gentlemen communicated his first essays on electricity to Mr Collinson, in a series of letters, which were then published, and have been reprinted in a late edition of the Doctor's ingenious discoveries and improvements. Perhaps, in some future period, the account procured of the management of thcep in Spain, published in the Gentleman's Magazine for May and June 1764, may not be considered among the least of the benefits accruing from his extensive and inquisitive correspondency. His conversation, cheerful and usefully entertaining, rendered his acquaintance much desired by those who had a relish for natural history, or were anxious in cultivating rural improvements; and secured him the intimate friendship of some of the most eminent personages in Britain, as distinguished by their taste in planting and horticulture, as by their rank and dignity. He was the first who introduced the great variety of seeds and shrubs which are now the principal ornament of every garden; and it was owing to his indefatigable industry, that so many persons of the first distinction are now enabled to behold groves transplanted from the western continent flourishing as luxuriantly in their several domains as if they were already become indigenous to Britain. He had some correspondents in almost every nation in Europe, some in Asia, and even at Pekin; who all transmitted to
Collinsonia him the most valuable seeds they could collect, in return for the treasures of America. The great Linnaeus, during his residence in England, contracted an intimate friendship with Mr. Collinson, which was reciprocally increased by a multitude of good offices, and continued to the last. Besides his attachment to natural history, he was very conversant in the antiquities of Great Britain, having been elected a member of the Society of Antiquaries April 7, 1737; and he supplied them often with many curious articles of intelligence and observations, respecting both his own and other countries. He died in 1768, leaving behind him many materials for the improvement of natural history.

Collinsonia, in botany: A genus of the mono­gnia order, belonging to the decalidria class of plants; and in the natural method ranking under the 40th order, Perinato. The corolla is unequal, with its under lip multifid, and the segments capillary. There is only one perfect seed. There is but one species, a native of North America, but possessed of no remarkable properties.

Colliquamentum, in natural history, an extreme transparent fluid in an egg, observable after two or three days incubation, containing the first rudiments of the chick. It is included in one of its own proper membranes, distinct from the albumen. Harvey calls it the nectar.

Colliquation, in chemistry, is applied to animal, vegetable, and mineral substances, tending towards fusion. See Fusion.

Colliquation, in physic, a term applied to the blood, when it loses its coars or balsamic texture; and to the solid parts, when they waste away, by means of the animal fluids flowing off through the several glands, and particularly those of the skin, fatter than they ought: which occasions fluxes of many kinds, but mostly profuse, greasy, and clammy sweats.

Colliquative fever, in physic, a fever attended with a diarrhoea, or with profuse sweats.

Colliquation, the friction of one hard body against another; or the friction or percussion of bodies moving violently with different directions, and dashing against each other.

Collum, the same with the neck.

Collusion, in law, a secret understanding between two parties, who plead or proceed fraudulently against each, to the prejudice of a third person.

Colluthians, a religious sect, who rofe about the beginning of the fourth century: on occasion of the indulgence offered to Arius by Alexander patriarch of Alexandria. Several people being incited by so much contention; and, among the rest, Colluthus, a priest of the same city: he hence took a great deal for holding separate assemblies, and by degrees proceeded to the ordination of priests, as if he had been a bishop; pretending a necessity for this authority, in order to oppose Arius. To his schism he added hereby: teaching, that God did not create the wicked; that he was not author of the evils that befal men, &c. He was condemned by a council held at Alexandria by Oinas, in the year 330.

Collubus (κολλους), in antiquity, the name with what is now called the rate of exchange.

Collyre, or Collyrites, in antiquity, a cer-
The city of Cologne and county of Meurs, though neighbours. This city is yola at their head; and in the church, which is the Confrantine Cologne. Neuys, Heizarwart, Kempen, Rhynberg, and within the diocese of Cologne, do not belong to it; markable of any in the of Westphalia and the county of Rechlinchufen. This that prelate is one of the of the empire in Italy; which dignity was very im- vat fays, he faw between 4 and 5000 skulls, decked with garlands, and coronets, ranged on shelves. The canonesses of St Ursula, who must be all countesses, have a handfome income. In their church they pretend to show three of the thorns of our Saviour's crown, and one of the vessels which contained the water that he converted into wine at the marriage of Cana. In the church of St Gereon are 900 heads of Moorish Cavaliers, said to have been in the army of Constance before it was converted, and have been beheaded for refusing to sacrifice to idols. Every one of the heads has a cap of scarlet, adorned with pearls. In the magnificent cathedral of St Peter, the three wise men who came from the east to visit our Saviour, are said to be interred. They lie in a large purple shrine spangled with gold, set upon a pede- tal of brass, in the midst of a square mausoleum, faced within and without with marble and Jasper. It is opened every morning at nine o'clock, if two of the canons of the cathedral are present, when these kings or wise men are seen lying at full length, with their heads bedecked with a crown of gold garnished with precious stones. Their names, which are Gaspur, Mel- chior, and Barthafar, are in purple characters on a little grate, which is adorned with an infinite number of large rich pearls and precious stones, particularly an oriental topaz as big as a pigeon's egg, and valued at above 30,000 crowns. Over against them are six large branches of silver, with wax candles, which burn night and day. The bones of these men, we are told, were brought to Constaninople by Helena mother to Constantine, from thence to Milan by Eutropius bishop of that fee, and afterwards hither by archbishop Rainold. In the Jeluites college are the portraits of the first 13 generals of that order, with Ignatius Loyola at their head; and in the church, which is the finest in Cologne, are many rich altars, with an amaz- ing quantity of fine silver plate; and the utensils for mass are all of gold enriched with precious stones. In the Cordeliers church, is the tomb of the famous Duns Scoto, surnamed Doctor Subtilis, with this epigraph, “Scotia me genuit, Anglia me fuccepit, Gaba me ducuit, Colognia me tenet.” Cologne is a free imperial city, and as fuch has a seat and voice at the diets of the empire, and circle of the Lower Rhine. In those of the empire, it has the first place on the Rhenish bench. Towards the defence of the empire, its atten- ment is 825 florins; and towards the maintenance of the chamber-court, 405 rix-dollars, 721 kruitzers each term. Its militia consists of four companies of foot, who keep guard at the gates. It is governed by its own senate, in respect to civil matters and emis; but the criminal jurisdiction belongs to the elector and his chapter; and so jealous are the inhabi-
COLOMBO [147]

COLOMBO, a handsome, pleasant, and strong town of Asia, seated on the eastern side of the island of Ceylon in the East Indies. It was built by the Portuguese in 1638; and in 1658 they were driven from it by the Natives, assisted by the Dutch, who are now in possession of it. It is about three quarters of a mile long, and as much in breadth. The natives live in the old town, without the walls of the new; the streets of this last are wide and spacious; and the buildings are in the modern taste, particularly the government's house, which is a handsome structure. E. Long. 80° 15'. N. Lat. 7° 0'.

COLOMEY, or COLOMIA, a town of Poland in Red Ruifs, seated on the river Pruth, in E. Long. 25° 9'. N. Lat. 48° 45'.

COLOMNA (Fabio), a very learned botanist, born at Naples about the year 1567. He became skilled in the languages, in music, designing, painting, and the mathematics; and died about the middle of the 17th century. He wrote, 1. Quibusam, seu Plantarium aliquot (ac plicium) historia. 2. Minus cognitarum rariorumque filipium sexdecim; et itemque aquilibas, alilique nonnullis animalibus, libellus; and other works.

COLON, in anatomy, the first and most considerable of the large intestines. See Anatomy, under n° 93.

Colon, in grammar, a point, or character formed thus [••], serving to mark a pause, and to divide the members of a period. See Pointing: see also Period, Comma, and Semicolon. Grammarians generally assign the use of a colon to be, to mark the middle of a period; or to conclude a sentence less perfect than the dot or period.—but, a sentence less perfect than the period, is an expression extremely vague and indeterminate. See Period.

Others say, a colon is to be used when the sentence is imperfect, but the sentence not concluded: but neither is this over clear and express.

A late author, in an ingenious discourse, De ratione interponendi, marks the office of the colon, and where it differs from the semicolon, &c. more precisely. A colon, on his principles, serves to distinguish those conjunct members of a sentence, which are capable of being divided into other members; whereas one, at least, is conjunct. Thus, in the sentence, As we cannot discern the shadow moving along the dial-plate, so the advances we make in knowledge are only perceived by the eye more, than the members being both simple, are only separated by a comma. In this, As we perceive the shadow to have moved, but did not perceive it moving; so the advances we make in understanding, is that they consist of such minute steps, are only perceptible by the difference—the sentence being divided into two equal parts, and those conjunct ones, since they include others; we separate the former by a semicolon, and the latter by commas. But in this, As we perceive the shadow to have moved along the dial, but did not perceive it moving; and it appears the glass has grown, though no body ever saw it grow; so the advances we make in knowledge, as they consist of such minute steps, are only perceptible by the difference — the advancement in knowledge is compared to the motion of a shadow, and the growth of grass; which comparison divides the sentence into two principal parts; but since what is said of the movement of the shadow, and likewise the growth of grass, contains two simple members, they are to be separated by a semicolon; consequently a higher pointing is required to separate them from the other parts of the sentence, which they are opposed to: and this is a colon. See Punctuation.

COLONEL, in military matters, the commander in chief of a regiment, whether horse, foot, or dragoons. Skinner derives the word from colony; being of opinion, the chiefs of colonies, called coloniales, might give the name to chieftains of forces. In the French and Spanish armies, colonel, is confined to the infantry and dragoons: the commanding officer of a regiment of horse they usually call major de cappe. Formerly, instead of colonel, the French used the word colonel; and this old spelling comes nearer to our common way of pronouncing the word colonel.

A colonel may lay any officer of his regiment in arrest, but must acquaint the general with it; he is allowed a guard, only a century from the quarter-guard.

Colonel-Lieutenant, he who commands a regiment of guards, whereof the king, prince, or other person of the first eminence, is colonel. These colonel-lieutenants have always a colonel's commission, and are usually general-officers.

Lieutenant-Colonel, the second officer in a regiment, who is at the head of the captains, and commands in the absence of the colonel.

COLONIA, (anc. geog.) a town of the Trinbantes, a little above Camedouum. Now Colchester in Essex, according to Cambden, who supposes it to take its name from the river Colne, and not that it was a colony. Though others think Antonine's distances agree with Sudbury.

Colonia Equesiris, an ancient and noble colony on the Locus Lemanus. It appears to be the work of Julius Caesar, who settled there Equites Limitanis: and to this Lucan is thought to refer. By the itinerary it is supposed to have stood between Launf and Geneva, 12 miles from the last place by Petinger's map; which directs to Nyon, placed in Cavo Lemanus, according to Lucan's expression, that is, a bay or cove of the lake. Its ancient name was Noviodvum, (Notitia Galliarum): hence its modern name.

Colonia Metallina, or Metallinenis, a town of Lucitania, situated on the right or west side of the Agus, or Guadiana: but now on the left or east side, from the river's shifting its bed or channel, and called Medelir, a town in Estremadura. W. Long. 6° 12'. Lat. 38° 45'.

Colonia Morinorum, a town of Belgica, thought to be Tarvenna, the capital of the Morini. Now Terraouen, a town of Artois. E. Long. 2° 15'. Lat. 50° 27'.

Colonia Norbentis, or Norba Caesarea, a town of Lusitania, to the south of Trajan's bridge on the Tagus.
Colonies (anc. geog.) an eminence near Athens, whither Oedipus, after his banishment from Thebes, is said to have retired; and hence it is that Sophocles calls the tragedy on the subject, Oedipus Colonus. A place sacred to Neptune, and where flood an equestrian statue of him. Here also stood Timon's tower; who, for his love of solitude, and hatred to mankind, was called Misanthropos. (Pausanias.)

Colonies, one of the Hebrides or Western Islands belonging to Scotland. It comprehends that of Oronsay, from which it is only separated in time of flood, and both belong to the same proprietor viz. Mr M'Neil. See Oronsay.

Colonus, an husbandman, or villager, who was bound to pay yearly a certain tribute, or at certain times of the year to plough some part of the lord's land; and from hence comes the word clown, who is called by the Dutch boer.

Colony, a company of people transplanted into a remote province in order to cultivate and inhabit it.

We may distinguish three kinds of colonies. First, those serving to ease or discharge the inhabitants of a country, where the people are become too numerous, so that they cannot any longer conveniently subsist.

The second are those established by victorious princes and people in the middle of vanquished nations, to keep them in awe and obedience.

The third may be called colonies of commerce; because, in effect, it is trade that is the sole occasion and object thereof.

It was by means of the first kind of colonies that, some ages after the deluge, the east first, and successively all the other parts of the earth, became inhabited: and without mentioning any thing of the Phoenician and Grecian colonies, so famous in ancient history, it is notorious that it was for the establishment of such colonies, that, during the declension of the empire, those torrents of barbarous nations, lifting, for the generality, out of the north, over-ran the Gauls, Italy, and the other four bound parts of Europe; and, after several bloody battles, divided it with the ancient inhabitants.

For the second kind of colonies, the Romans used them more than any other people, and to secure the conquests they had made from the west to the east. Every one knows how many cities in Gaul, Germany, Spain, and even England, value themselves on their having been of the number of Roman colonies.

There were two kinds of colonies among the Romans: those sent by the senate; and the military ones, consisting of old soldiers, broken and disabled with the fatigues of war, who were thus provided with lands as the reward of their services. See Beneficium.

The colonies sent by the senate were either Roman or Latin, i.e. composed either of Roman citizens or Latins. The Coloniae Latinae were such as enjoyed the jus Latii, i.e. suffrage.}

The Coloniae Romanae, were such as had the jus Romanum, but not in its full extent; namely, in the right of suffrage, putting up for honours, magistracies, command in the army, &c., but the jus Quiritium only, or private right: as right of liberty, of gentility, or dignity of family, sacrae, marriage, &c. For it was long a rule, never to grant the liberty of the city in full to colonies: nor is there any instance to the contrary, till after the social war, in the year of the city fix hundred and sixty-two, after the social war, the freedom of the city was granted to all Latium by the lex Julia. The Coloniae Romanae, were such as had the jus Romanum, but not in its full extent; namely, in the right of suffrage, putting up for honours, magistracies, command in the army, &c., but the jus Quiritium only, or private right: as right of liberty, of gentility, or dignity of family, sacrae, marriage, &c. For it was long a rule, never to grant the liberty of the city in full to colonies: nor is there any instance to the contrary, till after the social war, in the year of the city fix hundred and sixty-two, after the social war, the freedom of the city was granted to all Latium by the lex Julia. The Coloniae Romanae, were such as had the jus Romanum, but not in its full extent; namely, in the right of suffrage, putting up for honours, magistracies, command in the army, &c., but the jus Quiritium only, or private right: as right of liberty, of gentility, or dignity of family, sacrae, marriage, &c. For it was long a rule, never to grant the liberty of the city in full to colonies: nor is there any instance to the contrary, till after the social war, in the year of the city fix hundred and sixty-two, after the social war, the freedom of the city was granted to all Latium by the
Colony. The ordinary symbol they engraved on their medals, was either an eagle; as when the veteran legions were distributed in the colonies; or a labourer, holding a plough drawn by a pair of oxen; as when the colony consisted of ordinary inhabitants. On all the medals are seen the names of the deceased, who held the same rank and had the same authority there as the consuls had at Rome.

Lastly, the colonies of commerce, are those established by the English, French, Spaniards, Portuguese, and other nations within these two last centuries, and which they continue still in existence, in several parts of Asia, Africa, and America; either to keep up a regular commerce with the natives, or to cultivate the ground, by planting sugar-canes, indigo, tobacco, and other commodities. The principal of this kind of colonies, are in the one and the other America, northern and southern; particularly Peru, Mexico, Canada, ( lately Virginia, New-England, Carolina, &c.) the Lousitians, I'Acadia, Hudson's Bay, the Antilles Islands, Jamaica, Domingo, and the other islands.—In Africa, Madagascar, Cape of Good Hope, Cape Verd, and its islands, and all those vast coasts extended thence as far as to the Red Sea. Lastly, in Asia, the famous Batavla of the Dutch; Goa, Diu, of the Portuguese; and some other less considerable places of the English, French, and Danes.

The practice of settling commercial colonies in distant countries hath been adopted by the wildest nations of America, who acted with absolute commanders of found policy. This appears to have been the case with the ancient Egyptians, the Chinese, the Phoencians, the commercial states of Greece, the Carthaginians, and even the Romans; for though the colonies of the latter were chiefly military, it could easily be shown that they were likewise made use of for the purposes of trade. The savage nations who ruined the Roman empire, fought nothing but to extirpate or hold in vassalage those whom they overcame; and therefore, whenever princes enlarged their dominions at the expense of their neighbours, they had recourse to strong forts and garrisons to keep the conquered in awe; and this they have been continually done in Machiavel; who labours to show, that the settling of colonies would have been a cheaper and better method of bridling conquered countries, than building forresses in them. John de Witt, who was one of the ablest and best statesmen that ever appeared, strongly recommended colonies; as affording a refuge to such as had been unfortunate in trade; as opening a field for such men to exert their abilities, as through want of interjed could not raise themselves in their own country; and as a supplement to hospitals and other charitable foundations, which he thought in time might come to be overcharged. Some, however, have ridiculed the supposed advantages of colonies, and affirmed that they must always do mischief by depopulating the mother-country.

The history of the British colonies undoubtedly shows, that when colonists become numerous and opulent, it is very difficult to retain them in subjection to the parent state. It becomes then a question of importance how far they are entitled to the rights they had as inhabitants of the mother-country, or how far they are bound by its laws? On this subject Mr Blackstone hath the following observations:

"Plantations, or colonies in distant countries, are either such where the lands are claimed by the right of occupancy only, by finding them defert and uncultivated, and peopling them from the mother-country; or where, when already cultivated, they have either been gained by conquest, or ceded to us by treaties. And both the rights are founded upon the law of nature, or at least on that of nations. But there is a difference between these two species of colonies with respect to the laws by which they are bound. For it hath been held, that if any uninhabited country be discovered and planted by English subjects, all the English laws then in being, which are the birthright of every subject, are immediately there in force. But this must be understood with many and very great restrictions. Such colonists carry with them only so much of the English law as is applicable to their own situation, and the condition of an infant colony; such, for instance, as the general rules of inheritance, and of protection from personal injuries. The artificial refinements and distinctions incident to the property of a great and commercial people, the laws of policy and revenue (such especially as are enforced by penalties), the mode of maintenance for the established clergy, the jurisdiction of spiritual courts, and a multitude of other provisions, are neither necessary nor convenient for them, and therefore are not in force. What shall be admitted, and what rejected, at what times, and under what restrictions, must, in cases of dispute, be decided in the first instance by their own provincial legislature, subject to the revision and control of the king in council; the whole of their constitution being also liable to be new-modelled and reformed by the general superintending power of the legislature in the mother-country. But in conquered or ceded provinces, there are already laws of their own, the king may indeed alter and change those laws; but, till he does actually change them, the ancient laws of the country remain, unless such as are against the law of God, as in an infidel country. Our American plantations are principally of this latter sort. They were being obtained in the last century, either by right of conquest and taking out the natives (with what natural justice I shall not at present inquire), or by treaties. And therefore, the common law of England, as such, has no allowance or authority there; they being no part of the mother-country, but distinct (though dependent) dominions. They are subject, however, to the control of the parliament; though (like Ireland, Mann, and the rest) not bound by any acts of parliament, unless particularly named."

With respect to their interior polity, the British colonies, whether those they formerly policed or still policed, may be distinguished into three sorts. 1. Provincial establishments, the constitutions of which depend on the respective commissions in the crown to the governors, and the instructions which usually accompany those commissions; under the authority of which provincial assemblies are constituted, with the power of making local ordinances not repugnant to the laws of Britain. 2. Proprietary governments, granted out by the crown to individuals, in the nature of feudatory principalities, with all the inferior regalities,
Coloquintida, in botany. See Cucumis.

Coloratura, in music, denotes all manner of variations, trills, diminutions, &c., serving to make a song agreeable.

Colorno, a town of Italy, in the Parmuzan, near the river Po, eight miles from Parma. The duke of Parma has a pleasure-house here, one of the most delightful seats in all Italy, and the gardens are very fine. E. Long. 9° 15'. N. Lat. 44° 54'.

Colossae, or Coloseae (anc. geog.), a considerable town of Phrygia Magna, in which the Lycus falls into a gulph, and at the distance of five stadia emerges again, and runs into the Meander (Herodotus). Others say, the genuine name is Colaffae, and the people Cloaffenfis, to whom St Paul wrote an epistle: Strabo calls them Colaffeni. In Nero's time the town was destroyed by an earthquake (Orofinus).

Colossus, a statue of enormous or gigantic size. The most eminent of this kind was the Colossus of Rhodes; a statue of Apollo, so high, that ships passed with full sails between its legs. It was the workmanship of Chares, a disciple of Lysippus; who spent 12 years in making it: it was at length overthrown by an earthquake, after having stood 15 years. Its height was six score and six feet: there were few people could fathom its thumb, &c. When the Saracens became possessed of the island, the statue was found prostrate on the ground: they sold it to a Jew, who loaded 900 camels with the brash.

The basin that supported it was a triangular figure; its extremities were full of pillars of marble. There was a winding stair-case to go up to the top of it; from whence one might discover Syria, and the ships that went into Egypt, in a great looking-glass, that was hung about the neck of the statue. Among the antiquities of Rome, there are two most famous Colossi: two of Jupiter, as many of Apollo, one of Nero, one of Domitian, and one of the Sun.

Colostrum, the first milk of any animal after bringing forth young, called heesings. It is remarkable that this milk is generally cathartic, and purges the meconium; thus serving both as an aliment and medicine.

An emulsion prepared with turpentine dissolved with the yolk of an egg, is sometimes called by this name.

Coloswar, a large and celebrated town of Transylvania, where the senate have their meetings. It is seated on the river Samos, in E. Long. 22° 45'. N. Lat. 46° 32'.

Colour, in physics, a property inherent in light, by which, according to the various fizes of its parts, or from some other cause, it excites different vibrations in the optic nerve; which propagated to the fenforium, affect the mind with different sensations. See Chromatics and Optics.

Colour, in painting, is applied both to the drugs, and to the tints produced by those drugs variously mixed and applied.

The principal colours used by painters are red and white lead, or cerus; yellow and red ochres; several kinds of earth, umber, umber, umber, lamp-black, burnt ivory.
Of these colours some are used tempered with gum-water: some ground with oil; others only in fresco; and others for miniature. Painters reduce all the colours they use under these two classes, of dark and light colours: dark colours are black, and all others that are obscure and earthy, as umbre, bistre, &c.

Under light colours are comprehended white, and all that approach nearest to it. Painters also distinguish colours into simple and mineral.

Under simple colours they rank all those which are extracted from vegetables, and which will not bear the fire: as the yellow made of saffron, French berries, lacca, and other tinctures extracted from flowers used by limners, illuminers, &c.

The mineral colours are those which are being drawn from metals, &c. are able to bear the fire, and therefore used by enamellers. Changeable and permanent colours is another division, which, by some, is made of colours.

Changeable colours are such as depend on the situation of the objects with respect to the eye, as that of a pigeon's neck, taffeties, &c. first, however, being attentively viewed by the microscope, each fibre of the feathers appears composed of several little squares, alternately red and green, so that they are fixed colours.

Water colours, are such as are used in painting with gum-water or lime, without being mixed with oil.

Incapacity of distinguishing colours. Of this extraordinary defect in vision, we have the following instances in the Philosophical Transactions for 1777. One of the persons lived at Maryport in Cumberland. The account was communicated by Mr Huddart to Dr Priestley, and is as follows: "His name was Harris, by trade a shoemaker. I had often heard from others, that he could discern the form and magnitude of all objects very distinctly, but could not distinguish colours. This report having excited my curiosity, I conversed with him frequently on the subject. The account he gave was this: That he had reason to believe other persons saw something in objects which he could not see; that their language seemed to mark qualities with precision and confidence which he could only guess at with hesitation, and frequently with error. His first suspicion of this arose when he was about four years old. Having by accident found in the street a child's stock, he carried it to a neighbouring bosile to inquire for the owner; he observed the people called it a red stock, though he did not understand why they gave that denomination, as he himself thought it completely deferm of being called a flocking. This circumstance, however, remained in his memory; and, together with subsequent observations, led him to the knowledge of his defect.

"He also observed, that when young, other children could discern cherries on a tree, by some pretend-
he replied, No, he did imagine there was some other difference.

"It is proper to add, that the experiment of the striped ribbon was made in the day-time and in a good light."

Colours for staining different kinds of Stones. See Chemistry, no 753.

Colour, in dyeing. See Dyeing.

Colour of Plants, is an attribute found to be very variable. Different colours are observed, not only in different individuals of the same species, but likewise in different parts of the same individual. Thus, marvell of Peru, and sweet-William, have frequently petals of different colours on the same plant. Three or four different colours are frequently found upon the same leaf or flower; as on the leaves of the amaranthus, tricolor, and the flowers of the tulip, auricula, three-coloured violet, and others. To produce the most beautiful and striking variety of colours in such flowers, is the principal delight and business of the florist.

The primitive colours, and their intermediate shades or gradations enumerated by botanists, are as follow.

Water-colours, hyalinus.  
White.  
Lead-colour, cinereus.  
Black, niger.  
Brown, fulceus.  
Pitch-Black, ater.  
Yellow, lutus.  
Straw-colour, flaurus.  
Flame-colour, fulceus.  
Iron-colour, gilvus.  
Red.  
Flux-colour, incarnatus.  
Scarlet, coccineus.  
Purple.  
Violet-colour, caroelo-purpureus.  
Blue, caeruleus.  
Green.

These colours seem to be appropriated to particular parts of the plant. Thus, white is most common in roots, sweet berries, and the petals of spring flowers. Water-colour, in the filaments and styles. Black, in the roots and seeds; rarely in the feed-veild, and scarce ever to be found in the petals. Yellow is frequently in the antherae or tops of the stamens; as likewise in the petals of autumnal flowers, and the compound legilated flowers of Linneas. Red is common in the petals of summer flowers, and in the acid fruits. Blue and violet colour, in the petals. Green in the leaves and calyx, but rarely in the petals. In the interchanging of colours, which in plants is found to depend upon differences in heat, climate, soil, and culture, a sort of elective attraction is observed to take place. Thus, red is more easily changed into white and blue: blue into white and yellow; yellow into white; and white into purple. A red colour is often changed into white, in the flowers of heath, mother of thyme, betony, pink, vicous camion, cistus, trefoil, orchis, fox-glove, thistle cudweed, saw-wort, rose, poppy, fumitory, and geranium. Red passes into blue in pimpernel. Blue is changed into white in bell-flower, green-valerian, bindweed, cumbeline, violet, vetch, milk-wort, goat's rue, viper's bugloss, comfrey, borage, hyssop, dragon's-head, scabious, blue bottle, and fiddery. Blue is changed into yellow in crocus. Yellow fades easily into white in melilot, agrimony, mullein, tulip, blattoria, or moth-mullein, and corn marigold. White is changed into purple in wood-forrel, thorn-apple, pea, and daily.

Although plants are sometimes observed to change their colour upon being moistened with coloured juices, yet that quality in vegetables seems not so much, owing to the nature of their nourishment, as to the action of the internal and external air, heat, light, and the primitive organisation of the parts. In support of this opinion, we may observe with Dr Grew, that there is a far lefs variety in the colours of roots than of the other parts of the plant; the pulp, within the skin, being usually white, sometimes yellow, rarely red. That this effect is produced by the small interchange with the external air appears from this circumstance, that the upper parts of roots, when they happen to stand naked above the ground, are often dyed with several colours: thus the tops of forrel roots turn red; those of turnips, mullein, and radishes, purple; and many others green: whilst those parts of the same roots which lie more under ground are commonly white. The green colour is proper to leaves, that many, as those of lage, the young sprouts of St John's wort, and others which are reddish when the bud, acquire a perfect green upon being fully expanded. In like manner, the leaves of the sea-side grape, polygonum, which when young are entirely red, become as they advance in growth, perfectly green, except the middle and transverse ribs, which retain their former colour.

As flowers gradually open and are exposed to the air, they throw off their old colour, and acquire a new one. In fact, no flower has its proper colour till it is fully expanded. Thus the purple stock-juiflowers are white or pale in the bud. In like manner bachelor's buttons, blue-bottle, poppy, red dalias, and many other flowers, though of divers colours when blown, are all white in the bud. Nay, many flowers lose their colours three successively; thus, the very young buds of lady's looking-glaas, buglefs, and the like, are all white; the larger buds purple, or mucry; and the open flowers blue.

With respect to the colours of the juices of plants, we may observe, that most renuous gums are tinctured; some however, are limpid; that which drops from the domestic pine is clear as rock-water. The milk of some plants is pale, as in burdock; of others white, as in dandelion, euphorbium, and scorriones; and of others yellow, as in lavoage, and greater celandine. Most mucilages have little colour, taitle, or fhmall. Of all the colours above enumerated, green is the most common to plants, black the most rare.

Colour being a quality in plants so apt to change, ought never to be employed in distinguishing their species. These ought to be characterized from circumstances not liable to alteration by culture or other accidents. The same inconstancy of colour observed in the flowers, is likewise found to be in the other parts of plants. Berries frequently change from green to red, and from red to white. Even in ripe fruits, the colour, whether white, red, or blue, is apt to vary; particularly
particularly in apple, pear, plum, and cherry trees. Seeds are more abundant in point of colour than the vegetable which contains them. In the seeds, however, of the poppy, oats, pea, bean, and kidney-bean, variations are frequently observed. The root, too, although not remarkably subject to change, is found to vary in some species of carrot and radish. Leaves frequently become spotted, as in a species of orchis, hawk-weed, ranunculus, knot-grass, and lettuce; but seldom relish with their green colour altogether. Tho' of some species of amaranthus, or flower-gentle, are beautifully coloured. The spots that appear on the surface of the leaves are of different colours, liable to vary, and not seldom disappear altogether. The leaves of officinal lung-wort, and some species of low-bread, forre! and trefoil, and ranunculus, are covered with white spots. Tho' of dog's-tooth violet, with purple and white. Tho' of several species of ranunculus, and orchis, with black and purple. Tho' of amaranthus, tricolor, with green, red, and yellow. Tho' of ranunculus acris, and a species of bog-bean, with red or purple. The under surface of the leaves of some species of pimpernel and the tea-plantain is marked with a number of dots or points; a white line runs through the leaves of Indian reed, black-berried heath, and a species of Canary grass; and the margin or brim of the leaf, in some species of box, honey-buckle, groundivy, and the green oak, is of a silver-white colour. The whole plant is often found to assume a colour that is unnatural or foreign to it. The varieties in some species of crypogy, mugwort, orach, amaranthus, purfule, and lettuce, furnish examples.

Such being the inconstancy of colour in all the parts of the plant, specific names derived from that quality are, very properly, by Linnaeus, deemed erroneous; whether they respect the colour of the flower, fruit, seeds, root, leaves, or express in general the beauty or deformity of the entire plant, with a particular view to that circumstance. Of this impropriety committed by former botanists, Linnaeus himself is not always guiltless. Thus the two species of *forre* are distinguished by the colour of their petals into the yellow and purple *forre*; although the shapes and figure of the leaves afforded much more constant as well as striking characters. The same may be said of his lupinus albus and luteus; re-feda alba, glauca, and lutea: angelica atro-purpurea; dicamnus albus; lamium album; felago coccinea: sida alba; pfiiffora rubra, lutea, incarnata, et coerulea; and of many others, in which the specific name is derived from a character or quality that is liable to vary in the same species.

We shall conclude this article with observing, that of all sensible qualities, colour is the least useful in indicating the virtues and powers of vegetables. The following general positions on this subject are laid down by Linnaeus, and seem sufficiently confirmed by experiment. A yellow colour generally indicates a bitter taste; as in gentian, aloes, celandine, turmeric, and other yellow flowers. Red indicates an acid or sour taste; as in cranberries, barberries, currants, raspberries, mulberries, cherries; the fruit of the rofe, sea-buckthorn, and service tree. Herbs that turn red towards autumn, have likewise a sour taste; as forre! wood-forre!, and bloody dock. Green indicates a crude alkaline taste, as in leaves and unripe fruits. A pale colour denotes an insipid taste, as in endive, asparagus, and lettuce. White promises a sweet luciduous taste; as in white currants and plums, sweet apples, &c. Lastly, black indicates a harsh, nauseous, disagreeable taste; as in the berries of deadly nightshade, myrtle-leaved fumach, herb-christopher, and others; many of which are not only unpleasant to the taste, but pernicious and deadly in their effects.

To be ascertained of the acid or alkaline property of any plant, express some of the juice, and rub it upon a piece of blue paper; which, if the plant in question is of an acid nature, will turn red; if of an alkaline, green. For the methods of extracting colours from the different parts of plants, see the article Colour-Making.

**Colour of the Human Species, Difference of.** See Complexion.

**Colour, in heraldry.** The colours generally used in heraldry are, red, blue, black, green, and purple; which the heralds call *gules, azure, fiesle, vert or sable,* and *purpure,* tenne, or tawny, and fanguine, are not so common as to yellow and white, called ar or argent, they are metals, not colours.

The metals and colours are sometimes expressed in blazon by the names of precious stones, and sometimes by those of plants or stars. See Blazoning.

*Enomaeus* is said first to have invented the distinction of colours, to distinguish the garments of combatants of the Circenian games; the green for those who represented the earth, and blue for those who represented the sea.

**Colours, in the military art, include the banners, flags, ensigns, &c. of all kinds, borne in the army or fleet.** See Flag and Standard.

**Colours, in the Latin and Greek churches, are used to distinguish several mysteries and feasts celebrated therein.**

Five colours only are regularly admitted into the Latin church; these are white, green, red, violet, and black. The white is for the mysteries of our Saviour, the feast of the Virgin, those of the angels, saints, and confessors; the red is for the mysteries and solemnities of the holy sacrament, the feasts of the apostles and martyrs; the green for the time between pentecost and advent, and from epiphany to feptuagesima; the violet in advent and Christmas, in vigils, rogations, &c. and in votive masses in time of war; lastly, the black is for the dead, and the ceremonies thereto belonging.

In the Greek church, the use of colours is almost abolished, as well as among us. Red was, in the Greek church, the colour for Christmas and the dead, as black among us.

*To Colour Stranger's Goods,* is, when a freeman allows a foreigner to enter goods at the custom-house in his name.

**Colour-Making, the art of preparing the different kinds of colours used in painting.**

This art properly belongs to chemistry; and is one of the most curious, though least understood, parts of it. The principles on which colour-making depends are entirely different from those on which the theory of other parts of chemistry is founded; and the practice.
Colours in the hands of those who find it their interest to conceal their methods as much as possible, it thence happens, that there is not only no distinct theory of this art, but scarce a single good receipt for making any one colour hath ever appeared.

The first general division of colours is into opaque and transparent. By the first are meant such colours as, when laid over paper, wood, &c. cover them fully so as to efface any other painting or stain that might have been there before; the others are of such a nature as to leave the ground on which they are laid visible through them. Of the first kind are white-lead, red-lead, vermilion, &c.; of the latter kind are the colours used for illuminating maps, &c.

Another division is into oil-colours and water-colours; by which is meant, such as are appropriated to painting in oil and in water. Most of those which are proper for painting in water, are also proper for being used in oil. There is, however, this remarkable difference between colours when mixed with water and with oil, that such as are quite opaque in water will become perfectly transparent in oil. Thus, blue verditer, though exceedingly opaque in water, if ground with oil, seems totally to dissolve, and will become very transparent. The same thing happens to such colours as have for their bases the cals of tin, alabaster, or calcareous earth. The most perfectly opaque colours in oil are such as have lead, mercury, or iron, for their bases: to the latter, however, Prussian blue is an exception; for though the bases of that colour is iron, it proves quite transparent when ground with oil. In water-colours, those prepared from metals, Prussian blue alone excepted, are always opaque; from vegetables or animals, transparent. Coals, however, whether vegetable or animal, are opaque both in water and oil.

Colours again, may be considered as either simple or compound. The simple ones are such as require nothing to be superadded to them, in order to make a full strong colour, without regarding whether they are formed of many or few ingredients; and in this view, white-lead, red-lead, vermilion, calxes of iron, &c. are simple colours. The compound ones are formed by the union of two or more colouring substances; as blue and yellow mixed together to form a green, red and yellow to form an orange, a white earth or calx with the red colour of cochineal or Brazil to form a lake, &c.; and thus carmine, lake, rose-pink, Dutch-pink, English-pink, &c. are compound colours.

The left and most important division of colours is into true and false. By the former are meant those which retain their colour under every possible variety of circumstances, without fading in the least: the others are such as do not; but either lose their colour altogether, or change to some other. What is chiefly apt to affect colours, is their being exposed to the sun in summer, and to the cold air in winter: but to this there is one exception, vis. white-lead; which, when ground with oil, retains its whiteness if exposed to the weather, but degenerates into a brownish or yellowish colour if left in water. In water this substance is very apt to lose its colour, whether exposed to the air or not. The great deaderatum in colour-making is to produce the first kind of colours, vis. such as will not fade by exposure to the weather; and indeed it is to be regretted, that the most beautiful are in general the least permanent. It may, for the most part, however, be expected, that the more simple any colour is, the less liable will it be to change upon exposure to the air.

The great difficulty of knowing a priori whether a colour will fade or not, is owing to our ignorance concerning the nature of colouring substances. With all our disadvantages, however, we may observe, that whatever change of colour is produced in any substance by exposure to the sun and air, that colour to which it changes will bid fair for being permanent, and therefore ought to be employed where it can be done. Of these changes the colours are but very rare. Influences of

One is in the purple of the ancients, which assumed its colour by exposure to the sun, and consequently was exceedingly permanent. Another is in the solution of silver; which, being mixed with chalk, the precipitate turns to purplish black where it is exposed to the sun. A third is in solutions of indigo by alkaline substances, which constantly appear green till exposed to the air by spreading them very thin, upon which they become almost instantaneously blue, and continue so forever. Sometimes, though still more rarely, a very remarkable change of colour happens, on the mixing two vegetable juices together. Almost vegetable the only influences of this we have on the authority of juices.

Mr George Forster, who informs us, that the inhabitants of Ostiaetc dye their cloth of a crimson colour, by mixing together the yellow juice of a small species of fig with the greenish juice of a kind of fern. But this is very generally the case, we are not to expect that all acids are equally powerful in this respect. The nitrous acid is found to heighten the most of any, and the marine acid the leaf of the mineral ones. The vegetable, as might be expected, are less powerful than the mineral acids. Thus, if with a tincture of cochineal, either in water or spirit of wine, is mixed the pure nitrous acid, it will change the colour to an exceeding high orange or flame colour, which it will impart to cloth. If the vitriolic acid is used, a full scarlet, inclining to crimson rather than orange, is produced. With marine acid a true crimson colour, bordering on purple, is the consequence. Alkalis, both fixed and volatile, change the colour to a purple, which is brighter with the volatile than the fixed alkalis.

Here it is obvious, that whatever colours are produced by the mixtures of different substances together, the permanency of these colours can only be in proportion to the ability of such mixtures to resist the weather. 

The effects of
weather. Thus, suppose a high scarlet or orange colour is produced by means of spirit of nitre, it is plain that, was such a colour exposed to the air, it could remain no longer than the spirit of nitre which produced it be preserved. In proportion, therefore, as the spirit of nitre was exhaled into the air, or otherwise destroyed, it behoved the colour to fade, and at last to be totally destroyed; and thus, in proportion to the destructibility of the substances by which colours are produced, will be the disposition of such colours to fade, or the contrary. In this respect alkalies are much more destructible than acids, and consequently less proper for the preparation of colours. With regard to acids, the nitrous fumes most destructible, the vitriolic fels fo, and the marine the least of all. From the extreme finity of the phosphoric acid and fodic salt, perhaps they might be of service in preserving colours.

As all colours, whether derived from the animal or vegetable kingdom, must be extracted either by pure water or some other liquid menstruation, they cannot be used for the purposes of painting till the colouring substance is united with some earthy or solid matter, capable of giving it a body, as the workmen call it; and according to the nature of this substance, the colour will be transparent or otherwise. This basis ought to be of the most fixed and durable nature; unalterable by the weather, by acids, or by alkalies. It ought also to be of a pure white colour, and easily reducible into an impalpable powder. For this reason all earthy substances should be avoided as being acted upon by acids; and therefore, if any of these were added to heighten the colour, they would not fail to be destroyed, and their effect totally lost. Precipitates of lead, bismuth, &c, though exceedingly fine and white, ought also to be avoided, as being apt to turn black by exposure. The only substance to be chosen in preference to all others, is calx of tin, prepared either by fire or the nitrous acid. This is so exceedingly refractory as not only to be unalterable by alkalies, acids, or the sun and weather, but even by the focus of a very large burning mirror. It is besides white as snow, and capable of being reduced to an extreme degree of fineness, so much that it is made use of for polishing metallic speculum. For this reason it is the most proper basis for all fine colours. For coarse ones, the white precipitate of lead, mentioned under the article Chemistry, n° 703, will answer very well. It hath a very strong body, i.e. is very opaque, and will cover well; may be easily ground fine, and is much less apt to turn black than white lead; it is besides very cheap, and may be prepared at the small expense of 3d. per pound.

If we have yet now observed is attended to, the general method of extracing colours from any vegetable or animal substance, and fixing them on a proper basis, must be very easily understand. For this purpose, a quantity of calx of tin is to be procured in proportion to the quantity of colour desired. This must be well rubbed in a glass mortar, with a little of the substance designed for brightening the colour, as alum, cream of tartar, spirit of nitre, &c. after which it must be dried, and left for some time, that the union between the two substances may be as perfect as possible. If the colour is to be a very fine one, suppose from cochineal, the colouring matter must be extracted with spirit of wine without heat. When the spirit is sufficiently impregnated, it is to be poured by little and little upon the calx, rubbing it constantly, in order to distribute the colour equally through all parts of the calx. The spirit soon evaporates, and leaves the calx coloured with the cochineal. More of the tincture is then to be poured on, rubbing the mixture constantly as before; and thus, with proper management, may very beautiful colours, not inferior to the best carmini, be prepared at a moderate expense. If, instead of cochineal, we subtilitute brazil-wood, turmeric, logwood, &c. different kinds of red, yellow, and purple, will be produced. For the coarser colours, aqueous decoctions are to be used in a similar manner; only as these are much longer of evaporating than the spirit of wine, very little must be poured on at a time, and the colours ought to be made in large quantity, on account of the tediousness of the process.

Hitherto we have considered only the effects of the effects of pure and simple salts, viz. acids and alkalies, on different kinds of colours; but by combining the acids with alkalies, earths, or metals, these effects may be varied almost ad infinitum; neither is there any rule yet laid down by which we can judge a priori of the changes of colour that will happen on the admixture of this or that particular salt with any colouring substance. In general, the perfect neutrals act weakly; the imperfect ones, especially those formed from metals, much more powerfully. Sulphur and falt ammoniac confiderably brighten the colour of cochineal, brazil, turmeric, fufc, madder, logwood, &c. The same thing is done, though in a lefs degree, by common falt, Glauber's falt, falpetre, and many other neutrals. Solutions of iron in all the acids strike a black with every one of the abovementioned substances, and likewise with fumach, galls, and other astringents. Solutions of lead, or facharum saturni, universally deftroy red colours to a dull purple. Solution of copper changes the purple colour of logwood to a pretty good blue; and, in general, folutions of this metal are friendly to blue colours. The effects of folutions of gold, silver, and mercury, are not so well known; they seem to produce dark colours of no great beauty. The most powerful substance, however, with regard to a great number of colours, is tin in the method of tin, made in aqua-regia. Hence we may fee the fallacy of Mr Delaval's hypothesis concerning colours, that the least refrangible ones are produced by the most dense metals: for tin, which hath the least density of any metal, hath yet, in a state of solution, the most extraordinary effects upon the least refrangible colours as well as those that are most so. The colour of cochineal is changed by it into the most beautiful scarlet; a similar change is made upon the colouring matter of gum-lac. Brazil-wood is made to yield a fine purplish crimson; logwood, a beautiful dark purple; turmeric, fufc, weld, and all yellow-colouring woods and flowers, are made to communicate colours far more beautiful than can be got from them by any other method. The blue colour of the flowers of violets, eye-bright, iris, &c. are heightened so as to equal, if not excelled, the blue produced by a solution of copper in volatile alkali. In short, this solution seems to be of much more extensive ufe in colour-making.
when properly applied, than any thing hitherto thought of. It is not, however, universally serviceable. The colour of madder it totally destroys, and likewise that of frit-flower, changing them both to a dull orange. It likewise spoils the colour of archil; and what is very remarkable, the fine red colour of tincture of roses made with oil of vitriol, is by solution of tin changed to a dirty green.

The most important consideration in colour making is to make choice of such materials as produce the most durable colours; and of these there can be procured, an ordinary colour from them is to be preferred to a bright one from those which fade sooner. In what the difference consists between the colours that fade and those which do not, is not known with any degree of certainty. From some appearances it would seem, that those substances which are most remarkable for keeping their colour, contain a viscid glutinous matter, so combined with a resinous one as to be soluble both in water and spirit of wine. The most durable red colour is prepared from gum-lac. This is a very strongly refrinous, though at the same time so far glutinous, that the colouring-matter can be extracted from it by water. Next to gum-lac are madder roots and cochineal. The madder is an exceedingly penetrating substance, so much that, when given to animals along with their food, it tinges their bones of a deep red colour. Its colouring-matter is soluble both in water and spirit of wine. Along with the pure red, however, there is in madder a kind of viscid astringent substance, of a dark brown colour, which seems to give the durability to the whole. The colouring-matter of cochineal, though soluble both in water and spirit of wine, is very tenacious and mucilaginous, in which it bears some resemblance to purpura of the ancients, which kept its colour exceedingly well. When the colours are fugitive, the tingeing substance seems to be too refrinous or too mucilaginous. Thus the colours of brazil, turmeric, &c. are very refrinous, especially the latter; insomuch that the colouring-matter of turmeric can scarcely be extracted from water. Both these are perishable, though beautiful colours; and much more are the red, purple, and blue flowers, commonly to be met with. These seem to be entirely mucilaginous without the least quantity of refrinous matter. The yellow flowers are different, and in general keep their colour pretty well. Whether it would be possible, by adding occasionally a proper quantity of gum or resin, to make the fugitive colours more durable, hath not yet been tried, but seems to have some probability.

What lends a little to confirm this, is a process given by Mr Hellor for imparting durability to the colour of braz. It consists only in letting decoctions of the wood stand for some time in wooden casks till they grow stale andropy. Pieces of wooden cloth now dyed in the liquor acquired a colour so durable, that they were not in the leaf altered by exposure to the air during four months in the winter season. Whether this change in the durability of the colour was effected by the rosin in following the fermentation, or by some other cause, or whether the experiment can be at all depended upon, must be referred to future observations.

Having thus collected all that can as yet be depended upon for establishing a general theory of colour-making, we shall now proceed to give an account of the different pigments generally to be met with in the colour-shops.

1. Black. These are lamp-black, ivory-black, blue-lamp-black, and Indian-ink. The first is the finest of what black are called the foot-black, and is more used than any other. Its preparation is described in the Swedish Transactions for the year 1754, as a process dependent on the making of common resin: the impure refrinous juice collected from incisions made in pine and fir trees, is boiled down with a little water, and strained whilst hot through a bag: the dregs and pieces of bark left in the strainer are burnt in a low oven, from which the smoke is conveyed through a long passage into a square chamber, having an opening on the top on which is a large sack made of thin woollen stuff: the foot, or lamp-black, concretes partly in the chamber, from whence it is swept out once in two or three days, and partly in the sack, which is now and then gently struck, both for shaking down the foot, and for clearing the interfaces between the threads, so as to procure a sufficient draught of air through it. In this manner lamp-black is prepared at the tarpentine houses in England, from the dregs and refuse of the refrinous matters which are there manufactured.

On this subject Dr Lewis hath made some curious observations. "The foot (says he) arising in common chimneys, from the more oily or refrinous woods, as the fir and pine, is observed to contain more dissoluble matter than that from the other woods: and this dissoluble matter appears, in the former, to be more of an oily or refrinous nature than in the latter: spirit of wine extracting it most powerfully from the one, and water from the other. The oiliness and solubility of the foot seeming therefore to depend on those of the subject it is made from, it has been thought that lamp-black must possess these qualities in a greater degree than any kind of common foot. Nevertheless, on examining several parcels of lamp-black, procured from different shops, I could not find that it gave any tincture at all, either to spirit or to water."

"Suspecting some mistake or sophification, or that the lamp-black had been burnt or charred, as it is to fit it for some particular uses, I prepared myself some foot from linseed oil, by hanging a large copper pan over the flame of a lamp to receive its smoke. In this manner the more curious artificers prepare lamp-black for the nicer purposes; and from this collection of it from the flame of a lamp the pigment probably received its name. The foot so prepared gave no tincture either to water or to spirits, any more than the common lamp-black of the shops. I tried different kinds of oily and refrinous bodies with the same event; even the foot obtained from fish-oils and tallow did not appear to differ from those of the vegetable oils and resins. They were all of a finer colour than the lamp-black commonly sold.

"Some foot was collected in like manner from fir and other woods, by burning small pieces of them slowly over a copper-pan. All the foot were of a deeper black colour than those obtained from the same kinds of woods in a common chimney; and very little, if at all, inferior to those of the oils: they gave only
Colours-making. - A just discernible tincture to water and spirit, while the foot of the chimney imparted a strong deep one to both. The foot of mineral bitumens, in this close way of burning, appears to be of the same qualities with those of woods, oils, and resins: in some parts of Germany, great quantities of good lamp-black are produced from a kind of pine-tree.

It appears, therefore, that the differences of foots do not depend altogether on the qualities of the subjects, but in a great measure on the manner in which the subject is burnt, or the foot caught. The foots produced in common chimneys, from different kinds of wood, resinous and not resinous, dry and green, do not differ far much from one another, as those which are produced from one kind of wood in a common chimney, and in the confined way of burning abovementioned.

Ivory-black is prepared from ivory or bones burnt in a close vessel. This, when finely ground, forms a more beautiful and deeper colour than lamp-black; but in the common methods of manufacturing, it is so much adulterated with charcoal dust, and so greatly leviaged, as to be unfit for use. An opaque deep black for water-colours, is made by grinding ivory-black with gum-water, or with the liquor which frets from the white of eggs after they have been suffered to stand a little. Some use gum-water and the whites of eggs together, and report, that a small addition of the latter makes the mixture flow more freely from the penel, and improves its glittiness. It may be observed, however, that though ivory-black makes the deepest colour in water as well as in oil-painting, yet it is not on account always to be preferred to other black pigments. A deep jet-black colour is seldom wanted in painting; and in the lighter shades, whether obtained by diluting the black with white bodies, or by applying it thin on a white ground, the particular beauty of the ivory-black is in a great measure lost.

Blue-black is said to be prepared from the burnt stalks and tendrils of the vine. Thence, however, the colour-makers seldom give themselves the trouble of procuring, but substitute in its place a mixture of ivory-black and the common blue used for clothes.

Indian-ink is an excellent black for water-colours. It hath been discovered by Dr. Lewis to consist of a mixture of lamp-black and common glue. Ivory-black, or charcoal, he found to answer equally well, provided they were leviaged to a sufficient degree of fineness, which indeed requires no small trouble.

White-colours. - The white colours commonly to be met with are, white-flake, white lead, calcined harthorn, pearl-white, Spanish-white, egg-shell white, and magistery of bismuth. The flake-white and white-lead are properly the same. The preparation of the former is kept a secret; the method of preparing the latter is described under Chemistry, n° 875. These are the only whites that can be used in oil, all the rest being transparent unless they are laid on with water. Calcined harthorn is the most useful of the earthy whites, as being the least alkaline. Spanish-white is only finely prepared chalk. Pearl-white is made of oyster-shells; and egg-shell white from the shells of eggs. All these, by their attractions for acids, must necessarily destroy such colours as have any acid or metallic salt in their composition. The magistery of bismuth is apt to turn black, as are also lake-white and white-lead, when used in water. The white precipitate of lead recommended under Chemistry, n° 703, is greatly superior as a water-colour to all these, being perfectly free of any alkaline quality, and not at all apt to lose its own colour, or to injure that of other substances.

Red. - The red colours used in painting are of red-co two forms; viz., those which incline to the purple, and lours.

We have already (n° 12.) laid down some general rules for the preparation of carmine and lake. Particular receipts have been delivered with the greatest confidence for making these fine colours; but all of them must necessarily prove ineffectual, because an earthy basis is recommended for brightening the colour upon: from the principles of chemistry, however, we are certain, that if aquafortis, or solution of tartar, is made use of for brightening a colour made with any earthy basis, it must infallibly be destroyed by that basis, by reason of its alkaline quality. Carmine is the brightest and most beautiful red colour known at present; the best comes from France. Lake differs from it in being capable of mixture with oil; which carmine is not, unless with great difficulty. The former is also much more inclined to purple than carmine. This last quality, however, is reckoned a defect; and accordingly, the more that lake approaches to the scarlet or true crimson, the more it is valued. On dropping solution of tin into an aqueous tincture of brazil-wood, a beautiful precipitate falls, of a purplish crimson colour. This may be very well substituted in place of the dearer lakes on many occasions.

Rope-pink is a very beautiful colour, inclining more to the purple than scarlet. It seems to be made of chalk, coloured with a decoction of brazil-wood, heightened by an alkaline salt; for which reason it is exceedingly perishable, and but little esteemed. The colour might be made much more durable as well as better, by employing for a basis the white precipitate of lead abovementioned, and brightening it with solution of tin.

On dropping solution of vitriol and a little lead in water from the colouhour of vitriol well calced. The calcium of iron may be made to appear either purplish, or inclining to the scarlet, according to the manner in which the calcination is performed. If the matter is perfectly deprived of its phlogiston, and subjected to an intense fire, it always turns out red; but the mixture of a small quantity of inflammable matter gives it a purplish cast. Hence various paints are kept in the shops under different names, which yet differ from each other only in the flight circumstance abovementioned: and such are the scarlet ochre, Spanish-brown, and terra di Sienna, burnt. It is remarkable, that the cates of iron never show their colour till they become cold. Colouhour of vitriol, white hot, always appears of a very dark dusky purple.

Of the preparation of vermilion and red lead, an account is given under the article Chemistry, n° 1213, 1404. These are very durable colours; the best
**5. Yellow.** The yellow paints most commonly in use are, king's-yellow, Naples-yellow, Dutch-pink, English-pink, masticot, common orpiment, yellow ochre, terra di Sienna unburnt, and turpith-mineral.

King's-yellow is evidently an arsenical preparation. Its colour is exceedingly beautiful, but apt to fade; on which account, and its great price, it is seldom used.

Naples-yellow was for a long time thought to be a preparation of arsenic, but is now discovered to have lead for its basis. It is therefore apt to turn black and lose its colour, which makes it the less valuable. It is nevertheless used in preference to king's-yellow, on account of its inferiority in price. This colour is particularly liable to be spoiled by iron when moist, and therefore should never be touched by that metal unless previously ground in oil.

Dutch-pink is said to be prepared by striking the colour of yellow berries upon finely levigated chalk. But of this there is great reason to doubt; the basis of Dutch-pink seems much more hard and gritty than chalk, and its colour more durable than those struck upon that earth usually are. Very good yellows may be prepared with the white precipitate of lead, formerly mentioned, by using either yellow berries, fuscic, or any other substance capable of yielding that colour. English-pink is paler than the Dutch, and keeps its colour greatly worse.

Masticot is prepared by calcining white-lead till it attains a yellowish colour. It is not apt to change, but the colour is so dull that it is seldom used either in oil or water.

Common orpiment is a pretty bright greenish-yellow, prepared by subliming arsenic with sulphur. Its nauseous smell, which is greatly increased by grinding in oil, makes it very disagreeable; nor does it keep its colour for any length of time. That kind of orpiment least inclined to green is to be preferred for the purposes of painting.

Yellow-ochre and terra di Sienna, are ferruginous earths, capable of becoming red by calcination. Green vitriol precipitated by lime may be advantageously substituted to either of them. See Chemistry, p. 609.

Turpith-mineral is but little used in painting, though its fine yellow colour seems greatly to recommend it. This preparation is in all probability very durable; and should seem therefore worthy of a preference either to king's or Naples yellow. The method of preparing it is described under Chemistry, p. 705.

Gamboge is a paint that can only be used in water, and is the most common yellow made use of for colouring maps, &c. but for this it is not very proper, being neither quite transparent, nor very durable.

6. Green. The only simple green colour that hath a tolerable degree of brightness is verdigris, or preparations of it. This, however, though a very beautiful colour, is far from being durable. It is improved in colour, though not in durability, by distillation and crystallization in distilled vinegar; in which state it is called distilled verdigris. A more durable water-colour is made by dissolving the verdigris in cream of tartar, or rather the pure tarsatic acid, but in oil this is found to be equally fugitive with the verdigris itself.

For an account of these preparations, see Chemistry, n° 894.

Compound greens are either made of Prussian or some other blue, mixed with yellow; but in whatever way these colours can be compounded, the beauty of the green produced is greatly inferior to distilled, or even common, verdigris. The tarsatic solution of verdigris, mixed with a little gamboge, is the best transparent green water-colour we have had an opportunity of trying; and a mixture of Prussian-blue and turpith-mineral is probably the best opaque one.

Sap-green is a simple colour, but exceedingly inferior to distilled verdigris, or even to the tarsatic solution of verdigris with gamboge. It is prepared from the juice of untirp buckthorn berries evaporated to the consistence of a gum. Its green colour is greatly inclined to yellow. A kind of compound green has been sometimes used, called Prussian-green, which consists only of Prussian blue and yellow-ochre. It has no beauty, nor is it durable. It is prepared as Prussian-blue, only not pouring on any spirit of salt to dissolve the ochreous sediment which falls at the same time.

Another green sometimes used is called terra verde. This is a native earth, probably impregnated with copper. It is of a bluish green colour, much of that tint called sea-green. It is gritty, and therefore must be well levigated before it is used. Its colour is durable, but not very bright.

7. Blue. The blue colours are ultramarine, Prussian blue, verditer, smalt, bice, and indigo. Of these ultramarine is the finest, but its great price hinders its being much used. It is a preparation from lapis lazuli; is an exceeding bright colour, and never fades with whatever substance it is mixed. It is now, however, in a great measure superseded by Prussian blue, to the disadvantage of painting in general; as Prussian blue, though very beautiful, is far from being durable. For an account of its preparations see the article Ultramarine.

The process for making Prussian blue is described, and its nature fully considered, under Chemistry, n° 1163: so that if it is sufficient here to observe, that Prussian blue is to be accounted of the best quality when it is deep, bright, and not inclined to purple. It ought to be tried by mixture with white lead, as the brightens of the colour will appear much more when diluted than when concentrated in the lumps of the blue itself.

The preparation of blue verdites is kept a secret, and the best chemists have been puzzled to find out the method. The colour is exceedingly bright, and has a col-
Considerable tinge of green. A method of preparing a colour equally beautiful, and agreeing in all respects with what is sold in the shops, except that of ever-varying with acids, we have found to be as follows: Dissolve copper in strong caustic alkali, until the liquid has assumed a very deep blue colour; and the deeper this colour is, the finer will your verditer be. When the menstruum has dissolved as much of the metal as it can take up, it is to be poured out into a broad and well glazed earthen pan, held over a very gentle fire; and from the moment it is put on the liquor is to be continually agitated with a wooden spatula, so that the liquor may be heated as equally as possible. The whole secret consists in properly regulating the degree of heat; for if it exceeds the due proportion ever so little, the verditer will turn out of a dirty green. The proper degree is about 90° of Fahrenheit's thermometer. In this gentle heat the alkali slowly evaporates; and in proportion to its doing fo the verditer falls to the bottom. After it is once formed, freed from the alkaline liquor, and dried, it can bear the affusion of boiling water without the least injury. Dr Priestley, in his sixth volume, takes notice, that solution of copper in volatile alkali affords a blue precipitate by heat, but without taking notice of the requisite for its success. In making this preparation, it is necessary to dissolve copper in its metallic state; for the solution of any calx will not yield a blue, but a green colour. This colour is durable in water, but dissolves in oil, and has then all the inconveniences of verdigris above mentioned.

Smalt is glas-coloured with zaffre, a preparation from cobalt*. It is commonly so grossly powdered that it cannot be used in painting, and its texture is so hard that it cannot easily be levigated. Its colour is exceedingly bright and durable; so that when finely levigated it is used instead of ultramarine. The most proper materials for levigating this substance seem to be the plates of M. Reaumur's porcelain recommended by Dr Lewis. See Chemistry, n° 592, 599. For the preparation of the quills of bice, see the articles Arménus Lapis and Bice.

Indigo is but little used in painting either in oil or water, on account of the dulness of the colour. It requires no other preparation than being washed over. Its goodness is known by the darknes and brightness of the colour. See Indigo.

8. Purple. The only simple colour of this kind used at present is colcothar of vitriol. A beautiful purple lake may be prepared from logwood by means of solution of tin; but this method of preparing colours is very little known as yet.

9. Brown. The brown colours are, bistre, brown-ochre, Cologne-earth, umbre, and brown-pink. Under the article Bistre is given a process for making that colour, by infusing foot in water, pouring off the tincture, and then evaporating it to an extract: but Dr Lewis is of opinion, with Mr Landais in the French Encyclopédie, that the foot is either boiled in water, or ground with a little liquid of some kind into a smooth paste; it is then diluted with more water, and after standing for about half an hour till the greater substance of the foot has settled, the liquor is poured off off into another vessel, and let for by two or three days, that the finer parts may fall to the bottom, and this

fine matter is the bistre. This is a very useful colour in water, being exceedingly fine, durable, and not apt to spoil any other colours with which it is mixed. The brown pink is said to consist of chalk tinged with the colouring matter of fulic, heightened with fixed alkaline salts. It is therefore very periflabile, and is seldom used. The other browns are a kind of ochreous earths; for a description of which see their proper articles.

Having now considered most of the colouring substances usually to be met with in the shops, we shall next take notice of some attempts that have been made to produce all the different colours from vegetables, after the manner of lakes; which, though the methods hitherto tried have for the most part failed of success, may perhaps some time or other be found applicable to valuable purposes.

From infusions of astringent vegetables mixed with black from green vitriol, is produced a deep black liquor of very astringent, extensive use in dyeing+. The substances which produce the deepest blacks are galls and logwood. When a decoction or infusion of the galls is dropped into a solution of the vitriol largely diluted with water, the first drops produce bluish or purplish red clouds which soon mingling with the liquor, turn it uniformly of their own colour. It seems to be on the quality of the water that this difference in the colour depends. With distilled water, or the common spring-waters, the mixture is always blue. If we previously dissolve in water the most minute quantity of any alkaline salt too small to be discovered by any of the common means by which waters are usually tried, or if the water is in the least putrid, the colour of the mixture proves purple a reddish. Rain-water, caught as it falls from the clouds in an open field in clean glass-vessels, gives a blue; but such as is collected from the tops of the houfes, grows purple with the mixture of vitriol and galls: from whence it may be presumed, that this last has contracted a putrid tendency, or received an alkaline impregnation, though so slight as not to be sensible on other sorts of trial.

Both the purple and blue liquors, on adding more of the astringent infusion, deepen to a black, more or less intense according to the nature of dilution: if the mixture proves of a deep opaque blackness, it again becomes bluish or purplish when further diluted. If suffered to stand in this diluted state for two or three days, the colouring matter settles to the bottom in form of a fine black mud, which by slightly shaking the vessel, is diffused again through the liquor, and tinged with its former colour. When the mixture is of a full blackness, this separation does not happen, or in a far less degree; for though a part of the matter precipitates in standing, yet so much remains dissolved, that the liquor continues black. This suspension of the colouring substance, in the black liquid, may be attributed in part to the gummy matter of the astringent infusion increasing the consistence of the watery fluid; for the separation is retarded in the diluted mixture by a small addition of gum Arabic. If the mixture either in its black or diluted state is poured into a filter, the liquor passes through coloured; only a part of the black matter remaining on the filter. The filtered liquor on standing for some time becomes turbid and full of fine black flakes: being freed
Dr. Lewis, from whose Philosophical Commerce of Arts this account is taken, further informs us, that this colouring matter, when separated from the liquor and dried, appeared of a deep black which did not seem to have suffered any change from the air by exposure for upwards of four months. Made red-hot, it glowed and burnt, but did not flame, and became a ruddy brown powder, which was readily attracted by a magnetic bar; though in its black state the magnet had no action upon it. The vitriolic acid, diluted with water and digested on the black powder, dissolved the greatest part of it, leaving only a very small quantity of whitish matter. Solution of pure fixed alkaline salt dissolved very little of it: the liquor received a reddish brown colour, and the powder became blackish brown. This residuum was attracted by the magnet after being red-hot, though not before: the alkaline tincture, passed through a filter, and mixed with a solution of green vitriol, struck a deep brownish black colour to the same with that which results from mixing with the vitriolic solution, an alkaline tincture of galls.

It hath also been attempted to produce black from a combination of other colours; as green may be produced from a mixture of blue and yellow. Mr. Le Blon, in his Harmony of Colours, gives a method of forming black, by mixing together the three colours called primitive, viz. blue, red, and yellow; and Mr. Castel in his Optique des Couleurs, published in 1740, says that this compound black has an advantage, in painting, above the simple ones, of answering better for the darkening of other colours. Thus it blue, by the addition of black, is to be darkened into the colour called blue-black, the timple black, according to him, if used in sufficient quantity to produce the requisite deepness, conceal the blue, while the compound blacks leave it distinguishable. Le Blon does not mention the proportions of the three colours necessary for producing black. Castel directs 15 parts of blue, five of red, and three of yellow; but takes notice, that these proportions are rather speculatively than practically just, and that the eye only can be the true judge; our colours being all very imperfect, and our pigments or other bodies of one denomination of colour being very unequal in their degree of intensity. He observes that the pigments should all be of the deepest and darkest kind: and that, instead of taking one pigment for each colour, it is better to take as many as can be got; for the greater discord there is of heterogeneous and discordant drugs, the more true and beautiful, he says, will the black be, and the more capable of uniting with all other colours, without suppressing them, and even without making them tawney.

Dr. Lewis acquaints us, that by mixing different blue, red, and yellow colours, he has not been able to produce a perfect black; but has often obtained from them very dark colours, such as may be called brown-black, or grey-black; such as we commonly see in the dark parts of paintings, and such as the charcoal and foot blacks appear when diluted a little. The ingredients being each of a dark deep colour is a very necessary condition; for bright blues, bright reds, and bright yellows, mixed in such proportions that neither colour prevailed, produced only a grey. In effect, all compositions of this kind, physically considered, can be no other than greys, or some of the intermediate tints between whites and darks; and these greys will be so much the lighter or darker as the component colours of themselves are bright or dark.

With regard to the extraction of the colouring matter from the different kinds of vegetables commonly to be met with of all colours, this would certainly be a very valuable acquisition, could the colours so procured be made durable. On this subject nothing hath yet appeared more satisfactorily than what is delivered by Dr. Lewis in his notes on Neuman's chemistry. His observations are curious, but promise very little inaccess to any who shall attempt to fix these vegetable colours.

Among the infinite variety of colours (says he), Dr. Lewis's which glow in the flowers of plants, there are very few which have any durability, or which soften the beauty which can be arrested by air, so as to be applied to any durable purposes. The only permanent ones are the yellow, the red, the blue; and all the intermediate shades of purple, crimson, violet, &c. are extremely perishable. Many of these flowers lose their colours on being barely dried; especially if they are dried slowly, as has been usually directed, in a shady, and not warm place. The colours of all of them perish on keeping even in the closet vessels. The more hastily they are dried, and the more perfectly they are secured from the air, the longer they retain their beauty. The colouring matter extracted and applied on other bodies is still more perishable: oftentimes it is changed or destroyed in the hands of the operator.

The colour of many blue flowers is extracted by infusion in water; but there are some from which water gains only reddish, or purplish blue. Of those that have been tried there is not one which gives any blue tincture to spiritsuous liquors: some give no colour at all, and some a reddish one. The juice pressed out from the fresh flowers is for the most part blue. The blue juices and infusions are changed red by all acids. The marine acid seems to strike the most florid red. The flowers themselves, macerated in acide liquors, impart also a deep red tincture. Alkalies, both fixed and volatile, and lime-water, change them to a green. Those infusions of the juices which have nothing of the native colour of the flowers, suffer the change from the addition of acid and alkaline liquors: even when the flowers have been kept till their colour is lost, infusions made from them acquire filling a red colour from the one, and a green from the other, though in a less degree than when the flowers were fresh. The red colour produced by acids is scarcely more durable than the original blue: applied upon other bodies and exposed to the air, it gradually degenerates into a faintish purple, and at length disappears, leaving hardly any stain behind. The green produced by alkalies changes to a yellow, which does not fade so soon. The green, by lime-water, is more permanent and more beautiful: green lakes, prepared from these flowers by lime-water, have been used as pigments by
the painter. The flowers of cyanus have been greatly recommended, as affording elegant and durable blue pigments; but I have never been able to extract from them any blue colour at all. They retain their colour indeed, when habitually dried, longer than some other blue flowers: but they communicate nothing of it to any kind of menstruum. Infusions of them in watery, spiritious, and oily liquors, are all of them more or less of a reddish cast, without any tendency to blue. Alum, which is said to heighten and preserve their blue colour, changes it, like that of other blue flowers, to a purplish red; acids to a deep red; alkalies and lime-water to a green; solution of tin added to the watery infusion, turns it of a fine crimson; on standing, a beautiful red succulent subfides, but it loses all its colour by the time it is dry. The watery infusion, infused to the consistence of an extract, appears of a dark reddish brown: an extract made with rectified spirit is of a purplish colour. The colour of both extracts spread thin and exposed to the air quickly fades. The flowers employed in these experiments were those of the common blue-bottle of the blue; but this is far from the truth. The flowers employed in these experiments gives a fine bright yellow to spirit, acids, and neutralized lime-water for some time, a beautiful red vegetable yellow that is turned red by acids. Both the watery infusions were heightened by alkaline liquors, turned red by acids, and again to a deep yellow on adding more of the alkali: I know no other vegetable yellow that is turned red by acids.

"Red flowers readily communicate their own red colour to watery menstrua: among those that have been tried, there is not one exception. Those of a full red colour give to rectified spirit also a deep red tincture, brighter, though somewhat paler, than the watery infusion: but the lighter red flowers, and those which have a tendency to purplish, impart very little colour to spirit, and seem to partake more of the nature of the blue flowers than of the pure red. Infusions of red flowers are supposed to be heightened by acids, and turned green by alkalies, like those of the blue, but this is far from being universal. Among those I have examined, the red-colours and purplish reds were changed nearly in the same manner as the blue: but the full deep reds were not the deep infusion of red poppies is changed by alkalies, not to a green, but to a dusky purple.

"The colours of yellow flowers, whether pale or deep, are in general durable. Many of them are as much so, perhaps, as any of the native colours of vegetables. The colour is extracted both by water and by spirit. The watery infusions are the deepest. Neither alkalies nor acids alter the species of the colour, though both of them vary its shade; acids rendering it paler, and alkalies deeper: alum likewise considerably heightens it, though not so much as alkalies. An infusion of the flowers, made in alkaline ley, precipitated by alum, gives a durable yellow lake. In some of the deep reddish, or orange-coloured flowers, the yellow matter seems to be of the same kind with that of the pure yellow flowers, but the red to be of a different kind from the pure red ones; watery menstrua take up only the yellow, and leave the red, which may afterwards be extracted by rectified spirit of wine, or by water aerated by fixed alkaline salt. Such particularly are the saffron-coloured flowers of carthamines. These, after the yellow matter has been extracted by water, are said to give a red tincture to ley; from which, on flying about for some time, a deep bright red succulent subfides; called from one of the nines of the plant which produces it, jaffover; and from the countries whence it is commonly brought to us, Spanish-red, and China-lake. This pigment impregnates spirit of wine with a beautiful red tincture, but communicates no colour to water. I have endeavoured to separate, by the same treatment, the red matter of some of the other reddish yellow flowers, as those of garden marigold, but without success. Plain water extracted a yellow colour, and alkaline ley extracted afterwards only a paler yellow; though the digested water was changed till the flower was lost, yet their colour, the tinctures were no other than yellow, and not so deep as those obtained from the pure yellow flowers. The little yellow flocculi, which in some kinds of flowers are collected into a compact round disc, as in the daisy and corn-marigold, agree, so far as they have been examined, with the expanded yellow petals. Their colour is affected in the same manner by acids, by alkalies, and by alum; and equally extracted by water and by spirit. But the yellow farina, or fine dust, lodged on the tips of the flamina of flowers, appears to be of a different kind. It gives a fine bright yellow to spirit, and a dulter yellow to water; the undissolved part proving in both cases of a pale yellowish white. Both the watery tinctures were heightened by alkaline liquors, turned red by acids, and again to a deep yellow on adding more of the alkali: I know no other vegetable yellow that is turned red by acids.

"White flowers are by no means delitute of colouring matter. Alkaline liliaceae extract from some of them a green tincture, and change their colourless expressed juices to the same colour; but I have not observed that they are turned red by acids. The flowers of the common wild convolvulus or bindweed, which in all their parts are white, give a deep yellow or orange tincture to plain water; which, like the tinctures of flowers that are naturally of that colour, is rendered paler by acids, heightened a little by alum, and more considerably by alkaline salts. The vapours of the volatile vitriolic acid, or of burning sulphur, which whiten or destroy the colour of the coloured flowers, make no change in the white.

"The red juices of fruits, as currants, mulberries, Colours elder-berries, morello, and black cherries, &c. were turned red by acids, and sometimes made dull, and sometimes more florid, by acids, and generally turned purplish by alkalies. The colours of these juices are for the most part perifable. They refist, indeed, the power of fermentation, and continue almost unchanged, after the liquor has been converted into wine; but when the juice is spread thin upon other bodies, excitted, and exposed to the air, the colour quickly alters and decays: the bright lively red changes the fomew; the dark dull red stain from the juice of the black cherry, is of considerable durability. The fruit of the American opuntia or prickly pear, the plant upon which the cochineal insect is produced, is perhaps an exception: This bright red fruit, according to Labar, gives a beautiful red dye. Some experiments, however, made upon the juice of that fruit,
The ripe berries of buckthorn loan paper of a green colour. From these is prepared the substance called sap-green, a pigment sufficiently durable, readily soluble in water, but not miscible with oil. The berries dried white green, and macerated in alum-water, are said to yield a yellow pigment; and when they have grown over ripe so as to fall off spontaneously, a purple one. It is said that the berry of the heliotropium tricoccum, which grows wild about Montpellier, flains paper of a green colour, and that this green turns presently to a blue: that the common blue paper receives its colour from this juice: and that the red rags called turnefl, employed for colouring wines and other liquors, are tinted by the same juice turned red by acids. According to M. Nifole of the French academy of sciences (as quoted by Savary in his Dictionaire de Commerce), the colouring juice is obtained not from the berries, but from the tops of the plant gathered in August, ground in mills, and then submitted to the press. The juice is exposed to the sun about an hour, the rags dip in it, dried in the sun, moistened by the vapour which arises during the drying of quicklime with urine, then dried again in the sun, and dipped again in the juice. The Dutch and others are said to prepare turneful rags, and tUrns of the mass, from different ingredients, among which archil is a principal one.

In some plants, p-oxy for instance, the seeds at a certain point of maturity are covered with a fine thinning red membrane. The pelliges of the seeds of a certain American tree afford the red mafes brought into Europe under the names of annette, orleau, and rancou. Mr Pott, in the Berlin Memoirs for the year 1752, mentions a very extraordinary property of this concrete. With the vitriolic acid it produces a blue colour, of extreme beauty; but with this capital defect, that all fats and liquors, and even common water, destroy it. The specimen of annette, which I examined, was not sensibly affected upon by spirit of vitriol; it received no change in its own colour, and communicated none to the liquor. Nor did any visible change ensue upon dropping the acid into tinctures of annette made in water, or in spirit.

The green colour of the leaves of plants is extracted by rectified spirit of wine and by oils. The spirituous tinctures are generally of a fine deep green, even when the leaves themselves are dull-coloured, or yellowish, or hoary. The colour, however, seldom abides long even in the liquor; much less when the tincting matter is separated in a solid form, and exposed to a large surface to the air. The editor of the Wurtzburg Pharmacopoeia observes, that the leaves of acanthus, brankwine, or bear's-breach, give a more durable green tincture to spirit than those of any other herb. Alkalies heighten the colour both of the tinctures and green juices; acids weaken, destroy, or change it to a brownish: lime-water improves both the colour and durability: by means of lime, not inelegant green lakes are procured from the leaves of acanthus, lily of the valley, and several other plants. There are very few herbs which communicate any share of their green colour to water; perhaps none that give a green of any considerable deepness. It is said, however, that the leaves of some plants give a green dye to woolen, without the addition of any other colouring matter; particularly those of the wild chervil, or cow-weed, the common ragwort, and devil's-bit. The leaves of many kinds of herbs and trees give a yellow dye to wool or woolen cloth that has been previously boiled with a solution of alum and tartar. Wield, in particular, affords a fine yellow, and is commonly made use of for this purpose by the dyers, and cultivated in large quantity in some parts of England. There is no colour for which we have such plenty of materials as for yellow. Mr Heliot observes, that all leaves, barks, and roots, which on being chewed disclose a flight astringency, as the leaves of the almond, peach, and pear-trees, ad-bark (especially that taken off after the first rising of the sap in the spring), the roots of wild patience, &c. yield durable yellows, more or less beautiful according to the length of time that the boiling is continued, and the proportions of alum and tartar in the preparatory liquor: that a large quantity of alun makes these yellows approach to the elegant yellow of weld: that if the tartar is made to prevail, it inclines them to an orange: that if the roots, barks, or leaves, be too long boiled, the yellow proves tarnished, and acquires shades of brown. See the article DYEING.

The most capital preparations from the leaves of plants, are those of indigo and weld; which are both very much used in dyeing, though the first only in painting.* Both the indigo and woad plants give out their colour, by proper management, to water, in form of a blue fcella or lake. Mr Heliot supposes that a like blue fcella is procurable from many other vegetables. Blue and yellow blended together, compose a green. He supposes the natural greens in vegetables to be compounded in like manner of these two colours; and that the blue is oftentimes the most permanent, so as to remain entire after the putrefaction or destruction of the yellow. The theory is specious, and perhaps just; we know of no other that accounts in any degree for the production of the indigo and woad blue. Dr Lewis, however, informs us, that he never was able to produce the least appearance of either blue or yellow from any of the plants he tried by treating them in the manner used for the preparation of indigo.

There are sundry modes, which in their natural Colours resemble, the indigo and woad plants, promise nothing of the elegant colours that can be extracted from them by art. The most remarkable of these is archil: for the preparation of which, and the colours that may be produced from it, see the article. Linnaeus suspects that there are several more common modes from which valuable colours might be extracted: a quantity of sea-mofs, having rooted in heaps on the shore, he observed the liquor in the heaps to be as red as blood: the sea-water, the sun, and the putrefaction, having brought out the colour. Mr Kalm, in an appendix to Linnaeus's paper, in 1745, mentions two sorts of mofs actually employed in Sweden for dyeing woollen red: one is the Lichenoides coralliforme apicibus coccinis of Ray's Synopsis; the other the Lichenoides tartareum, farinaceum, scutellatum.
Colour-making.

Larum umbone fuso, of Dillenius. This is a white substance like meaal clotted together, found on the sides of boys and hills. It is found with other woods in the rocks after rain, washed from the stony matters intermixed among it by washing with water, then dried in the sun, ground in mills, and again washed and dried; it is then put into a vessel with urine, and left for a month: a little of this tincture added to boiling water makes the dyeing colour. In the same Tranactions for the year 1754, there is an account of another moss which, prepared with urine, gives a beautiful and durable red or violet dye to wool and flax. This is the fichen foliaceous umbilicus fustus lacteuncus, Linnaeus. See. It grows upon rocks, and is readily distinguishable from others of that clafs, by looking as if burnt or parched, consisting of leaves as thin as paper, convex all over on the upper side, with corresponding cavities underneath, adhering firmly to the stones by a little root under the leaves, and coming auster, when dry, as soon as touched. It is gathered after rain, as it then holds best together, and parts eafiest from the stone. In France, a crustaceous moss, growing upon rocks in Auvergne, is prepared with lime and urine, and employed by the dyers as a growing upon rocks in Auvergne, is prepared with which, together with the juice, combing it with tobacco pipe clary, and brightening it with a little alum. The root of the red beet is also said to yield a durable colour of a beautiful red, inclining to scarlet; but this we cannot affirm from our own experience.

With regard to liquid colours for maps, &c. We colour apprehend there can be very little difficulty of preparing all the possible varieties of them, in what we have above laid down is attended to. The only colour with which there can be any difficulty is blue; but the common solutions of indigo in alkalies or acids may be made to answer this purpose; though, on account of their strongly saline quality, they are not very proper. A very curious method of procuring a beautiful transparent blue colour is by extracting the colouring matter from Prussian blue, by means of a caustic alkali. This when laid upon paper appears of a dirty brown colour; but if washed over with a weak solution of green vitriol, it is instantly changed to a most beautiful blue. This seems to afford a method of procuring blue transparent colours of greater durability than they are usually met with. See specimens of transparent colours prepared according to the above rules, on the Chart subjoined to HISTORY.

Colouring, among painters, the manner of applying and conducting the colour of a picture; or the mixtures of light and shadows, formed by the various colours employed in painting. See Painting.

Colouring of Glass. See Glass.

Colouring of Porcelain. See Porcelain.

COLOUR, in zoology, a general name for the young of the horse-kind: the male being likewise, for distinction's sake, called a horse-cub, the female, a filly.

After the colts have been foaled, you will suffer them to run with the mare till about Michaelmas, some 40 or later, according as the cold weather comes in; then they must be weaned: though some persons are for having them weaned after Martinmas, or the middle of November. The author of the Complete Horfman is of opinion, that the reason why most foals advance so flowly, and are not capable of service till they are six or seven years old, is because they have not sucked long enough; whereas, if they had sucked the whole winter over, they would be as good at four or five years old as they are now at eight.

They ought now to be kept in a convenient house, with a low rack and manger for their hay and oats, which must be sweet and good; with a little wheaten bran mixed with the oats to cause them to drink, and keep their bodies open. But, since there are some persons who assert that oats make foals become blind, or their teeth crooked; the same author is of opinion, that oats will wear their teeth, and make them the sooner to change, and also to raze; therefore he judges it to be the best way to break them in a mill, because that by endeavouring with their jaws to bruise

X 2
and chew them, they stretch and swell their eye and nether-jaw veins, which do attract the blood and humours that they fall down upon the eyes, and frequently occasion the los of them; so that it is not the heating quality of the oats, but the difficulty in chewing, that is the cause of their blindness.

Further, colts thus fed with grain do not grow thickish upon their legs, but grow broader and better knotted, and they had eaten nothing but hay and bran, and will endure fatigue the better. But above all, they must be kept from wet and cold, which are hurtful to them, nothing being more tender than they are.

For proof of this, take a Spanish stallion, and let him cover two mares, which for age, beauty, and comeliness may admit of no difference between them; and if they produce both horse-colt, or both fillies, which is one and the same thing, let one run abroad, and the other be housed every winter, kept warm, and ordinarily attended: and that colt that has been kept abroad shall have large feathery shoulders, flabby and gouty legs, weak patterns, and ill hoofs; and shall be a dull heavy jade, in comparison to the other which is houfed, and ought to run; and with which you may start him now, he will have a fore head, be fine shaped, and have good legs and hoofs, and be of good strength and spirit: by which you may know, that to have the finest stallion, and the best-feated mare, is nothing if they are spoiled in the breeding up. It is worth observation, that some foals, under six months old, though their dams yield plenty of milk, yet decay daily, and have a cough, proceeding from certain pellicles or skins that breed in their stomacks, which obstruct their breathing, and at last destroy them entirely. To remedy this malady, take the bag wherein the colt was foaled, dry it, and give him as much of it in milk as you can take up with three fingers; but if you have not preferred the bag, procure the lungs of a young fox, and use it instead of the aforesaid powdered.

It will be proper to let the colts play an hour or two in some court-yard, &c. when it is fair weather, provided you put them up again carefully, and see that they take no harm. When the winter is spent, turn them in some dry sweet ground, where the grass is short and sweet, and where there is good water, that they may drink at pleasure: for it is necessary that a colt should fill his belly immediately, like a horse that labours hard. The next winter you may take them into the house, and use them just as you do your other horses; but let not your horse-colts and fillies be kept together after the first year. This method may be observed every summer and winter till you break them, which you may do after they have been three years old; and it will be a very easy thing, if you observe the aforesaid method of housing them: for ordering them the second year as you do your other horses, they will be so tame and gentle, that you need not fear their leaping, plunging, kicking, or the like; for they will take the saddle quietly. As for all those ridiculous methods of beating and cowing them, they are in effect spoiling them, whatever they call it, in ploughed fields, or deep ways, or the like; instead of which, let the rider strive to win them by gentle usage, never correcting them but when it is necessary, and then with judgement and moderation. You will not need a cavesson of cord, which is a head strain, nor a pad of straw; but only a common saddle, and a common cavesson on his nose, such as other horses are ridden with; and it ought to be well lined with double leather; and if you please you may put on his mouth a watering bit, but without reins, only the head-stall, and this but for a few days; and then put on such a bit as he should be always ridden with: and be sure not to use spurs for some time after backing.

Take notice, that as yearlings must be kept abroad together, so those of two years old together; the like for those of three years old: which ordering is most agreeable to them.

In order make him endure the saddle the better, the way to make it familiar to him will be by clapping the saddle with your hand as it stands upon his back, by striking it, and fwaying upon it, dallying the stirrups by his sides, rubbing them against his sides, and making much of them, and bringing him to be familiar with all things about him; as straining the crupper, fastening and losing the girths, and taking up and letting out the stirrups. Then as to the motion of him, when he will trot with the saddle on, and the bridle be the same, you may stir him on his haunches to the forepart of the saddle, so that he may have a full feeling of it; then put on a martingale, buckled at such a length that he may but just feel it when he jerks up his head; then take a broad piece of leather, and put it about his neck, and make the ends of it fast by plaiting of it, or some other way, at the withers, and the middle part before his withers, about two handfuls below the throat, betwixt the leather and his neck; let the martingale pass so, that when at any time he offers to buck, or throw down his head, the cavesson being placed upon the tender gristle of his nose, may correct and punish him; which will make him bring his head to, and form him an absolute rein; trot him abroad, and if you find the reins or martingale grow slack, tighten them, for when there is no feeling there is no virtue.

Colt-Evil, among farriers. See Farriery, § xxviii. 4.

Colt-Taming, is the breaking of a colt so as to endure a rider. Colts are most easily broke at three or four years of age; but he who will have patience to see his horse at full five, will have him much more free of diseases and infirmities than if he was broke sooner.

Preparatory to their breaking for the saddle, they should be used to familiar actions, as rubbing, clawing, haltering, leading to water, taking up their feet, knocking their hoofs, &c. In order to bridle and saddle a colt, when he is made a little gentle, take a sweet watering trench; washed and anointed with honey and salt, which put into his mouth, and so place it that it may hang about his thu; then offer him the saddle, but take care not to fright him with it. Suffer him to smell at it, to be rubbed with it, and then to feel it: after that, fix it and gird it fast; and make that motion the most familiar to him to which he seems most averse. Being thus saddled and bridled, lead him out to water and bring him in again: when he has flood reined upon the trench an hour or more, take off the bridle and saddle, and let him go to his meat till the evening, and then lead him out as before.
COLO

fore; and when you carry him in again to set him up, take off his faddle gently, clothing him for all the night.

The body is very short; and of a pale colour, with brownish spots; and the head is gibbous, and covered with small scales. It is a native of Egypt, and other warm countries. It has always been remarkable for its poisonous nature; inasmuch that vipers, when numerous, have often been thought the ministers of divine vengeance, like the plague, famine, and other national calamities. A notion also prevailed among the ancients, that few or none of the parts of a viper were free from poison; for which reason they made no experiments or discoveries concerning the nature of these creatures. It is now, however, proved, by undoubted experiments, that the poison of vipers, as well as of all other serpents whose bite is hurtful, lies in a bag at the bottom of their two greater teeth or fangs. These teeth are perforated; and when the creature bites, the compression of the bag forces out a little drop of the poison into the wound, where it produces its mischievous effects. The purpose answered by this poisonous liquor to the creatures themselves, is probably the destruction of their prey; for as serpents frequently feed upon animals of very considerable magnitude and strength, they would often undoubtedly make their escape, did not the poisonous juice intinct into the wounds made by the serpent's teeth almost instantly deprive them of life, or at least of all power to struggle with their enemy. For an account of the venomous produced by the bites of vipers and other venomous serpents in the human body, together with the best methods of cure, see the Index subjoined to Medicine. After the viper is deprived of those bags which contain its poison, it is entirely harmless: may the flesh of it is highly nutritive, and justly esteemed a great restorative. It hath been much recommended in febulous, leprous, and other obnoxious chronic disorders; but, to answer any good purpose, it must undoubtedly be used for a considerable time as food. The dried skin which is brought to England, is justly esteemed by Dr Lewis to be totally insignificant. A volatile oil was formerly drawn from vipers, and sold at a great price, as a sovereign remedy against the bites of vipers and other poisonous animals: but it is now found not to be materially different from the volatile distillate thus procured by distilling other animal substances.

2. The berus, or common British viper, is found in many countries of Europe. They swarm in the He-

rides, or western British isles, and abound in many parts of Britain; particularly in the dry, stony, and chalky counties. According to Mr Pennant and other naturalists, they are viviparous, but proceed from an internal egg. The eggs are, as it were, chained together, and each about the size of the egg of a blackbird. This viper seldom grows longer than two feet; though Mr Pennant tells us he once saw a female (which is nearly a third larger than the male) almost three feet long. The ground colour of the male is of a dirty yellow, that of the female deeper. Its back is marked the whole length with a series of rhomboidal black spots, touching each other at the points; the sides with triangular ones; the belly entirely black. It hath 146 scuta, and 39 fcelae. There is a variety wholly black; but the rhomboidal marks are very conspicuous even in this, being of a deeper and more glossy hue than the rest. The head of the viper, says Mr Pennant, is inflated, which distinguishes it from the common snake. Mr Catesby assures us, that the difference between the vipers and serpents, or other serpents, is, that the former have long hollow fangs, or fticks, with an opening near the point: the neck is small, the head broad, the cheeks extending wide, scales rough, the body for the most part flat and thick; they are slow in motion; swell the head and neck when irritated, and have a terrible and ugly aspect. Another material difference, however, consists in the production of their young: the viper hatches its eggs within itself, and then discharges the young, whereas the snake deposits its eggs, which are therefore externally hatched. The tongue is forked, the teeth small; the four canine teeth are placed two on each side of the upper jaw: these instruments of poison are long, crooked, and moveable; capable, like those of the former species, of being raised or depressed at pleasure of the animal, and they infilt their poison in the same manner. The vipers are said not to arrive at their full growth till they are fix or seven years old; but they are capable of engendering at two or three. They copulate in May, and go about three months with their young. Mr White informs us, that the viper which he opened had 15 young ones of the size of earthworms, 7 inches long. This little fry issued into the world p. 210, with the true viper-spirit about them. They twisted and wriggled about with great alacrity; and when touched, they erected themselves, and gaped very wide, showing immediate tokens of menace and defiance, tho' no fangs could be perceived even with the help of glasses: which the author remarks as an instance among others of that wonderful instinct which inspires young animals with a notion of the situation and use of their natural weapons even before these weapons are formed. Mr Pennant tells us, that he has been favoured of a fact mentioned by Sir Thomas Brown*, who was far from being a credulous writer (A.), that the young of the viper, when terrified, will run down the trunk of the parent, and seek for shelter in its belly, in the same manner as the young of the opilion retire into the ventral pouch of the old one. From this some have imagined that the viper is fo unnatural as to devour

(a) The viper catchers, however, infift, that no such thing ever happens. See White's Nat. Hist. of Selborus,
Coluber. its own young: but the assertion deserves no credit; it being well known that the food of these serpents is frogs, toads, lizards, mice, and, according to Dr Mead, even an animal so large as a mole, which they are able to swallow entire, their throat and neck being capable of great distention. It is also said, from good authority, that vipers prey on young birds; but whether on such as nestle on the ground, or whether they catch prey for them, as the Indian serpents do, is quite uncertain; the fact, however, is very far from being recent; for Horace tells us,

Ut affidentem impluvit pullis avis Serpentium aliiapisis tomit.

Thus for its young the anxious bird

The gliding serpent fears.

The viper is capable of supporting very long sublimence; it being known, that some have been kept in a box six months without food, and yet did not abate of their vivacity. They feed only a small part of the year, but never during their confinement; for if mice, their favourite diet, should at that time be thrown into their box, though they will kill, yet they never eat them. The violence of their poison decreases in proportion to the length of their confinement, as does also the virtue of their flesh whatever it is. The animals, when at liberty, remain torpid throughout the winter; but, when confined, have never been observed to take their annual repose. The method of catching them is by putting a cleft stone on or near their head; after which they are fixed by the tail, and instantly put into a bag. The vipers are very frequently bit by them in the pursuit of their business, yet we very rarely hear of their bite being fatal. Salad oil, if applied in time, is said to be a certain remedy. The flesh of the British viper has been celebrated as a restorative, as well as that of other countries. Mr Keyler relates, that Sir Kenelm Digby used to feed his wife, who was a most beautiful woman, with capons fattened with the flesh of vipers.

3. The punctatus of Linnaeus, by Mr Catesby called the water-viper, is a native of Carolina. According to Linnaeus it is ash-coloured, variegated with yellow spots. Mr Catesby informs us, that the head and back of this serpent are brown: the belly marked transversely with yellow, and also the sides of the neck. The neck is small, the head large, and the mouth armed with the destructive fangs of the viper or rattlesnake, next to which it is reckoned the largest serpent in this country. Contrary to what is observed in most other vipers, these are very nimble and active, and very dexterous in catching fish. In summer, great numbers are seen lying on the branches of trees hanging over rivers; from which, on the approach of a boat, they drop into the water, and often into the boat on the men's heads. They lie in wait in this manner to surprise either birds or fish: after the latter they plunge with surpising vigour, and catch some of a large size, which they bring ashore and swallow whole. The tail of this animal is small towards the end, and terminates in a blunt horny point about half an inch long. This harmless little horn hath been the occasion of many terrible reports: as, that by a jerk of its tail, the animal is capable of instantly destroying both men and beasts; that a tree struck with this terrible horn, in a short time grows black, withers, and dies, &c., but all these Mr Catesby affures us have not the least foundation in fact.

4. The chersea is a native of Sweden, where it is called apping. It is a small reddish serpent, whose bite is said to be mortal. Concerning this species Mr Catesby asks, "Is it possible that this could be the species which has hitherto escaped the notice of its naturalists? I rather suspect it, as I have been informed that there is a small snake that lurks in the low grounds of Galloway, which bites and often proves fatal to the inhabitants."

5. The pretler of Linnaeus, or black viper of Mr Catesby, is a native of Carolina and Virginia. It is short and thick, slow of motion, spreads its head sprightly when irritated, very flat and thick, threatening with a horrid hiss. They are very venomous; their bite being as deadly as that of the rattlesnake. They frequent the higher lands, and are of a ruddy black colour.

The coluber luridus of Forster, called by Mr Catesby the bruus vipers, is a native of the same countries with the preceding. It is about two feet long, and large in proportion; very slow in its motion, even when threatened with danger: notwithstanding which, it defends itself very fiercely when attacked, and its bite is as venomous as any. They prey upon efts, lizards, and other animals of that kind.

Besides these species of which we have a particular description, the following are also reckoned among the poisonous serpents, viz.

7. The artopos, with 131 scuta and 22 scutellae. It is a native of America, the body white, and the eyes brown, with a white iris. 8. The leberis, with 110 scuta and 50 scutellae, is a native of Canada, and has many black linear rings. 9. The ammodites, with 142 scuta and 32 scutellae, is a native of the East. It is about six inches long, and has a dryish prounance on its nose. 10. The aspis, with 146 scuta and 46 scutellae, is a native of France; and is of a reddish colour, with dusky spots on the back. 11. The lebetinus, with 155 scuta and 46 scutellae, is a native of Asia, and is of a cloudy colour, with red spots on the belly. 12. The severus, with 170 scuta and 42 scutellae, is likewise a native of Asia, and is ashy-coloured with white belt. 13. The rialbus, with 143 scuta and 76 scutellae, is a native of Asia, and is of a greyish colour, with two white fillets. 14. The legetus, with 203 scuta and 32 scutellae, is a native of the Indies. Its colour is white, with black spots. 15. The naja, with 193 scuta and 60 scutellae, is a native of the East Indies, and is reckoned the most venomous of all serpents. The root of the lignum colubrinum (ophiorrhiza) is said to have been pointed out to the Indians as an antidote against the bite of this serpent by the vireira ichneumon, a creature which fights with this serpent, and cures itself by eating of this plant when wounded. The Indians, when bit, instantly chew it, swallow the juice, and apply the masticated root to the puncture. It is killed by the ichneumon. 16. The atrox, with 169 scuta and 69 scutellae, is a native of Asia. It is of a hoary colour, and the head is compressed and covered with small scales. 17. The niveus, with 200 scuta and 62 scutellae, is a native of Africa. It is white, and with-out

The fulvius, or corn fnaie, is beautifully marked with red and white, reffembling a fpecies of Indian corn, whence its name. It is harmlefs as to its bite, but frequently robs hen-roofs.

The alevins, or green fnaie, is all over of a green colour. It inhabits Carolina; where it lives among the branches of trees on flies and other insects. It is of a small fize, and eafily becomes tame and familiar, infomuch that fome people will carry them in their bodom.

The fulcatus, or wampum fnaie, derives its name from its refemblance to the Indian wampum. It sometimes grows to the length of five feet; and like other large fnares, is very voracious, but its bite is not venemous. The back is of a dark blue, the belly finely clouded with spots of a brighter blue; the head is small in proportion to the ref of the body. See further the article SERPENT.

Colomka, the Pigeon, in ornithology, a genus belonging to the order of palaters. The characters of this genus are as follow : the bill is atrat, and de-

cends towards the point, the noftrels are oblong, and half covered with a soft tumid membrane; and the tongue is entire, i. e. not cloven. There are about 70 fpecies, all natives of different countries. The following are the most remarkable.

1. The cenus, or domefic pigeon, and all its beau-

The characters of the domestic fpecies are the following. It is of a deep blufh all colour; the breast dafhcd with a fine changeable green and purple: the fides of the neck with shining copper colour; its wings marked with two black bars, one on the coverts of the wings, the other on the quill-feathers; the black, white, and the tail barred near the end with black. They weigh 14 ounces. In the wild fiate it breeds in holes of rocks and hollows of trees; for which rea-

Son fome people ftyle columba caverntis, in oppo-

tion to the ring-dove, which makes its nest on the branches of trees. Nature always prefers the agreement in the manners, characters, and colours of birds reclaimed from their wild fate. This fpecies of pigeon foon takes to build in artificial cavities, and from the temptation of a ready provision becomes eafily domeficated. Multitudes of these wild birds are observed to migrate into the south of England: and while the beech-woods were fuffered to cover large tracts of ground, they used to haunt them in myrads, reaching in ftrings a mile in length, as they went out in the morning to feed. They visit Britain the latest of any bird of paffage, not appearing till November, and retiring in the spring. Mr Pennant imagines, that the summer haunts of these creatures are in Sweden, as Mr Eckmack makes their retreat thence coincide with their arrival in Britain. Numbers of them, however, breed on cliffs at the coast of Wales, and of the Hebrides. The varieties produced from the domefic are very numerous and extremely elegant; they are diftinguifhed by names ex-

predive of their feveral properties, as tumblers, car-

riers,
2. The palumbus, or ring-dove, is a native of Europe and Asia. It is the largest pigeon we have, and might be distinguished from all others by its size alone. Its weight is about 20 ounces; its length 18 inches. The head, back, and covers of the wings, are of a bluish ash-colour; the lower side of the neck and breast are of a purplish red, dashed with ash-colour: on the hind part of the neck is a semicircular line of white; above and beneath that, the feathers are glossy, and of changeable colours as opposed to the light. This species forms its nest of a few dry sticks in the boughs of trees. Attempts have been made to domesticate them by hatching their eggs under the common pigeon in dove-houses; but as soon as they could fly, they always took to their proper haunts. In the beginning of winter they assemble in great flocks, and leave off cooing, which they begin in March when they pair.

3. The turto, or turtle-dove, is a native of India. The length is 12 inches and a half; its breadth 21 inches; the weight four ounces. The irides are of a fine yellow, and the eye-lids encumbered with a beautiful crimson circle. The chin and forehead are whitish; the top of the head ash-coloured, mixed with olive. On each side of the neck is a spot of black feathers prettily tipped with white: the back ash-coloured, bordered with brown: the feather and covers of a reddish brown spotted with black: the breast a bright purplish red, having the verge of each feather yellow: the belly white. The tail is three inches and a half long; the two middle feathers of a dusky brown: the others black, with white tips; the end and exterior side of the outmost feathers wholly white. In the breeding season these birds are found in Buckinghamshire, Gloucestershire, Shropshire, and the west of England. They are very shy and retiring, breeding in thick woods, generally of oak; in autumn they migrate into other countries.

4. The palumbina, or ground-dove of Carolina, is about the size of a lark. The bill is yellow, and black at the end: the iris red; the breast and whole front of a changeable purple, with dark purple spots: the large quill-feathers are of a ruddy purple: the legs and feet of a dirty yellow; but the whole bird has such a composition of colours in it, that a very particular description is impossible. They fly many of them together, and make short flights from place to place, generally lighting on the ground.

5. The migratoria, or pigeon of passage, is about the size of an English wood-pigeon; the bill black; iris red; the head of a dusky blue; the breast and belly of a faint red; above the shoulder of the wing there is a patch of feathers shining like gold; the wing is coloured like the head, having some few spots of black (except that the larger feathers of it are dark brown), with some white on the exterior vanes; the tail is very long, and covered with a black feather, under which the rest are white; the legs and feet are red. They come in prodigious numbers from the north, to winter in Virginia and Carolina. In these countries they roost upon one another’s backs; in such quantities that they often break down the limbs of oaks which support them, and leave their dung some inches thick below the trees. In Virginia Mr. Catesby has seen them fly in such continual trains for three days successively, that they were not at sight of for the least interval of time, but somewhere in the air they were seen continuing their flight southward. They breed in rocks by the sides of rivers and lakes far north of St. Lawrence. They fly to the south only in hard winters, and are never known to return.

6. The coronata, or great crowned pigeon, is a very large species, the size of a turkey. The bill is black, and two inches long; the irides are red; the head neck, breast, belly, sides, thighs, and under tail coverts, cinereous blue; the head is crested; the back, rump, capulars, and upper tail coverts, are of a deep ash-colour, with a mixture of purplish chestnut on the upper part of the back and capulars; the wing-coverts are ash-coloured within, and purplish chestnut on the outside and tip; quills deep blackish ash-colour; tail the same, but of a light ash-colour at the tip; the legs are blackish. This species inhabits the Moluccas and New Guinea, and has been brought to England alive. Buffon mentions five having been at once alive in France. In size it far exceeds any of the pigeon tribe; but its form and manners tell us that it can belong to no other. Indeed D’Eville has placed it with the pheasants; and the planches enluminées have copied that name; but whoever has observed it cannot doubt in the least to which it belongs. Its note is cooing and plaintive, like that of the chaffinch; but in a more loud and proportion. The mournful notes of these birds alarmed the crew of Bougainville much, when in the neighbourhood of them, thinking they were the cries of the human species. In France they were never observed to lay eggs, nor in Holland, though they were kept for some time; but Scopoli assures us, that the male approaches the female with the head bent into the breast, making a noise more like lowing than cooing; and that they not only made a nest on trees, in the menagery where they were kept, but laid eggs. The nest was composed of hay and twigs. The female never sat, but stood upon the eggs; and she supposed it was from this cause that there was no produce. They are said to be kept by some in the East Indies, in their court-yards, as domestic poultry. The Dutch at the Moluccas call them crow-wegel. M. Sonnerat, as well as Dampier, found these in plenty at New Guinea; and it is probable that they were originally transported from that place into Bandia, from whence the Dutch chiefly now procure them.

Among the great number of other species of columba, there are some very small, not larger than a wood-lark. The Malacca pigeon described by Sonnerat is little bigger than the house-sparrow. It is a most beautiful
Columba, a beautiful species, and the fift said to be extremely delicate. It has been transported into the Isle of France, where it has multiplied exceedingly.

Pigeons, besides being esteemed as a delicacy for the table, are of value on other accounts. Their dung is thought to be so good an amendment for some kinds of land, that it has been fetched 16 miles, and a load of coal has been given for a load of it; it is also used for tanning the upper-leathers of shoes, as well as applied as a caustic to this day. Indeed formerly salt-petre was collected from it. The greatest use of pigeons is at Ifaphan in Persia, where there are recorded to be above 3000 pigeon-houses, and these kept by the Turks alone, as Christians are not allowed to keep any.

Dr Pococke mentions the frequency of pigeon-houses in Egypt: adding, that the pigeon-house is reckoned a great part of the estate of the husbandman; and the common proverb in those parts is, that a man who has a pigeon-house need not care about the disposal of his daughter. Tavernier says that their dung is used to smoke melons. The usual way taken to entice pigeons to remain where they are is by playing as a cataplasma to this day. Indeed formerly thought to be his native country, Ireland, in the year 565, with the will of St Columbanus, who has a pigeon-house named after him. It is not yet well known. According to Dr Percival's account it grew originally on the continent of America; from whence it was transplanted to Columbo, a town in Ceylon, which gives name to it, and supplies all India with it. The inhabitants of these countries have for a long time used it in disorders of the stomach and bowels. They carry it about with them, and take it sliced or scraped in Madeira wine. This root comes to us in circular pieces, which are from half an inch or an inch to three inches in diameter; and divided into fritibus, which measure from two inches to one quarter of an inch. The sides are covered with a thick corrugated bark, of a dark brown hue on its external surface, but internally of a light yellow colour. The surfaces of the transverse sections appear very unequal, hightest at the edges, and forming a concavity towards the centre. On separating this surface, the root is observed to consist of three laminae, viz. the cortical, which, in the larger roots, is a quarter of an inch thick.
Columbo-root has an aromatic fmell; but is disagreeably bitter, and slightly pungent to the taste, somewhat resembling mustard-seed, when it has lost, by long keeping, part of its essential oil. Yet, though ungrateful to the taste, when received into the stomack, it appears to be corroborant, antifeptic, feutive, and powerfully antifemetic. In the choleramurbus it alleviates the violent vertmima, checks the punging and vomiting, corrects the putrid tendency of the bile, quiets the inordinate motions of the bowels, and speedily recruits the exhausted strength of the patient. It was administered to a great number of patients, sometimes upwards of 20 in a day, afflicted with the choleramurbus, by Mr. Johnfon of London. He generally found that it soon stopped the vomiting, which was the most fatal symptom, and that the purging and remaining complaints quickly yielded to the same remedy. The dose he gave was from half a drachm to two drachms of the powder, every three or four hours, more or less according to the urgency of the symptoms. Though this medicine possesses little or no aromaticity, it has been observed to be of great service in diarrhées, and even in the dysentery. In the first stage of these disorders, where astringents would be hurtful, Columbo-root may be prescribed with safety; as, by its antifeptic, feutive, and antifemetic remedy, it answers better when given towards their decline. Its efficacy has also been observed in the vomitings which attend the bilious cholic; and in such cases, where an emetic is thought neceffary, after administering a small dose of ipecacuan, the stomack may be washed with an infusion of Columbo-root. This will tend to prevent those violent and convulsive reachings which in irritable habits abounding with bile are sometimes excited by the mildest emetic. In bilious fevers, 15 or 20 grains of this root, with an equal or double quantity of vitriolated tartar, given every four, five, or six hours, produce very beneficial effects. From its efficacy in these bilious difeases of this country, it is probable that it may be useful in the yellow fever of the West Indies, which is always attended with great ficknefs, violent reachings, and a copious discharge of bile. The vomiting recurs at short intervals, often becomes almost incontinent, and an incredible quantity of bile is sometimes evacuated in a few hours. Children during dention are often subjedt to severe vomitings and diarrhées. In these cases the Columbo-root is an useful remedy, and hath often procured almost instant relief, when other efficacious remedies have been tried in vain. This root is also extremely beneficial in a languid state of the stomack, attended with want of appetite, indigeflion, vaufes, and flatulence, in which cases it invariably produces a beneficent effect, and is given in the form of a ftrong and fome grateful aromatic, or infused in Madeira wine. Habitual vomiting, when it proceeds from a weaknefs or irritability of the stomach, from an irregular gout, acidities, acrimonious bile, or an increafed and depraved fecretion of the pancreatic juice, is greatly relieved by the ufe of Columbo-root, in conjunction with aromatics, chalybees, or the tefaceous powders. In the naufa and vomiting occafioned by pregnancy, an infusion of Columbo-root succeeds better than any other medicine that hath been tried.

From Dr Percival's experiments on this root, it appears, that refifted spirit of wine extracts its virtues in the greatest perfection. The watry infuflon is more perifhable than that of other bitters. In 24 hours a copious precipitation takes place; and in two days it becomes grop, and even mufty. The addition of orange-peel renders the infuflon of Columbo-root lefs ungrateful to the palate. An ounce of the powdered root, half an ounce of orange-peel, two ounces of French brandy, and 14 ounces of water, macerated 12 hours without heat, and then filtered through paper, affords a sufficiently strong and tolerably pleafant infuflon. The extract made firft by spirit and then reduced to water, and reduced by evaporation to a pillar consistency, is found to be equally efficacious in eftacy to the powder. As an antifeptic, Columbo-root is inferior to the bark; but as a correcr of putrid gall, it is much superior to the bark; whence also it is probable that it would be of service in the West India yellow fever. It also restraints alimentary fermentation, without impairing digestion; in which property it refembles mustard. Hence its great service in preventing acidities. It hath also a remarkable power of neutralizing acids already formed. It doth not appear to have the least heating quality; and therefore may be used with propriety and advantage in the phthisis pulmonalis and in feptic cafes, to correct acrimony and strengthen digestion. It occafions no dilubrance, and agrees very well with a milk diet, as it abates flatulence, and is indifposed to acidity.

Columbo, or Congregation of St Columbus, a society of regular canons, who formerly had 100 abbeys or nunneries in the Britifh isles.

Columbus, (Christopher) a Genoese, the celebrated navigator, and firft discoverer of the iflands of America, was a fubject of the republic of Genoa.

Neither the time nor the place of his birth, however, are known with certainty; only he was defcended of an honourable family, who, by various misfortunes, had been reduced to indigence. His parents were fea-faring people; and Columbus having discovered, in his early youth, a capacity and inclination for that way of life, was encouraged by them to follow the fame profeflion. He went to fea at the age of 14; his firft voyages were to those ports in the Mediterranean frequented by the Genoese; after which he took a voyage to Iceland; and proceeding fill further north, advanced several degrees within the polar circle. After this, Columbus entered into the service of a famous fea-captain of his own name and family. This man commanded a small squadron, fifted out at his own expence; and by cruifing, fometimes againft the Mahometans and fometimes againft the Venetians, the
Columbus, the rivals of his country in trade, had acquired both wealth and reputation. With him Columbus continued for several years, no less distinguished for his courage than his experience as a sailor. At length, in an obstinate engagement off the coast of Portugal, with some Venetian caravels returning richly laden from the Low Countries, the vessel on board which he served took fire, together with one of the enemy's ships to which it was fast grappled. Columbus threw himself into the sea; held on a floating oar; and by the support of it, and his dexterity in swimming, he reached the shore, though above two leagues distant.

After this disaster, Columbus repaired to Lisbon, where he married a daughter of Bartholomew Pereyrrello, one of the captains employed by Prince Henry in his early navigations, and who had discovered the islands of Porto Santo and Madeira. Having got possession of the journals and charts of this experienced navigator, Columbus was seized with an irrepressible desire of visiting unknown countries. In order to indulge it, he made a voyage to Madeira, and continued during several years to trade with that island, the Canaries, Azores, the settlements in Guinea, and all the other places which the Portuguese had discovered on the continent of Africa.

The experience thus acquired in such a number of voyages, Columbus now became one of the most skilful navigators in Europe. At this time, the great object of discovery was a passage by sea to the East Indies. This was attempted, and at last accomplished by the Portuguese, by doubling the Cape of Good Hope. The danger and tediousness of the passage, however, supposing it to be really accomplished, which as yet it was not, set Columbus on considering whether a shorter and more direct passage to these regions might not be found out; and, after long consideration, he became thoroughly convinced, that, by passing across the Atlantic Ocean, directly towards the west, new countries, which probably formed a part of the vast continent of India, must infallibly be discovered. His reasons for this were, in the first place, a knowledge he had acquired of the true figure of the earth. The continents of Europe, Asia, and Africa, as far as then known, form but a small part of the globe. It was suitable to our ideas, concerning the wisdom and beneficence of the Author of nature, to believe that the vast space, still unexplored, was not entirely covered by a waste and barren ocean, but occupied by countries fit for the habitation of man. It appeared likewise extremely probable, that the continent on this side the globe was balanced by a proportional quantity of land in the other hemisphere. These conjectures were confirmed by the observations of modern navigators. A Portuguese pilot having stretched farther to the west than was usual at that time, took up a piece of timber, artificially carved, floating upon the sea; and as it was driven towards him by a westerly wind, he concluded that it came from some unknown land situated in that quarter. Columbus's brother-in-law had found to the west of the Madeira islands a piece of timber fastened in the same manner, and brought by the same wind; and had seen also canes of an enormous size floating upon the waves, which resembled those described by Ptolemy, as productions peculiar to the East Indies. After a course of westerly winds, trees torn up by the roots were often driven upon the coast of the Azores; and at one time the dead bodies of two men, with singular features, which resembled neither the inhabitants of Europe nor Africa, were cast ashore there. The most cogent reason, however, was a mistaken notion of the ancient geographers concerning the immense extent of the continent of India. Though hardly any of them had penetrated beyond the river Ganges, some Greek writers had ventured to describe the provinces beyond that river, which they represented as regions of an immense extent. Ctesias affirmed that India was as large as all the rest of Asia. Heracleitus, whom Pliny the Naturalist follows, contended that it was equal to a third part of the habitable earth. Nearchus affirmed that it would take four months to march from one extremity of it to the other in a straight line. The journal of Marco Polo, who travelled into Asia in the 13th century, and who had proceeded towards the east far beyond the limits to which any European had ever advanced, seemed also so much to confirm these accounts, that Columbus was persuaded, that the distance from the most westerly part of Europe to the most easterly part of Asia was not very considerable; and that the shortest, as well as most direct course to the unexplored regions of the east, was to be found by sailing due west.

In 1474, Columbus communicated his ideas on this subject to one Paul a physician in Florence, a man eminent for his knowledge in cosmography. He approved of the plan, suggested several facts in confirmation of it, and warmly encouraged Columbus to persevere in an undertaking so laudable, and which must redound so much to the honour of his country and the benefit of Europe. Columbus, fully satisfied of the truth of his system, was impatient to set out on a voyage of discovery. The first step towards this was to secure the patronage of some of the considerable powers of Europe capable of undertaking such an enterprise. He applied first to the republic of Genoa; but his countrymen, strangers to his abilities, inconsiderately rejected his proposal as the dream of a chimerical projector, and thus lost for ever the opportunity of restoring their commonwealth to its ancient lustre. His next application was to the court of Portugal, where King John II. listened to him in the most gracious manner, and referred the consideration of his plan to Diego Ortiz, bishop of Ceuta, and two Jewish physicians, eminent cosmographers, whom he was accustomed to consult in matters of this kind. Unhappily these were the persons who had been the chief directors of the Portuguese navigations, and had advised to search for a passage to India by steering a course directly opposite to that which Columbus had recommended as shorter and more certain. They could not therefore approve of his proposal, without submitting to the double mortification of condemning their own theory, and of acknowledging his superiority. The result of their conferences was, that they advised the king to fit out a vessel privately, in order to attempt the proposed discovery, by following exactly the course which Columbus seemed to point out. John, forgetting on this occasion the sentiments of a monarch, meanly adopted this pernicious counsel. But the pilot chosen to execute Columbus's plan had neither the genius...
C O L

Columbus immediately quitted Portugal, and applied to the king of Spain; but left he should be here again disappointed, he sent his brother Bartholomew into England, to whom he had fully communicated his ideas, in order that he might negotiate at the same time with Henry VII, who was reckoned one of the most fagacious as well as opulent princes of Europe. Bartholomew was very unfortunate in his voyage: he fell into the hands of pirates, who stripped him of everything, and detained him a prisoner for several years. At last he made his escape, and arrived in London, but in such extreme indigence, that he was obliged to employ himself, during a considerable time, in drawing and selling maps, in order to pick out the points on which he might venture to appear at court. The proposals were received by Henry with more approbation than by any monarch who had been presented.

Columbus himself made his proposals to the king of Spain, not without many doubts of success, which soon appeared to be well founded. True science had as yet made so little progress in the kingdom of Spain, that most of those to whom the consideration of his plan was referred were utterly ignorant of the first principles on which he founded his hopes. Some, from mistaken notions concerning the dimensions of the globe, contended that a voyage to those remote regions of the East which Columbus expected to discover, could not be performed in less than three years. Others concluded, that either he would find the ocean of infinite extent, according to the opinion of some ancient philosophers; or that if he should perform in steering westwards beyond a certain point, the convex figure of the globe must infallibly prevent his return, and he must perish in the vain attempt to unite the two opposite hemispheres, which nature had for ever disjoined. Even without regarding into any particular diffusion, some rejected the scheme in general, upon the credit of a maxim made use of by the ignorant in all ages, "That it is presumption in any person to suppose that he alone possesses knowledge superior to all the rest of mankind united." By continual disappointments and delays, he was at last wearied out, and resolved to repair to the court of England in person, in hopes of meeting with a favourable reception there. He had already made preparations for this purpose, and taken measures for the disposal of his children during his absence, when Juan Perez, the prior of the monastery of Rabida near Palos, in which they had been educated, earnestly solicited him to defer his journey for a short time. Perez was a man of considerable learning, and some credit with Queen Isabella. To her therefore he applied; and the consequence of his application was a gracious invitation of Columbus back to court, accompanied with the present of a small sum to equip him for the journey. Ferdinand, however, still regarded the project as chimerical; and had the address to employ, in this new negotiation with him, some of the persons who had formerly pronounced his scheme to be impracticable. To their astonishment, Columbus appeared before them with the same confident hopes of success as formerly, and insinuated on the same high recompense. He proposed that a small fleet should be fitted out, under his command, to attempt the discovery: and demanded to be appointed perpetual and hereditary admiral and viceroy of all the seas and lands which he should discover; and to have the tenth of the profits arising from them settled irrevocably upon him and his descendants for ever. At the same time he offered to advance the eighth part of the sum necessary for accomplishing his design, on condition that he should be intitled to a proportional share in the adventure. If the enterprise should totally miscarry, he made no stipulation for any reward or emolument whatever. These demands were thought unreasonable; Isabella broke off the treaty she had begun, and Columbus was once more disappointed. He now resolved finally to leave Spain; and had actually proceeded some leagues on his journey, when he was overaken by a messenger from Isabella, who had been prevailed upon by the arguments of Quintanilla and Santangel, two of Columbus's patrons, again to favour his undertakings. The negotiation now went forward with all manner of facility and dispatch; and a treaty with Columbus was signed on the 17th of April 1492. The chief articles of it were, that Columbus should be constituted high admiral in all the seas, islands, and continents he should discover, with the same powers and prerogatives that belonged to the high admiral of Castile within the limits of his jurisdiction. He was also appointed viceroy in all those countries to be discovered; and a tenth of the produce accruing from their productions and commerce was granted to him for ever. All controversies or law-suits with respect to mercantile transactions were to be determined by the sole authority of Columbus, or of judges to be appointed by him. He was also permitted to advance one-eighth part of the expense of the expedition, and of carrying on commerce with the new countries; and was intitled, in return, to an eighth part of the profits. But, though the name of Ferdinand was joined with Isabella in this transaction, his distrust of Columbus was still so violent, that he refused to take any part in the enterprise as king of Aragon; and as the whole expense of the expedition was to be defrayed by the crown of Castile, Isabella reserved for her subjects of that kingdom an exclusive right to all the benefits which might accrue from its success.

At last our adventurer set sail with three small ships, the whole expense of which did not exceed L.4000, during his voyage he met with many difficulties from the mutinous and timid disposition of his men. He was the first who observed the variation of the compass, which threw the sailors into the utmost terror. For this phenomenon Columbus was obliged to invent a reason, which, though it did not satisfy himself, yet served to dissipate their fears, or silence their murmurs. At last, however, the sailors lost all patience; and the admiral was obliged to promise solemnly, that in case land was not discovered in three days he should return to Europe. That very night, however, the island of San Salvador was discovered, which quickly put
COLUMBUS, put an end to all their fears. The sailors were then as extravagant in the praise of Columbus as they had before been infolent in reviling and threatening him. They threw themselves at his feet, implored his pardon, and pronounced him to be a person inspired by heaven with more than human sagacity and fortitude, in order to accomplish a design so far beyond the ideas and conception of all former ages. Having visited several of the West India islands, and settled a colony in Hispaniola, he again set sail for Spain; and after escaping great dangers from violent tempests, arrived at the port of Palos on the 15th of March 1493.

As soon as Columbus's ship was discovered approaching, all the inhabitants of Palos ran eagerly to the shore, where they received the admiral with royal honours. The court was then at Barcelona, and Columbus took care immediately to acquaint the king and queen of his arrival. They were not less delighted than astonished with this unexpected event. They gave orders for conducting him into the city with all imaginable pomp. They received him clad in their royal robes, and seated on a throne under a magnificent canopy. When he approached, they stood up; and, raising him as he kneeled to kiss their hands, commanded him to take his seat upon a chair prepared for him, and to give a circumstantial account of his voyage. When he had finished his narration, which he delivered with much modesty and simplicity, the king and queen, kneeling down, offered up solemn thanks to God for the discovery. Every possible mark of honour that could be suggested by gratitude or admiration was conferred on Columbus; the former capitulation was confirmed, his family was enabled him to settle, and to give a circumstantial account of his voyage. When he had finished his narration, which he delivered with much modesty and simplicity, the king and queen, kneeling down, offered up solemn thanks to God for the discovery. Every possible mark of honour that could be suggested by gratitude or admiration was conferred on Columbus; the former capitulation was confirmed, his family was enabled, and a fleet was ordered to be equipped, to enable him to go in quest of those more opulent countries which he still confidently expected to find.

Notwithstanding all this respect, however, Columbus was no longer regarded than he was successful. The colonists he carried over with him were to the last degree unreasonable and unmanageable; so that he was obliged to use some severity with them; and notwithstanding his wise regulations, the court of Spain treated him for cruelty. On this, Francis de Bovadilla, a knight of Calatrava, was appointed to inquire into the conduct of Columbus; with orders, in case he found the charge of maladministration proved, to supersede him, and assume the office of governor of Hispaniola. The consequence of this was, that Columbus was sent to Spain in chains. From thence, however, he was freed immediately on his arrival, and had an opportunity granted him of vindicating his innocence. He was, however, deprived of all power; and notwithstanding his great services, and the solemnity of the agreement between him and Ferdinand, Columbus never could obtain the fullness of any part of that treaty. At last, disgusted with the ingratitude of a monarch whom he had served with such fidelity and success, and exhausted with fatigue, he ended his life on the 29th of May 1506.

COLUMBUS (Bartholomew), brother to Christopher, famous for his marine charts and spheres, which he presented to Henry VII. of England. He died in 1514.

COLUMBUS (Don Ferdinand), son of Christopher, and writer of his life. He entered into the ecclesiastical state; and founded a library; which he bequeathed to the church of Seville, to this day called the Columbus library. He died in 1560.

COLUMNELA (Lucius Junius Moderatus), a Roman philosopher, was a native of Cadiz, and lived under the emperor Claudius about the year 42. He wrote a book on agriculture intitled De Re Rustica, and another De Arboribus.

COLUMNEY, a town of Real Russia in Poland, seated on the river Pruth, towards the confines of Moldavia, about 50 miles from Halicz, and 63 south of Leopol. This town has been very ill treated by the Cossacks, infomuch that it is now inconsiderable, tho' there are several mines of salt in its district. E. Long. 16. 25. N. Lat. 48. 45.

COLUMN, in architecture, a round pillar made to support and adorn a building, and composed of a base, a shaft, and capital. See ARCHITECTURE, n. 22.

Columns, denominated from their use.—Astronomical column is a kind of observatory, in form of a very high tower built hollow, and with a spiral ascent to an amillary sphere placed a-top for observing the motions of the heavenly bodies. Such is that of the Doric order erected at the Hotel de Salons at Paris by Catherine de Medicis for the observations of Oronius Finesus, a celebrated astronomer of that time.

Chronological column, that which bears some historical inscription digested according to the order of time; as by Jufufes, olympiads, faith, epochs, annals, &c. At Athens, there were columns of this kind, wherein were inscribed the whole history of Greece digested into olympiads.

Funeral column, that which bears an urn, wherein are supposed to be inclosed the ashes of some deceased hero; and whose shaft is sometimes overspread with tears and flames, which are symbols of grief and of immortality.

Gnomonic column, a cylinder whereon the hour of the day is represented by a shadow of a needle. See DIAL.

Historical column, is that whose shaft is adorned with a baso-relievo, running in a spiral line its whole length, and containing the history of some great personage: such are the Trajan and Antonine columns at Rome.

Hollow column, that which has a spiral stair-case within, for the convenience of ascending to the top; as the Trajan column, the stair-case whereof consists of 185 steps, and is illuminated by 43 little windows, each of which is divided by tambours of white marble. The monument, or fire-column, at London, has also a stair-case; but it does not reach to the top. These kinds of columns are also called columnae colonicia, or coloniciae.

Indicative column, that which serves to show the tides, &c. along the sea-coasts. Of this kind there is one at Grand Cairo of marble, whereon the over-flowings of the Nile are expressed: by this they form a judgement of the succeeding season; when the water, for instance, ascends to 23 feet, it is a sign of great fertility in Egypt. See NIVIOMETRE.

Instructive column, that raised, according to Jofephus, lib. 1. cap. 3. by the sons of Adam, wherein were engraved the principles of arts and sciences. Bau-
Baudelot tells us, that the son of Philistias raised another of this kind of stone, containing the rules and precepts of agriculture.

Itinerary Column, a column with several sides, placed in the cross ways in large roads; serving to show the different routes by inscriptions thereon.

Ladle Column, at Rome, according to Festus, was a column erected in the herb-market, now the place Montanara, which had a cavity in its pedestal, wherein young children abandoned by their parents, out of poverty or inhumanity, were exposed, to be brought up at the public expense.

Legal Column. Among the Lacedemonians there were columns raised in public places, wherein were engraven the fundamental laws of the state.

Limitrophe or Boundary Column, that which shows the limits of a kingdom or country conquered. Such was that which Pliny says Alexander the Great erected at the extremities of the Indies.

Manubrial Column, from the Latin manubiae, "spoils of the enemy;" a column adorned with trophies built in imitation of trees, wherein the spoils of enemies were anciently hung. See Trophy.

Memorial Column, that raised on occasion of any remarkable event; as the monument of London, built in imitation of trees, whereon the spoils of enemies were anciently hung. See Column.

Notitia Column, any Column which supports a statue or monument.

Memorial Column, that raised on occasion of any remarkable event; as the monument of London, built in imitation of trees, whereon the spoils of enemies were anciently hung. See Trophy.

Military Column, among the Romans, a column whereon was engraved a list of the forces in the Roman army, ranged by legions, in their proper order; with design to preserve the memory of the number of soldiers, and of the order prevailed in any military expedition. They had another kind of military column, which they called columna bellum, standing before the temple of Janus; at the foot whereof the conful declared war, by throwing a javelin towards the enemies countries.

Sepulchral Column, anciently was a column erected on a tomb or sepulchre, with an inscription on its base.

Those over the tombs of persons of distinction were very large; those for the common people small; these last are called stele and cippi.

Statuary Column, that which supports a statue. Such was that erected by Pope Paul V. on a pedestal before the church of St Maria at Rome; to support a statue of the Virgin, which is of gilt brass. This column was dug up in the temple of peace; its shaft is a single block of white marble 49 feet high, and five feet eight inches diameter, of the Corinthian order.

The term statuary column may likewise be applied to Caryatides, perians, termini, and other human figures, which do the office of columns; and which Vitruvius calls telamonies and atlantes. See Architecture, n° 54.

Triumphal Column, a column erected among the ancients in honour of a hero; the joints of the fones, or curfes whereof, were covered with as many crowns as he had made different military expeditions. Each crown had its particular name, as oellantis, which was beft with spikes, in memory of having forced a pala- fide. Murialis, adorned with little turrets or battle- ments, for having mounted an allait. Novilis, of prons and beaks of vellics; for having overcome at last. Obifidivatis, or gramaules, of grass; for having raised a sige. Ovatus, of myrtle; which expressed an ovation, or little triumph; and triumphalis, of laurel, for a grand triumph. See Crow.

Columnarum, in Roman antiquity, a heavy tribute, demanded for every pillar of a house. It was first laid on by Julius Caesar, in order to put a flop to the extravagant expenses laid out on fumptuous buildings.

Columnea, in botany: A genus of the angu- phora order, belonging to the didynamia class of plants; and in the natural method ranking under the 40th order, Perfomae. The calyx is quinquepartite; the upper lip of the corolla arched and entire; gibbous above the base; the antherae convex; the capsule bic- locular. There is but one species, a native of Marti- nico, of which we have no particular description.

Columniferi, in botany, an order of plants in the fragmenta methodi naturalis of Linnaeus, in which are the following genera, viz. bixa, corchorus, helio- carpus, kiggealaria, micrones, munitlingia, thea, tice, turnera, triumfiteta, ayenia, grevia, heliceteres, klein- hovia, adamonia, alcaea, althaea, bombax, camellia, guyfylpmn, hermannia, hibiscus, lavatera, malope, malva, melochia, napaca, pentapetes, fida, fweatania, theo- broma, urina, waltharia.

Colures, in astronomy and geography, two great circles supposed to intersect each other at right angles in the poles of the world, and to pass through the fol- lititial and equinoctial points of the ecliptic. See Geo- graphy.

Coluri, a little island in the gulf of Engia, in the Archipelago, formerly called Salamis. The principal town is of the same name, and seated on the south side, at the bottom of the harbour, which is one of the finest in the world. The famous Grecian hero, Ajax, who makes such a figure in Homer's Iliad, was king of this island. It is now, however, but a poor place; its commodities consist of wheat, barley, tar, rosin, pit-coal, sponges, and pot-alhes, which they carry to Athens.
COLYBA, or COLUMBUS; a term in the Greek liturgy,signifying an offering of corn and boiled pulse, made in honour of the saints, and for the sake of the dead.

Balfamon, P. Goar, Leo, Allatius, and others, have written on the subject of colaee: the substance of what they have said is as follows: The Greeks boil a quantity of wheat, and lay it in little heaps on a plate; adding beaten peas, nuts cut small, and grape-flakes, which they divide into several compartments, separated from each other by leaves of parsley. A little heap of wheat, thus seasoned, they call colaee. They have a particular formula for the benediction of the colysene wherein, praying that the children of Babylon may be fed with pulse, and that they may be in better condition than other people, they desire God to bless those fruits, and those who eat them, because offered to his glory, to the honour of such a saint, and in memory of the faithful deceased. Balfamon refers the institution of this ceremony to St. Athanasius; but the Greek Synaxary to the time of Julian the apostate.

COLUMBUS, in ornithology, a genus belonging to the order of aniferes. The bill has no teeth, is faborated, straight, and sharp-pointed; the teeth are in the throat; the nostrils are linear, and at the base of the bill; and the legs are unfit for walking. This genus includes the divers, guillemots, and grebes of which the following are the most remarkable species.

1. The grylle, or black guillemot, is in length 14 inches; in breadth 22; the bill is an inch and a half long, straight, slender, and black; the inside of the mouth red; on each wing is a large bed of white, which in young birds is spotted; the tips of the little quill-feathers, and the coverts of the wings, are white: except those, the whole plumage is black. In winter it is falted to white; and a variety spotted with black and white is not uncommon in Scotland. The tail consists of 12 feathers; the legs are red. These birds are found on the Bass Isle in Scotland; in the island of St Kilda, and, as Mr Ray imagines, in the Faro Islands off the coast of Northumberland. It has also been seen on the rocks of Llandindo, in Caernarvonshire, in Wales. Except in breeding-time it keeps always at sea; and is very difficult to be shot, diving at the flash of the gun. The Welch call this bird calcan longuer, or "the sailor's harried," from a notion that its appearance forebodes a storm. It visits St Kilda's in March; makes its nest far under ground; and lays a grey egg, or, as Steller says, white, and spotted with yellow, and speckled with ash-colour.

2. The trolle, or foolish guillemot, weighs 24 ounces; its length is 17 inches, the breadth 27; the bill is three inches long, black, straight, and sharp-pointed; near the end of the lower mandible is a small process; the inside of the mouth yellow; the feathers on the upper part of the bill are short and soft like velvet; from the eye to the hind part of the head is a small division of the feathers. The head, neck, back, wings, and tail, are of a deep moule-colour; the tips of the little quill-feathers white; the whole under part of the body is of a pure white; the fides under the wings marked with dusky lines. Immediately above the thighs are some long feathers that curl over them. The legs are dusky. They are found in amazing numbers on the high cliffs of several of the British coasts, and appear at the same time with the auk. They are very simple birds: for notwithstanding they are shot at, and see their companions killed by them, they will not quit the rock. Like the auk they lay only one egg, which is very large; some are of a fine pale blue; others white, spotted, or most elegantly flecked with lines crossing each other in all directions. They continue about the Orkneys the whole winter. The chief places they are known to breed in are the uninhabited isle of Priestholm, near the isle of Anglesey; on a rock called Godrevy, not far from St Ives in Cornwall; the Farm isles near the coast of Northumberland; and the cliffs about Scarborough in Yorkshire. They are also found in most of the Northern parts of Europe, to Spitzbergen, the coast of Lapmark, and along the white and icy sea quite to Kamtschatka. It is frequently met with on the coasts of Italy in the winter. It is also known in Newfoundland, and in a few parts of the continent of North America, but has not hitherto been talked of as common. The last British voyagers met with it on the coast north of Nootka Sound. It is known by several names; by the Welch, guilem; at Northumberland and Durham, guilemote or fea-hen; in Yorkshire, a joust; by the Cornish, kiddab; in the southern parts, willock; and in Kamtschatka, arr or kara. The inhabitants of the last kill them in numbers for the sake of their flesh, though it is certainly very tough and ill tasted; but more especially for their skins, of which, as of other fowls, they make garments: the eggs are also accounted a great delicacy.

3. The septentrionalis, or red-throated diver, is more elegantly shaped than the others. It weighs three pounds. The length to the end of the tail is two feet; to the toes two feet four inches; the breadth three feet five inches. The head is small and taper, the bill straight; the head and chin are of a fine uniform grey; the hind part of the neck marked with dusky and white lines pointing downwards; the throat is of a dull red; the whole upper part of the body, tail, and wings, of a deep grey, almost dusky; but the covers of the wings and the back are marked with a few white spots; the under side of the body is white; the legs dusky. This species breeds in the northern parts of Scotland, on the borders of the lakes. It is found also in Russia, Siberia, and Kamtschatka; but does not haunt the inland lakes. It is common in Iceland.
land and Greenland, where it breeds in June, and lays two ash-coloured eggs, marked with a few black spots; it makes its nest in the grasses, composed of mosses and grasses, and placed contiguous to the water. It swims and dives well, and flies admirably, and while flying is very noisy. It feeds on small fish, crabs, and sea insects. In the summer, it inhabits the rivers of Hudson's bay, appearing as soon as the rivers are open. Here it lays in June, and lines the nest with a little down from its own breast; the young fly before the end of August, and they all depart in September. They are called by the natives affies-moqua. They prey much on the fish entangled in the nets; but are often thereby caught themselves.

4. The arcticus, or black-throated diver, is somewhat larger than the last; the bill is black, and also the front; the hind part of the head and neck cincereos; the sides of the neck marked with black and white lines pointing downwards; the fore-part of a glossy variable black, purple, and green. The back, scapulars, and coverts of the wings, are black, marked, the two first with square, the last with round spots of white; the quill-feathers dusky; the breast and belly white; the tail short and black; legs partly dusky, and partly reddish. This species is now and then found in England, but is not common. It is sufficiently plentiful in the northern parts of Europe, Norway, Sweers, and Denmark. Frequent in the inland lakes of Siberia, especially those of the arctic regions; in Iceland, Greenland, and the Ferroce islands; and in America at Hudson's bay. It is supposed to cry and be very restless before rain, making a great noise; hence the Norwegians think it impious to destroy this species; but the Swedes, less superstitious, dresf their skins, which, like all of this genus, are exceedingly tough, and use them for gun-cafes and facings for winter caps.

5. The glacialis, or northern diver, is three feet five inches in length; the breadth four feet eight; the bill to the corners of the mouth four inches long, black and strongly made. The head and neck are of a deep black; the hind part of the latter is marked with a large familiar white band; immediately under the throat is another; the under part of the neck is of a deep black; gloosed with a rich purple; the whole under side of the body is white; the sides of the breast marked with black lines; the back, coverts of the wings, and scapulars, are black marked with white spots; those on the scapulars are very large, and of a square shape; two at the end of each feather. The tail is very short, and almost concealed by the coverts, which are dusky, spotted with white; the legs are black. This species inhabits several parts of the north of Europe, but is not very frequent on the British shores; nor ever seen southward except in very severe winters. It is seldom met with on land, being for the most part on the open sea, where it is continually diving for fish, which it does with great agility, and flies high and well. It is commonly in Iceland and Greenland, where it breeds, and at that time frequents the freshest waters. It is sufficiently plentiful in Norway, and all along the Arctic coasts, as far as the river Ob, in the Russian dominions. The Barabinzians, a nation situated between that river and the Iritich, tan the breasts of this and other water-fowl; whose skins they prepare in such a manner as to preserve the down upon them; and sewn a number of Colymas. 4.

2. The mermer, or amber-goofe, is superior in size to a common goose. The head is dusky; the back, coverts of the wings, and tail, clouded with lighter and darker shades of the fame. The primaries and tail are black; the under side of the neck spotted with dusky; the breast and belly fihery: the legs black. They inhabit the seas about the Orkney is:lands; but in severe winters visit the southern parts of Great Britain. They are found also in Iceland, and most parts of northern Europe; likewise in Kamchatka; but not in any parts of Siberia or Russia. It likewise inhabits Switzerland, particularly on the lake Conflance, where it is known by the name of fluder. It is said to dive wonderfully well, and to rise at an amazing distance from the place where it plunged. The female makes its nest among the reeds and flags, and places it in the water; so that it is continually wet, as in some of the greebe genus. It is difficult to be taken, either on land or swimming on the water; but is not unfrequently caught under the water by a hook baited with a small fish, its usual food.

7. The Chinfe diver, described by Mr Latham; the size uncertain, but in the drawing the length was 14 inches. The bill dusky; irides ash-colour: the upper parts of the head, neck, body, wings, and tail, dusky greenish brown; the middle of the feathers much darker: the fore part of the neck the same, but considerably paler: chin pale rufous: breast and under parts of the body pale rufous white, marked with dusky rufous spots: the quills and tail are plain brown, the last short: legs ash-colour. Supposed to inhabit China, as Mr Latham saw it among other well painted drawings at Sir Joseph Banks's; it was in the attitude of fishing, with a brass ring round the middle of the neck, in the manner of the figure, Plate CXXVI. From the various and uncertain accounts of authors, we are not clear what birds the Chinese ufe for catching fish; the custom, however, of doing it is manifest, from the relations of many travellers. The bird ufed for this purpose has a ring fastened round the middle of the neck, in order to prevent its swallowing; besides this it has a flender long string fastened to it; and, thus accouRed, is taken by its master into his fishing boat, from the edge of which it is taught to plunge after the fish as they pass by; and as the ring prevents their puffing further downwards, they are taken from the mouth of the bird as fast as they are caught. In this manner sometimes a great many are procured in the course of a few hours. When the keeper of the bird has taken sufficient for himself, the ring is taken off, and the poor slave suffered to satisfy its own hunger. We do not here give this bird as the one most commonly ufed for the above purpose; but have
it is called by the boats while fishing. It is common about the Baltic
islands; and frequently approaching very close to them, may be
seen on the sea; they are sometimes blown from among the flags into the
water: it is rather scarce in England, but is common in the winters
when they are called goaf, dully, marked with a few black spots. These
birds frequent the meres of Shropshire and Cheshire, where they breed. No external difference is to be
noted between the male and the female of this species. They make their
nests very loosely, and lay four or five small eggs.

12. The horned grebe, is about the size of a teal; it weighs one pound; length, one foot; breadth, 16
inches. Bill one inch, dully; head very full of feathers,
and of a glossy deep green, nearly black: thro' each eye is a streak of yellow feathers, elongated into a
tuft as it passes to the hind head: the upper part of the
neck is a dusky brown; the fore part of the neck and breast, dark orange red: the iser wing
covers, cinereous; the greater end quills, black; middle
ones, white: belly, a glossy white: legs, cinereous,
blue before, pale behind.—It inhabits Hudson's bay; and first appears in May, about the fresh waters. It
lays from two to four white eggs in June, among the
aquatic plants; and is said to cover them when abroad,
but not to fly farther than the end of the lake. It skims
out of seaford about February, losing then its bright
colour; and in the breeding time its breast is almost
bare. The flesh is exceedingly rank.

10. The urinator, or tippet-grebe, thought by Mr Latham not to be a different species from the former,
being only somewhat less, and wanting the crest and
rudd. The sides of the neck are striped downwards from
the head with narrow lines of black and white; in other
parts the colours and marks agree with that bird. This
species has been shot on Rothen Mere in Cheshire.
It is rather scarce in England, but is common in the
winter time on the lake of Geneva. They appear
there in flocks of 10 or 12; and are killed for the
sake of their beautiful skins. The under side of them
being drested with the feathers on, are made into
muffs and tippets: each bird falls for about 14 shillings.

9. The crizlataus, eredfe dier, or cargoose, weighs two
pounds and an half. Its length is 21 inches the breadth
50; the bill is two inches and a quarter long, red at the
base, and black at the point: between the bill and the
eyes is a stripe of black naked skin: the irides are of
a fine pale red; the tongue is a third part white; the
fecondary feathers, which are white; the under
feide, belly, and inner coverts of the wings are
white; the subaxillary feathers, and some on the
under side of them being drested with the
feathers on, are made into
muffs and tippets: each bird
falls for about 14 shillings.

8. The stellatus, or speckled dier, a species less than
the former, weighs two pounds and a half: and is 27
inches in length and three feet nine in breadth. The
bill is three inches long, bending a trifle upwards: and
is of a pale horn colour, the top of the upper mandible
dusky: the head is dusky, dotted with grey; hind
part of the neck plain dusky: the tides under the eye,
the chin, and throat, white; fore part of the neck very
dusky: back dusky, marked with oval spots of
white; sides of the breast and body the same but
smaller; the spots on the rump and tail minute; breast
and under parts white; quills dusky; legs brown;
webs and claws pale. This bird is pretty frequent in
England; sufficiently so on the river Thames, where
it is called by the fishermen yeat dows; being often seen
in vast numbers among the shoals of that fish, diving
after them, and frequently approaching very near the
boats while fishing. It is common about the Baltic
and the White seas, but not observed in parts of
Russia; yea is a native of Kamtchatka. It lays two
eggs in the grass, on the borders of lakes not far from
the sea: they are exactly oval, the size of those of a
goose, dusky, marked with a few black spots. These
are also frequent about the fish ponds in France, except
they are frozen, when they betake themselves to
the rivers. This and the two last visit New York in winter,
but return very far north to breed.

1. The carrion, or carrion-duck, called by some a species
of the halcyon's nest may, in some measure, be vindi-
cated. It is a careful nurse of its young; being ob-
served to feed them most affiduously, commonly with
small eels; and when the infant brood is tired, the
parent will carry them either on its back or under
its wings. It preys on fish, and is almost perpetually
diving: it does not show much more than the head
above water; and is very difficult to be shot, as it darts
down on the least appearance of danger. It is never
seen on land; and, though disturbed ever so often,
will not fly farther than the end of the lake. Its skin
is out of season about February, losing then its bright
colour; and in the breeding time its breast is almost
bare. The flesh is exceedingly rank.
but has suffered greatly by the civil wars. E. Long. 49. 1. N. Lat. 34.

**COMA**, or **COMA-VIGIL**, a preternatural propensity to sleep, when, nevertheless, the patient does not sleep, or if he does, awakes immediately without any relief. See **Medicine-Index**.

**COMA Berenices**, Berenice's hair, in astronomy, a modern constellation of the northern hemisphere, composed of unformed stars between the lion's tail and Boötes. This constellation is said to have been formed by Conon, an astronomer, in order to confound the queen of Ptolemy Evergetes for the loss of a lock of her hair, which was stolen out of the temple of Venus, where she had dedicated it on account of a victory obtained by her husband. The stars of this constellation, in Tycho's Catalogue, are fourteen; in Hevelius's twenty-one; and in the Britannic Catalogue, forty-three.

**COMA Samoventum**, is when the patient continues in a profound sleep; and, when awakened, immediately relapses, without being able to keep open his eyes.

**COMARUM**, Marsh-Cinquefoil: A genus of the polygynia order, belonging to the icacinia class of plants; and in the natural method ranking under the 35th order, Senticofea. The calyx is deciduous; the petals five, less than the calyx; the receptacle of the seeds ovate, spongy, and perforated. There is but one species, a native of Britain. It rises about two feet high, and bears fruit somewhat like that of the strawberry. It grows naturally in woods, so as not easily be preferred in gardens. The root dyes a dirty red. The Irish rub their milking pails with it, and it makes the milk appear thicker and richer. Goats eat the herb; cows and sheep are not fond of it; horses and swine refuse it.

**COMB**, an instrument to clean, untangle, and drefs flax, wool, hair, &c.

Combs for wool are prohibited to be imported into England.

**COM** is also the creit, or red fishy tuft, growing upon a cock's head.

**COMBAT**, in a general sense, denotes an engagement, or a difference decided by arms. See **Battle**.

**COMBAT**, in ancient law, was a formal trial of some doubtful cause or quarrel by the swords or baftons of two champions. This form of proceeding was very frequent, not only in criminal but in civil causes; being built on a supposition that God would never grant the victory but to him who had the best right. The last trial of this kind in England was between Donald lord Ray appellant, and David Ramfay, esq; defendant, when, after many formalities, the matter was referred to the King's pleasure. See the article **Battle**.

**COMBER**, or **CUMBER** (Thomas), an eminent divine born at Weltram in Kent, in 1645, was educated at Cambridge; created doctor of divinity; and, after several preferments in the church, was made dean of Durham. He was chaplain to Anne princess of Denmark, and to king William and queen Mary. He was author of several works, viz. 1. A scholastic history of the primitive and general use of Liturgies. 2. A Companion to the Alter. 3. A brief discourse upon the offices of baptism, catechism, and confirmation. He died in 1659, aged 55.

**COMBINATION**, properly denotes an assemblage of several things, two by two.

**COMBINATION**, in mathematics, is the variation or alteration of any numbers of quantities, letters, or the Combinations, like in all the different manners possible. See **Changes**.

### Apophrasis
1. In all combinations, if from an arithmetical decreasing series, whose first term is the number out of which the combinations are to be formed, and whose common difference is 1, there be taken as many terms as there are quantities to be combined, and these terms be multiplied into each other; and if from the series 1, 2, 3, 4, &c., there may be taken the same number of terms, and they be multiplied into each other; and the first product be divided by the second; the quotient will be the number of the combinations required. Therefore, if you would know how many ways four quantities can be combined in seven, multiply the first four terms of the series, 1, 2, 3, 4, &c. together, and divide the product, which will be 840, by the product of the first four terms of the series, 1, 2, 3, 4, &c. which is 24, and the quotient 35 will be the combinations of 4 in 7.

2. In all permutations, if the series 1, 2, 3, 4, &c. be continued as many terms as their are quantities to be combined, and those terms be multiplied into each other; the product will be the number of permutations sought. Thus, if you would know how many permutations can be formed with five quantities, multiply the terms 1, 2, 3, 4, 5, together, and the product 120 will be the number of all the permutations.

#### Problems
1. To find the number of changes that may be rung on 12 bells. It appears by the second apophrasis, that nothing more is necessary here than to multiply the numbers from 1 to 12 continually into each other, in the following manner, and the last product will be the number sought.

<table>

</table>
The construction of this table is very simple. The line A a consists of the first 12 numbers. The line A b consists every where of units; and second term 3, of the line B c, is composed of the two terms 1 and 2 in the preceding rank: the third term 6, in that line, is formed of the two terms 3 and 3 in the preceding rank: and so of the rest; every term, after the first, being composed of the two next terms in the preceding rank: and by the same method it may be continued to any number of ranks. To find by this table how often any number of things can be combined in another number, under 13, as suppose 5 cards out of 8; in the eighth rank look for the fifth term, which is 56, and that is the number required.

Though we have shown in the foregoing problems the manner of finding the combination of all numbers whatever, yet as this table answers the same purpose, for small numbers, by inspection only, it will be found useful on many occasions; as will appear by the following examples.

V. To find how many different founds may be produced by striking on a harpsichord two or more of the seven natural notes at the same time. 1. The combinations of two in seven, by the foregoing triangle are 21. 2. The combinations of 3 in 7, are 35. 3. The combinations of 4 in 7, are 35. 4. The combinations of 5, are 21. 5. The combinations of 6, are 7. 6. The seven notes all together once is 1.

Therefore the number of all the founds will be 120.

VI. Take four square pieces of plateboard, of the same dimension, and divide them diagonally, that is by drawing a line from two opposite angles, as in the figures, into 8 triangles; paint 7 of these triangles with the primitive colours, red, orange, yellow, green blue, indigo, violet, and let the eighth be white. To find how many chequers or regular four-sided figures, different either in form or colour, may be made out of these eight triangles. First, by combining two of these triangles, there may be formed either the triangular square A, or the inclined square B, called a rhomb. Secondly, by combining four of the triangles, the large square C may be formed; or the long square D, called a parallelogram.

Now the first two squares, consisting of two parts out of 8, they may each of them, by the eighth rank of the triangle be taken 28 different ways, which makes 56. And the last two squares, consisting of four parts, may each be taken by the same rank of the triangle 70 times, which makes 140. To which add the foregoing number 56. And the number of the different squares that may be formed of the 8 triangles, will be 196.
VII. A man has 12 different sorts of flowers, and a large number of each sort. He is desirous of setting them in beds or flourishes in his parterre: Six flowers in some, 7 in others, and 8 in others; so as to have the greatest variety possible; the flowers in no two beds to be the same. To find how many beds he must have, 1. The combinations of 6 in 12 by the left rank of the triangle, are

\[ \binom{12}{6} = 924 \]

2. The combinations of 7 in 12 are

\[ \binom{12}{7} = 792 \]

3. The combinations of 8 in 12 are

\[ \binom{12}{8} = 495 \]

Therefore the number of beds must be 2211.

VIII. To find the number of chances that may be thrown on two dice. As each die has 6 faces, and as every face of one die may be combined with all the faces of the other, it follows, that 6 multiplied by 6, is 36, will be the number of all the chances; as is also evident from the following table:

<table>
<thead>

</tbody>
</table>

It appears by this table, 1. That the number of chances for each point continually increases to the point of seven, and then continually decreases till 12: therefore if two points are proposed to be thrown, the equality, or the advantage of one over the other, is clearly visible (A). 2. The whole number of chances on the dice being 252, if that number be divided by 36, the number of different throws on the dice, the quotient is 7; it follows therefore, that at every throw there is an equal chance of bringing seven points. 3. As there are 36 chances on the dice, and only 6 of them doublets, it is 5 to 1, at any one throw, against throwing a doublet.

By the same method the number of chances upon any number of dice may be found: for if 36 be multiplied by 6, that product, which is 216, will be the chances on 3 dice; and if that number be multiplied by 6, the product will be the chances on 4 dice, &c.

**Combinations of the Cards.** The following experiments, founded on the doctrine of combinations, may possibly amuse a number of our readers. The tables given are the basis of many experiments, as well on numbers, letters, and other subjects, as on the cards; but the effect produced by them with the last is the most surprising, as that which should seem to prevent any collision, that is the shuffling of the cards, is on the contrary the cause from whence it proceeds.

(A) It is easy from hence to determine whether a bet proposed at hazard, or any other game with the dice, be advantageous or not; if the dice be true, (which, by the way, is rarely the case for any long time together, as it is so easy for those that are possessed of a dexterity of hand to change the true dice for false.)
These tables, and the following examples at piquet, except the 30th, appear to have been composed by M. Guyot.

</table>

I. "Several letters that contain no meaning, being written upon cards, to make them, after they have been twice shuffled, give an answer to a question that shall be proposed; as, for example, What is "love?" Let 24 letters be written on as many cards which, after they have been twice shuffled, shall give the following answer:

A dream of joy that soon is o'er.

First, write one of the letters in that line on each of the cards (a). Then write the answer on a paper, and assign one of the 24 first numbers to each card, in the following order:

A D R E A M O F J O Y T H A T S O O N

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19

I S O' R.

20 21 22 23 24.

Next, write on another paper a line of numbers, from 1 to 24, and looking in the table for 24 combinations, you will see that the first number after the second shuffle is 21; therefore the card that has the first letter of the answer, which is A, must be placed against that number, in the line of numbers you have just made (c). In like manner the number 22 being the second of the same column, indicates that the card which

(b) These letters should be written in capitals on one of the corners of each card, that the words may be easily legible when the cards are spread open.

(c) For the same reason, if you would have the answer after one shuffle, the cards must be placed according to the first column of the table; or if after three shuffles, according to the third column.
The cards will then stand in the following order:

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16 17 18 19
OOF SAM NTO I S R H AE O'E J O
20 21 22 23 24
R A D Y T

From whence it follows, that after these cards have been twice shuffled, they must infallibly stand in the order of the letters in the answer.

Observe 1. You should have several questions with their answers, consisting of 24 letters, written on cards; these cards should be put in cases, and numbered, that you may know to which question each answer belongs. You then present the questions; and when any one of them is chosen, you pull out the case that contains the card that answers this question and perform as before.

2. To make this experiment the more extraordinary you may have three cards, on each of which an answer is written; one of which cards must be a little wider; and another a little longer, than the others. You give these three cards to any one, and when he has privately chosen one of them, he gives you the other two, which you put in your pocket without looking at them, having discovered by feeling which he has chosen. You then pull out the case that contains the cards that answer this question and perform as before.

3. You may also contrive to have a long card at the bottom, after the second shuffle. The cards may be then cut several times, till you perceive by the touch that the long card is at bottom, and then give the answer; for the repeated cuttings, however often, will make no alteration in the order of the cards.

The second of these observations is applicable to some of the frequent experiments, and the third may be practised in almost all experiments with the cards. You should take care to put up the cards as soon as the answer is written, and so that if any one should desire the experiment to be repeated, you may offer another question, and pull out those cards that contain the answer.

Though this experiment cannot fail of exciting at all times pleasure and surprize, yet it must be owned that a great part of the applause it receives arises from the address with which it is performed.

II. "The 24 letters of the alphabet being written upon so many cards, to shuffle them, and pronounce the letters shall then be in their natural order; but that not succeeding, to shuffle them a second time, and then show them in proper order." Write the 24 letters on the cards in the following order:

<table>
<thead>
<tr>
<th>R</th>
<th>S</th>
<th>H</th>
<th>Q</th>
<th>E</th>
<th>F</th>
<th>T</th>
<th>P</th>
<th>G</th>
<th>U</th>
<th>X</th>
<th>C</th>
</tr>
</thead>
<tbody>
<tr>
<td>13</td>
<td>14</td>
<td>15</td>
<td>16</td>
<td>17</td>
<td>18</td>
<td>19</td>
<td>20</td>
<td>21</td>
<td>22</td>
<td>23</td>
<td>24</td>
</tr>
</tbody>
</table>

The cards being disposed in this manner, show them upon the table, that it may appear they are promiscuously marked. Then shuffle and lay them again on the table, pronouncing that they will be then in alphabetical order. Appear to be surprized that you have failed; take them up again and give them a second shuffle, and then counting them down on the table they will all be in their natural order.

III. "Several letters being written promiscuously combined upon 32 cards, after they have been once shuffled, to find in a part of them a question; and then shuffling the remainder a second time, to show the answer. Suppose the question to be, What is each Briton's boast and the answer, His liberty; which taken together contain 32 letters."

After you have written those letters on 32 cards, write on a paper the words, his liberty, and annex to the letters the first ten numbers thus:

H I S L I B E R T Y
1 2 3 4 5 6 7 8 9 10

Then have recourse to the table of combinations for ten numbers, and apply the respective numbers to them in the same manner as in experiment 1, taking the first column, as these are to be shuffled only once, according to that order.

I 2 3 4 5 6 7 8 9 10
I B S L E R T H I Y

This is the order in which these cards must stand after the whole number 32 has been once shuffled, so that after a second shuffle they may stand in their proper order. Next dispose the whole number of letters according to the first column for 32 letters: the last ten are to be here placed in the order above; as follows:

W H A T I S E A C H B R I T O N S
1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
B O A S T?
18 19 20 21 22
I B S L E R T H I Y
23 24 25 26 27 28 29 30 31 32

Therefore, by the first column of the table, they will next stand thus:

1 2 3 4 5 6 7 8 9 10 11 12 13 14 15 16
I T B R O N S C H B O A E A S T long card.
17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 32
I I S B S L I B E R T W H I Y

You must observe, that the card here placed the 16th in order, being the last of the question, is a long card, that you may cut them, or have them cut, after the first shuffle, at that part, and by that means separate them from the other ten cards that contain the answer.

Your cards being thus disposed, you show that they make no meaning; then shuffle them once, and cutting them at the long card, you give the first part to any one, who reads the question, but can find no answer in the others, which you open before him; you then shuffle them a second time, and show the answer as above.

IV. "To write 32 letters on so many cards, then shuffle and deal them by two to two persons, in such manner, that the cards of one shall contain a question, and those of the other an answer. Suppose the question to be, Is nothing certain? and the answer, Yes, disappointment." Over the letters of this question and answer, write the following numbers, which correspond to the order in which the cards are to be by two and two.

I S N O T H I N G C E R T A I N?
3 1 2 2 27 28 23 24 19 20 15 16 11 12 7 8 3 4
Y E S D I S A P P O I N T M E N T,
29 30 25 26 21 22 17 18 13 14 9 10 5 6 1 2

Then have recourse to the first column of the table for...
for 32 members, and dispose these 32 cards in the following order, by that column.

|   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |   |
| 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | 10 | 11 | 12 | 13 | 14 | 15 | 16 | 17 | 18 | 19 | 20 | 21 | 22 | 23 | 24 | 25 | 26 | 27 | 28 | 29 | 30 | 31 | 32 |

The cards being thus disposed, shuffle them once, and deal them two and two; when one of the parties will necessarily have the question, and the other the answer.

Instead of letters you may write words upon the 32 cards, 16 of which may contain a question, and the remainder the answer; or what other matter you please.

If there be found difficulty in accommodating the number of cards, there may be two or more letters or syllables written upon one card.

V. "The five beauties." The five blessings we will suppose to be, 1. Science, 2. Courage, 3. Health, 4. Riches, and 5. Virtue. These are to be found upon cards that you deal, one by one, to be five persons. First write the letters of these words successively, in the order they stand, and then add the numbers here annexed to them.

</table>

In the second round of dealing, there will be two cards left, of which the letters are written, and the backs upwards, you divide the cards, by the table for 32 numbers, as in the last experiment. Thus,

The cards being thus disposed, shuffle them once, and deal them two and two; when one of the parties will necessarily have the question, and the other the answer.

VI. "The cards of the game of piquet being mixed together, after shuffling them, to bring, by cutting them, all the cards of each suit together." The order in which the cards must be placed before the first shuffle, will be sufficient to give the order in which they are to be placed before the first shuffle.

<table>

Order of the cards before shuffling.

You then shuffle the cards, and cutting at the wide card, which will be the seven of hearts, you lay the eight cards that are cut, which will be the suit of hearts, down on the table. Then shuffling the remaining cards a second time, you cut at the second wide card, which will be the seven of spades, down on the table. You shuffle the cards a third time, and offering them to anyone to cut, he will naturally cut them at the wide card (d), which is the seven of diamonds, and consequently divide the remaining cards into two equal parts, one of which will be diamonds and the other clubs.

VII. "The cards at piquet being all mixed together, to divide the pack into two unequal parts, and name the number of points contained in each part." You are first to agree that each king, queen, and knave shall count as usual, 10, the ace 1, and the other cards according to the number of the points. Then dispose the cards, by the table for 32 numbers, in the following order, and observe that the last card of the first division must be a wide card.

(d) You must take particular notice whether they be cut at the wide card, and if they are not, you must have them cut, or cut them again yourself.
The cards being thus disposed, you ask your adversary in what suit you shall repique him? If he lay in clubs or diamonds, you must deal the cards by threes, and the hands will be as follows:

**Elder Hand**
- Hearts, King
- Diamonds, Ace
- Clubs, Eight
- Spades, Nine
- Rentée, or take in of the elder.

**Younger Hand**
- Seven, Diamonds
- Ten, Clubs
- Nine, Hearts
- Ace, Spades
- Rentée.

If he against whom you play, who is supposed to be elder hand, has named clubs for the repique, and has taken in five cards, you must then lay out the queen, knave, and nine of diamonds, and you will have, with the three cards you take in, a septiem major of clubs, and quatorze tens. If he leave one or two cards, you must discard all the diamonds.

If he require to be repiqued in diamonds, then discard the queen, knave, and nine of clubs: or all the clubs, if he leave two cards; and you will then have a hand of the same strength as before.

Note, If the adversary should discard five of his hearts, you will not repique him, as he will then have a septiem in spades: or if he only take one card: but neither of these any one can do, who has the least knowledge of the game. If the person against whom you play should be repiqued in hearts or spades, you must deal the cards by twos, and the game will stand thus:

**Elder Hand**
- King
- Ace
- Eight
- Eight
- Eight

**Younger Hand**
- Knave
- Queen
- Nine
- Seven
- Nine

---

(ş) This manœuvre of piquet was invented by the countess of L—— (a French lady), and communicated by her to M. Guyot.
If he require to be repiqued in hearts, you keep the quint to a king in hearts; and the ten of spades, and lay out which of the rest you pleased: then, even if he should leave two cards, you will have a sixien major in hearts, and quarto de tens, which will make a repique.

But if he demand to be repiqued in spades; at the end of the deal you must dexterously pass the three cards that are at the bottom of the stock (that is, the ten of clubs, ten of diamonds, and ace of hearts) to the top, and by that means you reserve the nine, king, and ace of spades for yourself: so that by keeping the quint in hearts, though he will never do, unless he be quite ignorant of the game, or has some knowledge of your intention.

This last stroke of piquer has gained great applause, when those that have publicly performed it have known how to perform it dexterously. Many persons, who understand the nature of combining the cards, have gone as far as the passing the three cards from the bottom of the stock, and have then been forced to confess their ignorance of the manner in which it was performed.

IX. "The Metamorphosed Cards." Provide 32 cards that are differently coloured; on which several different words are written, and different objects painted. These cards are to be dealt two and two, to four persons, and at three different times, shuffling them each time. After the first deal, everyone's cards are to be of the same colour; after the second deal, they are all to have objects that are similar; and after the third cards, words that convey a sentiment.

Disposè of the cards in the following order.

COMBINATION, in chemistry, signifies the union of A with B.

---

(f) The manner of doing this is explained in the article LEGERDEMAIN.
of two bodies of different natures, from which a new compound body results. For example, when an acid is united with an alkali, we say that a combination between these two saline substances takes place; because from this union a neutral salt results, which is composed of an acid and an alkali.

**COMBUST**, in astronomy. When a planet is in conjunction with the sun, or not distant from it above half its disk; it is said to be combusted, or in combustion.

According to Argel, a planet is combusted, or in combustion, when not above eight degrees and thirty minutes distant from the sun, either before or after him.

**COMBUSTIO PECUNIÆ**, the ancient way of trying mixed and corrupt money, in Britain, by melting it down, upon payments into the Exchequer. In the time of king Henry II. a constitution was made, called the tryal by combustion; the practice of which differed little or nothing from the present method of assaying silver. But whether this examination of money by combustion was to reduce an equation of money only of silver, or to reduce it to pure fine silver, does not appear. On making the constitution of trial it was considered, that though the money did answer numero et ponderi, it might be deficient in value; because mixed with copper or brasses, &c.

**COMBUSTION**, a term denoting the operation of fire upon any inflammable substance, by which it melts, flames, and is reduced to ashes. There is not a phenomenon in nature by which the attention of philosophers has been more engaged, nor which has puzzled them more to account for, than this very common operation. To explain it, theories have been invented the most opposite and contradictory to one another that can be imagined; and, till very lately, the state of science did not afford data sufficient to explain it in a rational manner.

By former chemists it was supposed, that the parts of the combusible body itself were converted into fire. Accordingly Sir Isaac Newton propounded it as a query, whether gross bodies and light are not convertible into one another? and many chemists of a more modern date have determined this question in the affirmative, by maintaining that the light of the sun is or contains phlogiston. The interference of the air, however, in most cases of combustion known to us, proved a difficulty in this theory almost, if not totally, unsurmountable; for if the fire proceeds entirely from the combusible body, what occasion is there for any third substance distinct both from the air and that body to produce combustion? This naturally excited a conjecture, that the fire by which the combusible body is consumed, proceeds in reality from the air, and not from the body itself. And hence we see that Mr Hutchinson's system of fire and air being convertible into one another, might have passed as a rational human theory, if he had not attempted to force it upon mankind as a divine revelation. The modern discoveries in aerology, however, have entirely disproved this hypothesis with regard to our atmosphere considered as a whole, at the same time that they point out the true method, as far as our faculties are capable of comprehending it, by which this mysterious operation is performed. It is now almost universally known, that the air we breathe is composed of two kinds of elastic fluids, only one of which (called deglificated, pure, empyreal, or vital air) contributes to the support of flame, as well as of animal life; and this part is found to be by far the least in quantity of the atmosphere we breathe. It is computed from good observations, that, among the various component parts of our atmosphere, there is about one-fourth, according to Mr Scheele, or one-fifth according to Mr Cavendish, contained in it; and to this small part alone is owing the combustion of inflammable bodies.

Since the establishment of this important fact, several theories of combustion have been formed. According to M. Lavoisier, the phlogisticated air is a compound of two substances intimately combined; one is called by him the oxygenous principle, and the other specific elementary fire. During the combustion of sulphur, phosphorus, inflammable air, or any other substance of that kind, the oxygenous principle of the deglificated air, according to him, combines with these bodies, to which it has a strong attraction, and forms new compounds of salts and other bodies; at the same time that the elementary fire contained in these bodies is set at liberty, and becomes sensible, producing heat and flame, according to circumstances. Thus the fire produced in combustion does not proceed from the burned body, but from the decomposition of the deglificated air, in which it is contained in a latent and indefensible state; while its oxygenous principle combines with the sulphur, phosphorus, or inflammable air, and forms vital and phlogistic acids, or pure water. In like manner it is also suppos'd by this theory, 1. That metals are substances absolutely simple. 2. That metallic calces are true compounds formed by the oxygenous part of pure air with the metallic particles; and, 3. That pure water is a similar compound of the same principle with inflammable air.

According to Fourney, combusible bodies are Fourney's thofe which have a strong attraction to combine or theory. unite with pure or deglificated air; and combustion is nothing else but the act of that combination. This assertion is founded on the following facts; 1. That no substance can be burnt without air; 2. That the purer this air is, the more rapid is the combustion; 3. That in combustion, an abftention or waste of air always takes place; and, 4. That the residuum contains often a very sensible quantity of that pure air which it absorbed, and which may sometimes be extracted from it.

In Mr Scheele's new theory of heat, fire, light, and Scheele's phlogiston, he considers heat and light themselves as theory. compound substances. The former, according to him, consists of phlogiston and empyreal air. The calces of gold, reducible by heat alone, in a retort, shew that phlogiston is contained in heat; because it combines with the calces to revive them, and the dephlogificated air is found in the receiver. The precipitate is called by him the opportune, if reviv'd in his manner, affords, according to our author, another instance of the truth of his doctrine: "If phlogiston alone (says he) could pass through the retort, there would not be found the empyreal air in the receiver, and the ignoble metals might be reviv'd in the same manner."

Light, according to Mr Scheele, is a compound containing
Combustion.

containing phlogiston and heat, from which both may separate themselves in proper circumstances. A solution of silver in nitrous acid mixed with chalk, and exposed to the sunshine, is revived into a metallic form by the phlogiston of light. Nitrous acid also in a glass needle, receives phlogiston from light, and becomes of an orange colour: but if the glass be painted black, the acid receives the heat, not the phlogiston. Even the various coloured rays of light, according to our author, contain unequal shares of phlogiston; since the violet rays part more easily with their phlogiston to revive metals than any other. When light is not stopped in its passage, no heat is perceived; but if stopped in its course, the opposing body receives heat, and sometimes phlogiston. Light seems therefore to be the matter of heat, loaded with a superabundant quantity of phlogiston. That which comes out from a furnace, produces heat on the surrounding bodies, which ascends with the rarefied air; proceeds forward in straight lines; and may be reflected from polished surfaces, with this peculiarity, that a concave glass mirror retains the heat, whilst it reflects the light; for though its focus is bright, it is not warm. A pane of glass also put before a burning mirror, retains the heat, and allows the light to pass through it.

Fire is the more or less heated, or more or less luminous state of bodies, by which they are resolved into their constituent parts, and entirely destroyed. It requires, that they be previously heated in a contact with air; for to every combustible body a certain quantity of heat must be communicated, in order to set it in the fiery commotion.

Combustion is the action of heat penetrating the pores of bodies, and destroying their cohesion; in this case the body parts with its phlogiston, provided there be a substance present which has a strong attraction for the inflammable principle. If the heating be performed in open air, the empyreal part, on account of its stronger attraction, unites with the inflammable principle, which is thus set at liberty; from which the union of heat is compounded; and scarcely is this heat generated, when the combustible body is still more expanded by it than in the beginning, and its phlogiston more laid open. The more the heat is increased, the more minute are the particles into which the combustible body is dissolved. The empyreal air meets more surfaces; consequently comes in contact with more phlogiston; and, according to its nature, forms an union with a greater quantity of it, which produces a radiant heat. At this moment the constituent parts of the combustible body are so much disintegrated by the still increasing heat, that the empyreal air, continuing to pour in upon it in streams, attracts the phlogiston in still greater quantities; and hence the most elastic substance, light, is composed; which, according to the quantity of combustible matter, flows various colours.

The last theory we shall here take notice of is that of Dr Crawford.—He has by a great number of experiments endeavoured to show, that bodies which contain a large portion of phlogiston, and his followers in the same share of specific heat or fire; on the contrary, that those with a great share of this last, contain but little phlogiston; and lastly, those which are deprived of phlogiston, increase their capacity for specific fire. Thus, when sulphur of antimony is deprived of its phlogiston, by calcination, which is then called dephlogisticated, it nearly triples its specific fire. The same change takes place in gunpowder and in iron. This fact is generally true, whatever be the nature of the substance; and even the air now in the same state, for phlogism is air has more of it, and dephlogisticated air shows a most prodigious quantity. From these facts it is clear, that phlogiston and fire are distinct, and incompatible substances; so that when one enters into the composition of any body, the other of course is expelled from it. Thus metals are calcined in consequence of a double attraction, by which the metal imparts its phlogiston to the air, while the air communicates its fire to the metallic calces; which is further confirmed by the air that is found in metallic calces, whose increased weight by calcination corresponds to the air that is expelled from them by their reduction to a metallic state.

All combustible bodies are absolutely in the same case. By these means such bodies as contain a large quantity of phlogiston in their composition, but loosely adherent to them. Dephlogisticated air, which is greatly loaded with specific fire, has at the same time a strong attraction for phlogiston; and, in the act of combustion, communicates its fire to the combustible body, whilst the air becomes phlogisticated or loaded with phlogiston. Thus we find, that sulphur contaminates the air, when burned, by the phlogiston it throws into it, and the produced vitriolic acid, if any, becomes impregnated with the same.

In some cases the most intense heat or sensible fire is produced in the combustion; but in others it is very moderate. This variation generally depends on the quantity and quality of the vapours produced during the combustion: when these are very inconsiderable, and the residuum cannot absorb the fire which is emitted by the air, the remainder is precipitated, or diffused all around, and produces a very sensible fire. On the contrary, if the vapours are capable of absorbing it, very little heat is produced. We know, by the most certain experiments, that, for instance, the vapour of water absorbs about 800 degrees of heat beyond that of its boiling state; from whence it follows, that whenever there is a quantity of watery vapours produced by combustion, very little sensible fire must be felt. So when spirits of wine are fired, the heat then produced by the combustion is very inconsiderable, the greater part being absorbed by the watery vapours that are then produced: but when the phosphorus of Kunkel is set on fire, the heat is very strong; there being but a small quantity of acid to carry off the specific fire that is set loose.

These are the principal theories of combustion that M. Magellan has appeared. M. Magellan, from whose notes on Cronfed's Mineralogy the above account is taken, objects to M. Lavolier's opinion, that the oxygenous principle cannot be shown to our senses, nor is it better demonstrated than the phlogiston suppos'd by the great Stahl and his followers. M. Fourcroy's system he supposes to be less objectionable; but to the specie he objects from Mr Kirwan. That in no instance it appears that phlogiston penetrates glass, much less a compound.
compound of pure air and phlogiston; and, 2dly, That if Mr Scheele's notions were true, then other metallic caleces, or at least black manganife, would be reduced by heat alone: for this calx dephlogisticates nitrous acid, and has a stronger affinity with phlogiston than it; and therefore ought to decompose the heat with as great facility as the nitrous acid, or even with greater on account of its greater attraction. The former objection M. Magellan does not suppose to be altogether conclusive, as there are as many combinations (he says) of two or more substances that pass through bodies, each of which would be shaped before they were combined; and what Mr Scheele has said on light seems to prove that glass is not always quite impervious to phlogiston; but the latter he deems altogether unanswerable.

Having thus rejected three of these theories, he acquires in that of Dr Crawford, which, he tells us, "is the most satisfactory concerning the nature and processes of combustible bodies and of their combustion, so far as the present state of our knowledge has opened the field of our views into the operations of nature." Before such a full ascent, however, is given to any theory, it is altogether necessary that it should be consistent with every known fact, as far as that fact can be investigated by us in our present state of knowledge; and that this is not the case with the theories either of Fourcroy, Scheele, or Crawford, will appear from the following considerations.

I. With regard to that of Fourcroy, it is evidently deficient in one of the essential requisites to produce combustion, even fire itself; for if combustion depends only on the attraction between combustible bodies and pure air, then it ought to take place on all occasions wherever pure air and combustible bodies are present to each other. But this is not the case; for though we put a piece of unlighted charcoal into a jar full of dephlogisticated air, no combustion will ensue. To produce this it is necessary that the charcoal be already, in part at least, in a state of combustion, or that fire be applied to it from without. This theory therefore, instead of explaining the matter, gives not the smallest insight into it; since we are perpetually left to seek for the cause of the fire, which produced that in question: for the combination of a combustible body with air is the effect of combustion, not the cause.

II. Mr Scheele's theory is so exceedingly contrary to the common notions of mankind, that it can scarce ever be seriously believed. The pure light of the sun can never be supposed by any mortal to confit principally of a substance as gross as the foot of our chimney's, without a degree of evidence of which the subject is quite incapable.

III. Under the article Chemistry, Dr Crawford's theory of heat is fully considered, and found to be insufficient. It is there shown that the degree of specific heat contained in bodies cannot be measured by any method yet known to us; that the phrase, quantity of heat, so frequently made use of by Dr Crawford and others, is vague, inaccurate, and improper; as expressing only the degree of sensible heat extracted, produced, generated, or which becomes perceptible in certain circumstances by us, without regard to the real quantity contained in the body itself, either originally, or after it has parted with that in question. Thus all experiments founded on the quantities of specific heat contained in different bodies must be fallacious and inconclusive. Not to insist, however, on these general arguments, it is contrary to fact, that "bodies which contain a large portion of phlogiston contain but a small share of specific heat," and vice versa, as the Doctor afferts; which will appear from the following considerations.

1. The only methods by which we can measure the quantity of any material substance is either by its bulk or weight.
2. Whatever occupies space, and refists the touch, we have a right to call a material substance, whether we can see it and weigh it or not. Thus air, which is invisible, and not very easily ponderable, is universally allowed to be a substance and not a quality.
3. In cases where we cannot conveniently measure the weight of any substance, its quantity must always be judged of by its bulk. Thus the quantity of air contained in a bladder, or in a bellows, is always judged of by the degree of expansion of either.
4. Heat, which is still more subtle than air, is measured in this way, as Dr Crawford himself acknowledges; for the expansions of mercury are in an arithmetical progression expressive of the real degrees of heat.
5. Applying this rule to bodies in general, we must conclude, that the expansions of all bodies will be in proportion to the degrees of heat which they contain. Thus, if a body be expanded by heat to double its bulk, and in this state remains even when the heating cause is withdrawn, we may then lay with justice, that this body contains double the quantity of latent or specific heat that it did before; and so on (4).
6. As the vapour of water is found to absorb a vast quantity of heat, and likewise to become prodigiously expanded in comparison with the water from whence it is produced, we may justly conclude, that the quantity of heat absorbed, or of specific heat contained in the steam, is to the specific heat contained in the water as the bulk of the steam is to that of the water. It is difficult indeed to determine how much steam exceeds in bulk the water from which it is derived, but from some experiments, Dr Black concludes, that it is augmented in bulk between 1600 and 1700 times; and from the great quantity of heat emitted by steam during its condensation, which in some cases exceeds 1000 degrees of Fahrenheit, we have reason to believe

(4) This is not contradictory to the observation that the expansions of all bodies are not in proportion to the degree with which they are heated, nor equal at different times. It is the degree of heat absorbed and entangled among the particles of the body which expands it, not that which flows out from it, and affects our senses or the thermometer. Thus, though a body is heated to 100 degrees, it may absorb only 10, and, after it has done so, it may require 300 or 400 degrees more to cause it absorb other ten.
believe that the quantity of its expansion is proportionable to that of the heat absorbed.

7. As we thus are ascertained, by the great expansion of aqueous vapour, that it has absorbed a vast quantity of heat, it will evidently follow, that from the expansion of other substances we ought also to know the quantity of heat absorbed by them. To apply this then to the present case. In Dr Priestley's experiments on the conversion of charcoal into inflammable air, he found, that one grain of charcoal, diffused by the heat of the sun in vacuo, gave six ounce measures of inflammable air. In another experiment, he found that 24 grains of charcoal gave 15; ounce measures of the same kind of air. But from a computation of the weight of the air so produced, it appears, that at least an equal quantity of water with that of the charcoal goes to the composition of the aerial fluid. In measuring this expansion, therefore, we may allow one-half for that of the water requisite to form the inflammable air; and hence the grain of charcoal, properly speaking, absorbs only three ounce measures of fire. That this expansion was the effect of fire is very evident; for there was nothing else present but fire, or the concentrated light of the sun: the experiment being performed by means of a burning glass in vacuo. It cannot be a fact then, as Dr Crawford affirms, that a phlogistic body contains but a small quantity of specific heat; for here for each grain of charcoal, as one grain of charcoal was made to contain as much specific fire as is equivalent in bulk to three ounce measures. It appears, therefore, that the quantity of specific fire contained in bodies is not determined by their being combustible or not, or by their containing phlogiston or not: much less can we believe that heat and phlogiston are so incompatible with one another, that where one enters into the composition of any body the other is of course expelled from it; since we find the purest fire we know united in vast quantity with the purest phlogiston we know, and both together constituting one of the most inflammable substances in nature, viz. inflammable air.

8. In like manner must the last part of the Doctor's theory be erroneous, viz. that "in the act of combustion the dephlogisticated air communicates its fire to the combustible body." In the instance just now adduced, the combustible substances, inflammable air, contains already as much fire as it can hold; and according to the general rule in these cases, if it was to absorb more fire, it ought to become still more expanded. But instead of this, when dephlogisticated and inflammable air mixed together in due proportion, are set on fire, they shrink in a manner into nothing; so that it is plain, instead of one communicating its fire to the other, both of them throw out almost all the fire they contain; so that they are no longer air, but water, or some other substance about which philosophers are not yet agreed.

9. Dr Crawford's theory of combustion is liable to the very same objection with that of Fourcrroy, viz. that it sets aside the necessity of any external cause to set on fire the combustible bodies. If dephlogisticated air attracts the phlogiston of the combustible body, and the phlogiston in the latter attracts the fire of the dephlogisticated air, the consequence of which is combustion; then, wherever dephlogisticated and inflammable air are mixed, combustion ought immediately to ensue. But this is not the case. A candle, a spark of electricity, or, in a word, some body already in a state of combustion, must be applied before we can produce the effect in question. We must therefore seek for the cause of combustion in the burning body applied, which will be found equally inexplicable; and thus we cannot proceed a single step in real knowledge, though allowed by all that Dr Crawford has advanced.

10. The theory of M. Lavoisier, notwithstanding M. Magellan's criticism, seems to come much nearer the truth than that of Dr Crawford. With regard to the existence of what Lavoisier calls the oxygénous principle, it is certainly established on as sure grounds as that of any invisible substance can be. M. Magellan complains, without reason, that it "cannot be shown to our senses." It has not yet indeed been made visible per se; but it is found to increase the weight of bodies very sensibly. Perhaps, indeed, it may not be an oxygénous or acidifying principle; perhaps it may be water, or some other substance; but still it is something which, by being combined with elementary fire, is expanded into a vast bulk, and which, by being deprived of this fire, shrinks into its former dimensions. Thus it manifests itself to be a real substance; and not only so, but a terrestrial gravitating substance; and which, even when lightened by a mixture of charcoal so as to constitute the solid part of fixed air, has been shown nearly equal the density of gold. In this respect, therefore, M. Lavoisier's theory is faultless, as well as in that which affirms that in the act of combustion the dephlogisticated air parts with its fire; but it is imperfect in this respect, that he does not consider the quantity of fire contained in the inflammable body, which is thrown out at the same time, nor the occasion there is for some body in a state of actual inflammation to begin the combustion. That the combinations mentioned by him do actually take place is not denied; but they are undoubtedly consequences of the combustion, not causes of it, as they are generally supposed. To understand this subject fully, therefore, it will still be necessary to consider farther.

11. Under the article Chemistry, already quoted, Another it is shown that heat and cold are not essentially distinct in the sense of one another, but that heat consists in the motion of a certain subtile and invisible fluid from a centre towards a circumference, and that cold consists in the action of the same fluid from a circumference to a centre. In other words, when elementary fire acts from any body outwardwards, we say that body is hot, because it heats other bodies; but when it flows from others into any particular body, we call the latter cold, as depriving the neighbouring bodies of part of their relative quantity of heat. We may further illustrate this by the example of electricity, where the fluid running from any body produces a kind of electricity called positive; but, when entering into it, produces another, opposite in many respects to the former, called negative electricity. In like manner all bodies in the act of throwing out elementary fire are hot, and in the act of absorbing it cold. Vapours of all kinds, therefore, ought to be naturally cold; and experience shows that they really are so; for, by means of evaporation, very intense degrees of cold may be produced. See Cold and Evaporation.
12. In most terrestrial bodies the heat easily flows out from one to another, and therefore they are in a manner indifferent as to the state of being either hot or cold: but in vapours, the heat, having once flowed in to them, continues to have a tendency to do so without regard to the external temperature of bodies. Hence those who have been immersed in clouds on the tops of high mountains or otherwise have uniformly related that they found the vapour exceedingly cold; and thus our atmosphere, unless supplied by the powerful influence of the sun-beams, not only becomes extremely cold itself, but likewise cools to an extreme degree the surface of the earth and every thing upon it.

13. In all cases therefore, where a quantity of vapour, whether inflammable or not, is collected into one place, there is a constant influx, or at least a constant pressure inwards of the elementary fire existing invisibly all around; which pressure must continue until some means or other the flow or preffure of external fluid is dispersed or at any rate abduced from without inwards, is made to tend from within outwards.

14. One method of reversing this influx is by external pressure, or by any other means bringing the particles of vapour nearer to one another. On this subject, a treatise has been written by Dr Webster of Edinburgh, in which he endeavours to establish the doctrine, that condensation is in all cases the cause of heat. That it really is the immediate cause, in a great many cases, is very certain; but it is equally evident that even in these cases, the cause of condensation must be the ultimate cause of heat. Thus, if a quantity of air be compressed in an air-gun, it is found to become hot; but though the compreffion be the immediate cause, the force by which the compreffion is occasioned must be the ultimate cause of the heat. The immediate agent, however, by which the heat is produced, is neither the compreffing cause nor the condensation, but the influx of elementary fire from the air, by bringing the particles of the latter nearer to each other. In like manner, when iron is hammered until it becomes hot, the metal may probably be supposed to be condensed, and the elementary fire to be squeezed out of it as water from a sponge: but it is neither the action of the hammer, nor the approximation of the particles to each other, that is the cause of heat; but the influx of elementary fire directed from the iron every where from within outwards.

15. Thus we may now at once explain the action of combustion; to do which, we shall take the example of a mixture of inflammable and dephlogisticated air already mentioned. When these are mixed together, there is a constant pressure of the elemental fluid inwards from all quarters into the aerial vapours, by which their elasticity and form as airs are preserved, and this pressure will continue as long as we let them remain undisturbed. But when a burning body is brought into contact with them, the influx of the elementary fire is not only prevented but reversed in that part which comes in contact with the burning body. Thus the whole confluence of both inflammable and dephlogisticated airs is destroyed in a moment: for the flable fluid, feeling (if we may use the expression) that the pressure is relieved in one place, instantly directs its whole force thither: and the pressure inwards being thus reversed in this part instantly becomes so in every other, and the whole fluid contained in both is discharged with a bright flash and loud explosion.

16. In a similar manner may we explain the combustion of solid bodies. None of these can be ignited without the assistance of external fire. This in the first place rares to some part of them into vapours, which by means of dephlogisticated air is decomposed in the manner already mentioned; while, by means of the heat thrown out, a fresh quantity of vapour is raised, at the same time that the fire is augmented, and would continue to be so in infinitum, as long as fuel could be supplied. When no more inflammable vapour can be raised, the combustion ceases of course; and the remainder becomes charcoal, ashes, &c. according to its different nature, or the combinations it is capable of affuming with the terrestrial or gravitating part of the pure air by which the fire was supplied.

17. It may now be asked, If the cause of combustion be merely the reversing of the influx of elementary fire, why cannot inflammable vapours be fired in vacuo, by means of heat applied to some part externally? Thus, as inflammable air has a constant influx of elementary fire into it, why may not this influx be reversed, and a flame produced, not so violent as with dephlogisticated air, but sufficient to authorize us to say that such a body was actually in the state of combustion? But this, we know, cannot be the case unless some pure air be admitted; for a stream of inflammable air, if nothing else be admitted, will as effectively put out a fire as a stream of water. Here, however, we may reply, that this would suppofe inflammable air to be destroyed by the very power by which it was produced. It seems to be the nature of all vapours to absorb heat without any imitation, as is evident by the increase of elasticity in them by an increase of heat. Elementary fire is one of the component parts of vapour, and no substance can be decomposed merely by the action of one of its component parts. Something heterogeneous must therefore be added, on which one or both of the component parts may act; and then the vapour will be decomposed in vacuo as well as in the open air, though with less obvious circumstances. Thus charcoal once difperfed by heat into inflammable air cannot be decomposed merely by heat, because its tendency is always to absorb this element: But if into a jar full of inflammable air we introduce a quantity of calx of lead, and then heat it, the pressure of the fluid is interrupted in that part where the calx is, and presently becomes reversed by means of the additional heat there, which, at the same time that it furnishes no more charcoal, affords a substance with which the charcoal in the inflammable air may unite. The air is therefore decomposed, though too slowly to produce actual flame. For combustion, therefore, it is necessary that the following circumstances should concur: 1. The mixture of two vapours containing a great quantity of specific fire each. 2. That the terrestrial bases of these vapours should be capable of acting upon one another; but no third substance capable of immediately absorbing the fire should be present. 3. The presence of actual fire in some part, to lessen the pressure of the elementary fluid, let it in motion, and reverse it. This is the case when inflammable and dephlogisticated...
phlogificated airs are mixed together. Both those contain specific fire in great quantity. The basis of the one, known to be charcoal, is capable of being united by means of heat to the basis of phlogificated air, and of forming with it in some cases fixed air, in others water, or some other substance, according to their various proportions; and after this union is formed, there is no third substance by which the elementary fire may be absorbed. The inflamed body by which they are set on fire first leaffns the inward preface of the elementary fire on one part, by which the bafes are allowed to approach nearer each other, and to form a chemical union according to the general observation: But this union cannot be effected without the emission of part of the elementary fire, which being contained in the mixture in great quantity, produces a bright flame. This leaffns the preface still more; a new chemical union and a new flame are produced; and so on as long as any of the materials remain.

When all these circumstances concur, it is not a property peculiar to dephlogificated air to support flame, though it seems to be so to preserve animal life. It is well known that pyrophorus will burn in common nitrous air, and a candle will burn with an enlarged flame in that kind called dephlogificated nitrous air. But where any of the concurrent circumstances abovementioned is wanting, no combustion will be produced. Thus, though the steam of water contains a vast quantity of specific fire, and through it is decomposed by passing over red-hot iron, yet no combustion is produced; because, in the very moment of extrication, the elementary fire finds a quantity of phlogification either in the iron, the water itself, or both, with which it combines, and forms inflammable air, but without any flame.

With regard to the substances which have the property of taking fire spontaneouply, as Phosphorus and Pyrophorus, see those articles.

COMEDY, a sort of dramatic poetry, which gives a view of common and private life, recommends virtue, and corrects the vices and follies of mankind by means of ridicule. See the article Poetry.

This last kind alone was received among the Romans, who neverthelss made a new subdivision of it into ancient, middle, and new, according to the various periods of the commonwealth. Among the ancient comedies were reckoned those of Livius Andronicus; among the middle those of Pacuvius; and among the new ones, those of Terence. They likewise distinguished comedy according to the quality of the persons represented, and the dres they wore, into togata, praetextata, trabeata, and terbernariae, which last agrees pretty nearly with our farces. Among us, comedy is distinguished from farce, as the former represents nature as she is; the other dittorts and overcharges her. They both paint from the life, but with different views: the one to make nature known, the other to make her ridiculous.

COMENIUS (John Amos), a grammarian, and Protestant divine, born in Moravia in 1592. He was eminent for his diligence to introduce a new method of teaching, which he published in several essays in 1616, and had prepared some others, when the Spaniards pillaged his library, after having taken the city of Fulnece, where he was minister and master of the school. Comenius fled to Lefan; a city of Poland, and taught Latin there. The book he published in 1621, under the title of Jana Linguarum referata, gained him a prodigious reputation, insomuch that he was offered a commission for regulating all the schools in Poland. The parliament of England desired his assistance to regulate the schools in that kingdom. He arrived at London in 1641; and would have been received by a committee to hear his plan had not the parliament been taken up with other matters. He therefore went to Sweden, being invited by a generous patron, who settled a stipend upon him that delivered him from the fatigues of teaching; and now he employed himself wholly in discovering general methods for those who instructed youth. In 1657 he published the different parts of his new method of teaching. He was not only taken up with the reformation of schools; but he also filled his brain with prophecies, the fall of Antichrist, Millennium, &c. At last Comenius took it into his head to address Louis XIV. of France, and to send him a copy of the prophecies of Drabuickis; infinuating that it was to this monarch God promised the empire of the world. He became sensible at last of the vanity of his labours, and died in 1671.

COMET, an opaque, spherical, and solid body like a planet, performing revolutions about the sun in elliptical orbits, which have the sun in one of their foci.

There is a popular division of comets into tailed, bearded, and hairy comets: though this division rather relates to the different circumstances of the same comet, than to the phenomena of several. Thus when the light is westward of the sun, and moves after it, the comet is said to be tailed, because the train follows it in the manner of a tail: when the comet is eastward of the sun, and moves from it, the comet is said to be bearded, because the light marches before it in the manner of a beard. Lastly, when the comet and the sun are diametrically opposite (the earth between them), the train is hid behind the body of the comet, except a little that appears round it in the form of a border of hair: and from this last appearance the word comet is derived: as κοιμητης comets, comes from κοιμητης, hair. But there has been comets whose disk was as clear, as round, and as well defined, as that of Jupiter, without either tail, beard, or coma. See Astronomy-Index.

COMETARIUM, a curious machine, exhibiting an idea of the revolution of a comet about the sun. See Astronomy-Index.

COMETEAN, a town of Bohemia in the circle of Salz, with a handsome town-house. It was taken by storm in 1431, and all the inhabitants, men, women, and children, put to the sword. It is seated in a fertile plain, in E. Long. 13. 25. N. Lat. 50. 30.

COMETES, in botany: A genus of the monogynia order, belonging to the tetrandria class of plants. The involucrum is terephylous and triflorous; the calyx terephylous; the capsule trilocous.

COMFY. See Syphilis.

COMINES (Philip de), an excellent historian, born of a noble family in Flanders in 1446. He lived in a kind of intimacy with Charles the Bold, duke of Burgundy, for about eight years: but being seduced...
to the court of France by Louis XI., he was highly
promoted by him; and executed several successful
negociations. After this king's death he experienced
many troubles on account of being a foreigner, by the
envy of other courtiers, and lay long in prison before
he was discharged; he died in 1509. Comines was
a man of more natural abilities than learning; he
spoke several living, but knew nothing of the dead
languages; he left behind him some memoirs of his
own times, that are admired by all true judges of
history. Catherine de Medicis used to say, that Co-
mines made as many heretics in politics as Luther
had in religion.

Comines, a town of French Flanders on the lines
which the French have made to defend their country
against the Austrian Netherlands. It is situated on
the river Lis, in E. Long. 3. N. Lat. 50° 30'.

Comitatius, in law, a county. Ingulphus tells
us, that England was first divided into counties by
king Alfred; and the counties into hundreds, and
thence again into tythings; and Forrenus writes, that
regnum Angliae per comitatuum, ut regnum Franciae
per ballitatum distinguatur. Sometimes it is taken for
a territory or jurisdiction of a particular place; as in Mat.
Paris, anno 1234. See County.

Comitia, in Roman antiquity, were general as-
semblies of the people, lawfully called by some mag-
fidrates for the enjoinment or prohibition of any thing
by their votes.

The proper comitia were of three sorts; curiata,
centuriata, and tributa; with reference to the three
grand divisions of the city and people into curiae,
centuriæ, and tribes: For, by comitia calata, which we
sometimes meet with in authors, in elder times were
meant all the comitia in general; the word calata
from calae, or calo, being their common epithet; though
it was at last restrained to two sorts of assemblies, those
for the creation of priests, and those for the regulation
of laity and temples.

The comitia curiata owe their origin to the division
which Romulus made of the people into 30 curiae;
ten being contained in every tribe. They answered
in the same respects to the parishes in our cities, being
not only separated by proper bounds and limits, but dis-
tilguished too by their different places set apart for
the celebration of divine service, which was performed
by particular priests (one to every curia), with the
name of Curiones.

Before the institution of the comitia centuriata, all
the grand concerns of the state were transacted in the
assembly of the curiae; as the election of kings and other
chief officers, the making and abrogating of
laws, and the judging of capital causes. After the
expulsion of the kings, when the commons had obtained
the privilege to have tribunes and seiles, they elected
them for some time at these assemblies; but that cer-
emony being at length transferred to the comitia tri-
buta, the curiae were never convened to give their
votes, except now and then upon account of making
some particular law relating to adoptions, wills, and
testaments, or the creation of officers for an expedi-
dition; or for electing some of the priests, as the famil-
ies, and the curia maxima, or superintendant of the
curiones, who were themselves chosen by every partic-
ular curia.

The power of calling these assemblies belonged at
first only to the kings; but upon the establishment of
the democracy, the same privilege was allowed to mos-
t of the chief magistrates, and sometimes to the ponti-
ces.

The persons who had the liberty of voting here
were such Roman citizens as belonged to the curia;
or such as actually lived in the city, and conformed
to the customs and rites of their proper curiae; all
those being excluded who dwelt without the bounds
of the city, retaining the ceremonies of their own
country, though they had been honored with the jus
civitas, or admitted free citizens of Rome. The place
where the curiae met was the comitium, a part of
the forum: No fet time was appointed for the hold-
ing there, or any other of the comitia, but only as
business required.

The people being met together, and confirmed by
the report of good omens from the augurs (which was
necessary in all the assemblies), the rogatio, or busi-
nesses to be proposed to them, was publicly read. After
this (if none of the magistrates interposed), upon
the order of him that prefided in the comitia, the
people divided into their proper curiae, and consulted
of the matter; and then the curiae being called out,
as it happened by lot, gave their votes man by man,
in ancient times viva voce, and afterwards by tablets;
the most votes in every curia, going for the voice of the
whole curia, and the most curiae for the general con-
tent of the people.

In the time of Cicero, the comitia curiata were so
much out of fashion, that they were formed only by
30 lieftors representing the 30 curiae; whence, in his
second oration against Rutilus, he calls them comitia
dumbrata.

The comitia centuriata were instituted by Servius
Tullius: who, obliging every one to give a true ac-
count of what he was worth, according to those ac-
counts, divided the people into six ranks or classes,
which he subdivided into 193 centuries. The first
class, containing the equites and richest citizens,
consisted of 96 centuries. The second taking in the
trades and mechanics, consisted of 22 centuries. The
third, 20. The fourth, 22. The fifth, 6. The sixth,
filled up with the poorer fort, but one century:
and this, though it had the same name with the
reft, yet was seldom regarded, or allowed any
power in public matters. Hence it is a common thing
with the Roman authors, when they speak of the classes,
to reckon no more than five, the sixth not being
worth their notice. This last class or order was di-
vided into two parts, or orders; the proletarii and the
capite consi. The former, as their name implies, were
designed purely to flock the republic with men, since
they could supply it with so little money; and the
latter, who paid the lowest tax of all, were rather
counted and marhalled by their heads than by their
eraettes.

Persons of the first rank, by reason of their pre-em-
nence, had the name of claesë; whence came the name
of clades or authors for the most approved writers. All
others, of what class soever, were said to be infra
classes. The assembly of the people by centuries was
held for the electing of consuls, censors, and praetors;
as also for the judging of persons accused of what they
called
Comitia. called *crimem persuersionis* or actions by which the party had showed himself an enemy to the state, and for the confirmation of all such laws as were proposed by the chief magistrates, who had the privilege of calling these assemblies.

The place appointed for their meeting was the *comitia centuriataria*, because in the primitive times of the commonwealth, when they were under continual apprehensions of enemies, the people, to prevent any sudden assault, went armed, in martial order, to hold these assemblies; and were for that reason forbidden by the laws to meet in the city, because an army was upon no account to be marshalled within the walls: yet, in latter ages, it was thought sufficient to place a body of soldiers as a guard in the janiculum, where an imperial standard was erected, the taking down of which denoted the conclusion of the comitia.

Though the time of holding these comitia for other matters was undetermined; yet the magistrates, after the year of the city 601, when they began to enter on their places, on the kalends of January, were commonly designed about the end of July and the beginning of August.

All the time between their election and confirmation they continued as private persons, that inquisition might be made into the election, and the other candidates might have time to enter objections, if they met with any suspicion of foul dealing. Yet, at the election of the censors, this custom did not hold; but as soon as they were elected, they were immediately invested with the honour.

By the institution of these comitia, Servius Tullius secretly conveyed the whole of the power from the commons; for the centuries of the first and richest class being called out first, who were three more in number than all the rest put together, if they all agreed, as generally they did, the business was already decided, and the other classes were needless and insignificant. However, the three last sIRCcumstances ever came to vote.

The commons, in the time of the free state, to remedy this disadvantage, obtained, that before they proceeded to voting any matter at these comitia, that century should give their suffrages first upon whom it fell by lot, with the name of *centuria prerogativa*; the rest being to follow according to the order of their centuries, for the constitution of the 35 tribes into which the classes and their centuries were divided in the first place, the tribes cast lots which should be *prerogativa tribus*; and then the centuries of the tribes for the honour of being a prerogative century. All the other tribes and centuries had the appellation of *jure vocate*, because they were called out according to their proper places.

The prerogative century being chosen by lot, the chief magistrate, sitting in a tent in the middle of the campus martius, ordered that century to come out and give their voices, upon which they freely separated from the rest of the multitude, and came into an enclosed apartment, which they termed *fepha*, or *cubilia*, passing over the *pontes* or narrow boards laid there for the occasion; on which account, *de ponte dejicius* signifies to be denied the privilege of voting, and persons thus dealt with are called *deponentes*.

At the hither end of the pontes stood the *diribitores* (a sort of under officers so called from their marshalling the people), and delivered to every man, in the election of magistrates, as many tables as there appeared candidates, one of whose names was written upon every tablet. A proper number of great chefs were set ready in the *fepha*, and every body threw in which tablet he pleased.

By the chefs were placed some of the public servants, who taking out the tablets of every century, for every tablet, made a prick or a point in another tablet which they kept by them. Thus, the business being decided by the most points, gave occasion to the *omne tulit pandium*, and the like.

The same method was observed in the judiciary process at these comitia, and in the confirmation of laws; except that, in both these cases, only two tablets were offered to every person; on one of which was written *U. R.* and on the other *A.*, in capital letters: the two first standing for *aius rogat, * be it as you desire,* relating to the magistrate who proposed the question; and the last for *antiqua*, or *I forbid it.*

It is remarkable, that though in the election of magistrates, and in the ratification of laws, the votes of that century, whose tablets were equally divided, signified nothing; yet in trials of life and death, if the tablets *pro* and *con* were the same in number, the person was actually acquitted.

The division of people into *tribes* was an invention of Romulus, after he had admitted the Sabines into Rome; and though he constituted at that time only three, yet as the state increased in power, and the city in number of inhabitants, they rose by degrees to 35. For a long time after this institution, a *tribe* signified no more than such a space of ground with its inhabitants. But as at last the matter was quite altered, and tribe was no longer *pars urbis*, but *pars civitatis*, not a quarter of the city, but a company of citizens living where they pleased. This change was chiefly occasioned by the original difference between the *tribes* in point of honour. For Romulus having committed all fordid and mechanic arts to the care of strangers, slaves, and libertines; and reserving the more honest labour of agriculture to the freemen and citizens, who by this active course of life might be prepared for martial service; the *tribus urbis* were for this reason esteemed more honourable than the *tribus urbanae*. And now all persons being allowed of getting into the more creditable division; and their being several ways of accomplishing their wishes, as by adoption, by the power of censors, or the like; that rufilte tribe which had the most worthy names in its roll, had the preference to all others, though of the same general denomination. Hence all of the same great family, bringing themselves by degrees into the same tribe, gave the name of their family to the tribe they honoured; whereas at first the generality of the tribes did not borrow their names from persons but from places.

The first assembly of the tribes we meet with is about the year of Rome 263, convened by Sp. Sicinius, tribune of the commons, upon account of the trial of Coriolanus. Soon after, the tribunes of the commons were ordered to be elected here; and at last all the inferior magistrates, and the collegiate priests. The same comitia served for the enacting of laws relating to
Comitialis morsus, an appellation given to the epilepsy, by reason the comitia of ancient Rome were ordinarily held.

Comitium, in Roman antiquity, a large hall in the forum, where the comitia were ordinarily held.

Comma, among grammarians, a point or character marked thus (,), serving to denote a short pause, and to divide the members of a period. Different authors define and use it differently. According to F. Boffler, the comma serves to distinguish the members of a period, in each of which is a verb and the nominative case of the verb: thus, “That so many people are pleased with trifles, is owing to a weakness of mind, which makes them love things easy to be comprehended.” Besides this, the comma is used to distinguish in the same member of a period, several nouns-substantive, or nouns-adjective, or verbs not united by a conjunction: thus, “Virtue, wit, knowledge, are the chief advantages of a man:” or, “A man never becomes learned without studying confidently, methodically, with a gelt, application, &c.” If those words are united in the same phrase with a conjunction, the comma is omitted: thus, “the imagination and the judgment do not always agree.”

The ingenious author of the tract De ratione inter-pungendi, printed with Volisius’s Element. Rhetor. Lond. 1724, lays down the use of a comma to be, to distinguish the simple members of a period, or sentence; i.e., such as only consist of one subject, and one definite verb. But this rule does not go throughout; the same author inflicting many particular cases not yet included herein, where yet the comma is admissible. See Punctuation.

It is a general rule that a comma ought not to come between a nominative and a verb, or an adjective and substantive, when these are not otherwise disjoined: thus, in the sentence, God rules with infinite wisdom, a comma between God and rules, or between infinite and wisdom, would be absurd. But to this exceptions may occur: as when not a single word, but a sentence, happens to be the nominative: thus, in the example first above given, where the sentence that so many people are pleased with trifles, forms the nominative to the verb is, a comma at trifies is proper, both for the sake of perspicuity, and coinciding with a slight natural pause.

Comma, in music. See Interval.

Commandinus (Frederic), born at Urbino in Italy, and defended from a very noble family, in the 16th century. To a vast skill in the mathematics, he had added a great knowledge in the Greek tongue, by which he was qualified to translate the Greek mathematicians into Latin: accordingly he translated and published several, which no writer till then had attempted; as Archimedes, Apollonius, Euclid, &c.

Commandry, a kind of benefice or fixed revenue belonging to a military order, and conferred on ancient knights who had done considerable services to the order.

There are frieze or regular commandries, obtained in order, and by merit; there are others of grace and favour, conferred at the pleasure of the grand master; there are also commandries for the religious, in the orders of St Bernard and St Anthony. The kings of France have converted several of the hospitals for lepers into commandries of the order of St Lazarus.

The commandries of Malta are of different kinds; for as the order consists of knights, chaplains, and brothers-servitors, there are peculiar commandries or revenues attached to each. The knight to whom one of these benefices or commandries is given is called commander, which agrees pretty nearly with the praepositus set over the monks in places at a distance from the monastery, whose administration was called abedienia; because depending entirely upon the abbot who gave him his commendation. Thus it is with the simple commanders of Malta, who are rather farmers of the order than beneficiaries; paying a certain tribute or rent, called responsio, to the common treasurer of the order.

Commelina, in botany: A genus of the monogynia order, belonging to the triandria class of plants; and in the natural method of ranking under the 6th order, Ensatia. The corolla is hexapetalous; there are three nectaria, of a cruciform figure, and inferted into their proper filaments. There are ten stigmas, all of them natives of warm climates. They are herbaceous plants, rising from two to four feet high, and adorned with blue or yellow flowers. Their culture differs in nothing from that of the common exotics.

Commemoration, in a general sense, the remembrance of any person or thing, or the doing any thing to the honour of a person’s memory, or in remembrance of any past event. Thus the eucharist is a commemoration of the sufferings of Jesus Christ.

Commendam, in the ecclesiastical law, the trust or administration of the revenues of a benefice, given either to a layman, to hold by way of depozitum for six months, in order to repairs, &c. or to an ecclesiastical or beneficed person, to perform the pastoral duties thereof, till once the benefice is provided with a regular incumbent.

Anciently the administration of vacant bishoprics belonged to the nearest neighbouring bishop; which is still practiced between the archbishopric of Lyons and the bishopric of Autun; on this account they were called commendatory bishopps.

This custom appears to be very ancient. S. Athanasius.
COMMENDATUS, one who lives under the protection of a great man. Commendati homines, were persons who, by voluntary homage, put themselves under the protection of any superior lord: for ancient homage was either predial; due for some tenure; or personal, which was by compulsion, as a sign of necessity; or voluntary, with a desire of protection; and those who, by voluntary homage, put themselves under the protection of any man of power, were sometimes called homines ejus commendati, as often occurs in Doomsday. Commendati dimidii were those who depended on two several lords, and paid one-half of their homage to each; and sub-commendati were like under-tenants under the command of persons that were themselves under the command of some superior lord: also there were dimidii sub-commendati, who bore a double relation to such depending lords. This phrase seems to be still in use in the usual compliment “Commend me to such a friend,” &c. which is to let him know, “I am his humble servant.”

COMMENSURABLE, among geometers, an appellation given to such quantities as are measured by one and the same common measure.

COMMENSURABLE Numbers, whether integers or fractions, are such as can be measured or divided by some other number without any remainder: such are 12 and 3, as being measured by 6 and 2.

COMMENSURABLE in Power, is said of right lines, when their squares are measured by one and the same space or superficies.

COMMENSURABLE Surds, those that being reduced to their least terms, become true figurative quantities of their kind; and are therefore as a rational quantity to a rational one.

COMMENTARY, or Comment, in matters of literature, an illustration of the difficult or obscure passages of an author.

COMMENTARY, or Commentaries, likewise denotes a kind of history, or memoirs of certain transactions, wherein the author had a considerable hand: such are the Commentaries of Cesar.

COMMERCE

Is an operation by which the wealth, or work, either of individuals or of societies, may be exchanged by a set of men called merchants, for an equivalent, proper for supplying every want, without any interruption to industry, or any check upon consumption.

CHAP. I. History of Commerce.

§ 1. General History.

It is a point as yet undecided by the learned, to what nation the invention and first use of commerce belonged; some attribute it to one people, some to another, for reasons that are too long to be digested here. But it seems most probable that the inhabitants of Arabia were those that first made long voyages. It must be allowed, that no country was so happily favored for this purpose as that which they inhabited, being a peninsula washed on three sides by three famous seas, the Arabian, Indian, and Persian. It is also certain that it was very early inhabited; and the first notice we have of any considerable trade refers it to the Ishmaelites, who were settled in the hither part of Arabia: To them Joseph was sold by his brethren, when they were going down with their camels to Egypt with spicery, balm, and myrrh. It may seem strange to infer from hence, that commerce was already practised by this nation, since mention is here made of camels, or a caravan, which certainly implies an inland trade; and it must be likewise allowed, that balm and myrrh were the commodities of their country. But whence had they the spicery? Or how came Arabia to be so famous in ancient times for spices? Or whence proceeded that mistake of many great authors of antiquity, that spices actually grew there? Most certainly, because these people dealt in them; and that they dealt in them the first of any nation that we know of, appears from this very instance. Strabo and many other good authors assure us, that in succeeding times they were very great traders; they tell us particularly what ports they had; what prodigious magazines they kept of the richest kinds of goods, what wonderful wealth they obtained; in what prodigious magnificence they lived, and into what excesses they fell in respect to their expenses for carving, building, and statues. All this shows that they were very great traders: and it also shows, that they traded to the East Indies; for from thence only they could have their spicery, their rich gums, their sweet-scented woods, and their ivory, all which it is expressly
expressly said that they had in the greatest abundance. This therefore proves that they had an extensive and flourishing commerce; and that they had it earlier than any other nation, seems evident from their dealing at that time in spices. Besides, there is much less difficulty in supposing that they first discovered the route to the Indies, than if we ascribe that discovery to any other nation: for in the first place they lay nearest, and in the next they lay most conveniently; to which we may add, thirdly, that as the situation of their country naturally inclined them to navigation, so by the help of the monsoons they might make regular voyages to and from the Indies with great facility; nor is it at all unlikely that this discovery might be at first owing to chance, and to some of their vessels being blown by a strong gale to the opposite coast, from whence they might take the courage to return, by observing the regularity of the winds at certain seafarings. All these reasons taken together seem to favour this opinion, that commerce flourished first among them; and as to its consequences in making them rich and happy, there is no dispute about them.

We find in the records of antiquity no nation celebrated more early for carrying all arts to perfection than the inhabitants of Egypt; and it is certain also, that no art was there cultivated more early, with more facility, or with greater success, than trade. It appears from the foregoing instance, that the richest commodities were carried there by land; and it is no less certain, that the most valuable manufactures were invented and brought to perfection there many ages before they were thought of in other countries: for, as the learned Dr Warburton very justly observes, at the time that Joseph came into Egypt, the people were not only possessed of all the conveniences of life, but were remarkable also for their magnificence, their politeness, and even for their luxury; which argues, that traffic had been of long standing amongst them. To say the truth, the great advantages derived from their country’s lying along the Red Sea, and the many benefits that accrued to them from the Nile, which they very emphatically called The River, or The River of Egypt, and of which they knew how to make all the uses that can be imagined, gave them an opportunity of carrying their inland trade not only to a greater height than in any country at that time, but even higher than it has been carried anywhere, China only excepted; and some people have thought it no trivial argument to prove the defect of the Chinese from the Egyptians, that they have exactly the same fort of genius, and with wonderful industry and care have drawn so many cuts and canals, that their country is in almost every part of it navigable. It was by such methods, by a wise and well-regulated government, and by promoting a spirit of industry amongst the people, that the ancient Egyptians became so numerous, so rich, so powerful; and that their country, for large cities, magnificent structures, and perpetual abundance, became the glory and wonder of the old world.

The Phœnicians, though they possessed only a narrow strip of the coast of Asia, and were surrounded by nations so powerful and so warlike that they were never able to extend themselves on that side, became famous, by erecting the first naval power that makes any figure in history, and for the raising of which they took the most prudent and effectual measures. In order to this, they not only availed themselves of all the creeks, harbours, and ports, which nature had bestowed very liberally on their narrow territory, but improved them in such a manner, that they were no less remarkable for their strength than for their convenience; and so attentive they were to whatever might contribute to the increase of their power, that they were not more admired for the vast advantages they derived from their commerce, than they were formidable by their fleets and armies. They were likewise celebrated by antiquity as the inventors of arithmetic and astronomy; and in the last mentioned science they must have been very considerable proficient at, since they had the courage to undertake long voyages at a time when no other nation (the Arabians and Egyptians excepted) durst venture farther than their own coasts. By these arts Tyre and Sidon became the most famous marts in the universe, and were reported to by all their neighbours, and even by people at a considerable distance, as the great furnaces of the world. We learn from the Scriptures their knowledge of astrology and astronomy became to the two great kings of Israel, David and Solomon; and we see, by the application of the latter for architects and artists to Hiram king of Tyre, to what a prodigious height they had carried manufactures of every kind.

It is very certain that Solomon made use of their abundance in equipping his fleets at Elath and Ezion-geber; and it is very probable that they put him upon acquiring those ports, and gave him the first hints of the amazing advantages that might be derived from the possession of them, and from the commerce he might from thence be able to carry on. These ports were most commodiously situated on the Arabian gulf; and from thence his vessels, manned chiefly by Phœnicians, failed to Ophir and Tarshish, where-ever those places were. Some writers will needs have them to be Mexico and Peru, which is certainly a wild and extravagant supposition; others believe that we are to look for Ophir on the coast of Africa, and Tarshish in Spain; but the most probable opinion is, that they were both seated in the East Indies. By this adventurous navigation he brought into his country curiosities not only unlearned, but unheard of before, and riches in such abundance, that, as the Scripture finely expresses it, “He made silver in Jerusalem as stones, and cedar-trees as fycamores that grow in the plains.” The metaphor is very bold and emphatical; but when we consider that it is recorded in this History, that the return of one voyage only to Ophir produced 450 talents of gold, which makes 51,238 pounds of our Troy weight, we cannot doubt of the immense profit that accrued from this commerce. It is also observable that the queen of Sheba, or Saba, which lies in that part of Arabia before mentioned, surprised at the reports that were spread of the magnificence of this prince, made a journey to his court on purpose to satisfy herself, whether fame had not exaggerated the fact; and from the presents she made him of 120 talents of gold, of spices in great abundance, and precious stones, we may discern the true reason of her curiosity, which proceeded from an opinion...
COMMERC.

ition that no country could be so rich as her own. And there is another circumstance, very remarkable, and which seems strongly to fortify what we have advanced in the beginning of this section; it is added, "neither were there any such spices as the queen of Sheba gave to king Solomon," which seems to intimate, that the Arabians had penetrated farther into the Indies than even the fleets of this famous prince, and brought from thence other spices (perhaps nutmegs and cloves) than had ever been seen before. It was by his wisdom, and by his steady application to the arts of peace, all of which mutually support each other, as they are all driven on by the wheel of commerce, which supplies every want, and converts every superfluity into merchandise, that this monarch raised his subjects to a condition much superior to that of any of their neighbours, and rendered the land of Israel, while he governed it, the glory and wonder of the East. He made great acquisitions without making wars; and his successor, by making wars, lost those acquisitions. It was his policy to keep all his people employed; and, by employing them, he provided equally for the extension of their happiness, and his own power: but the following kings purged other measures, and other confquences attended them. The trade of Judea sunk almost as suddenly as it rose, and in process of time they lost those ports on the Red Sea, upon which their Indian commerce depended.

The whole trade of the universe became then, as it were, the patrimony of the Phenicians and the Egyptians. The latter monopolized that of the Indies, and, together with their corn and manufactures, brought such a prodigious balance of wealth continually into the country, as enabled the ancient monarchs of Egypt to compass all those memorable works that in spite of time and barbarous conquerors remain the monuments of their wisdom and power, and are like to remain so as long as the world subsists. The Phenicians drew from Egypt a great part of those rich commodities and valuable manufactures which they exported into all the countries between their own and the Mediterranean sea; they drew likewise a vast refor to their own cities, even from countries at a great distance; and we need only look into the prophets Isaiah and Ezekiel in order to be convinced that these governments, founded on trade, were infinitely more glorious and more stable than those that were erected by force. All this we find likewise confirmed by profane histories; and by comparing these, it is evident, that the industry of the inhabitants of this small country triumphed over all obstacles, procured the greatest plenty in a barren soil, and immense riches, where, without industry, there must have been the greatest indigence. It is true, that old Tyre was destroyed by Nebuchadnezzar, but not till she had flourished for ages; and even then she fell with dignity, and after a resistance that rained the army of the Great Conqueror of Asia. Out of the ashes of this proud city the great spirit of its inhabitants produced a Phoenix, little, if at all, inferior in beauty to its parent. New Tyre was situated on an island; and though her bounds were very narrow, yet she became quickly the mistress of the sea, and held that supreme dominion till subdued by Alexander the Great, whom no power could resist. The struggle he made, however, though unsuccessful, was great, and very much to the honour of her inhabitants: it must be owned, that the Greek hero found it more difficult to master this single place, than to overcome the whole power of Persia.

The views of the Macedonian prince were beyond comparison more extensive than his conquests; and whoever considers Alexander's plan of power, and enters into it thoroughly, will think him more a politician than he was a conqueror. He framed in his own mind an idea of universal monarchy, which it was indeed impossible to accomplish; but the very notion of it does him far greater honour than all his victories. He thought of placing his capital in Arabia; and of disposing things in such a manner, as to have commanded the most remote parts of the Indies, at the same time that he maintained a connection with the most distant countries in Europe. He was for making use of force to acquire, but he very well knew, that commerce only could preserve an empire, that was to have no other limits than those which nature had assigned the world. He desired to be master of all; but at the same time he was willing to be a wise and gracious master, and to place his happiness in that of his people, or rather in making all the nations of the earth but one people. A vast, an extravagant, an impracticable scheme it was, of which he lived not long enough to draw the outlines; but the sample he left in his new city of Alexandria sufficiently shows how just and how correct his notions were, and how true a judgement he had formed of what might be effected by those methods upon which he depended.

That city, which he might be said to design with his own hand, and which was built, as it were, under his eye, became in succeeding times all that he expected, the glory of Egypt, and the centre of commerce for several ages.

While Tyre was in the height of her glory, and had no rival in the empire of the sea, she founded her noble colony of Carthage on the coast of Africa. The situation of the city was everywhere admirable; whether considered in the light of a capital, of a strong fords, or of a commodious port. It was equally distant from all the extremities of the Mediterranean sea, had a very fine country behind it, and was not in the neighbourhood of any power capable of restraining its commerce or its growth. It is almost inexpressible how soon its inhabitants became not only numerous and wealthy, but potent and formidable. By degrees they extended themselves on all sides, conquered the whole part of Spain; and erected there a new Carthage, the islands of Sicily and Sardinia, or at least the west part of them, submitted likewise to their yoke. Their conquests, however, were inconsiderable in extent, when compared with their navigation. On one side they stretched as far westward as Britain; and the Scilly islands, which are now so inconsiderable, were to them an Indies, the route to which they used the utmost industry to conceal. On the other hand, they discovered a great part of the coast of Africa, the Canary islands; and some there are who believe they first found the way to America. While they confined themselves to trade, and the arts which belonged thereto, their power was continually increasing;

fong; but when industry gave way to luxury, and a spirit of ambition banished their old maxims of frugality and labour, their acquisitions remained at a stand. The Romans began to grow jealous of their naval power, which it cost them two obstinate wars of 40 years continuance to humble. When the was at length destroyed, her very ruins were majestic; for at the beginning of the third Punic war, this city contained 700,000 inhabitants alone, and had 500 cities in Africa under her dominion. Such was the empire of Carthage, raised entirely by commerce; and which, if self with the same as in her early beginnings, there is no doubt preserved as thrift, and diligence, and good faith, are the pillars it is not only natural that voidable also.

The Ptolemies, who were the successors of Alexander in Egypt, entered deeply into that hero's scheme, and reaped the benefit of his establishment. Ptolemy Philadelphus, by encouraging trade, made his subjects immensely rich, and himself inexpressibly powerful. We are told by an ancient author, that he had 120 galleys of war of an enormous size, and upwards of 4000 other vessels, small and great. This would appear incredible, if other wonders were not related of him, which seem to explain and illustrate his power. He raised a new city on the coasts of the Red Sea; he was at an immense expense in opening harbours, constructing quays, in raising inns at proper distances on the road, and in cutting a canal from sea to sea. A prince who comprehended the importance of commerce to a degree that induced him to dare for strangers to navigate them, these refugees found themselves tolerably safe; and uniting amongst themselves for the sake of improving their condition, and augmenting their security, they became in the 8th century a well-settled government, and assumed the form of a republic.

Simple and mean as this relation may appear, yet it is a plain and true account of the rise, progress, and establishment of the famous and potent republic of Venice. Her beginnings were indeed weak and slow; but when the foundation was once well laid, her growth was quick, and the increase of her power amazing. She extended her commerce on all sides; and taking advantage of the barbarous maxims of the Mohammedan monarchs, she drew to herself the profits of the Indian trade, and might, in some sense, be said to make Egypt a province, and the Saracens her subjects. By this means her traffic swelled beyond conception; she became the common mart of all nations; her naval power arrived at a prodigious height; and, making use of every favourable conjuncture, she stretched her conquest not only over the adjacent Terra Firma of Italy, but through the islands of the Archipelago, so as to be at once mistress of the sea, of many fair and fruitful countries, and of part of the great city of Constantinople itself. But ambition, and the desire of lording it over her neighbours, brought upon her those evils which first produced a decay of trade, and then a declension of power. General histories indeed ascribe this to the league of Cambrai, when all the great powers in Europe combined against this republic; and in truth, from that period the sinking of her power is truly dated; but the Venetian writers very justly observe, that though this effect followed the league, yet there was another more latent, but at the same time a more effectual cause, which was, the falling off of their commerce; and they
they have ever since been more indebted to their wisdom than their power; to the prudent concealing of their own weaknesses, and taking advantage of the errors of their enemies, than to any other cause, for their keeping up that part which they still bear, and which had been loft long ago by any other nation but themselves.

At the fame time that Venice rose, as it were, out of the sea, another republic was erected on the coast of Italy. There could not well be a worse situation than the narrow, marshy, unprofitable, and unwholesome islands in the Adriatic, except the rocky, barren, and inhospitable shores of Liguria; and yet as commerce raised Venice the Rich on the one, fo the erect ed Genoa the Proud on the other. In spite of ambitious and warlike neighbours, in spite of a confined and unproducing country, and, which were still greater impediments, in spite of perpetual factions and succedaneous revolutions, the trade of Genoa made her rich and great. Her merchants traded to all countries, and threw by carrying the commodities of the one to the other. Her fleets became formidable; and, besides the adjacent island of Corsica, she made larger and important conquests. She fixed a colony at Caffa, and was for some time in possession of the coasts on both sides of the Black Sea. That emulation which is natural to neighbouring nations, and that jealousy which riles from the pursuit of the fame miftris, commerce, begat continual wars between these rival republics; which, after many obstinate and bloody battles, were at last terminated in favour of Venice, by that famous victory of Chiozza gained by her doge Andrew Comarini, from which time Genoa never pretended to be mistres of the sea. These quarrels were fatal to both; but what proved more immediately destructive to the Genoese, was their avarice, which induced them to abandon the fair profits of trade for the sake of that vile method of acquiring wealth by usury.

But we must now look to another part of the world. In the middle age of the German empire, that is, about the middle of the 13th century, there was formed a confederacy of many maritime cities, or at least of cities not far from the sea. This confederacy formed alliances with all merchants who were friendly to them. The Teutonic Hanef, they did not however forbear associating many other cities, as well in France as in England and in the low countries; the whole, however, without hurting the authority, without prejudice to the rights, of the sovereigns on whom they depended. This confederacy had its laws, its ordinances, and its judgments, which were observed with the fame respect as the maritime code of the Rhodians, who paffing for the ablest seamen in all antiquity, their constitutions were observed by the Greeks and Romans. The Teutonic Hanef grew in a short time to fo high a rank in power and authority by the immense riches it acquired, that princes themselves rendered it a fitnere homage from principles of esteem and admiration. Thofe of the north principally had frequent occasion for their credit, and borrowed of them considerable sums. The grand masters of the Teutonic order, who were at that time soveraigns of Livonia, declared themselves conservators of the rights and privileges of the Hanef: all succeeded, not only to, but beyond their wishes; and Germany, charmed with their progress, looked on them with the same eyes as a curious gardener does on certain rare plants, though not of his own rearing and culture. The kings of France and England granted also various privileges to the Teutonic confederacy; they exempted their felvets in case of shipwreck from all demands whatever from the ministry, or from private persons; they forbade any disturbance to their navigation at all times, and even when France was at war with the emperor, or the princes of the north. In fine, during the course of those unhappy wars which were ftyled Crofades, the Hanef was fignally consulted, and gave always poffitive fupport in money and in flips to the chriftians opprefled by infidels. It is alluring, that cities at fo great a distance from each other, fubject to different kings, sometimes in open war, but always jealous of their rights, should be able to confederate and live together in fo strict an union. But when this union had rendered them very rich and powerful, it cannot feem at all strange, that on the one hand they grew arrogant and overbearing, took upon them not only to treat with soveraigns on the foot of equality, but even to make war with them, and more than once with fucces. It will, on the other hand, appear ftrange, that fuch behaviour as this awakened various princes to a more particular view of the dangers that fuch a league might produce, and the advantage that would naturally flow to their respective states, by recovering their trade thus made over, at leaft in some part to others, entirely to themselves; and thofe, in few words, were the caufes of the gradual declination of the Hanefian confederacy; which, however, is not totally diffoled at this day; the cities of Lubeck, Hamburg, and Bremen, maintaining fufficient marks of that splendor and dignity with which this confederacy was once adorned.

We must now turn our eyes to Portugal and Spain, where in the space of about 50 years there happened a train of events which gradually led on to fhuch difcoveries; and thefe, countenanced by an heroic young prince, pushed on their endeavours with fhuch fucces, that step by step the coaft of Africa was surveyed as far as the Cape of Good Hope, to which they
they gave that name. The point they had in view was a new route to the East Indies, which Vasqueze de Gama happily discovered; and in a short space of time Portugal, from one of the least considerable, grew to be one of the richest powers in Europe, gained prodigious dominions in Asia and Africa, and raised a naval power superior to any thing that had been seen for many ages before.

But while this was doing, Christopher Columbus, a Genoese of great capacity, though of almost unknown original, who had been bred to the sea from his youth, and who had carefully studied what others made a trade, formed in his mind the amazing project of counteracting experience, and failing to the Indies by a west course. He offered this project to the Portuguese, by whom it was considered and rejected as a chimera. He propounded it afterwards to other states, but with no better fortune; and at last owed the discovery of the New World to the high spirit of a heroine, the famous Isabella queen of Castile, who almost at her own expense, and with very little countenance from her husband, who yet was styled Ferdinand and the Wise, furnished the adventurous Columbus with that poor squadron, with which at once, in spite of all the difficulties that the envy of his officers, and the obstinacy of his mutinous crew, threw in his way, he perfected his design, and laid open a new Indies, though in reality he aimed at the discovery of the old. Neither was this noble effort of his matchless understanding defeated; for after his decease, Ferdinand Magellan, a Portuguese, proposed to the emperor Charles V. the discovery of a passage to the spice islands by the south seas, which was what Columbus aimed at; and though Magellan lived not to return, yet in one voyage the discovery was perfected. It is unconceivable how many and how great benefits accrued to Europe from these discoveries; of which, however, it is certain, that the Portuguese made a very indifferent, and the Spaniards much worse use of; the former making slaves of, and the latter robbing out, the natives. This, as it was a most ungrateful return to divine Providence, it might have been easily foreseen it would prove, as experience has shewn it did prove, highly prejudicial to their own interests, by depopulating very fine countries, which have been thereby turned into deserts: and though on their first discovery infinite treasures were returned from them, which were coined in the mints of Spain; yet by an obstinate pursuit of this falfe policy, the Spanish islands in the West Indies are now brought so low as to be a barren stock keeping. The consequences that naturally followed on the discovery of a passage by the Cape of Good Hope, and of a fourth part of the globe in the western hemisphere, were, as it has been already hinted, the cause of an entire change in the fate of Europe, and produced, not only in Portugal and Spain, but in most other nations, a desire of visiting their remote parts, of establishing colonies, of setting manufactures on foot, of exporting and importing commodities, and of raising, settling, and protecting new manufactories. By this means, as the reader cannot but perceive, not only particular nations brought about signal advantages to themselves, but Europe in general received a lasting and invaluable benefit: for its potentates made themselves terrible, and even terrible, in those distant parts of the earth, where their fame had hardly reached before. It is however true, that this has not been carried on as high as it might have been; for though there was room enough for every nation to have had its share, and though it might be demonstrated that the good of the whole would have contributed sufficiently to the profit of every state, the subjects of which had engaged in this traffic; yet, instead of profecting so natural and so equitable a measure, they have taken a quite contrary course; and by decrying, attacking, and destroying each other, have very much inflicted that prodigious reverence which the Athenians, Africans, and Americans, at first had for the inhabitants of Europe.

The naval power of the Portuguese received an incurable wound by falling under the power of the Spaniards: and though human policy would have suggested, that this alone must have raised the latter to the monopoly of commerce, and the universal dominion of the sea; yet the very pursuit of a design so visibly detrimental to the interest of mankind, proved very quickly their ruin also. For the Spaniards, from the natural haghness of their temper, misled by the boundless ambition of their princes, and endeavouring to become the lords of Europe, forced other nations in their own defence to make a much quicker progress in navigation than otherwise they could have done. For the English and Dutch, who till this time seemed blind to the advantages of their situation, had their eyes opened by the injuries they received; and by degrees the passion of revenge inspired them with designs that possibly public spirit had never excited. In short, the pains taken by Spain to keep all the riches that flowed from these discoveries to herself, and the dangerous, detestable, and destructive purposes to which she applied the immense wealth that flowed in upon her from them, produced effects directly opposite to those which she proposed, and made her enemies rich, great, powerful, and happy, in proportion as her commerce was extirpated. As for the Spaniards, Spain fell from the first stature of her power, and Holland became high and mighty; nay, in spite of the danger and expences which attended a war made all that time against a superior force, these people, surrounded with enemies, loaded with taxes, exposed to personal service, and to a thousand other disadvantages, grew up to such a strength as not only made the
the Spaniards desirous of reducing them any more under their dominion, but inclined them to wills, and at last forced them to seek their friendship.

This, at least as far as either ancient or modern histories inform us, was the quickest and strongest of all the productions of commerce that the world has ever seen. For it is out of dispute, that the republic of the United Provinces owes her freedom, her power, and her wealth, to industry and trade entirely. The greatest part of the country is far from being fertile; and what is so, produces not enough to suffice the tenth part of its inhabitants for the tenth part of the year: the climate is rather tolerable than wholesome, and its havens are rather advantageous from the difficulty of entering them, than from their commodiousness in any other respect. Native commodities they have few or none; timber and maritime stores are entirely wanting; their country cannot boast so much as of a coal-mine; and yet these provinces, upon which nature has bestowed so little, in consequence of an extensive trade, are enriched with all things. Their forchooses are full of corn, even when the harvest in corn-countries fails; there is no commodity, how bulky soever, or however scarce and hard to come at, which may not be had from their magazines. The shipping of Holland is prodigious; and to see the quantities of naval stores with which their yards and ports abound, astonishes those who are unacquainted with the vigour of that career which produces this abundance. But above all the populousness of this country is the greatest miracle. That men should refer to a Canaan, and desire to live in a land flowing with milk and honey, is nothing strange; but that they should make it their choice to force nature, to raise palaces, lay out gardens, dig canals, plant woods, and ramplack all the quarters of the earth for fruits and flowers, to produce an artificial paradise in a dead plain, or upon an ingrateful heath in the midst of fogs and standing lakes, would, in so critical an age as this, pass for a fable, if the country did not lie so near us, as to put the truth of it out of question.

§ 2. British History.

We may easily conceive, that foreign commerce by the natives of England, must have been a work of time; for men think first of necessities, then of conveniences, and last of superfluities. Those who came originally from the continent might have better notions of things; but as it must be presumed that either care or indigence drove them hither, so it is easy to apprehend, that succeeding generations must for some time sink much below their ancestors, in their notions of the commodities of life; and, deriving their manners from their circumstances, became quite another sort of people. But those on the opposite continent, knowing that Britain was inhabited, and having the ufe, though in ever so imperfect a degree, of vessels, and of foreign traffic, came over hither, and bartered their goods for the raw commodities of the Britons, till by degrees perhaps they taught the latter to make some improvement in those flight leather and wicker boats, which they used for paffing their own rivers and creeping along their coasts, till at last they ventured themselves over to Gaul, and entered upon some kind of correspondence with their neighbors. All this is so deductible from the laws of nature, that we might have divined this much by the light of reason, if we had not the commentators of Caesar to guide us, and to strengthen by the authority of history the facts that might have been found out by the force of rational conjecture.

Things were precisely in this situation when the Romans invaded Britain; and there is no doubt that its inhabitants falling under the power of that empire, and under its power at a time when with respect to arms and sciences it was in a most flourishing condition, was a great advantage to them; and though from their love of civil liberty, which, when under the direction of reason, is the most natural and laudable of all passions, they made a long and vigorous, and in some sense a noble and glorious resistance; yet by degrees they caught the manners and customs of their conquerors, and grew content to be happy rather than free. With learning and politeness the Romans introduced foreign commerce; and according to the nature of their policy, as they made high roads through the island, established colonies in proper places, and fixed standing camps, which were a kind of fortresses, where they thought proper; so they were no less careful with regard to marts or emporiums for the convenience of traders, and of which they found is uncertain: but that they left many, is not more famous for her present extensive trade, than venerable for her unrecorded antiquity.

When the Romans unwillingly left Britain, and the Britons as unwillingly made way for the Saxons, a new deluge of barbarity overflowed the island: almost all the improvements of the civilized conquerors were defaced; and, upon the establishment of it were of a new people, things were all to begin again. This necessity took up a great deal of time; and before they were in any tolerable posture, the Saxons found themselves disfrocked by fresh swarms of barbarians. Yet there still remains some evidences of their having been acquainted with, inclined to, and, if their circumstances would have permitted, must certainly would have entered upon, and carried foreign commerce to a great height. We have authentic testimonies, that Alfred the Great formed projects of vast discoveries to the North, as he actually sent persons of great prudence and abilities into the East; and the curiosities which they brought home were for many ages preferred in the treasury of the church of Salisbury.

As for the Danes, they were not long masters in Britain: but as they became so by a maritime force, and as their countrymen had established themselves not only on the opposite shore of France, but in other parts of Europe; so it is reasonable to believe that they held some correspondence with them from the time; and that, if their dominion had lasted longer, this might have been better regulated, and productive of many advantages. But they had soon to do with their brethren in another way: for the Normans, men of the same race, but better establishted in another country, dispossessed them there; and partly under the color of right, partly by force, erected that monarchy, which not without various alterations and changes, subsists even to our times, and to the subversion of which, with the help of those changes and alterations, the English nation owe that happy condition under which they live; that universal improvement which adorns the face
face of the country; that domestic trade which nourishes so numerous a people, by plentifully rewarding their industry; and that extensive commerce which is at once the source of their wealth and the support of their liberty.

It cannot be expected, that, in a work like this, we should attempt to trace the progress of trade through every reign, shew how it was encouraged and protected; or disconvenienced and checked; what occasions were luckily seized, or what opportunities unfortunately lost. It may be sufficient for us, after what has been already said, to observe, that the opinion commonly entertained, of the English having little or no trade before the reign of queen Elizabeth, is very far from being well founded.

In fact, the reign of that princess was great and glorious, in whatever light we consider it; but it was most so in this, that, under Providence, it became great and glorious by the wisdom and prudence of the queen and her ministers. The English nation never was in so desperate a condition as at her accession. The crown was in debt, the treasury empty, the nation involved in a foreign war directly against her own interests, her coasts naked; in a word, without credit abroad, and without concord at home, no settled religion, the great men split into factions, and the common people disaffected and defected. Sad circumstances these! and yet from hence arose the grandeur of that reign, and the establishment of commerce. The queen found herself obliged to act with great caution, to derive assistance from every quarter, to employ it faithfully, and to promote to the utmost of her power the welfare of her subjects, whom nothing but the public-spiritedness of her government could enable to grow rich enough to support the necessary expenses of the crown. It was this gave a popular turn to her councils. She encouraged her subjects to arm against the Spaniards, that they might be accustomed to the sea, and acquire that knowledge in navigation, with which, till then, they had been unacquainted. She passed many laws for the public good, erected several companies, and saw that those companies pursued the ends for which they were erected; in short, she did every thing that could be expected, during the whole course of her reign, to excite and encourage industry at home, and to enable her people to make a proper figure abroad. In a word, she furnished them with stock and credit, put them upon improving their commodities and manufactures, brought the art of ship-building amongst them, filled their ports with able seamen, showed a just respect to English merchants, reduced Ireland to as to render it beneficial to Britain, and approved their sending colonies into America; and thus the seeds of British wealth were sown in her time, though the harvest was reaped in the days of her successors. See the articles COALERY COLONY, FISHERIES, MANUFACTURES, SHIPPING, and TRADE.

CHAP. II. PRINCIPLES OF COMMERCE.

§ 1. ORIGIN OF TRADE.

The most simple of all trade is that which is carried on by bartering the necessary articles of subsistence. If we suppute the earth free to the first possessor, this person who cultivates it will first draw from its food, and the surplus will be the object of barter; he will give this in exchange to any one who will supply his other wants. This naturally supposes both a surplus quantity of food produced by labour, and also free hands; for he who makes a trade of agriculture cannot supply himself with all other necessaries, as well as food; and he who makes a trade of supplying the farmers with such necessaries, in exchange for his surplus of food, cannot be employed in producing that food. The more the necessities of man increase, the more free hands are required to supply them; and the more free hands are required, the more surplus food must be produced by additional labour, to supply their demand.

This is the least complex kind of trade, and may be carried on to a greater or less extent, in different countries, according to the different degrees of the wants to be supplied. In a country where there is no money, nor any thing equivalent to it, the wants of mankind will be confined to few objects; to win, the removing the inconveniences of hunger, thirst, cold, heat, danger, and the like. A free man, who, by his industry, can procure all the comforts of a simple life, will enjoy his rest, and work no more: and, in general, all increase of work will cease, so soon as the demand for the purposes mentioned comes to be satisfied. There is a plain reason for this. When the free hands have procured, by their labour, wherewith to supply their wants, their ambition is satisfied: so soon as the husbandmen have produced the necessary surplus for relieving theirs, they work no more. Here then is a natural stop put to industry, consequently to bartering.

The next thing to be examined is, how bartering grows into trade, properly so called, and understood, according to the definition given of it above; how trade comes to be extended among men; and how manufactures, more ornamental than useful, come to be established; and how men come to submit to labour, in order to acquire what is not absolutely necessary for them.

This in a free society, is chiefly owing to the introduction of money, and a taste for superfluities in those who possess it.

In ancient times, money was not wanting; but the taste for superfluities, in being in proportion to it, the species was locked up. This was the case in Europe four hundred years ago. A new taste for superfluity has drawn, perhaps, more money into circulation, from our own treasuries, than from the mines of the new world. The poor opinion we entertain of the riches of our forefathers, is founded upon the modern way of emulating wealth, by the quantity of coin in circulation, from which we conclude, that the greatest part of the species now in our hands must have come from Mexico and Peru.

It is more, therefore, through the taste of superfluity, than in consequence of the quantity of coin, that trade comes to be established; and it is only in consequence of trade that we see industry carry things in our days to so high a pitch of refinement and delicacy. Let us illustrate this, by comparing together the different operations of barter, sale, and commerce.

When
COMMERCE.

When reciprocal wants are supplied by barter, there is not the smallest occasion for money: this is the most simple of all combinations.

When wants are multiplied, barter becomes more difficult; upon this money is introduced. This is the common price of all things: it is a proper equivalent in the hands of those who want, perfectly calculated to supply the occasions of those who, by industry, can relieve them. This operation of buying and selling is a little more complex than the former; but still we have no idea of trade, because we have not introduced the merchant by whose industry it is carried on.

Let this third person be brought into play, and the whole operation becomes clear. What before we called wants, is here represented by the consumer; what we called industry, by the manufacturer; what we called money, by the merchant. The merchant receives the money, by substituting credit in its place; and as the money was invented to facilitate barter, to the merchant, with his credit, is a new refinement upon the use of money. This renders it still more effectual in performing the operations of buying and selling. This operation is trade: it relieves both parties of the whole trouble of transportation, and adjuts wants to wants, or wants to money: the merchant represents by turns both the consumer, the manufacturer, and the money. To the consumer he appears as the whole body of manufacturers; to the manufacturers as the whole body of consumers; and to the one and the other class his credit supplies the use of money. This is sufficient at present for an illustration. We now return to the simple operations of money in the hands of the two contracting parties, the buyer and the seller, in order to show how men come to submit to labour in order to acquire superfluities.

So soon as money is introduced into a country, it becomes an universal object of want to all the inhabitants. The consequence is, that the free hands of the state, who before floated working, because all their wants were provided for, having this new object of ambition before their eyes, endeavour, by refinements upon their labour, to procure themselves different sorts of apparel properly adapted to summer and winter, which the ingenuity of manufacturers, and their desire of getting money, may have fogged to their invention.

Indeed these refinements seem more generally owing to the industry and invention of the manufacturers (who by their ingenuity daily contrive means of softening or relieving inconveniences, which mankind seldom perceive to be such, till the way of removing them is contrived), than to the taste of luxury in the rich, who, to indulge their safe, engage the poor to become industrious.

Let any man make an experiment of this nature upon himself, by entering into the first shop. He will no sooner quickly discover his wants as there. Everything he sees appears either necessary, or at least highly convenient; and he begins to wonder how he could have been so long without that which the ingenuity of the workman alone had invented, in order that from the novelty it might excite his desire; for perhaps when it is bought, he will never once think of it more, nor ever apply it to the use for which it at first appeared to be necessary.

Here then is a reason why mankind labour though not in want. They become desirous of possessing the very instruments of luxury, which their avarice or ambition prompted them to invent for the use of others.

What has been said represents trade in its infancy, or rather the materials with which that great fabric is built.

We have formed an idea of the wants of mankind multiplied even to luxury, and abundantly supplied by the employment of all the free hands set apart for that purpose. But if we suppose the workman himself disposing of his work, and purchasing with it food from the farmer, clothes from the clothier; and, in general seeking for the supply of every want from the hands of the person directly employed for the purpose of relieving it; this will not convey an idea of trade according to our definition.

Trade and commerce are an abbreviation of this long process: a scheme invented and set on foot by merchants, from a principle of gain, supported and extended among men, from a principle of general utility to every individual, rich or poor, to every society, great or small.

Instead of a pin-maker exchanging his pins with 50 different persons, for whose labour he has occasion, he sells all to the merchant for money or for credit; and as occasion offers, he purchases all he wants, either directly from those who supply them, or from other merchants who deal with manufacturers in the same way his merchant dealt with him.

Another advantage of trade is, that industrious people in one part of the country, may supply customers in another, though distant. They may establish themselves in the most commodious places for their respective business, and help one another reciprocally, without making the distant parts of the country suffer for want of their labour. They are likewise exposed to no avocation from their work, by seeking for customers.

Trade produces many excellent advantages; it marks out to the manufacturers when their branch is under or overstocked with hands. If it is understocked, they will find more demand than they can answer: if it is overstocked, the sale will be slow.

Intelligent men, in every profession, will easily discover when these appearances are accidental, and when they proceed from the real principles of trade.

Polls, and correspondence by letter, are a consequence of trade; by the means of which merchants are regularly informed of every augmentation or diminution of industry in every branch, in every part of the country. From this knowledge they regulate the prices they offer; and as they are many, they serve as a check upon one another, from the principles of competition.

From the current prices, the manufacturers are as well informed, as if they kept the correspondence themselves: the state of hands are
are wanting, and young people destined to industry, obey, in a manner, the call of the public, and fall naturally in to supply the demand.

Two great alliances to merchants, especially in the infancy of trade, are public markets for collecting the work of small dealers, and large undertakings in the manufacturing way by private hands. By these means the merchants come at the knowledge of the quantity of work in the market, as on the other hand the manufacturers learn, by the fate of the goods, the extent of the demand for them. These two things being justly known, the price of goods is easily fixed.

Public fates serve to correct the small inconveniences which proceed from the operations of trade. A set of manufacturers got all together into one town, and entirely taken up with their industry, are thereby as well informed of the rate of the market as if every one of them carried this his work; and upon the arrival of the merchant, who readily takes it off their hands, he has not the least advantage over them from his knowledge of the state of demand. This man both buys and sells, in what is called whole sale; and from him retailers purchase, who distribute the goods to every consumer throughout the country. These last buy from wholesale merchants in every branch, that proportion of every sort of merchandise, which is suitable to the demand of their borough, city, or province.

Thus all inconveniences are prevented, at some additional cost to the consumer, who must naturally reimburse the whole expense. The distance of the manufacturer, the obscurity of his dwelling, the capital in selling his work, are quite removed; the retailer has all in his shop, and the public buys at a current price.

§ 2. How the prices of Goods are determined by Trade.

In the price of goods, two things must be considered as really existing, and quite different from one another; to wit, the real value of the commodity, and the profit upon alienation.

I. The first thing to be known of any manufacture, when it comes to be sold, is, how much of it a person can perform in a day, a week, a month, according to the nature of the work, which may require more or less time to bring it to perfection. In making such estimates, regard is to be had only to what, upon an average, a workman of the country in general may perform, without supposing him the best or the worst in his profession, or having any peculiar advantage or disadvantage as to the place where he works.

Hence the reason why some people thrive by their industry, and others not; why some manufactures flourish in one place and not in another.

II. The second thing to be known is, the value of the workman’s subsistence, and necessary expense, both for supplying his personal wants, and providing the instruments belonging to his profession, which must be taken upon an average as above; except when the nature of the work requires the presence of the workman in the place of consumption; for although some trades and almost every manufacture, may be carried on in places at a distance, and therefore may fall under one general regulation as to prices; yet others there are, which, by their nature, require the presence of the workman in the place of consumption; and in that case the prices must be regulated by circumstances relative to every particular place.

III. The third and last thing to be known, is the value of the materials, that is, the first matter employed by the workman; and if the object of his industry be the manufacture of another, the fame processes of inquiry must be gone through with regard to the first as with regard to the second: and thus the most complex manufactures may be at last reduced to the greatest simplicity.

These three articles being known, the price of manufacture is determined. It cannot be lower than the amount of all these, that is, than the real value; whatever it is higher, is the manufacturer’s profit. This will ever be in proportion to demand, and therefore will fluctuate according to circumstances.

Hence appears the necessity of a great demand, in order to promote flourishing manufactures.

By the extensive dealings of merchants, and their constant application to the study of the balance of work and demand, all the above circumstances are known to them, and are made known to the industrious, who regulate their living and expense according to their certain profit.

Employ a workman in a country where there is little trade or industry, he proportions his price always to the urgency of your want, or your capacity to pay; but seldom to his own labour. Employ another in a country of trade, he will not impose upon you, unless perhaps you be a stranger, who supposes your being ignorant of the value; but employ the same workman in a work not usual in the country, consequently not demanded, consequently not regulated as to the value, he will proportion his price as in the first supposition.

We may therefore conclude, from what has been said that in a country where trade has been established, manufactures must flourish, from the ready sale, the regulated price of work, and the certain profit resulting from industry. Let us next inquire into the consequences of such a situation.

§ 3. How foreign Trade opens to an industrious People, and the Consequences of it to the Merchants who set it on foot.

The first consequence of the situation described in the preceding section is, that wants are easily supplied for the adequate value of the thing wanted.

The next consequence is, the opening of foreign trade, under its two denominations of passive and active. Strangers and people of distant countries, finding the difficulty of having their wants supplied at home, and the ease of having them supplied from this country, immediately have recourse to it. This is passive trade. The active is when merchants, who have executed this plan at home with success, begin to transport the labour of their countrymen into other regions, which either produce, or are capable of producing such articles of consumption, proper to be manufactured, as are most demanded at home; and consequently will meet with the readiest sale, and fetch the largest profits.

Here
COMMERCIA.

Here then is the opening of foreign trade, under its two denominations of active and passive.

What then are the consequences of this new commerce to our merchants, who have left their homes in quest of gain abroad?

The first is, that, arriving in any new country, they find themselves in the same situation, with regard to the inhabitants, as the workman in the country of no trade, with regard to those who employ him; that is, they proportion the price of their goods to the eagerness of acquiring, or the capacity of paying, in the inhabitants, but never to their real value.

The first profits then, upon this trade, must be very considerable; and the demand from such a country will be high or low, great or small, according to the spirit, not the real wants of the people: for these in all countries must first be supplied by the inhabitants themselves, before they cease to labour.

If the people of this not-trading country are abundantly furnished with commodities useful to the traders, they will easily part with them, at first, for the instruments of luxury and safety; but the great profit of the traders will infinitely increase the demand for the productions of their new correspondents; this will have the effect of producing a competition between themselves, and thereby throwing the demand on their side. This is perpetually a disadvantage in traffic: the most unpolished nations in the world quickly perceive the effects of it; and are taught to profit by the discovery, in spite of the address of those who are the most expert in commerce.

The traders will therefore be very fond of falling upon every method and contrivance to inspire this people with a taste of refinement and delicacy. Abundance of fine presents, consisting of every instrument of luxury and superfluity, the best adapted to the genius of the people, will be given to the prince and leading men among them. Workmen will even be employed at home, to study the taste of the strangers, and to capitulate their desires by every possible means. The more eager they are of presents, the more lavish will the traders be in bestowing and diversifying them. It is an animal put up to fattening; the more he eats, the sooner he is fit for slaughter. When their taste for superfluity is fully formed, when the relish for their former simplicity is subsituted with poisoning, and obliterates, they are surefly in the fatter of the traders, and the deeper they go, the less possibility there is of their getting out. The presents then will die away, having served their purpose: and if afterwards they are found to be continued, it will probably be to support the competition against other nations, who will incline to share of the profits.

If, on the contrary, this not-trading nation does not abound with commodities useful to the traders, those will make little account of trading with them, whatever their turns may be; but, if we suppose this country inhabited by laborious people, who, having taken a taste for refinement from the traders, apply themselves to agriculture, in order to produce articles of subsistence, they will sollicit the merchants to give them part of their manufactures in exchange for those; and this trade will undoubtedly have the effect of multiplying numbers in the trading nation. But if food cannot be furnished, nor any other branch of production found out to support the correspondence, the taste for refinement will soon die away, and trade will stop in this quarter.

Had it not been for the furs in those countries adjacent to Hudson's Bay, and in Canada, the Europeans never would have thought of supplying instruments of luxury to those nations; and if the inhabitants of those regions had not taken a taste for the instruments of luxury furnished to them by the Europeans, they never would have become so indefatigable nor so dexerious hunters. At the same time we are not to suppose, that ever these Americans would have gone to Europe in quest of their manufactures. It is, therefore, owing to merchants, that these nations are become in any degree fond of refinement; and this taste, in all probability, will not exceed from the proportion of the productions of their country. From these beginnings of foreign trade it is easy to trace its increase.

One step towards this, is the establishing correspondences in foreign countries; and these are more or less necessary in proportion as the country where they are established is more or less polished or acquainted with trade. They supply the want of polams, and point out to the merchants what proportion the productions of the country bear to the demand of the inhabitants for manufactures. This communicates an idea of commerce to the not-trading nation, and they incaibly begin to fix a determined value upon their own productions, which perhaps bore no determined value at all before.

Let us trace a little the progress of this refinement in the savages, in order to show how it has the effect of throwing the demand upon the traders, and of creating a competition among them, for the productions of the new country.

Experience shows, that, in a new discovered country, merchants constantly find some article or other of its productions, which turn out to a great account in commerce; and we see that the longer such a trade subsists, and the more the inhabitants take a taste for European manufactures, the more their own productions rise in their value, and the less profit is made by trading with them, even in places where the trade is carried on by companies; which is a very wise institution for one reason, that it cuts off a competition between the merchants.

This is the best means of keeping prices low in favour of the nation: however it may work a contrary effect with respect to individuals who must buy from these monopolies.

When companies are not established, and when trade is open, the merchants, by their eagerness to profit by the new trade, betray the secrets of it; they enter into competition for the purchase of the foreign produce; and this raises prices, and favours the commerce of the most ignorant savages.

We now suppose the arrival of traders, all in one interest, with instruments of luxury and refinement, at a port in a country of great simplicity of manners, abundantly...
abundantly provided by nature with great advantages for commerce, and peopled by a nation capable of adopting a taste for superfluities.

The first thing the merchants do is, to expose their goods, and point out the advantages of many things, either agreeable or useful to mankind in general, such as wines, spirits, instruments of agriculture, arms and ammunition for hunting, nets for fishing, manufactures for clothing, and the like. The advantages of these are prettily perceived, and such commodities are eagerly sought after.

The natives, on their side, produce what they most esteem, generally something superfluous or ornamental. The traders, after examining all circumstances, determine the object of their demand, giving the least quantity possible in return for this superfluity, in order to impress the inhabitants with a high notion of the value of their own commodities; but as this parsimony may do more hurt than good to their interest, they are very generous in making presents; from the principles mentioned above.

When the exchange is completed, and the traders depart, regret is commonly mutual; the one and the other are sorry that the superfluities of the country fall short. A return is promised by the traders, and advantages are given by the natives of a better provision another time.

What are the first consequences of this revolution? It is evident, that in order to supply an equivalent for this new want, more hands must be set to work than formerly. And it is evident also, that this augmentation of industry will not essentially increase numbers: Why? Because the produce of the industry is in this case, intended to be exported. But, if we can find out any additional consumption at home, even implied by this new trade, it will have the effect of augmenting numbers. An example will make this plain.

Let us suppose the superfluity of this country to be the skins of wild beasts, not proper for food; the manufacture sought for, brandy. The brandy is sold for furs. He who has furs, or he who can spare time to hunt for them, will drink brandy in proportion: but there is no reason to conclude from this simple operation, that one man more in the country must necessarily be fed, or that any augmentation of agriculture must of consequence ensue from this new traffic.

But let us throw in a circumstance which may imply an additional consumption at home, and then examine the consequences.

A poor creature who has no equivalent to offer for food, who is miserable, and ready to perish for want of subsistence, goes a hunting, and kills a wolf; he comes to a farmer with the skin, and says, You are well fed, but you have no brandy; if you will give me a loaf, I will give you this skin, which the strangers are so fond of, and they will give you brandy. But, says the farmer, I have no more bread than what is sufficient for my own family. As for that, replies the other, I will come and dig in your ground, and you and I will settle our account as to the small quantity I require of you. The bargain is made; the poor fellow gets his loaf, and lives at least; perhaps he marries, and the farmer gets a dram. But had it not been for this dram, that is, this new want, which was purchased by the industry of this poor fellow, by what argument could he have induced the farmer to part with a loaf?

Here the sentiment of charity is excluded. This alone is the principle of multiplication; but as true it is, on the other hand, that could the poor fellow have got bread by begging, he would not probably have gone a hunting.

Here then it appears, that the very dawning of trade, in the most unpolluted countries, implies a multiplication. This is enough to point out the first step, and to connect the subject of our present inquiries with what has already been discussed in relation to other circumstances.

So soon as all the furs are disposed of, and a taste for superfluity is introduced, both the traders and the natives will be equally interested in the advancement of industry in this country. Many new objects of profit for the first will be discovered, which the proper employment for the inhabitants, in reaping the natural advantages of their soil and climate, will make effectual. The traders will therefore endeavour to set on foot many branches of industry among the savages, and the allurements of brandy, arms, and clothing, will animate them in the pursuit of them.

When once this revolution is brought about; when those who formerly lived in simplicity became industrious; manners put on a new face.

That is to say, we now find two trading nations instead of one, with this difference, however, that as hitherto we have supposed the merchants all in one interest, the compound demand, that is, the competition of the buyers, has been, and must still continue on the side of the natives. This is a great prejudice to their interest; but as it is not supposed sufficient to check their industry, nor to restrain their consumption of the manufactures, let us here examine a little more particularly the consequences of the principle of demand in such a situation; for although we allow, that it can never change fully, yet it may admit of different modifications, and produce different effects, as we shall presently perceive.

The merchants we suppose all in one interest, consequently there can be no competition among them; consequently no check can be put upon their raising their prices, as long as the prices they demand are complied with. So soon as they are raised to the full extent of the abilities of the natives, or of their inclination to buy, the merchants have the choice of three things, which are all perfectly in their option; and the preference to be given to the one or the other, depends entirely upon themselves, and upon the circumstances we are going to point out.

Firstly, they may support their high demand; that is not lower their price; which will preserve a high estimation of the manufactures in the opinions of the inhabitants, and render the profits upon their trade the greatest possible. This part they may possibly take, if they perceive the natives doubling their diligence, in order to become able, in time, to purchase considerable cargoes at a high value; from which supposition is implied a strong disposition in the people to become luxurious, since nothing but want of ability prevents them from complying with the highest demand; but still another circumstance must concur, to engage the merchants not to lower their price. The great
great proportion of the goods they seek for in return, must be found in the hands of a few. This will be the case if slavery be established; for then there must be many poor and few rich: and they are commonly the rich consumers who proportion the price they offer, rather to their desires, than to the value of the thing.

The second thing which may be done is, to open the door to a great demand; that is to lower their prices. This will sink the value of the manufactures in the opinion of the inhabitants, and render profits less in proportion, although indeed, upon the voyage, the profits may be greater.

This part they will take, if they perceive the inhabitants do not incline to confume great quantities of the merchandize at a high value, either for want of abilities or inclination; and also, if the profits upon the trade depend upon a large consumption, as is the case in merchandize of a low value, and lifted chiefly to the occasions of the lower sort. Such motives of expediency will be sufficient to make them neglect a high demand, and prefer a great one: and the more, when there is a likelihood that the consumption of low-priced goods in the beginning may beget a taste for others of a higher value, and thus extend in general the taste of superfluity.

A third part to be taken, is the least polite, and perhaps the most familiar. It is to profit by the competition between the buyers, and encourage the rising of demand as long as possible; when this comes to a flop, to make a kind of auction, by first bringing down the prices to the level of the highest bidders, and so to defend by degrees, in proportion as demand sinks. Thus we may say with propriety, that demand commonly becomes great, in proportion as prices sink. By this operation, the traders will profit as much as possible, and sell off as much of their goods as the profits will permit.

But this plan, in a new discovered country, is not politic, as it both discovers covetousness and a want of faith in the merchants, and also throws open the secrets of their trade to those who ought to be kept ignorant of them.

Let us next suppose, that the large profits of the merchants shall be discovered by others, who arrive at the same period in a separate interest, and who enter into no combination which might prevent the natural effects of competition.

Let the states of demand among the natives be supposed the same as formerly, both as to height and greatness, in consequence of the operation of the different principles, which might have induced the merchants to follow one or other of the plans we have been describing; we must, however, still suppose, that they have been careful to preserve considerable profits upon every branch.

If we suppose the inhabitants to have increased in numbers, wealth, and taste for superfluity, since the last voyage, demand will be found rather on the rising hand. Upon the arrival of the merchants in competition with the former, both will offer to sale: but if both stand to the same prices, it is very natural to suppose, that the former dealers will obtain a preference; as, ceteris paribus, it is always an advantage to know and to be known. The last comers, therefore, have no other way left to counterbalance this advantage, but to lower their prices.

This is a new phenomenon: here the fall of prices is not voluntary as formerly; nor confined to from expectancy; not owing to a failure of demand, but to the influence of a new principle of commerce, to wit, a double competition, which we shall now examine.

§ 5. Of double Competition.

When competition is much stronger on one side of the contract than on the other, it is called simple. This is the species of competition which is implied in the term high demand, or when it is said that demand raises prices.

Double competition is, when, in a certain degree, it takes place on both sides of the contract at once, or vibrates alternately from one to the other. This is what restrains prices to the adequate value of merchandize etc.

The great difficulty is to distinguishing clearly between the principles of demand and those of competition; here then follows the principal differences between the two, relating to the effects they produce severally in the mercantile contract of buying and selling, which we here express shortly by the word contract.

Simple demand is what brings the quantity of a commodity to market. Many demand, who do not buy; many offer, who do not sell. This demand is called great or small; it is said to increase, to augment, to swell; and is expressed by these and other synonymous terms, which mark an augmentation or diminution of quantity. In this species, two people never demand the same thing, but a part of the same thing, or things quite alike.

Compound demand is the principle which raises prices, and can never make them sink; because in this case more than one demands the very same thing. It is solely applicable to the buyers, in relation to the price they offer. This demand is called high or low, and is said to rise, to fall, to mount, to sink, and is expressed by these and other synonymous terms.

Simple competition, when between buyers, is the same as compound or high demand, but differs from it in so far, as this may equally take place among sellers, which compound demand cannot: and then it works a contrary effect: it makes prices sink, and is synonymous with low demand: it is this competition which over-turns the balance of work and demand.

Double competition is what is understood to take place in almost every operation of trade; it is this which prevents their excessive rise of prices; it is this which prevents their excessive fall. While double competition prevails, the balance is perfect, trade and industry flourish.

The capital distinction, therefore, between the terms demand and competition is, that demand is constantly relative to the buyers; and when money is not the price, as in barter, then it is relative to that side upon which the greatest competition is found.

We therefore say, with regard to prices, demand is high or low. With regard to the quantity of merchandize, demand is great or small. With regard to competition, it is always called great or small, strong or weak.

Competition is, with equal propriety, applicable to both
both parties in the contract. A competition among buyers is a proper expression; a competition among sellers, who have the merchandize, is fully as easily understood, though it be not quite so striking, for reasons which an example will make plain.

You come to a fair, where you find a great variety of every kind of merchandize, in the possession of different merchants. Here, by offering their goods to sale, constitute a tacit competition; every one of them wishes to sell in preference to another, and at the same time with the best advantage to himself.

The buyer begins, by cheapening at every step. The first price asked marks the covetousnefs of the seller; the first price offered, the avarice of the buyer. From this operation competition begins to work its effects on both sides, and so becomes double. The principles which influence this operation are now to be deduced.

It is impossible to suppose the fame degree of eagerness, either to buy or sell, among several merchants; because the degree of eagerness is exactly in proportion to their views of profit; and as these must necessarily be influenced and regulated by different circumstances, the buyer who has the best prospect of selling again with profit, obliges him, whose prospect is not so good, to内容 himself with less; and that seller, who has bought to the best advantage, obliges him, who has paid dearer for the merchandize, to moderate his desire of gain.

It is from these principles, that competition among buyers and sellers must take place. This is what confines the fluctuation of prices within limits which are compatible with the reasonable profits of both buyers and sellers; for we must constantly suppose the whole operation of buying and selling to be performed by merchants; the buyer cannot be supposed to give so high a price as that which he expects to receive when he distributes to the consumers, nor can the seller be supposed to accept of a lower than that which he paid to the manufacturer. This competition is properly called double, because of the difficulty to determine upon which price it stands; the. same merchant may have it in his favour upon certain articles, and against him upon others; it is constantly in vibration, and the arrival of every post may lefs or more pull down the heavy scale.

In every transaction between merchants, the profit resulting from the sale must be exactly distinguished from the value of the merchandize. The first may vary, the last never can. It is this profit alone which can be influenced by competition; and it is for that reason we find such uniformity everywhere in the prices of goods of the same quality.

The competition between sellers does not appear so striking as that between buyers; because he who offers to sale, appears only passive in the first operation; whereas the buyers present themselves one after another; they make a demand when the merchandize is refused to one at a certain price; a second either offers more, or does not offer all; but so soon as another seller finds his account in accepting the price the first had refused, then the first enters into competition, providing his profits will admit his lowering the first price; and thus competition takes place among the sellers, until the profits upon their trade prevent prices from falling lower.

In all markets this competition is varying, though infensibly, on many occasions; but in others the vibrations are very perceptible. Sometimes it is found strongest on the side of the buyers; and in proportion as this grows, the competition between the sellers diminishes. When the competition between the former has raised prices to a certain standard, it comes to a stop; then the competition changes sides, and takes place among the sellers, eager to profit of the highest price. This makes prices fall; and according as they fall, the competition among the buyers diminishes. They still wait for the lowest period. At last it comes; and then perhaps some new circumstance, by giving the balance a kick, disappoints their hopes. If therefore it ever happens, that there is but one interest upon one side of the contract, as in the example in the former section, where we supposed the sellers united, you perceive, that the rise of the price, occasioned by the competition of the buyers, and even its coming to a stop, could not possibly have the effect of producing any competition on the other side; and therefore, if prices come afterwards to sink, the fall must have proceeded from the prudential considerations of adapting the price to the faculties of those who, from the height of it, had withdrawn their demand.

From these principles of competition, the foreselling of markets is made a crime, because it diminishes the competition which ought to take place between different people, who have the same merchandize to offer to sale. The foreseller buys all up, with an intention to sell with more profit, as he has by that means taken other competitors out of the way, and appears with a single interest on one side of the contract, in the face of many competitors on the other.

This person is punished by the state, because he has prevented the price of the merchandize from becoming justly proportioned to the real value; he has robbed the public, and enriched himself; and in the punishment he makes restitution. Here occur two questions to be resolved, for the sake of illustration.

Can competition among buyers possibly take place, when the provision made is more than sufficient to supply the quantity demanded? On the other hand, can competition take place among the sellers, when the quantity demanded exceeds the total provision made for it?

We think it may in both cases; because in the one and the other, there is a competition implied on one side of the contract, and the very nature of this competition implies a possibility of its coming on the other. Provided separate interests be found upon both sides.

But to be more particular:

1. Experience shows, that however justly the proportion between the demand and the supply may be determined in fact, it is still next to impossible to discover it exactly, and therefore the buyers can only regulate the prices they offer, by what they may reasonably expect to sell for again. The sellers, on the other hand, can only regulate the prices they expect, by what the merchandize has cost them when brought to market. We have already shown, how, under such circumstances, the several interests of individuals affect each other, and make the balance vibrate.

2.
2. The proportion between the supply and the demand is seldom other than relative among merchants, who buy and sell, and among manufacturers, who make their provisions; but from a view to profit. What we mean by relative is, that their demand is great or small according to prices; there may be a great demand for grain at 35s. per quarter, and no demand for it at all at 40s.; that is, among merchants.

It is essential to attend to the smallest circumstances in matters of this kind. The circumstance we mean, is the difference we find in the effect of competition, when it takes place purely among merchants on both sides of the contract, and when it happens, that either the consumers mingle themselves with the merchant-buyers, or the manufacturers, that is, the furnishers, mingle themselves with the merchant-sellers. This combination we shall illustrate by the solution of another question, and then conclude with a few reflections upon the whole.

Can there be no case formed, where the competition upon one side may be without a possibility of its taking place on the other, although there should be separate interests upon both?

The case is hardly fuppofible among merchants, who buy and sell with a view to profit; but it is absolutely fuppofible, and that is all, when the direct consumers are the buyers; when the circumstances of one of the parties is perfectly known; and when the competition is so strong upon one side, as to prevent a possibility of it being carried on, before the whole provision is sold off, or the demand finished. Let us have recourse to examples.

Grain arriving in a small quantity, at a port where the inhabitants are starving, produces so great a competition among the consumers, who are the buyers, that their necessity becomes evident; all the grain is generally bought up before prices can rise so high as to come to a flop; because nothing but the want of money, that is, an impossibility of complying with the prices demanded by the merchants, can restrain them: but if you fuppofe, even here, that prices come naturally to a flop; or that, after some time, they fall below the prifons due the prudent considerations; then there is a possibility of a competition taking place among the sellers, from the principles above deduced. If, on the contrary, the flop is not natural, but occasioned by the interposition of the magistrate, from humanity, or the like, there will be no competition, because then the principles of commerce are suspended; the sellers are restrained on one side, and they restrain the buyers on the other. Or rather indeed, it is the magistrate, or compassion, who in a manner fixes the price, and performs the office of both buyer and seller.

A better example still may be found, in a competition among sellers, where it may be so strong as to render a commodity in a manner of no value at all, as in the case of an uncommon and unexpected dreadful dearth of fish, in a place of small consumption, when no preparations have been made for falling them. There can be then no competition among the buyers; because the market cannot last, and they find themselves entirely masters, to give what price they please, being sure the sellers must accept of it, or lose their merchandise. In the first example, humanity commonly stops the activity of the principle of competition; in the other, it is stopped by a certain degree of fair dealing, which forbids the accepting of a merchandise for nothing.

In proportion therefore as the rising of prices can stop demand, or the sinking of prices can increase it, in the same proportion will competition prevent either the rise or the fall from being carried beyond a certain length: and if such a case can be put, where the rising of prices cannot stop demand, nor the lowering of prices augment it, in such cases double competition has no effect; because these circumstances unite the most separate interests of buyers and sellers in the mercantile contract; and when upon one side there is no separate interest, there can then be no competition.

From what has been said, we may form a judgment of the various degrees of competition. A book not worth a shilling, a fish of a few pounds weight, are often sold for considerable sums. The buyers here are not merchants. When, an ambassador leaves a court in a hurry, things are sold for less than half of their value: he is no merchant, and his situation is known. When, at a public market, there are found consumers, who make their provision; or manufacturers, who dispose of their goods for present subsistence; the merchants, who are respectively upon the opposite side of the contract to these, profit of their competition; and those who are respectively upon the same side with them, stand by with patience until they have finished their businesses. Then matters come to be carried on between merchant and merchant, and then profits may rise and fall, in the proportion of quantity to demand; that is to say, if the provision is less than the demand, the competition among the demanders, or the rise of the price, will be in the compound proportion of the falling short of the commodity, and of the prospect of selling again with profit. It is this combination which regulates the competition, and keeps it within bounds. It can affect but the profits upon the transact; the intrinsic value of the commodity stands immovable: nothing is ever sold below the real value; nothing is ever bought for more than it may probably bring. We mean in general, who buy and sell. If such as consumers and needy manufacturers mingle in the operation, all proportion is lost. The competition between them is too strong for the merchants; the balance vibrates by jerks. In such markets merchants seldom appear; the principal objects there, are the fruits and productions of the earth, and articles of the first necessity for life, not manufactures strictly so called. A poor fellow often sells to purchase bread to eat; not to pay what he did eat while he was employed in the work he disposed of. The consumer often measures the value of what he is about to purchase, by the weight of his purse, and his desire to consume.

§ 6. Of what is called Expenditure, Profits, and Loss.

The term expenditure, when simply expressed, without any particular relation, is always understood to be relative to money. This kind is distinguished under the three heads of private, public, and national.

1. Private expenditure is what a private person, or private society, lays out, either to provide articles of consumption, or something more permanent, which may be conducive to their cafe, convenience, or advantage.

Thus
Thus we say, a large domestic expense, relative to one who spends a great income. We say, a merchant has been at great expense for magazines, for living, for clerks, &c. but never that he has been at any in buying goods. In the same way a manufacturer may expend for building, machines, horses, and carriages, but never for the matter he manufactures. When a thing is bought in order to be sold again, the sum employed is called money advanced; when it is bought not to be sold, it may be said to be expended.

2. Public expense is the employment of that money which has been contributed by individuals for the current service of the state. The contribution, or gathering together, represents the effects of many articles of private expense; the laying it out when collected, is public expense.

3. National expense is what is expended out of the country; this is what diminishes national wealth. The principal distinction to be here attended to is between public expense, or the laying out of public money, and national expense, which is the alienating the nation's wealth in favour of strangers. Thus the greatest public expense imaginable may be no national expense; because the money may remain at home. On the other hand, the smallest public or even private expense, may be a national expense; because the money may go abroad.

Profit and loss is divided into positive, relative, and compound. Positive Profit implies no loss to any body; it results from an augmentation of labour, industry, or ingenuity, and has the effect of swelling or augmenting the public good.

Positive loss implies no profit to any body; it is what results from the effusion of the former, or of the effects resulting from it, and may be laid to diminish the public good.

Relative profit is what implies a loss to somebody; it marks a vibration of the balance of wealth between parties, but implies no addition to the general flock.

Relative loss is what, on the contrary, implies a profit to somebody; it also marks a vibration of the balance, but takes nothing from the general flock.

The compound is easily understood; it is that species of profit and loss which is partly relative and partly positive.

§ 7. The general consequences resulting to a trading Nation, upon the opening of an active foreign commerce.

A nation which remains passive in her commerce is at the mercy of those who are active, and must be greatly favoured indeed by natural advantages, or by a constant flux of gold and silver from her mines, to be able to support a correspondence not entirely hurtful to the augmentation of her wealth.

When we look upon the wide field which here opens to our view, we are perplexed with too great a variety of objects. In one part we see a decent and comely beginning of industry; wealth flowing gently in to recompense ingenuity; numbers both augmenting, and every one becoming daily more useful to another; agriculture proportionally extending itself; no violent revolutions; no exorbitant profits; no inconstancy among the rich; no excessive misery among the poor; multitudes employed in producing; a great economy upon consumption; and all the instruments of luxury, daily produced by the hands of the diligent going out of the country for the service of strangers; not remaining at home for the gratification of sensuality. At last the augmentations come infensibly to a stop. Then these rivers of wealth, which were in brisk circulation through the world, and which returned to this trading nation as blood returns to the heart, only to be thrown out again by new pulsations, begin to be obstructed in their course; and flowing abroad more slowly than before, come to form stagnations at home. Thefe, impatient of restraint, soon burst out into domestic circulation. Upon this cities swell in magnificence of buildings; the face of the country is adorned with palaces, and becomes covered with groves; luxury thines triumphant in every part; inequality becomes more striking to the eye; and want and misery appear more deformed, from the contrast: even fortune grows more whimsical in her inconstancy; the beggar of the other day now rides in his coach; and he who was born in a bed of state, is seen to die in a gaol or in an almshouse. Such are the effects of great domestic circulation.

The statesman looks about with amazement; he who was wont to consider himself as the first man in the society in every respect, perceives himself, perhaps, eclipsed by the lustre of private wealth, which avoids his grasp when he attempts to seize it. This makes his government more complex and more difficult to be carried on; he must now avail himself of art and address, as well as of power and force. By the help of caressing and intrigues, he gets a little into debt; this lays a foundation for public credit, which, growing by degrees, and in its progress swallowing many new forms, becomes, from the most tender beginnings, a most formidable monster, striking terror into those who cherished it in its infancy. Upon this, as upon a triumphant war-horse, the statesman gets astride; he then appears formidable anew; his head turns giddy; he is chased with the dust he has raised; and at the moment he is ready to fall, to his utter confuion and forpart, he finds a strong monied interest, of his own creating, which, instead of swallowing him up as he apprehended, flies to his support. Through this he gets the better of all opposition, he establishes taxes, multiplies them, mortgages his fund of subsistence; either becomes a bankrupt, and rises again from his ashes; or, if he be left audacious, he flails trembling and tottering for a while on the brink of the political precipice. From one or the other of these perilous situations, he begins to discover an endless path, which, after a multitude of windings, still returns into itself, and continues an equal course through this vast labyrinth.

It is now full time to leave off rhapsody, and return to reasoning and cool enquiry, concerning the more immediate and more general effects and revolutions produced by the opening of a foreign trade in a nation of industry.

The first and most sensible alteration will be an increase of demand for manufacturers, because by supplying the wants of strangers, the number of con- sumers will now be considerably augmented. What again will follow upon this, must depend upon circumstances.

If
COMMENCE.

If this revolution in the state of demand should prove too violent, the consequence of it will be to raise demand, if it should prove gradual, it will increase in degree. This distinction is well understood, and the consequence appears just: for, if the supply do not increase in proportion to the demand, a competition will ensue among the demanders; which is the common effect of such sudden revolutions. If, on the other hand, a gentle increase of demand should be accompanied with a proportional supply, the whole industrious society will grow in vigour, and in wholesome fashion, without being sensible of any great advantage or inconvenience; the change of their circumstances will even be imperceptible.

The immediate effects of the violent revolution will, in this example, be flattering to some and disagreeable to others. Wealth will be found daily to augment, from the rising of prices, in many branches of industry. This will encourage the industrious classes, and the idle consumers at home will complain. We have already dwelt abundantly long upon the difficulty in finding servants, who, instead of turning themselves to manufactures. This we have considered in the light of purging the lands of superfluous mouths; but every consequence in this great chain of politics draws other consequences after it, and as they follow one another, things put on different faces, which affect classes differently. The purging of the land is but one of the first; here follows another.

Farmers, as has been observed, will have a greater difficulty in finding servants, who, instead of labouring the ground, will decline to turn themselves to manufactures. This we have considered in the light of purging the lands of superfluous mouths; but every consequence in this great chain of politics draws other consequences after it, and as they follow one another, things put on different faces, which affect classes differently. The purging of the land is but one of the first; here follows another.

The defertion of the lands employed in a trifling agriculture will at first, no doubt embarrass the farmers; but in a little time every thing becomes balanced in a trading nation, because here every industrious man must advance in prosperity, in spite of all general combinations of circumstances.

In the case before us, the relative profits upon farming must soon become greater than formerly, because of this additional expense which must affect the whole class of farmers; consequently, this additional expense, instead of turning out to be a loss to either landlord or farmer, will, after some little time, turn out to the advantage of both; because the produce of the ground, being indispensably necessary to every body, must in every article increase in its value. Thus in a short time accounts will be nearly balanced on all hands; that is to say, the same proportion of wealth will, ceteris paribus, continue the same among the industrious. We lay among the industrious; for those who are either idle, or even negligent, will be great losers.

A proprietor of land, inattentive to the causes of his farmer's additional expense, may very imprudently suffer his rents to fall, instead of affilling him on a proper occasion, in order to make them afterwards rise the higher.

Those who live upon a determined income in money, and who are nowise employed in traffic, nor in any scheme of industry, will, by the augmentation of prices, be found in worse circumstances than before.

In a trading nation every man must turn his talents to account, or he will undoubtedly be left behind in this universal emulation, in which the most industrious, the most ingenious, and the most frugal, will constantly carry off the prize.

This consideration ought to be a spur to every body. The richest men in a trading nation have no security against poverty; we mean proportional poverty; for though they diminish nothing of their income, yet, by not increasing it in proportion to others, they lose their rank in wealth, and from the first class in which they float they slide insensibly down to a lower.

There is one consequence of an additional beneficial trade, which raises demand and increases wealth; but if we suppose no proportional augmentation of supply, it will prove at best but an airy dream which lasts for a moment; and when the guided scene is passed away, numberless are the inconveniences which are seen to follow.

We shall now point out the natural consequences of this augmentation of wealth drawn from foreign nations, when the state remains inattentive to increase the supply both of food and manufactures, in proportion to the augmentation of mouths, and of the demand for the produce of industry.

In such a situation profits will daily swell, and every scheme for reducing them within the bounds of moderation, will be looked upon as a hurtful and unpopular measure: be it so; but let us examine the consequences.

We have said, that the rise of demand for manufactures naturally increases the value of work: now we must add, that under such circumstances, the augmentation of riches in a country, either not capable of improvement as to the foil, or where precautions have not been taken for facilitating a multiplication of inhabitants, by the importation of subsistence, will be productive of the most calamitous consequences.

On one side, this wealth will effecitively diminish the mass of the food before produced; and on the other, will increase the number of useless consumers. The first of these circumstances will raise the demand for food; and the second will diminish the number of useful free hands, and consequently raise the price of manufactures; here are shortly the outlines of this progress.

The more rich and luxurious a people are, the more delicate they become in their manner of living; if they fed on bread formerly, they will now feed on meat; if they fed on meat, they will now feed on fowl. The same ground which feeds a hundred with bread, and a proportional quantity of animal food, will not maintain an equal number of delicate livers. Food must then become more scarce; demand for it rises; the rich are always the strongest in the market; they consume the food, and the poor are forced to starve. Here the wide door to modern distresses opens; to wit, a hurtful competition for subsistence. Further, when a people become rich, they think less
of economy; a number of useless servants are hired, to become an additional dead weight on consumption; and when their starving countrymen cannot supply the extravagance of the rich so cheaply as other nations, they either import instruments of foreign luxury, or seek to enjoy them out of their own country, and thereby make restitution of their gains.

As it not therefore evident, that if, before things come to this pass, additional subsistence be not provided by one method or other, the number of inhabitants must diminish; although riches may daily increase by a balance of additional matter, supposing to be brought into the country in consequence of the hitherto beneficial foreign trade? This is not all. We say farther, that the beneficial trade will last for a time only. For the infallible consequence of the rife of prices at home will be, that those nations which at first conformed your manufacturers, perceiving the gradual increase of their price, will begin to work for themselves; or finding out your rivals who can supply them cheaper, will open their doors to them. These again, perceiving the great advantages gained by your traders, will begin to supply the market; and since every thing must be cheaper in countries where we do not suppute the concurrence of all the circumstances mentioned above, these nations will supplant you, and be enriched in their turn.

Here comes a new revolution. Trade is come to a stop: what then becomes of all the hands which were formerly employed in supplying the foreign demands?

Were revolutions so sudden as we are obliged to represent them, all would go to wreck; in proportion as they happen by quicker or slower degrees, the inconveniences are greater or smaller.

Prices, we have said, are made to rise by competition. If the competition of the strangers was what raised them, the distress upon the manufacturers will be in proportion to the suddenness of their disagreeing the market. If the competition was divided between the strangers and the home-consumers, the inconveniences which ensue will be less; because the defection of the strangers will be in some measure made up by an increase of home consumption which will follow upon the fall of prices. And if, in the third case, the natives have been so imprudent, as not only to support a competition with the strangers, and thereby disjoint them from coming any more to market, but even to continue the competition between themselves, the whole loss sustained by the revolution will be national. Wealth will cease to augment; but the inconveniences, in place of being felt by the manufacturers, will only affect the state; these will continue in influence, extolling the generosiry of their countrymen, and defiling the poverty of the strangers who had enriched them.

Domestic luxury will here prove an expedient for preserving from ruin the industrious part of a people, who in subsisting themselves had enriched their country. No change will follow in their condition; they will go on with a painful affiduity to labour: and if the consequences of it become now hurtful to one part of the state, they must at least be allowed to be essentially necessary for the support of the other.

But that luxury is no necessary concomitant of foreign trade, in a nation where the true principles of it are understood, will appear very plain, from a contrast we are now going to point out, in the example of a modern state, renowned for its commerce and frugality. The country is Holland.

A set of industrious and frugal people were assembled in a country by nature subject to many inconveniences, the removing of which necessarily employed abundance of hands. Their situation upon the continent, the power of their former masters, and the ambition of their neighbours, obliged them to keep great bodies of troops. These articles added to the numbers of the community, without either enriching the state by their labour exported, or producing food for themselves or countrymen.

The scheme of a commonwealth was calculated to draw together the industrious; but it has been still more useful in subsisting them; the republican form of government being there greatly subdivided, vests authority sufficient in every part of it, to make suitable provision for their subsistence; and the tie which unites them, regards only matters of public concern. Had the whole been governed by one sovereign, or by one council, this important matter never could have been effected.

It would be impossible for the most able minister that ever lived, to provide nourishment for a country so extended as France, or even as England, supposing these as fully peopled as Holland is; even although it should be admitted that a sufficient quantity of food might be found in other countries for their subsistence. The enterprise would be too great, abuses would multiply; the consequence would be, that the inhabitants would die for want. But in Holland the case is different; every little town takes care of its own inhabitants; and this care being the object of application and profit to so many persons, is accomplished with success.

When once it is laid down as a maxim in a country, that food must of necessity be got from abroad in order to feed the inhabitants at home, the commerce becomes considerable, and at the same time certain, regular, and permanent. This was the case in Holland; as the inhabitants were industrious, the necessary consequence has been, a very extraordinary multiplication; and at the same time such an abundance of grain, that, instead of being in want themselves, they often supply their neighbours. There are many examples of England's being supplied with grain from thence; and, which is still more extraordinary, from the re-exportation of the very produce of its own fruitful soil.

It is therefore evident, that the only way to support industry, is to provide a supply of subsistence, conjunctly proportional to the demand that may be made for it. This is a precaution indispensible necessary for preventing hurtful competition. This is the particular care of the Dutch; so long as it can be effectual, their state can fear no decline; but whenever they come to be disturbed in the markets, upon which they depend for subsistence, they will sink into ruin. It is by mere dint of frugality, cheap and parjimonious living, that the navigation of this industrious people is supported. Confiant employment, and an accumulation of almost imperceptible gains, fill their
COMMERCE.

their coffers with wealth, in spite of the large outgoings to which their own proper nourishment yearly forces them. The large profits upon industry in other countries which are no proof of generosity, but a fatal effect of a feamy subsistence, is far from dazzling their eyes. They seldom are found in the list of competitors at any foreign port; if they have their cargo to dispose of, they wait with pleasure in their own vessels, consuming their own provisions, and at last accept of what others have left. It may be said, that many other circumstances concur in favour of the Dutch, besides the article of subsistence. Without disputing this matter, it may be observed, that if a computation be made of the hands employed in providing subsistence, and of those who are severally taken up in supplying every other want, their numbers will be found nearly to balance one another in the most luxurious countries. From this we may conclude, that the article of food, among the lower classes, must bear a very high proportion to all the other articles of their consumption; and therefore a diminution upon the price of subsistence, must be of infinite consequence to manufacturers who are obliged to buy it. From this consideration, let us judge of the consequence of such augmentations upon the price of grain as are familiar to us; 30 or 40 per cent. seems nothing. Now this augmentation operates upon two-thirds, at least, of the whole expence of a labouring man; let any one who lives in tolerable affluence make the application of this to himself, and examine how he would manage his affairs, if, by accidents of rain or wind, his expences were to rise 30 per cent. without a possibility of restraining them; for this is unfortunately the case with all the lower classes. From whence it may be concluded, that the keeping food cheap, and still more the preferring it at all times at an equal standard, is the fountain of the wealth of Holland; and that any hurtful competition in this article must beget a disorder which will affect the whole of the manufacturers of a state.

COMMERCY, a handsome town of France in the duchy of Bar, with the title of a principality, and a magnificent castle. It is seated on the river Menfe, in E. Long. 5. 24. N. Lat. 48. 20.

COMMersonia, in botany: A genus of the pentagony order, belonging to the pentandria class of plants. The calyx is a monophyllous, five- parted, corolliferous perianthium, with sharp ovated segments; the corolla has five linear petals; the flaminis are five very short filaments at the bafes of the petals; the pericarpium a globular, hard, quinqueocular nut, with two ovated seeds in each division.

COMMINATION, an office in the liturgy of the church of England, appointed to be read on Ash-Wednesday, or the first day of Lent. It is substi tuted in the room of that godly discipline in the primitive church, by which (as the introduction to the office expresses it), "such persons, as being convicted of notorious sins, were put to open penance and punished in this world, that their souls might be saved in the day of the Lord; and that others, admonished by their example, might be the more afraid to offend." This discipline, in after ages, degenerated, in the church of Rome, into a formal confession of sins upon Ash-Wednesday, and the empty ceremony of sprinkling ashes upon the heads of the people. Our reformers wisely rejected this ceremony, as mere shadow and shew; and substituted this office in its room, which is, A denunciation of God's anger and judgment against sinners; that the people, being apprized of God's wrath and indignation against sin, may not, through want of discipline in the church, be encouraged to follow and pursue them, but rather be moved to supply that discipline to themselves, and so to avoid being judged and condemned at the tribunal of God.

COMMINATORY, an appellation given to whatever threatens punishment, or some penalty. Thus, in France, when an exile is enjoined not to return under pain of death, it is deemed a comminatory penalty; since, if he do return, it is not strictly executed; but a second injunction is laid on him, which is more than comminatory, and, from the day of the date thereof, imports death without remedy.

COMMISSION, a province of France, 45 miles in length; and 15 in breadth; bounded on the north by Galicy, on the south by Catalonia, on the east by Conflaroles, and on the west by Bigorra. Its principal trade consists in cattle, mules, and corn. St Bertrand is the capital town.

COMMINATION, denotes the breaking, or rather grinding, a body to very small particles.

COMMIRE (John), a celebrated Latin poet, born at Ambuife in 1625, entered into the society of the Jesuits, and taught polite literature and divinity. He died at Paris in 1702. We have a volume of his Latin poems, and a collection of his posthumous works. His odes and fables are more particularly admired.

COMMISsARY, in the ecclesiastical law, an officer of the bishop, who exercises spiritual jurisdiction in places of a diocese so far from the Episcopal seat, that the chancellor cannot call the people to the bishop's principal consistory court, without giving them too much inconvenience.

COMMISsary-Court, in Scotland, a court originally constituted by the bishops for executing in their name an untried jurisdiction; and was anciently called the bishop's court, curia Christianitatis, or consistorial court. This court was modelled by queen Mary at the Reformation, and it continues till this day.

COMMISsARY, in a military sense, is of different sorts.

COMMISsary-General of the Munsters, an officer appointed to muster the army, as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact state of the strength of the army.

COMMISsary of Horfes, an officer in the artillery, appointed to have the inspection of the artillery-horses, to receive them mustered, and to send such orders as he receives
receives from the commanding officer of the artillery, by some of the conductors of horses, of which he has a certain number for his assistants.

**Commissary of Provisions**, an officer who has the charge of furnishing the army with provisions.

**Commissary of Stores**, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

**Commission**, in common law, the warrant or letters patent, which all persons exercising jurisdiction have to empower them to hear or determine any case or suit, as the commission of the judge, &c.

**Commission of Bankruptcy,** is the commission that issues from the chancellor, on a person's becoming a bankrupt within any of the statutes, directed to certain commissioners appointed to examine into it, and to secure the bankrupt's lands and effects for the satisfaction of his creditors. See the article Bankruptcy.

The proceedings on a commission of bankruptcy may be divided, 1. Into those which affect the bankrupt himself. 2. Into those which affect his property.

**Blackstone's Comment.**

1. As to those of the former kind, there must in the first place be a petition to the lord chancellor by one creditor to the amount of L. 100, or by two to the amount of L. 150, or by three or more to the amount of L. 200; upon which he grants a commission to such different persons as to him shall seem good, who are then styled commissioners of bankrupt. The petitioners, to prevent malicious applications, must be bound in a security of L. 200, to make the party amend, in case they do not prove him a bankrupt. And if, on the other hand, they receive any money or effects from the bankrupt, as a recom pense for doing out the commission, so as to receive more than their rateable dividends of the bankrupt's estate, they forfeit not only what they shall have so received, but their whole debt. When the commission is awarded and issued, the commissioners are to meet at their own expense, and take an oath for the due execution of their commission, and to receive a sum not exceeding 30s. per diem each, for every sitting. And no commission of bankruptcy shall abate or be void on any demise of the crown.

When the commissioners have received their commission, they are first to receive proof of the person's being a trader, and having committed some act of bankruptcy: and then to declare him bankrupt, if proved so; and to give notice thereof in the gazette, and at the same time to appoint three meetings. At one of these meetings an election must be made of assignees, or persons to whom the bankrupt's estate shall be assigned, and in whom it shall be vested for the benefit of the creditors; which assignees are chosen by the major part, in value, of the creditors who shall then have proved their debts; but may be originally appointed by the commissioners, and afterwards approved or rejected by the creditors: but no creditor shall be admitted to vote in the choice of assignees, whole debt, on the balance of accounts, does not amount to L. 10. And at the third meeting at farthief, which must be on the 42d day after the advertisement in the gazette, the bankrupt, upon notice also personally served upon him, or left at his usual place of abode, must surrender himself personally to the commissioners, and must thereupon in all respects conform to the directions of the statutes of bankruptcy; or, in default thereof, shall be guilty of felony without benefit of clergy, and shall suffer death, and his goods and estate shall be divided among his creditors.

In case the bankrupt absconds, or is likely to run away between the time of the commission issued and the last day of surrender, he may, by warrant from any judge or justice of the peace, be apprehended and committed to the county gaol, in order to be forthcoming to the commissioners, who are also empowered immediately to grant a warrant for seizing his goods and papers.

When the bankrupt appears, the commissioners are to examine him touching all matters relating to his trade and effects. They may also summon before them, and examine, the bankrupt's wife, and any other person whatsoever, as to all matters relating to the bankrupt's affairs: And in case any of them shall refuse to answer, or shall not answer fully, to any lawful question, or shall refuse to subscribe such their examination, the commissioners may commit them to prison without bail, till they make and sign a full answer; the commissioners specifying in their warrant of commitment the question so refused to be answered. And any gaoler, permitting such person to escape or go out of prison, shall forfeit L. 500 to the creditors.

The bankrupt upon this examination, is bound, upon pain of death, to make a full discovery of all his estate and effects as well in expectancy as possession, and how he has disposed of the same; together with all books and writings relating thereto; and is to deliver up all in his power to the commissioners (except the necessary apparel of himself, his wife, and his children); or, in case he conceals or embezzles any effects to the amount of L. 20, or with-holds any book or writings, with intent to defraud his creditors, he shall be guilty of felony without benefit of clergy.

After the time allowed the bankrupt for such discovery is expired, any other person voluntarily discovering any part of his estate before unknown to the assignees, shall be entitled to five per cent. out of the effects so discovered, and such further reward as the assignees and commissioners shall think proper. And any trustee wilfully concealing the estate of any bankrupt, after the expiration of 42 days, shall forfeit L. 100, and double the value of the estate concealed, to the creditors.

Hitherto every thing is in favour of the creditors; and the law seems to be pretty rigid and severe against the bankrupt; but, in case he proves honest, it makes him full amends for all this rigour and severity. For, if the bankrupt hath made an ingenious discovery, hath conformed to the directions of the law, and hath acted in all points to the satisfaction of his creditors; and if they, or four parts in five of them in number and value (but none of them creditors for less than L. 20), will sign a certificate to that purport; the commissioners are then to authenticate such certificate under their hands and seals, and to transmit it to the lord chancellor: and he, or two judges whom he shall appoint, on oath made by the bankrupt that such certificate
If no cause be shown to the contrary, the certificate is allowed of course; and then the bankrupt is entitled to a decent and reasonable allowance out of his effects, for his future support and maintenance, and to put him in a way of honesty and industry. This allowance is also in proportion to his former good behaviour, in the early discovery of the decline of his affairs, and thereby giving his creditors a larger dividend. For if his effects will not pay one half of his debts, or 10s. in the pound, he is left to the direction of the commissioners and assignees, to have a competent sum allowed him, not exceeding 3 per cent.; but if they pay 10s. in the pound, he is to be allowed 5 per cent.; if 12s. and 6d. then 7½ per cent.; and if 15s. in the pound, then the bankrupt shall be allowed 10 per cent.; provided that such allowance do not in the first case exceed £200, in the second £250, and in the third £300.

Besides this allowance, he has also an indemnity granted him, of being free and discharged for ever from all debts owing by him at the time he became a bankrupt; even though judgment shall have been obtained against him, and he lies in prison upon execution for such debts; and, for that among other purposes, all proceedings on commissiion of bankrupt, are, on petition, to be entered on record, as a perpetual bar against actions to be commenced upon this account: though, in general, the production of the certificate properly allowed shall be sufficient evidence of all previous proceedings. Thus the bankrupt becomes a clear man again, and, by the affiance of his allowance and his own industry, may become a useful member of the commonwealth: which is the rather to be expected, as he cannot be intitled to these benefits, but by the testimony of his creditors themselves of his honest and ingenious disposition; and unless his failures have been owing to misfortunes, rather than to misconduct and extravagance.

2. As to the proceedings which affect the bankrupt's property.

By virtue of the statutes before mentioned, all the personal estate and effects of the bankrupt are considered as vested, by the act of bankruptcy, in the hands of the commissioners, whether they be goods in actual possession, or deeds, contracts, and other choses in action; and the commissioners by their warrant may cause any house or tenement of the bankrupt to be broken open, in order to enter upon and seize the same. And when the assignees are chosen or approved by the creditors, the commissioners are to assign every thing over to them; and the property of every part of the estate is thereby as fully vested in them as it was in the bankrupt himself, and they have the same remedies to recover it.

The property vested in the assignees is the whole that the bankrupt had in himself, at the time he committed the first act of bankruptcy, or that has been vested in him since, before his debts are satisfied or assigned for. Therefore it is usually said, that once a bankrupt, and always a bankrupt: by which is meant, that a plain direct act of bankruptcy once committed, cannot be purged, or explained away, by any subsequent conduct, as a dubious equivocal act may be; but that, if a commiision is afterwards awarded, the commission and the property of the assignees shall have a relation, or reference, back to the first original act of bankruptcy. In so much that all transactions of the bankrupt are from that time absolutely null and void, either with regard to the alienation of his property or the receipt of his debts from those as are privy to his bankruptcy; for they are no longer his property, or his debts, but those of the future assignees. And if an execution be fixed out, but not served and executed on the bankrupt's effects till after the act of bankruptcy, it is void, as against the assignees. But the king is not bound by this fictitious relation, nor is within the statutes of bankrupts: for if, after the act of bankruptcy committed, and before the assignment of his effects, and extent if the debts of the crown, the goods are bound thereby. In France this doctrine of relation is carried to a very great length; for there, every act of a merchant, for 100 days precedent to the act of bankruptcy, is presumed to be fraudulent, and is therefore void. But in England the law stands upon a more reasonable footing: for these acts of bankruptcy may sometimes be secret to all but a few, and it would be prejudicial to trade to carry this notion to its utmost length, it is provided by flat. 19 Geo. II. c. 32. that no money paid by a bankrupt to a bona fide, or real creditor, in a course of trade, even after an act of bankruptcy done, shall be liable to be refunded. Nor by flat. 1 Jac. I. c. 15. shall any debtor of a bankrupt that pays him his debt without knowing of his bankruptcy, be liable to account for it again. The intention of this relative power being only to reach fraudulent transactions, and not to interfere the fair trader.

The assignees may pursue any legal method of recovering this property so vested in them, by their own authority, but cannot commence a suit in equity, nor compound any debts owing to the bankrupt, nor refer any matters to arbitration, without the consent of the creditors, or the major part of them in value, at a meeting to be held in pursuance of notice in the gazette.

When they have got in all the effects they can reasonably hope for, and reduced them to ready money, they assignes must, within 12 months after the commission is filled, give 21 days notice to the creditors of a meeting for a dividend or distribution; at which time they must produce their accounts, and verify them upon oath, if required. And then the commissioners shall direct a dividend to be made, at so much in the pound, to all creditors who have before proved or shall then prove, their debts. This dividend must be made equally, and in a raseable proportion, to all the creditors, according to the quantity of their debts; no regard being had to the quality of them. Mortgages, indeed, for which the creditor has a real security in his own hands, are entirely safe; for the commission of bankruptcy reaches only the equity of redemption. So are all personal debts, where the creditor has a chattel in his hands, or a pledge or pawn, for the payment, or has taken the debtors lands or goods in execution. And, upon the equity of the flat. 8 An. c. 14 (which directs, that upon all executions of goods being on any premises demised to a tenant,
COMMISSION in the General Assembly of the church of Scotland. See Assembly (General).

Commissioners of the Customs. See Customs.

Commissioners of Excise. See Excise.

Commissioners of the Navy. See Navy.

Lords Commissioners of the Treasury. See Treasury and Exchequer.

COMMISSURE, a term used by some authors, for the small measures or interstices of bodies; or the little clefts between the particles; especially when those particles are broad and flat, and lie contiguous to one another, like thin plates or lamellae. The word literally signifies a joining, or connecting of one thing to another.

COMMISSURE, in architecture, &c. denotes the joint of two stones, or the application of the surface of the one to that of the other. See Masonry.

Among anatomists, commissure is sometimes also used for a future of the cranium or skull.

COMMISIONER, in criminal law, is the sending to prision a person who has been guilty of any crime. This takes place where the offence is not bailable, or the party cannot find bail; must be by proper warrant, containing the cause of the commitment; and continues till put an end to by the course of law (see Trial); imprisonment being intended only for safe custody, and not for punishment (see Arrestment and Bail). In this dubious interval between the commitment and trial, a prisoner ought to be used with the utmost humanity; and neither be loaded with needless fetters or subjected to other hardships than such as are absolutely requisite for the purpose of confinement only: though what are so requisite must too often be left to the discretion of the gaolers; who are frequently a merciless race of men, and, by being convervants in feences of misery, fleeced against any tender fentation.

COMMITTEE, one or more persons to whom the consideration or ordering of a matter is referred, either by some court, or by the consent of parties to whom it belongs.

COMMITTEE of Parliament, a certain number of members appointed by the house for the examination of a bill, making a report of an inquiry, process of the house, &c. See Parliament.

Sometimes the whole house is resolved into a committee; on which occasion each person has a right to speak and reply as much and as often as he pleases; an expedient they usually have recourse to in extraordinary cases, and where anything is to be thoroughly canvassed. When the house is not in a committee, each gives his opinion regularly, and is only allowed to speak once, unless to explain himself.

The standing committees, appointed by every new parliament, are those of privileges and elections, of religion, of grievances, of courts of justice, and of trade, though only the former ad.

COMMIXTION, in Scots law, is a method of acquiring property, by mixing or blending together different substances belonging to different proprietors. See Law, Part III. No. clix. 8.

COMMODATE, COMMODATUM, in the civil jurisdiction, the loan or free concession of any thing moveable or immoveable, for a certain time, on condition
The commodi-
dition of restoring again the same individual after a
certain term. The commodare is a kind of loan ;
there is this difference, however, between a loan and
a commodate, that the latter is gratis, and does not
transfer the property; the thing must be returned in
esse, and without impairment: so that things which
conflume yf or time cannot be objects of a com-
date, but of a loan; in regard they may be returned
ed in kind, though not in identity. See Law, Part III.
No. elxxii. 8.

Commodius (Gazæus), a Christian author
in the 4th century, who wrote a work in Latin verse,
invented Instructton; the moral of which is excellent,
but the verse extremely heavy. M. Davies published
a fine edition of it in 1711, at the end of Minucius
Felix.

Commodita, in a general sense, denotes all
forts of wares and merchandizes whatsoever that a per-
son deals or trades in.

Staple Commodities, such wares and merchandizes
as are commonly and readily sold in a market or ex-
ported abroad: being for the most part the proper
produce or manufacture of the country.

Commodore, a general officer in the British
marine, invested with the command of a detachment of
ships of war destined on any particular enterprise,
during which time he bears the rank of brigadier-
general in the army, and is distinguished from the in-
ferior ships of his squadron by a broad red pendant
tapering towards the outer end, and sometimes fork-
ed. The word is corrupted from the Spanish, cornec-
dedor.

Commodore is also a name given to some fea-capt-
in a fleet of merchantmen, who leads the van in time
of war, and carries a light in his top with a knot-
ed, or, for more room, the two
lines are to be cut perpendicularly by others, drawn
from top to bottom; and in the several spaces thereof,
the several letters of the alphabet, both capital and
minufcule, are to be duly wrote.

The form of the lines and divisions, both horizontal
and perpendicular, with the manner of writing the let-
ters therein, will be conceived from the following spe-
cimen; wherein, what is to be done in the book for
all the letters of the alphabet, is here shown in the

A
The chief judge of this court is called lord chief justice of the common pleas, who is assisted by three other judges. The other officers of the court are: the esuis brevium, who is the chief clerk; three prothonotaries, and their secretaries; the clerk of the warrants, clerk of the ellions, 158 clerks, 4 exquirers, a clerk of the rollage, the choirographer, the clerk of the king's siller, clerk of the treasury, clerk of the seal, clerk of the outlaws, clerk of the inrolment of fines and recoveries, and clerk of the errors.

Common Prayer is the liturgy in the church of England. (See Liturgy.) Clergymen are to use the public form of prayers prescribed by the Book of Common Prayer: and refusing to do so, or using any other public prayers, are punifiable by Stat. 1 Eliz. c. ii.

Common, in grammar, denotes the gender of nouns which are equally applicable to both sexes: thus, patre, "a parent," is of the common gender.

Common, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures.

Common Divisor, a quantity or number which exactly divides two or more other quantities or numbers, without leaving any remainder.

Commonalty, the lower of the two divisions of the civil state. See Civil State.

The commonalty, in Britain, like the nobility, are divided into several degrees: and as the lords, though different in rank, yet all of them are peers in respect of their nobility; so the commoners, though some are greatly inferior to others, yet all are in law commonalty, in respect of their want of nobility.

1. The first name of dignity next beneath a peer was anciently that of viscount, vic-dominus, or viscount: who are mentioned by ancient lawyers as visiri magne dignitas; and Sir Edward Coke speaks highly of them. Yet they are now quite out of use; and our legal antiquaries are not agreed upon their original or ancient office.

2. Now, therefore, the first personal dignity after the nobility is a knight of the order of St George, or of the garter, first instituted by Edw. III. A. D. 1344.

3. Next (but not till after certain official dignities, as privy-councillors, the chancellors of the exchequer and duchy of Lancaster, the chief justice of the king's bench, the master of the rolls, and the other English judges), follows a knight banneret; who, indeed, by statutes 5 Richard II. Stat. 2. c. 4. and 14 Richard II. c. 11, is ranked next after barons; and his precedence before the younger sons of viscounts was confirmed to him by order of King James I. in the tenth year of his reign. But in order to intitle him to this rank, he must have been created by the king in person, in the field.
COMMUNIA CURTIAE ROYALIS, the assembly of all the freeholders of the realm, in one or more houses, the place of which is the diet of the country. See PARLIAMENT.

1. The commons consist of all such men of any property in the kingdom as have not seats in the house of lords, every one of whom has a voice in parliament, either personally or by his representatives. In a free state, every man, who is supposed a free agent, ought to be in some measure his own governor; and therefore a branch at least of the legislative power should reside in the whole body of the people. And this power, when the territories of the state are small, and its citizens easily known, should be exercised by the people in their aggregate or collective capacity, as was wisely ordained in the petty republics of Greece, and the first rudiments of the Roman state. But this will be highly inconvenient when the public territory is extended to any considerable degree, and the number of citizens is increased. Thus when, after the social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public assemblies, it became impossible to distinguish the proper from the real voter, and from that time all elections and popular deliberations grew tumultuous and disorderly; which paved the way for Mariss and Sylla, Pompey and Caesar, to trample on the liberties of their country, and at last to dissolve the commonwealth. In so large a state as Britain, therefore, it is very wisely contrived, that the people should do that by their representatives which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, wherein all the votes are or may be easily distinguished. The counties are therefore represented by knights, elected by the proprietors of lands; the cities and boroughs are represented by citizens and burgesses, chosen by the mercantile or supposed trading interest of the nation; much in the same manner as the burglers in the diet of Sweden are chosen by the corporate towns, Stockholm sending four, as London does, other cities two, and some only one. The number of English representatives is 513, of Scots 45; in all 558; and every member, though chosen by one particular district, when elected and returned, serves for the whole realm: for the end of his coming thither is not particular but general; not barely to advantage his constituents, but the commonwealth; to advise his majesty, as appears from the writ of summons, "de communi concilio super negotios quibusdam arduis et urgentibus, regem, statum, et defensionem regni Anglie et ecclesiae Anglicanae concernentibus." And therefore he is not bound, like a deputy in the United Provinces, to consult with, or take the advice of, his constituent upon any particular point, unless he himself thinks it proper or prudent so to do.

The peculiar laws and customs of the house of commons relate principally to the raising of taxes, and the elections of members to serve in parliament. See TAXES AND ELECTIONS.

COMMON, of HOUSE of COMMONS, a denomination given to the British lower house of parliament. Common.

The commons consist of all such men of any property in the kingdom as have not seats in the house of lords, every one of whom has a voice in parliament, either personally or by his representatives. In a free state, every man, who is supposed a free agent, ought to be in some measure his own governor; and therefore a branch at least of the legislative power should reside in the whole body of the people. And this power, when the territories of the state are small, and its citizens easily known, should be exercised by the people in their aggregate or collective capacity, as was wisely ordained in the petty republics of Greece, and the first rudiments of the Roman state. But this will be highly inconvenient when the public territory is extended to any considerable degree, and the number of citizens is increased. Thus when, after the social war, all the burghers of Italy were admitted free citizens of Rome, and each had a vote in the public assemblies, it became impossible to distinguish the proper from the real voter, and from that time all elections and popular deliberations grew tumultuous and disorderly; which paved the way for Mariss and Sylla, Pompey and Caesar, to trample on the liberties of their country, and at last to dissolve the commonwealth. In so large a state as Britain, therefore, it is very wisely contrived, that the people should do that by their representatives which it is impracticable to perform in person; representatives chosen by a number of minute and separate districts, wherein all the votes are or may be easily distinguished. The counties are therefore represented by knights, elected by the proprietors of lands; the cities and boroughs are represented by citizens and burgesses, chosen by the mercantile or supposed trading interest of the nation; much in the same manner as the burglers in the diet of Sweden are chosen by the corporate towns, Stockholm sending four, as London does, other cities two, and some only one. The number of English representatives is 513, of Scots 45; in all 558; and every member, though chosen by one particular district, when elected and returned, serves for the whole realm: for the end of his coming thither is not particular but general; not barely to advantage his constituents, but the commonwealth; to advise his majesty, as appears from the writ of summons, "de communi concilio super negotios quibusdam arduis et urgentibus, regem, statum, et defensionem regni Anglie et ecclesiae Anglicanae concernentibus." And therefore he is not bound, like a deputy in the United Provinces, to consult with, or take the advice of, his constituent upon any particular point, unless he himself thinks it proper or prudent so to do.

The peculiar laws and customs of the house of commons relate principally to the raising of taxes, and the elections of members to serve in parliament. See TAXES AND ELECTIONS.

DOCTORS COMMONS. See COLLEGE OF CIVILIANS.

PROCTOR OF THE COMMONS. See PROCTOR.
COMMUNION, in matters of religion, the being united in doctrine and discipline; in which sense of the word, different churches are said to hold communion with each other.

In the primitive Christian church, every bishop was obliged, after his ordination, to send circular letters to foreign churches, to signify that he was in communion with them. The three grand communions into which the Christian church is at present divided, is that of the church of Rome, the Greek church, and communion with the Protestant church; but originally all Christians were in communion with each other, having one common faith and discipline.

COMMUNION is also used for the act of communicating the sacrament of the eucharist, or the Lord's supper.

The fourth council of Lateran decrees, that every believer shall receive the communion, at least, at Easter; which seems to import a tacit desire, that they should do it oftener; as, in effect, they did it much oftener in the primitive days. Gratian, and the master of the sentenches, prescribe it as a rule for the laity, to communicate three times a year, at Easter, Whitsuntide, and Christmas. But in the 15th century, the practice was got on foot, never to approach the eucharist except at Easter; and the council thought fit to enjoin it then by a law, lest their coldness and remissness should go farther still. And the council of Trent renewed the same injunction, and recommended frequent communion without enforcing it by an express decree.

In the ninth century, the communion was still received by the laity in both kinds; or, rather, the species of bread was dipped in the wine, as is owned by the Romanists themselves. (Acla SS. Benedicti. Sec. III.) M. de Marca observes, that they received it at first in their hands, Hift. de Bearm, and believes the communion under one kind alone to have had its rise in the West under Pope Urban II. in 1056, at the time of the conquest of the Holy Land. And it was more solemnly enjoined by the council of Constance in 1414. The twenty-eighth canon of the council of Clermont enjoins the communion to be received under both kinds, distinctly; adding, however, two exceptions; the one of necesity, the other of caution, nisi per necessitatem & cautelam; the first in favour of the sick, the second of the abstemious, or those who had an aversion for wine.

It was formerly a kind of canonical punishment, for clerks guilty of any crime, to be reduced to lay communion, i.e. only to receive it as the laity did, viz. under one kind.

They had another punishment of the same nature, though under a different name, called foreign communion; to which the canons frequently condemned their bishops and other clerks. This punishment was not any excommunication, or deposition; but a kind of suspension from the function of the order, and a degradation from the rank they held in the church. It had its name because the communion was only granted to the criminal on the foot of a foreign clerk, i.e. being reduced to the lowest of his order, he took place after all those of his rank, as all clerks, &c. did in the churches to which they did not belong. The second council of Agda orders every clerk that absents himself from the church to be reduced to foreign communion.

COMMUNION Service, in the liturgy of the church of England, the office for the administration of the holy sacrament, extracted from several ancient liturgies, as those of St Basil, St Ambrose, &c.

By the last rubric, part of this service is appointed to be read every Sunday and holyday, after the morning prayer, even though there be no communicants.
COMMUNITY, denotes a society of men living in the same place, under the same laws, the same regulations, and the same customs.

COMMUTATION, in law, the change of a penalty or punishment from a greater to a less; as when death is commuted for banishment, &c.

COMNENA (Anna), daughter of Alexius Conemnus emperor of the East; memorable for her great learning and virtue, and for her History of the life and actions of her father, which is highly esteemed. She flourished about the year 1177. The history, which is in 15 books, was first published very imperfectly by Heselchius in 1610; and afterwards printed in the collection of the Byzantine historians, with a diffuse and incorrect Latin version by the Jesuit Pallinus, but with excellent notes by the learned Du Fresne.

COMO, a strong and populous town of Italy, in the duchy of Milan, and in the Comasco, with a bishop's See. It was taken by the imperialists in 1706, and is seated on a lake of the same name in E. Long. 8°. 57'. N. Lat. 45'.

COMOIS, or CAPE COMORIN, the most southern promontory of the Higher India, lying north-west of the island of Ceylon.

COMORRAS, a handsome and large town of Lower Hungary, and capital of a territory of the same name. It is so well fortified, that the Turks could never take it. The greatest part of the inhabitants are Hungarians or Ruffians, who are very rich, and are of the Greek religion. It is seated on the river Danube, in the island of Siht. E. Long. 18°. 25'. N. Lat. 47°. 50'.

COMOSE, in botany, from Como. An order of plants in the former editions of Linnaeus's Fragments of a Natural Method, consisting of the spiked willow or spireae fruticae, dropwort, and greater meadow-sweet. These, though formerly distinct genera, are by Linnaeus collected into one, under the name of spireae. The flowers growing in a head, resemble a bush, or tuft of hair, which probably gave rise to the epithet Comosa.

COMPACT, in philosophy, is said of bodies which are of a close, dense, and heavy texture, with few pores, and whose very small. Compact, in a legal sense, signifies an agreement, or contract flipulated between several parties.

COMPANION, one with whom a man frequently converses.
nor degenerate into excess. You will not desire to company. Such science, or accomplishment; that so, in the course of established, that it will be the ambition of others to be admitted members of your society. Select those for your companions who are men of good sense and understanding; and, if possible, who excel in some art, science, or accomplishment; that so, in the course of your acquaintance, your very hours of amusement may contribute to your improvement; and for the most part such are open and communicative, and take as useful a member of society.

COMPANY, a collective term, understood of several persons assembled together in the same place, or with the same design. The word is formed of the French compagnie, and that of compagnie, or companies, which, Chifflet observes, are found in the Salic law, tit. 66. and are properly military words, understood of soldiers, who, according to the modern phrase, are comrades or men-mates, i.e. lodge together, eat together, &c of the Latin cum "with," and panis "bread." It may be added, that in some Greek authors under the western empire, the word συνεδρία occurs in the sense of society.

COMPANY, in a familiar or fashionable sense, is used for an assemblage of persons met for the purpose of conversation, pastime, or festivity.

The love of company and of social pleasures is natural, and attended with some of the sweetest satisfactions of human life; but, like every other love, when it proceeds beyond the limits of moderation, it ceases to produce its natural effect, and terminates in disgusting satiety. The foundation-stone and the pillar on which we build the fabric of our felicity, must be laid in our own hearts. Amusement, mirth, agreeable variety, and even improvement, may be sometimes sought in the gaiety of mixed company, and in the usual diversions of the world; but if we found our general happiness on these, we shall do little more than raise cinders in the air, or build hovels on the sand.

To derive the proper pleasure and improvement from company, it ought to be select, and to consist of persons of character, respectable both for their morals and their understandings. Mixed and undistinguished society tends only to dilute our ideas, and induce a laxity of principles and practice. The pleasure it affords is of a coarse, mixed, noisy, and rude kind. Indeed, it commonly ends in weariness and disgust, as even they are ready to confess who yet constantly pursue it, as if their chief good consisted in living in a crowd.

Among these, indeed, who are exempted by their circumstances from professional and official employments, and who professedly devote themselves to a life of pleasure, little else seems to constitute the idea of it, but an unceasing succession of company, public or private. The divers, and other circumstances preparatory to the enjoyment of this pleasure, scarcely leave a moment for reflection. Day after day is spent in the same toilsome round, till a habit is formed, which renders dilipation necessary to existence. One week without it would probably induce a lowness of spirits, which might terminate in despair and suicide. When the mind has no anchor, it will suffer a kind of shipwreck; it will sink in whirlpools, and be dashed on rocks. What, indeed, is life or its enjoyments without settled principles, laudable purposes, mental exertions, and internal comfort? It is merely a vapour, or, to drop the language of figure on a ferious subject, it is a flate worse than non-entity, since it possesses a reflected power of action, productive of nothing but misery.

It is recommended, therefore, to all who wish to enjoy their existence (and who entertain not that wish?), that they should acquire a power not only of bearing, but of taking a pleasure in, temporary solitude. Every one must, indeed, sometimes be alone. Let him not repine when he is alone, but learn to set a value on the golden moments. It is then that he is enabled to study himself and the world around him. It is then that he has an opportunity of seeing things as they are, and of removing the deceitful veil, which almost every thing assumes in the busy scene of worldly employments. The soul is enabled to retire into itself, and to extract those energies which are always attended with sublime pleasure. She is enabled to feel the dependent, frail, and wretched state of man as the child of nature; and incited by her discovery, to imploy grace and protection from the Lord of the universe. They, indeed, who fly from solitude, can seldom be religions; for religion requires meditation. They may be said to "live without God in the world;" not, it is true, from atheistical principles, but from carelessness in disposition; a truly deplorable state, the consequence of which could not fail to cloud the gaiety of those gilded beings who sport in the sunshine of unremitting pleasure.

There is no doubt but that man is made for action, and that his duties and pleasures are often most numerous and most important amidst the busy hum of men. Many vices, and many corrupt dispositions, have been fostered in a solitary life. Monastery is not favourable to human nature or human happiness; but neither is unlimited dilipation.

In short, let there be a sweet interchange of retirement and association, of repose and activity. A few hours spent every day by the votaries of pleasure in serious meditation, would render their pleasure pure, and more unmixed with misery. It would give them knowledge, so that they would see how far they might advance in their pursuit without danger; and resolution, so that they might retreat when danger approached. It would teach them how to live, a knowledge which indeed they think they possess already; and it would also teach them, what they are often too little solicitous to learn, how to die.

COMPANY, in a commercial sense, is a society of merchants, mechanics, or other traders, joined together in one common interest.

When there are only two or three joined in this manner, it is called a partnership; the term company being restrained to societies consisting of a considerable number of members, associated together by a charter obtained from the prince.

The mechanics of all corporations, or towns incorporated, are thus erected into companies, which have charters of privileges and large immunities.

COMPANY seems more particularly appropriated to thes

Company. those grand associations set on foot for the commerce of the remote parts of the world, and vested by charter with peculiar privileges.

When companies do not trade upon a joint flock, but are obliged to admit any person, properly qualified, upon paying a certain fine, and agreeing to submit to the regulations of the company, each member trading upon his own flock and at his own risk, they are called Regulated Companies. When they trade upon a joint flock, each member sharing in the common profit, or loss in proportion to his share in this flock, they are called Joint-flock Companies. Such companies, whether regulated or joint-flock, sometimes have and sometimes have not, exclusive privileges.

However injurious companies with joint-flock, and incorporated with exclusive privileges, may at this time be reckoned to nations in general, it is yet certain that they were the general parent of all foreign commerce; private traders being discouraged from hazarding their fortunes in foreign countries, until the method of traffic had been first settled by joint-flock companies. For since the trade of kingdoms and the number of traders have increased, and the methods of assurance of shipping and merchandize, and the navigation to all parts of the known world have become familiar, those companies, in the opinions of most men, have been looked upon in the light of monopolies; their privileges have therefore been levied from time to time, in order to favour a free and general trade: and experience has shown, that the trade of nations has advanced in proportion as monopolies have been discouraged. In short, as all restrictions of trade are found to be hurtful, nothing can be more evident, than that no company whatsoever, whether they trade in joint flock or only under regulation, can be for the public good, except it may be easy for all or many of the subjects to be admitted into all or any of the said companies, at any time, and for a very inexorable fine.

1. Regulated Companies resemble, in every respect, the corporations of trades, so common in the cities and towns of all the different countries of Europe; and are a sort of enlarged monopolies of the same kind. As no inhabitant of a town can exercise an incorporated trade, without first obtaining his freedom in the corporation, so in most cases no subject of the state can lawfully carry on any branch of foreign trade for which a regulated company is established, without first becoming a member of that company. The monopoly is more or less strict, according as the terms of admission are more or less difficult; and according as the directors of the company have more or less authority, or have it more or less in their power to manage in such a manner as to confine the greater part of the trade to themselves and their particular friends. In the most ancient regulated companies the privileges of apprenticeship were the same as in other corporations; and intituled the person who had served his time to a member of the company, to become himself a member, either without paying any fine, or upon paying a much smaller one than what was exacted of other people. The usual corporation spirit, wherever the law does not restrain it, prevails in all regulated companies. When they have been allowed to act according to their natural genius, they have always, in order to confine the competition to as small a number of persons as possible, endeavoured to subject the trade to many burthensome regulations. When the law has restrained them from doing this, they have become altogether useless and insignificant.

1. The Hamburgh Company is the oldest trading establishment in the kingdom; though not always known by that name, nor restrained to those narrow bounds under which it is now confined. It was first called the Company of merchants trading to Calais, Holland, Zealand, Brabant, and Flanders: then it acquired the general title of Merchant-adventurers of England; as being composed of all the English merchants who traded to the Low Countries, the Baltic, and the German ocean. Lastly, it was called the Company of Merchant-adventurers of England trading to Hamburgh.

This company was first incorporated by Edward I. in 1296; and established again, by charter, in 1406, under the reign of king Henry IV. It was afterwards confirmed, and augmented with divers privileges by many of his successors. Before the charter of Henry IV. all the English merchants who trafficked out of the realm, were left to their own discretion, and managed their affairs with foreigners as might be most for their respective interests, without any regard to the general commerce to the nation. Henry, observing this disorder, endeavoured to remedy it, by uniting all the merchants in his dominions into one body; wherein, without losing the liberty of trading each for himself, they might be governed by a company still subsisting; and be subject to regulations, which should secure the general interest of the national commerce, without prejudice to the interest of particulars. With this view, he granted all the merchants of his states, particularly those of Calais, then in his hands, a power of associating themselves into a body politic, with directors and governors, both in England and abroad; to hold assemblies, both for the direction of business and the deciding of controversies among merchants; make laws; punish delinquents; and impose moderate duties and taxes on merchandizes, and merchants, to be employed in the service of the corporation. Thos few articles of the charter of Henry IV. were afterwards much augmented by Henry VII. who first gave them the title of Merchant-adventurers to Calais, Holland, &c. gave them a power of proclaiming and continuing free fairs at Calais; and ordered, that to be reputed a member of the society, each person pay twenty marks sterling; and that the several members should attend the general meetings, or courts, appointed by the directors, whether at London, Calais, or elsewhere.

A petition being made to queen Elizabeth, in 1564, for an explanation of certain articles in the charter of Henry VII. and a confirmation of the charter granted by other kings; that princes, by a charter of the same year declares, that to end all disputes, they shall be incorporated anew, under the title of the Company of Merchant-adventurers of England; that all who were members of the former company should, if they desired
Company: fired it, admitted members of this; that they should have a common seal; that they should admit into their society what other persons, and on what terms, they pleased, and expel them again on misbehaviour: that the city of Hamburgh and neighbouring cities should be reputed within their grant, together with those of the Low Countries, &c. in that of the former company: that no member should marry out of the kingdom, nor purchase lands, &c. in any city beyond sea; and that those who do, shall be ipso facto, excluded for ever. Twenty-two years after this first charter, queen Elizabeth granted them a second; confirming the former, and further granting them a privilege of exclusion; with a power of erecting in each city within their grant a standing council.

The revolutions which happened in the Low Countries towards the end of the sixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn itself wholly to the side of Hamburgh, and the cities on the German ocean: from which change, some people took occasion to change its name to that of the Hamburgh Company; though the ancient title of Merchant-adventurers is still retained in all their writings.

About the middle of the last century, the fine for admission was fifty, and at one time one hundred pounds, and the conduct of the company was said to be extremely oppressive. In 1643, in 1645, and in 1661, the clothiers and free traders of the west of England complain'd of them to parliament, as of monopolists who confined the trade and oppressed the manufacturers of the country. Though these complaints produced no act of parliament, they had probably intimidated the company so far as to oblige them to reform their conduct. The terms of admission are now said to be quite easy: and the directors either have it not in their power to subject the trade to any burdensome restraint or regulations, or at least have not of late exercised that power.

The East India Company was first projected towards the end of the reign of king Edward VI. executed in the first and second years of Philip and Mary; but had not its perfection till its charter was confirmed by act of parliament, under queen Elizabeth, in 1566. It had its rise from certain adventurers, who were sent in three vessels on the discovery of new countries; and to find out a north-east passage to China: these, falling into the White Sea, and making up to the port of Archangel, were exceedingly well received by the Muscovites; and at their return, solicited letters patent to secure to themselves the commerce of Russia, for which they had formed an association.

By their charter, the association was declared a body politic, under the name of the Company of Merchant-adventurers of England, for the discovery of lands, territories, islands, &c. unknown, or unfrequented. Their privileges were, to have a governor, four consuls, and twenty-four assistants, for their commerce: for their policy, to make laws, inflict penalties, send out ships to make discoveries, take possession of them in the king's name, set up the banner royal of England, plant them; and lastly, the exclusive privilege of trading to Archangel, and other ports of Muscovy, not Company: fired it, admitted members of this; that they should have a common seal; that they should admit into their society what other persons, and on what terms, they pleased, and expel them again on misbehaviour; that the city of Hamburgh and neighbouring cities should be reputed within their grant, together with those of the Low Countries, &c. in that of the former company: that no member should marry out of the kingdom, nor purchase lands, &c. in any city beyond sea; and that those who do, shall be ipso facto, excluded for ever. Twenty-two years after this first charter, queen Elizabeth granted them a second; confirming the former, and further granting them a privilege of exclusion; with a power of erecting in each city within their grant a standing council.

The revolutions which happened in the Low Countries towards the end of the sixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn itself wholly to the side of Hamburgh, and the cities on the German ocean: from which change, some people took occasion to change its name to that of the Hamburgh Company; though the ancient title of Merchant-adventurers is still retained in all their writings.

The revolutions which happened in the Low Countries towards the end of the sixteenth century, and which laid the foundation of the republic of Holland, having hindered the company from continuing their commerce with their ancient freedom; it was obliged to turn itself wholly to the side of Hamburgh, and the cities on the German ocean: from which change, some people took occasion to change its name to that of the Hamburgh Company; though the ancient title of Merchant-adventurers is still retained in all their writings.

About the middle of the last century, the fine for admission was fifty, and at one time one hundred pounds, and the conduct of the company was said to be extremely oppressive. In 1643, in 1645, and in 1661, the clothiers and free traders of the west of England complain'd of them to parliament, as of monopolists who confined the trade and oppressed the manufacturers of the country. Though these complaints produced no act of parliament, they had probably intimidated the company so far as to oblige them to reform their conduct. The terms of admission are now said to be quite easy: and the directors either have it not in their power to subject the trade to any burdensome restraint or regulations, or at least have not of late exercised that power.

The East India Company was first projected towards the end of the reign of king Edward VI. executed in the first and second years of Philip and Mary; but had not its perfection till its charter was confirmed by act of parliament, under queen Elizabeth, in 1566. It had its rise from certain adventurers, who were sent in three vessels on the discovery of new countries; and to find out a north-east passage to China: these, falling into the White Sea, and making up to the port of Archangel, were exceedingly well received by the Muscovites; and at their return, solicited letters patent to secure to themselves the commerce of Russia, for which they had formed an association.

By their charter, the association was declared a body politic, under the name of the Company of Merchant-adventurers of England, for the discovery of lands, territories, islands, &c. unknown, or unfrequented. Their privileges were, to have a governor, four consuls, and twenty-four assistants, for their commerce: for their policy, to make laws, inflict penalties, send out ships to make discoveries, take possession of them in the king's name, set up the banner royal of England, plant them; and lastly, the exclusive privilege of trading to Archangel, and other ports of Muscovy, not
that of the East, shall be admitted gratia; provided he procures the same favour for a merchant of the East willing to fill his place. That the merchant adventurers who never dealt in the East, in the places expressed in the charter, may be received as members of the company on paying forty marks; that, notwithstanding this union of the Adventurers of England with the company of the East, each shall retain its rights and privileges. That they shall export no cloths but what are dyed and pressed, except a hundred pieces per annum, which are allowed them gratia. This charter, was confirmed by Charles II. in 1629, with this addition, that no person, of what quality ever, living in London, should be admitted a member, unless he were free of the city. This company was complained of as a monopoly, and first curtailed by legal authority in 1672; and since the declaration of rights in 1689, exist only in name; but still continue to elect their annual officers, who are a governor, a deputy, and twenty-four assistants.

4. The Turkey or Levant Company, had its rise under queen Elizabeth, in 1581. James I. confirmed its charter in 1603, adding new privileges. During the civil wars, there happened some innovations in the government of the company; many persons having been admitted members, not qualified by the charters of queen Elizabeth and king James, or that did not conform to the regulations prescribed. Charles II. upon his restoration, endeavoured to set it upon its ancient basis; to which end, he gave them a charter, containing not only a confirmation of their old one, but also several new articles of reformation. By this, the company is erected into a body politic, capable of making laws, &c., under the title of the Company of Merchants of England trading to the seas of the Levant. The number of members is not limited, but is ordinarily about three hundred. The principle qualification required is, that the candidate be a freeman of London, and a wholesale merchant, either by family or by serving an apprenticeship of seven years. Those under twenty-five years of age pay 251 sterling at their admission; those above, twice as much. This fine was reduced by act of parliament, in 1753, to 201. and the privilege of admission extended to every Briton capable of making laws, &c., under the title of the Company of Merchants of England trading to the seas of the Levant. The number of members is not limited, but is ordinarily about three hundred. The principle qualification required is, that the candidate be a freeman of London, and a wholesale merchant, either by family or by serving an apprenticeship of seven years. Those under twenty-five years of age pay 251 sterling at their admission; those above, twice as much. This fine was reduced by act of parliament, in 1753, to 201.

The ordinary commerce of this company employs from 20 to 25 vessels, carrying from 25 to 50 pieces of cannon. The mercantile exported thither are, cloths of all kinds and colours, pewter, lead, pepper, cochineal, and a great deal of silver, which they take up at Cadiz; the returns are in raw silk, galls, camlers, wools, cottons, Morocco leather, ashes for making glafs and soap, and several gums and medicinal drugs. The commerce to Smyrna, Constan­tinople, and Scand­eroon, is not esteemed much less considerable than that of the East India company; but is, doub­les, more advantageous to Britain; because it takes off much more of the British manufactures than the other, which is chiefly carried on in money. The places reserved for the commerce of this company are, all the states of Venice, in the gulf of Venice; the state of Ragusa; all the states of the grand seignior, and the ports of the Levant and Mediterranean; excepting Carthage, Alicante, Barcelona, Valencia, Mar­felles, Toulon, Genoa, Leghorn, Civita Vecchia, Palermo, Messina, Malta, Majorca, Minorca, and Cor­fica; and other places on the coasts of France, Spain, and Italy.

5. The Company of Merchants trading to Africa, established in 1750. Contrary to the former practice with regard to regulated companies, who were reckoned units for such sort of service, this company was subjected to the obligation of maintaining forts and garrison. It was expressly charged at first with the maintenance of all the British forts and garrisons that lie between Cape Blanc and the Cape of Good Hope, and afterwards with that of those only which lie between Cape Rouge and the Cape of Good Hope. The act which establishes this company (the 23d of George II. c. 31.) seems to have had two distinct objects in view; first, to restrain effectually the op­pressive and monopolizing spirit which is natural to the directors of a regulated company; and, secondly, to force them as much as possible to give an attention, which is not natural to them, towards the maintenance of forts and garrisons.

For the first of these purposes, the fine for admission is limited to forty shillings. The company is prohibited from trading in their corporate capacity, or upon a joint stock; from borrowing money upon common seal, or from laying any restraints upon the trade which may be carried on freely from all places, and by all persons being British subjects, and paying the fine. The government is in a committee of nine persons who meet at London, but who are chosen annually by the freemen of London.
Company. freemen of the company at London, Bristol, and Liverpool; three from each place. No committee-man can be continued in office for more than three years together. Any committee-man might be removed by the board of trade and plantations; now by a committee of council, after being heard in his own defence.

The committee are forbid to export negroes from Africa, or to import any African goods into Great Britain. But as they are charged with the maintenance of forts and garrisons, they may for that purpose export from Great Britain to Africa goods and stores of different kinds. Out of the money which they shall receive from the company, they are allowed a sum not exceeding eight hundred pounds for the salaries of their clerks and agents at London, Bristol, and Liverpool; the house-rent of their office at London; and all other expenses of management, commission, and agency, in England. What remains of this sum, after defraying those different expenses, they may divide among themselves, as compensation for their trouble, in what manner they think proper. By this constitution, it might have been expected (Dr Smith observes), that the spirit of monopoly would have been effectually restrained, and the first of these purposes sufficiently answered. It would seem, however, that it had not. Though by the 4th of George III. c. 20. the fort of Senegal, with all its dependencies, had been vested in the company of merchants trading to Africa, yet in the year following (by the 5th of George III. c. 44.), not only Senegal and its dependencies, but the whole coast from the port of Sallee, in South Barbary, to Cape Rouge, was exempted from the jurisdiction of that company, was vested in the crown, and the trade to it declared free to all his majesty's subjects. The company had been suspected of restraining the trade, and of establishing some fort of improper monopoly. It is not, however, very easy to conceive how, under the regulations of the 23d George II. they could do so. From the printed debates of the house of commons (not always the most authentic records of truth), it appears, however, that they have been accused of this. The members of the committee of nine being all merchants, and the governors and factors, in their different forts and settlements, being all dependent upon them, it is not unlikely that the latter might have given peculiar attention to the confinements and commissions of the former, which would establish a real monopoly.

For the second purpose mentioned, the maintenance of the forts and garrisons, an annual sum has been allotted to them by parliament, generally about 13,000l. For the proper application of this sum, the committee is obliged to account annually to the curator baron of exchequer; which account is afterwards to be laid before parliament. But parliament (continues our author), which gives so little attention to the application of millions, is not likely to give much to that of 13,000l. a year; and the curator baron of exchequer, from his profession and education, is not likely to be profoundly skilled in the proper expense of forts and garrisons. The captains of his majesty's navy, indeed, or any other commissioned officers, appointed by the board of admiralty, may enquire into the condition of the forts and garrisons, and report their observations to that board. But that board seems to have no direct jurisdiction over the committee, nor any authority to correct those whole council it may thus enquire into; and the captains of his majesty's navy, besides, are not supposed to be always deeply learned in the science of fortification. Removal from an office, which can be enjoyed only for the term of three years, and of which the lawful emoluments, even during that term, are so very small, seems to be the utmost punishment to which any committee-man is liable; for any fault, except direct malversation, or embezzlement either of the public money or of that of the company, and the fear of that punishment, can never be a motive of sufficient weight to force a continual and careful attention to a business to which he has no other interest to attend. The committee are accused of having sent out bricks and stones from England for the repair of Cape Coast Castle on the coast of Guinea, a business for which parliament had several times granted an extraordinary sum of money. These bricks and stones too, which had thus been sent upon so long a voyage, were said to have been of so bad a quality, that it was necessary to rebuild from the foundation the walls which had been repaired with them. The forts and garrisons which lie north of Cape Rouge, are not only maintained at the expense of the state, but are under the immediate government of the executive power; and why those which lie south of that Cape, and which too are, in part at least, maintained at the expense of the state, should be under a different government, it seems not very easy even to imagine a good reason.

The above company succeeded that called The Royal African Company, which traded upon a joint stock with an exclusive privilege. Though England began to trade to Africa as early as the year 1556, and several voyages were made to Guinea in 1588, and some following years, for the importation of gold and elephants' teeth, nothing like a company was formed till the year 1668, when queen Elizabeth granted a patent of exclusive privilege to certain persons for ten years. In 1668, king James I. established a company by charter, which was soon dissolved. Another company was erected by charter of Charles I. in 1631, which met with little success; but the demand for negroes in the English American plantations increasing, a third company was established by a charter granted 1662, in favour of the duke of York; securing to him the commerce of all the country, coasts, islands, &c. belonging to the crown of England, or not possessed by any other Christian prince; from Cape Blanco in 20° N. Lat. to the Cape of Good Hope in 34° 24'. S. Lat. The charter was soon after returned into the king's hands by the duke, and revoked, by consent of the parties associated with him in the enterprise; in consequence of which, the fourth and last exclusive company was established and incorporated by letters patent in 1672, under the title of the Royal African Company. A capital was soon raised of 111,000l. and this new company improved their trade, and increased their forts; but after the Revolution in 1689, this trade was laid open. In 1698, all private traders to Africa were obliged by stat. 9 and 10 Will. to pay ten per cent. in order to assist the company, in maintaining their forts and factories. But notwithstanding this heavy tax, the company were still unable to maintain the competition; their stock and credit gradually declined. In
Company. In 1712, their debts had become so great, that a particular act of parliament was thought necessary, both for their security and for that of their creditors. It was enacted, that the resolution of two-thirds of these creditors in number and value, should bind the rest, with regard to the time which should be allowed to the company for the payment of their debts, and with regard to any other agreement which it might be thought proper to make with them concerning those debts. In 1730, their affairs were in so great disorder, that they were altogether incapable of maintaining their forts and garrisons; the sole purpose and pretext of their initiation. From that year till their final dissolution, the parliament judged it necessary to allow the annual sum of ten thousand pounds for that purpose. In 1732, after having been for many years losers by the trade of carrying negroes to the West Indies, they at last resolved to give it up altogether; to sell to the private traders to America the negroes which they purchased upon the coast; and to employ their servants in a trade to the inland parts of Africa for gold dust, elephants teeth, dyeing drugs, &c. But their success in this more confined trade was not to sell to the private traders to America the negroes which they purchased upon the coast; but each member, in every respect a bankrupt company, they were dissolved by act of parliament, and their forts and garrisons vested in the present Regulated Company of Merchants trading to Africa.

II. Joint-Stock Companies, established either by royal charter or by act of parliament, differ in several respects, not only from regulated companies, but from private copartnery. 1. In a private copartnery, no partner, without the consent of the company, can transfer his share to another person, or introduce a new member into the company. Each member, however, may, upon proper warning, withdraw from the copartnery, and demand payment from them of his share of the common flock. In a joint-stock company, on the contrary, no member can demand payment of his share from the company; but each member can, without their consent, transfer his share to another person, and thereby introduce a new member. The value of a share in a joint-stock is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the flock of the company. 2. In a private copartnery, each partner is bound for the debts contracted by the company to the whole extent of his fortune. In a joint-stock company, on the contrary, each partner is bound only to the extent of his share.

The trade of a joint-stock company is always managed by a court of directors. This court indeed is frequently subject, in many respects, to the control of a general court of proprietors. But the greater part of those proprietors seldom pretend to understand any thing of the business of the company; and when the spirit of faction happens not to prevail among them, give themselves no trouble about it, but receive contentedly such half yearly or yearly dividend as the directors think proper to make them. This total exemption from trouble and from risk, beyond a limited sum, encourages many people to become adventurers in joint-stock companies, who would upon no account hazard their fortunes in any private copartnery. Such companies, therefore, commonly draw to themselves much greater flocks than any private copartnery can boast of. The trading flock of the South Sea company, at one time, amounted to upwards of thirty-three millions eight hundred thousand pounds. The directors of such companies, however, being the managers rather of other peoples money than of their own, it cannot well be expected that they should watch over it with the same anxious vigilance with which the partners in a private copartnery frequently watch over their own. Like the stewards of a rich man, they are apt to consider attention to small matters as not for their masters honour, and very easily give themselves a dispensation from having it. Negligence and profition, therefore, must always prevail, more or less, in the management of the affairs of such a company. It is upon this account that joint-flock companies for foreign trade have seldom been able to maintain the competition against private adventurers. They have, accordingly, very seldom succeeded without an exclusive privilege; and frequently have not succeeded with one. Without an exclusive privilege they have commonly mismanaged the trade. With an exclusive privilege they have both mismanaged and confined it.

The principal joint-flock companies presently subsisting in Great Britain are, the South Sea and the East Indies companies; to which may be added, though of very inferior magnitude, the Hudfons Bay company.

1. The South-Sea Company. During the long war with France in the reign of queen Anne, the payment of the sailors of the royal navy being neglected, they received tickets instead of money, and were frequently obliged, by their necessities, to sell these tickets toavaricious men at a discount of 40 and sometimes 50 per cent. By this and other means, the debts of the nation provided for by parliament, and which amounted to £9,471,321, fell into the hands of these usurers. On which Mr Harley, at that time chancellor of the Exchequer, and afterwards earl of Oxford, proposed a scheme to allow the proprietors of these debts and deficiencies 6 per cent. per annum, and to incorporate them for the purpose of carrying on a trade to the South Sea; and they were accordingly incorporated under the title of "the Governor and Company of Merchants of Great Britain trading to the South Seas, and other parts of America, and for encouraging the Fishery," &c.

Though this company seem formed for the sake of commerce, the ministry never thought seriously, during the course of the war, about making any settlement on the coast of South America, which was what startled the expectations of the people; nor was it ever carried into execution by this company.

Some other sums were lent to the government in the reign of queen Anne, at 6 per cent. In the third of George I. the interest of the whole was reduced to 5 per cent. and the company advanced two millions more to the government at the same interest. By the statute of the 6th of George I. it was declared, that they might redeem all or any of the redeemable national debts; in consideration of which, the company were empowered to augment their capital according to the sums they should discharge; and for enabling them to raise such sums for purchasing annuities, ex-

changing
Changing for ready money new exchequer bills, carrying on their trade, &c. they might, by such means as they should think proper, raise such sums of money as in a general court of the company should be judged necessary. The company were also empowered to raise money on the contracts, bonds, or obligations under their common seal, on the credit of their capital stock. But if the sub-governor, deputy-governor, or other members of the company, would purchase lands or revenues of the crown upon account of the corporation, or lend money by loan or anticipation on any branch of the revenue, other than such part only on which a credit of loan was granted by parliament, such sub-governor, or other member of the company, should forfeit treble the value of the money so lent.

The fatal South Sea scheme, transacted in the year 1720, was executed upon the last mentioned statute. The company had at first set out with good success, and the value of their stock, for the first five years, had risen faster than that of any other company; and his majesty, after purchasing 10,000l. stock, had condescended to be their governor. Things were in this situation, when, taking advantage of the above statute, the South Sea bubble was projected. The pretence was, to raise a fund for carrying on a trade to the South Sea, and purchasing annuities, &c. paid to the other companies; and proposals were printed and distributed, showing the advantages of this design. The sum necessary for carrying it on, together with the profits that were to arise from it, were divided into a certain number of shares, or subscriptions, to be purchased by persons disposed to adventure therein. And the better to carry on the deception, the directors engaged to make very large dividends; and actually declared, that every 100l. original stock would yield 50l. per annum; which occasioned so great a rise of their stock, that a share of 100l. was sold for upwards of 800l. This was in the month of July; but before the end of September it fell to 150l. by which multitudes were ruined, and such a scene of distress occasioned, as is scarcely to be conceived. But the consequences of this infamous scheme are too well known; most of the directors were severely fined, to the loss of nearly all their property; some of them had no hand in the deception, nor gained a farthing by it; but it was agreed, they ought to have opposed and prevented it.

The South Sea company never had any forts or garrisons to maintain, and therefore were entirely exempted from one great expense, to which other joint-stock companies for foreign trade are subject. But they had an immense capital divided among an immense number of proprietors. It was naturally to be expected, therefore, that folly, negligence, and profulation, should prevail in the whole management of their affairs.

Their stock-jobbing speculations were succeeded by mercantile projects, which, Dr Smith observes, were not much better conducted. The first trade which they engaged in, was that of supplying the Spanish West Indies with negroes, of which (in consequence of what was called the Affiento contract granted them by the treaty of Utrecht) they had the exclusive privilege. But as it was not expected that much profit could be made by this trade, both the Portuguese and French companies, who had enjoyed it upon the same company terms before them, having been ruined by it, they were allowed, as compensation, to send annually a ship of a certain burden to trade directly to the Spanish West Indies. Of the ten voyages which this annual ship was allowed to make, they are said to have gained considerably by one, that of the Royal Caroline in 1731, and to have been losers, more or less, by almost all the rest. Their ill success was imputed, by their factors and agents, to the extortion and oppression of the Spanish government; but was, perhaps, principally owing to the profusion and depredations of those very factors and agents; some of whom are said to have acquired great fortunes even in one year. In 1734, the company petitioned the king, that they might be allowed to dispose of the trade and tonnage of their annual ship, on account of the little profit which they made by it, and to accept of such equivalent as they could obtain from the King of Spain.

In 1724, this company had undertaken the whalefishery. Of this indeed they had no monopoly; but so long as they carried it on, no other British subjects appear to have engaged in it. Of the eight voyages which their ships made to Greenland, they were gainers by one, and losers by all the rest. After their eighth and last voyage, when they had sold their ships, stores, and utensils, they found that their whole loss, upon this branch, capital and interest included, amounted to upwards of L. 237,000.

In 1722, this company petitioned the parliament to be allowed to divide their immense capital of more than L. 33,800,000, the whole of which had been lent to government, into two equal parts: The one half, or upwards of L. 16,900,000, to be put upon the same footing with other government annuities, and not to be subject to the debts contracted, or losses incurred, by the directors of the company, in the prosecution of their mercantile projects; the other half to remain, as before, a trading stock, and to be subject to those debts and losses. This petition was reasonable not to be granted. In 1723, they again petitioned the parliament, that three-fourths of their trading stock might be turned into annuity stock, and only one-fourth remain as trading stock, or exposed to the hazards arising from the bad management of their directors. Both their annuity and trading stocks had, by this time, been reduced more than L. 5,000,000 each, by severall different payments from government; so that this fourth amounted only to L. 3,662,784, 8s. 6 d. In 1748, all the demands of the company upon the king of Spain, in consequence of the Affiento contract, were by the treaty of Aix-la-Chapelle, given up for what was supposed an equivalent. An end was put to their trade with the Spanish West Indies, the remainder of their trading stock was turned into annuity stock, and the company ceased in every respect to be a trading company.

This company is under the direction of governor, sub-governor, deputy governor, and 21 directors; but no person is qualified to be governor, his majesty excepted, unless such governor has in his own name and right, L. 5000 in the trading stock; the sub-governor is to have L. 4000 the deputy-governor L. 3000, and a director L. 2000, in the same stock. In every general court, every member having in his own name and right L. 500 in trading
Wealth

Company. trading flock, has one vote; if L. 2000 two votes; if L. 3000 three votes; and if L. 5000 four votes.  

2. The East India Company. The first, or as it is called the Old East India Company, was established by a charter from queen Elizabeth in 1600; but for some time the partners seem to have traded with separate flocks, though only in the ships belonging to the whole company. In 1612, they joined their flocks into one common capital; and though their charter was not as yet confirmed by act of parliament, it was looked upon in that early period to be sufficiently valid, and no body ventured to interfere with their trade. At this time their capital amounted to about L. 740,000; and the shares were as low as L. 50; their trade was in general successful, notwithstanding some heavy losses, chiefly sustained through the malice of the Dutch East India company. In process of time, however, it came to be understood that a royal charter could not by itself convey an exclusive privilege to traders, and the company was reduced to divide its reason of the multitude of interlopers who carried off the most of their trade. This continued during the latter part of the reign of Charles II. the whole of that of James II. and part of William III. when in 1692 a proposal was made to parliament for advancing the sum of L. 2,000,000 to government, on condition of creating the subscribers into a new company with exclusive privileges. The old company endeavored to prevent the appearance of such a formidable rival, by offering government L. 700,000, nearly the amount of their capital, at that time; but such were the exigencies of the state at that time, that the larger sum, at eight per cent. interest, was preferred to the smaller at one half the expense.  

Thus were two East India Companies erected in the same kingdom, which could not but be very prejudicial to each other. Through the negligence of those who prepared the act of parliament also, the new company were not obliged to unite in a joint-flock. The consequence of this was, that a few private traders, whose subscriptions far exceeded L. 7200, infilled on a right of trading separately at their own risk. Thus a kind of third company was established; and by their mutual contentions with one another, all the three were brought to the brink of ruin. Upon a subsequent occasion (in 1713) a proposal was made to parliament for putting the trade under the management of a regulated company, and thus laying it in some measure open. This, however, was opposed by the company, who represented in strong terms the mischief likely to arise from such a proceeding. "In India (they said) it raised the price of goods so high, that they were not worth the buying; and in England, by overstocking the market, it sunk the price to such a degree, that no profit could be made of them." Here Dr Smith remarks, that by a more plentiful supply, to the great advantage and convenience of the public, it must have reduced very much the price of Indian goods in the English market, cannot well be doubted; but that it should have raised very much their price in the Indian market, seems not very probable, as all the extraordinary demand which that competition could occasion, must have been but as a drop of water in the immense ocean of Indian commerce. The increase of demand, adds he, though in the beginning it may sometimes raise the price of goods, never fails to lower it in the Company, long run. It encourages production, and thereby increases the consumption of the producers, who, in order to underfell one another, have recourse to new divisions of labour and new improvements of art, which might never otherwise have been thought of. The miserable effects of which the company complained, were the cheapness of consumption and the encouragement given to production, precisely the two effects which it is the business of political economy to promote. The competition, however, of which they gave this doleful account, had not been allowed to continue long. In 1702 the two companies were, in some measure, united by an indenture tripartite, to which the queen was the third party; and in 1708, they were, by act of parliament perfectly consolidated into one company by their present name of The United Company of Merchants trading to the East Indies. Into this act it was thought worthy to insert a clause, allowing the separate traders to continue their trade till Michaelmas 1711, but at the same time empowering the directors, upon three years notice, to redeem their capital of L. 7200, and thereby convert the whole capital of the company into a joint-flock. By the same act, the capital of the company, in consequence of a new loan to government, was augmented from L.2,000,000 to L.3,200,000. In 1743, another million was advanced to government. But this being raised, not by a call upon the proprietors, but by telling annuities and contracting bonds-debts, it did not augment the flock upon which the proprietors could claim a dividend. Thus, however, their trading flock was augmented; it being equally liable with the other L.3,200,000, to the losses sustained, and debts contracted, by the company in the prosecution of their mercantile projects. From 1708, or at least from 1711, this company being freed from all competitors, and fully established in the monopoly of the English commerce to the East Indies, carried on a successful trade; and from their profits made annually a moderate dividend to their proprietors. Unhappily, however, in a short time an inclination for war and conquests began to take place among their servants; which, though it put them in possession of extensive territories and vast nominal revenues, yet embarrassed their affairs in such manner, that till this day they have not been able to recover themselves. The particulars of these wars are given under the articles Britain, and Indostan. Here it will be sufficient to observe, that they originated during the war in 1741 through the ambition of M. Duplex, the French governor of Pondicherry, who involved the company in the politics and disputes of the Indian princes. After carrying on hostilities for some time with various successe, they at last lost Madras, at that time the principal settlement in the East Indies, but it was restored by the treaty of Aix-la-Chapelle. During the war of 1755, they acquired the revenues of a rich and extensive territory, amounting, as was then said, to nearly L.3,000,000 per annum. For several years they remained in quiet possession of the revenue arising from this territory; though it certainly never answered the expectations that had been formed concerning it. But in 1767 the British ministry laid claim to the territorial possessions of the company.

about L.439,000.

The profits of

the company, too,

according to the evidence of their chairman before the

house of commons amounted to at least L. 400,000

per annum ; their accountant made it L.500,000; and

the lowest account stated it at least equal to the high-
est dividend paid to their proprietors. Notwithstanding

this apparent wealth, however, the affairs of the

company from this time fell into disorder; insomuch that

in 1773 their debts were augmented by an arrear to

the treasury in the payment of the L. 400,000

fipulated; by another to the customhouse for duties un-
paid; by a large sum borrowed from the bank; and

by bills drawn upon them from India to the amount of

more than L. 1,200,000. Thus they were not only obliged to reduce their dividend all at once to six

per cent. but to apply to government for alfliance. A

particular account of this transaction is given under the

article BRITAIN. Here it may be mentioned in general,

that the event proved very unfavourable to the

company, as they were now subjected to an interference

of government altogether unknown before. Several

important alterations were made in their constitution

both at home and abroad. The settlements of Madras

Bombay, and Calcutta, which had hitherto been entirely

independent of one another, were subjected to a govern-

nor-general, allified by a council of four affiliates. The

nomination of the first governor and council, who were

to reside at Calcutta, was affirmed by parliament; the

power of the court of Calcutta, which had gradually

extended its jurisdiction over the rest, was now redu-

ced and confined to the trial of mercantile causes, the

purpose for which it was originally instituted. In-

stead of it a new supreme court of judicature was esta-

blifhed, consisting of a chief justice and three judges

to-be appointed by the crown. Besides these altera-

tions, the stock necessary to intitle any proprietor to

vote at the general courts was raised from L. 500 to

L. 1000. To vote on this qualification, too, it was

necessary that he should have poifessed it, if acquired

by his own purchases and not by inheritance, for at

least one year, instead of six months, the term requisite

formerly. The court of 24 directors had before

been chosen annually; but it was now enacted, that

each director should for the future be chosen* for four

years; six of them, however, to go out of office by

rotation every year, and not to be capable of being re-

chosen at the election of the new directors for the

enuing year. It was expected that, in consequence of

these alterations, the courts both of proprietors and
directors would be likely to act with more
dignity and steadiness than formerly. But this was

far from being the case. The company and its serv-

ants showed the utmost indifference about the happi-

ness or misery of the people who had the misfortune

to be subjected to their jurisdiction. This indifference,

too, was more likely to be increased than diminished

by some of the new regulations. The house of com-

mons, for instance, had resolved, that when the

L.1,600,000 lent to the company by government should

be paid, and their bond-debts reduced to L.1,300,000,

they might then, and not till then, divide eight per

cent. upon their capital; and that whatever remained

of their revenues and nett profits at home should be

divided into four parts; three of them to be paid into

the exchequer for the use of the public, and the fourth
to be referred as a fund, either for the further reduc-

tion of their bond-debts, or for the discharge of other

contingent exigencies which the company might labour

under. But it could scarce be expected that, if

the company were bad rewards and bad sovereigns

when the whole of their nett revenue and profits be-

longed to themselves, they would be better when three

fourths of these belonged to other people. The regu-

lations of 1773, therefore, did not put an end to the

troubles of the company. Among other institutions,

it had been at this time enacted, that the presidency

of Bengal should have a superiority over the other pre-

sidencies in the country; the salary of the chief juf1:

tice was fixed at L.8000 per annum, and those of the other

judges at L. 6000 each. In confequence of this act,

Sir Elijah Impey, who was created a baronet on the

occasion, set fail, with three other judges, for India

in the year 1774. The powers with which they were

invested were very extraordinary. They had the title

of His Majesty's Supreme Court of Judicature in

India. Civil law, common law, ecclesiastical, criminal,

and admiralty jurisdiction, belonged of right to them.

They were empowered to try Europeans on perfonal

actions, and to affefs damages, without a jury. Every

native, either directly or indirectly in the service of the

company, or in their territories, was made subject to

their jurisdiction, with a view to prevent the Euro-

peans from eluding justice under the pretenfe of em-

ploying natives in the commifion of their crimes; so

that in fact they were absolute lords and sovereigns of

the whole country.

Such excessive and unlimited powers conferred on

any small number of men, could not but be extremely

disagreeable to the Europeans, who had been accustom-

ted to enjoy a liberty almost equally unbounded before;

nor was it to be supposed that the judges, thus sud-

ddenly raised from the rank of subjects to the height of

despotism, would always use their power in an unexcep-

}
Company: [231]

The design of the establishment was to preserve the commerce and revenues of the company from depreciation, by subjecting its servants to the control of the court; to relieve the subject from oppression by facilitating the means of redress; and to fix a regular course of justice for the security of liberty and property. In the event of considering the circumstances of the country, however, or the manners and customs of the natives, the judges now precipitously introduced the British laws in their full extent, without the least modification to render them agreeable to the Asiatics, who had been accustomed to others of a quite different nature; nor did they even pay the least regard to the religious institutions or habits to which the Indians are so obdurately attached, that they would sooner part with life itself than break through an article of them.

Besides this it was said, that, on the first arrival of the judges, they endeavoured to extend their authority beyond even what the British legislature had allowed them. Hence they were frequently at variance with the council; and complaints of their conduct were repeatedly sent to England by the servants of the company. These produced a letter in 1777 from the directors to Lord Weymouth, secretary of state for the southern department. In this they stated, that the supreme court of India had extended its jurisdiction to those whom it did not appear to have been the intention of the king or parliament to subject to its authority. It had also taken cognizance of matters which, they apprehended, belonged properly to other courts. That the judges considered the criminal law of England as in force, and binding on the natives of Bengal, though utterly repugnant to the laws and customs by which they had hitherto been governed; and that the jurisdiction exercised by the supreme court was incompatible with the powers given by parliament to the governor-general and council, obstructed the administration of government, and tended to alienate the minds of the natives; all which they feared would prevent the establishment of the government of India upon any settled or permanent foundation.

This letter not having produced any effect, the discontent of India, both in the Europeans and natives, continued and increased. The decisions of the judges were such as by no means did them honour. A number of petitions had also been brought along with them in hopes of enriching themselves under the new constitution. Some of these were of the lowest sort of people, who had rendered it in a manner impossible for them to remain in England on account of their vices or extravagance. Many such persons had enrolled themselves among the domestics of the judges, or had become their immediate dependants; and some of these were permitted to assume the characters of attorneys, court-officers, under-sheriffs, and bailiffs. It may easily be supposed, that people of such characters would find it for their interest to promote suits in the supreme court; and in this some of them employed themselves with great success. The consequence of it was, with the consent of the Directors, in December 1780, a petition was presented against the supreme court by a great number of British inhabitants in the kingdoms of Bengal, Bahar, and Orixa. In this, complaint was made of the indiscriminate manner in which the Judges of the supreme court attempted to exercise the English laws in that country, at the same time that they refused the undoubted right of every British subject, viz. that of trial by jury. They intreated the house to fix on the innumerable hardships which must ensue, and the universal confusion which must be occasioned, by giving to the voluminous laws of England a boundless retrospective power in the midst of Asia, and by an application of those laws made for the freest and most enlightened people on earth, the principle of whose constitution was founded on virtue and liberty, to transactions with the natives of India, who had, from time immemorial, lived under a despotick government founded on fear and restraint. What must be the terrors of individuals to find their titles to property, and their transactions with the natives previous to the establishment of this court of judicature, tried by the standard of the English law, and by men educated under its forms, and unwillingly imbuing its prejudices, when no such laws could be known to or practised by the natives or Europeans then residing in the country, and that at a time when there were few persons of legal knowledge in the country to advise or assist them? No tyranny could be more fatal in its consequences, than that a court, invested with all the authority of one of the first courts in England, should also possess undefined powers and jurisdiction, of which its judges were the sole interpreters, and at such an immense distance from the mother country. This was in truth the situation of the British subjects in India at that time; for the judges of the supreme court could at pleasure determine on the denomination of a civil jury, the degree of guilt incurred by any offence, the statute by which it should be tried, what penalties should be inflicted, as well as who were and who were not amenable to the jurisdiction of the court.

"Besides their other powers also, the judges of the supreme court were allowed to sit as a court of chancery, and in that capacity to revise, correct, recede, or confirm the decisions passed by themselves as a court of law; and, by another part of their constitution, they were allowed to stop execution in criminal causes until his Majesty's pleasure was known. The petitioners conceived, that there must be some fundamental error in that institution, which required a more than ordinary degree of temper, integrity, and ability, to carry its purposes into execution; and they did not hesitate to declare, that to administer the powers appertaining to the institution of the supreme court, without committing flagrant acts of injustice, and doing great detriment to the public, required more equity, moderation, discernment, and enlightened abilities, than they could hope to find in any set of men." They concluded with earnestly soliciting parliament, that a trial by jury might be granted to the British subjects in Bengal, in all causes where it was established by law in England; that the retrospective powers of the supreme court might be limited to the time of its establishment in Bengal; that it should be defined beyond the power of the judicial selection, who the persons were that properly came under the jurisdiction of the court, and who did not; that it should be expressly declared what statutes should, and what should not, be in force in Bengal; that distinct and separate judges for
This petition was soon followed by another signed by Warren Hastings, Esq; governor-general, Philip Francis and Edward Wheelier, Esqs; counsellors for the government and presidency of Fort-William in Bengal, in which they represented, "that though the jurisdiction of the supreme court of judicature at Calcutta, as well as the powers granted to the governor-general and council, were clearly limited by parliament and the king's letters patent, yet the chief justice and judges of that court had exercised authority over persons not legally within their jurisdiction, and had illegally and improperly advised and admitted suits against the governor-general and council; that they had attempted to execute their writs upon natives of high rank in the kingdom of Bengal, who were not within their jurisdiction: the governor and council therefore had found themselves under a necessity of opposing them, and of affording protection to the country and people, who were placed under their own immediate inspection, and freeing them from the terrors of a new and usurped dominion. They had even been obliged to make use of a military force, in order to resist the proceedings of the judges and their officers; and they declared, that no other conduct could have saved those provinces and the interests of the company, or of the British nation itself, from the ruin with which they were threatened. They also declared themselves to be of opinion, that the attempt to extend, to the inhabitants of those provinces, the jurisdiction of the supreme court of judicature, and the authority of the English law, which were still more intolerable than the law itself, would be such a constraint on the minds of the people of those provinces, by the difference of such laws and forms from their laws, that they might at last inflame them, notwithstanding their known mildness and patience, into an open rebellion." The petition was concluded, by soliciting an indemnity from the legal consequences of the refusal they had been obliged to make to that court.

While the British were thus expressing their displeasure against the conduct of those judges, the natives were thrown into the utmost consternation and despair by the acts of oppression and violence committed by them. A prosecution for forgery had been commenced against Nundcomar, a bramin of the fourth rank in Bengal. The crime was not capital by the laws of Hindostan, and had been committed many years before; yet with the utmost cruelty and injustice was this man condemned and executed on the British statute, by which forgery is made capital; a statute which, at the commision of the crime, he had never heard of, nor could ever dream that he would be subjected to its power. What rendered this execution the more remarkable was, that, at the very time when charge of forgery was brought against him, Nundcomar had been employed in exhibiting an accusation against Mr. Hastings. This, together with the hurry in which the court were to have him put to death (for the court refused to allow him a reprieve till his Majesty's pleasure was known), made the natives conclude, that he was executed, not on account of the forgery, but for having ventured to prefer an accusation against an English governor. In other respects they were terrified to such a degree, that many of them ran into the river on seeing a bramin put to death with such circumstances of ignominy.

The alarm excited by the execution of Nundcomar was kept up by fresh decisions of the supreme court. Among those the Patna caufe, as it is commonly called, was one of the most remarkable. An adventurer, named Shahaz Beg Cawn, had come from Cutch in Persia to Bengal, where he entered himself in the service of the company, and was preferred to the command of a body of horse. Having gained a competent fortune, and obtained from the Mogul a grant of lands called an Uultumghaw in the province of Bahar, he retired from the army, and settled in Patna. About this time, when advanced in years, he married a woman of low rank, named Nadara Begum, by whom he had no children. His brother, Allum Beg, came likewise to Patna; and on his leaving the place some time after, committed the care of one of his sons, named Behader Beg, to his brother Shahaz Beg Cawn. On the death of the latter in 1776, a dispute ensued concerning the inheritance between the widow and Behader Beg. The widow having taken possession of the whole property of Shahaz, the nephew, as adopted son and heir, gave in a petition to the provincial council at Patna, on the 2d of January 1777, setting forth his claim. In this petition he stated, that the widow was removing and secreting the effects of the deceased; and concluded, with a prayer, that orders should be given to prevent their removal; to recover such as had already been carried away; and that the cadi or Indian judge should be directed to ascertain his right. As the parties were Mahometants, the council of course referred the caufe to the cadi and two mufties, the proper officers for determining it according to the established laws of the country. These having inquired into the matter, reported, that the title-deeds, on which the widow pretended to found her right, appeared to be forged; and that, even if they had appeared in the lifetime of Shahaz, they were still informal, on account of a point of the Mahometan law, which requires, that to make deeds of gift valid, possession should be entered into at the time of executing or delivering them over; but that, as no possession of this kind had been given, the estate ought to be divided according to the Mahometan law; viz. one-fourth to the wife, and three-fourths to the nephew, as the representative of his father Allum Beg, who was considered as the more immediate heir of the deceased. This decision was confirmed by the council of Patna, with the following exception in favour of the widow, that the heir at law should pay her one-fourth of the rents of the ultumghaw, or royal grant, for her support during life. The widow, however, refused to submit to the decision, or to deliver up the effects of her husband; in consequence of which compulsory methods were used; when, by the advice of some English lawyers, an action of trespass was brought, according to the law of England, against the cadi and two mufties for their proceedings against her, laying the damages at about 66,000 l. Sterling. This process being brought before the supreme court, was by them conducted in such a manner as must entail everlasting infamy...
Company. infamy on the actors. They began with obliging the cadi and mufties to find bail in no less than 40,000 pounds for their appearance, which was immediately given by the council at Patna. The supreme court then having entered into the merits of the case, and decided the matter in the most rigorous manner, according to all the forms of English law, sentenced the cadi and mufties in damages to no less than 30,000l. Sterling. Their houses and effects were seized by the sheriff's officers, and publicly put up to sale: the cadi, who was upwards of 60 years of age, and had been in office for many years with great applause, died on his way to the common gaol at Calcutta, to which the nephew and two mufties were conveyed, being a distance of no less than 400 miles from their former residence at Patna. A fair, however, was commenced against the widow, on account of having forged the title-deeds by which she claimed her husband's fortune; which was afterwards sold at Patna in the manner of a public auction. The cadi, and mufties in damages to no less than 30,000l. Sterling.

Besides all this, the natives themselves testified their disapprobation of the conduct of the supreme court in very strong terms. A petition to his Britannic majesty was sent by the natives of Patna, in which are the following remarkable passages: “When the ordinances of this court of judicature were first introduced, as they were all contrary to the customs, modes, usages, and institutions of this country, they occasioned terror in us; and day by day, as the powers of this court have become more established, our ruin, uneasiness, dishonour, and discredit, have accumulated; till at last we are reduced to such a situation, that we consider death to us as infinitely preferable to the dread we entertain of the court: for from this court no credit or character is left to us, and we are now driven to the last extremity. Several who possessed means and ability, deeming flight as their only security, have banished themselves from the country; but bound as we are by poverty and inability, and fettered by the dearest ties of confanguinity, we do not all of us profess the means of flight, nor have we power to abide the oppression of this court.”—“If, which God forbid! it should so happen, that this our petition should not be accepted, and should be rejected at the chamber of audience, those amongst us who have power and ability, disdaining all affection for our families, will fly to any quarter we can; whilst the remainder, who have no means or ability, giving themselves up with pious resignation to their fate, will sit down in expectation of death.”

These repeated complaints could not but be taken notice of in parliament. On the 12th of February 1781, General Smith made a motion in the house of commons, that the petition from the British inhabitants of Bengal, Bahar, and Orixa, should be taken into consideration by a select committee, consisting of 15 persons, chosen by ballot. In the introduction to his motion, he stated briefly the bad conduct of the supreme court in the particulars already related; and concluded, that the affairs of Bengal required the immediate attention and consideration of parliament. The matter was accordingly debated; when, after various proposals, a motion was at length made by General Smith, for leave to bring in a bill “to explain and amend so much of an act passed in the 13th year of his present majesty, for the better regulation of the East India Company, ...
The debates on this subject were attended with the most violent charges against the minister, and afflicting the most humiliating and disgraceful to the British nation. Mr. Townshend affirmed, that it was from the minister’s screening the delinquents who came from India that all the evils in that quarter had originated; and if matters were suffered to go on in that country, as they had done for some time past, the conduct of the British in the East Indies must be viewed in a light still more detestable than that of the Spaniards in America. It was reported, that the nabob of Arcot had several members in the house of commons! If it were true, that by fending over a sum of money to England he could feat eight or ten members in that house, then Mr. Townshend declared, that in his opinion they were the most abject and contemptible beings in the world.—The bill for regulating the powers of the supreme court, also, though so evidently founded in reason and justice, did not pass without opposition, particularly from Mr. Dunning; who was thought on this occasion to have allowed his regard for his friend Sir Elijah Impey, the chief justice, to bias him too much.

The regulations just mentioned did not yet put an end to the troubles of the East India company, nor alay the ferment which had been so effectually excited. Their affairs were still a subject of parliamentary discussion; and in the month of April 1782, a motion was made by Mr. Dundas, then Lord Advocate of Scotland, for taking into consideration the several reports concerning affairs, which had been made by the secret committee appointed to inquire into them during the late and present session of parliament. In his speech on this occasion, he remarked, that the opinion of Lord Clive had been against keeping too extensive a territory in that country. Instead of this, he had restored Sojah Dowlat to the possession of his country; considering the British territories in Hindostan, with those on the coasts of Coromandel and Bombay, as sufficient for all the purposes by which this country could be benefited; but instead of adhering to the maxims of sound policy laid

Company, laid down by his Lordship, they had become so ambitious of extending their territories, that they had involved themselves in a war with almost all India. He then considered the finances of the company. The revenue of Bombay, he said, fell short of the necessary civil and military establishment by L. 200,000 a year, which was annually drawn from Bengal. With regard to that of Madras, it appeared, on an average of 12 years, from 1767 to 1779, that there had been eight years of war and only four of peace; and that, during the whole time of war, the revenue had not been able to support the civil and military establishments; though, in time of peace, it was able to do nearly one-half more. Bengal, however, was the most lucrative of all the East India settlements; but such had been the expences of the Mahratta war, that the support of the civil and military establishments; though, or Aurungzebe, and prefer frantic military exploits of the company; by which try, had so far derogated from the country.-General Sir Laurence East, as to accept of a place from the company; by which example."  

Elijah Impey, his majesty's chief justice, some had been ruined, and others died in jail. From all which considerations he moved, that the affairs of the company ought to be taken into consideration by the committee of the whole house. Some hints were thrown out by Mr. Dundas, that the territorial possessions in the East ought to be taken from the company entirely, and put under the direction of the crown; but this was opposed by Mr. Fox, as furnishing ministers with such ample means of corruption and undue influence, as might overthrow the constitution entirely. For this reason, he thought it would be more prudent to leave the appointment of its own servants to the company; but at the same time to keep a watchful eye over them, in order to be able to punish and remove those who should be found delinquent.  

The house having resolved itself into a committee, a motion was made by General Smith, "That Warren Hastings, Esq.; governor-general of Bengal, and Sir Elijah Impey, the chief justice, appear to have been concerned more distinctly the powers of the governor-general and council of Bengal; and votes of censure against Laurence Sullivan, Esq; chairman of the East India company, for having neglected to transmit to India an act for explaining and amending the act for regulating the affairs of the company, and for the relief of certain persons imprisoned at Calcutta. Among the number of this gentleman's transgressions, also, was his imposing an oath of secrecy on Mr. Wilkes, one of the company's clerks; and especially his refraining him from giving information to a select committee of the house of commons."  

Mr. Dundas having made several motions tending to criminate Sir Thomas Rumbold, formerly governor of Bengal, a bill was brought in, and passed into a law, for refraining him and Peter Ring, Esq; from going out of the kingdom for the space of one year, for discovering their estates, &c. An address was also presented to the king, requesting him to recall Sir Elijah Impey from India, in order to answer for high crimes and misdemeanors. A number of other resolutions were now passed by the house, in consequence of motions by Mr. Dundas, and which were founded on the reports of the Secret Committee. Among these it was resolved, "That the orders of the Court of Directors of the East India Company, which have conveyed to their servants abroad a prohibitory condemnation of all schemes of conquest and enlargement of dominion, by prescribing certain rules and boundaries for the operation of their military force, were founded no less in wisdom and policy than in justice and moderation. That every transgression of these orders, without evident necessity, by any of the several governments in India, has been highly reprehensible, and tended in a great degree to weaken the force and influence, and to diminish the influence of the company in those parts. That every interference of the company as a party in the domestic or national quarrels of the country powers, and all new engagements with them in offensive alliance, have been wildly and providentially forbidden by the company in their commands to their administrations in India. That every unnecessary deviation from these rules should be severely reproved and punished. That the maintenance of an inviolable character for moderation and good faith, and to prevent the company from being taken for the model of any other Europeans; and that the danger and detriment arising from the forfeiture of this pre-eminence, could not be compensated by the temporary success of any plan of violence and injustice. That should any relaxation take place, without sufficient cause, in those principles of good government in the part of the directors themselves, it would bring upon them, in a heavier degree, the renunciation of the legislative power of their country. That the conduct of the company, and their servants in India, in various instances specified, was contrary to policy and good faith; the company's favours in their presidency of Bombay, had been guilty of notorious instances of disobedience to the orders of their employers, particularly in forming an alliance with Raja, or Ragonant Row; that they had undertaken, without any adequate military force, or certainty of a sufficient revenue, and without proper communication with the superior government upon which they were to depend for sanction and support, to reinstate the
Company, unfurper above mentioned, and thereby to involve themselves in a war with the ruling ministers of the Mahratta state, while Ragobah himself was not in the mean time able to give the company any secure possession of the grants he had made to them for the purchase of their assistance. That it was the opinion of the house, that all the disasters in which the British empire in the East was involved, had proceeded from the unjustifiable manner in which the Mahrattas had been treated, and the conduct of the Madras presidency in other respects specified. That it is the opinion of this house, that it must be reckoned among the additional mischiefs arising chiefly from the provident war with the Mahrattas, that the military force of the Carnatic had been weakened by reinforcements sent to the Malabar coast; that the Bengal government had been under a necessity of supporting, on their confines, the army of a power confederated against them (A); that they had been under the necessity of fixing for the mediation of the same power; had submitted to a refusal, and purchased at last an uncertain, because apparently an unauthorized, treaty, on most extravagant and dishonourable conditions, with Chimnaghee the rajah of Berar’s son; and, finally, that being burdened with the expences of a variety of distant expeditions, while there allies were in difficulties, and their tributaries under oppression, there was also an alarming deficiency in the resources of revenue and commerce, by the accumulation of their debts, and the reduction of their infettment. That it was the opinion of the house, that an attempt made by the government-general, in the beginning of January 1761, to form an engagement of alliance, offensive and defensive, with the Dutch East India company, in the manner stated by the proceedings of their council, was unwarranted, impolitic, extravagant, and unjust.

Th ese severe censures extended even to the directors themselves, whose conduct on some occasions was declared to be indefensible, as well as that of their servants and agents. It was also resolved, “That Warren Hastings, Esq.; governor-general of Bengal, and William Hornby, Esq.; president of the council of Bombay, having, in sundry instances, acted in a manner repugnant to the honour and policy of this nation, and thereby brought great calamities on India, and enormous expenses on the India company, it was the duty of the directors to purifie all legal and ethical means for the removal of the said governor-general and president from their offices, and to recall them to Britain.”

The commons having thus seriously entered into a consideration of East India affairs, soon found still more abundant reason for censure. It was discovered, that corruption, fraud, and injustice, had pervaded every department. It had become an object with the servants of the company to oppress the natives by every possible method. They monopolized every article of trade, and seemed to have no other principle of commerce but lawful violence; the Court of Directors sent out instructions; but for the most part without any effect. Though the delegated administration of India ought to have preferred the strictest obedience to that of Britain; yet, being at so great a distance from the seat of supreme authority, and being possessed of endless means of abuse, it had become corrupt in an extreme degree. Instead of being subservient to government at home, the administration of India affected independence. The maxims of Mr Hastings were arbitrary; and he seemed to have no inclination to obey. He treated with sovereign contempt the authority of the Court of Directors; and the confusion produced by the disputes between them were fostered by the body of India proprietors, who were disposed to act as a check upon the directors. The necessity of new regulations in the government of India was universally admitted; and a bill for this purpose was accordingly brought in by Mr London. His propositions were, that the governor and council of Bengal should have a controlling power and jurisdiction over the inferior dependencies of India; and he was of opinion, that the governor-general should be invested with a power to act even against the will and opinion of the council, whenever he should imagine, by so doing, he could contribute to the public good; though, in these cases, he alone should be responsible for the event. With regard to the inferior governors, though he did not think it proper that they should be authorized to act contrary to the advice of the council, he was of opinion, that they ought to have a right of negativing every proposition, until application was made to the governor-general and council of Bengal. With regard to the Zemindaries, and other tenures of land, he observed, that when Hindostan had been conquered by the Moguls, a tribute was imposed upon the Zemindars; and while they continued to pay this tribute, they accounted themselves to be the real proprietors and masters of the lands they possessed. The people called Kyat, to whom these Zemindaries were let out, considered themselves likewise as secure in their posessions, while they performed the articles of their respective contracts. Of late, however, these rights had been infringed; and the Mogul came to consider himself as the absolute master of all the soil of Hindostan; which maxim he was inclined to destroy, and erect upon it another, that might secure the land-holders in their property. He proposed to secure the nabob of Arcot and rajah of Tanjore in their territories, by making an act of parliament in favour of the latter; but was of opinion, that the debts of these princes ought not to be too nicely inquired into, as the greatest part of them originated in corruption. He was clearly of opinion, however, that Governor Hastings ought to be recalled; and that steps ought to be taken to prevent the court of proprietors from prevailing to act in contradiction to parliament. Lord Cornwallis appeared to be the most proper successor to Mr Hastings. His personal honour, and that of his ancestors, were pledges for his good behaviour; and being independent in his fortune, he could have no view of repairing his estate out of the spoils of India; and from his profession, he could add to the character of governor that of com-

(A) The power here alluded to was Movdajee Boosla, Rajah of Berar. See INDOSTAN.
This is not a valid question. The text is not a question and does not require a response. If you have a question or need help with something else, please let me know.
The chairman, the pleasure of any five commissioners, and were disqualified from sitting in the house of commons. The whole system of government thus proposed, was to continue for the space of three or five years.

This was accompanied with another bill, the principal design of which was to preclude all arbitrary and despotic proceedings from the administration of the company's territorial possessions. By this the powers of the governor-general and supreme council were arrested, and more exactly than had hitherto been done; it deprived the governor-general of all power of acting independent of his council; proscribed the delegation of any trust; and declared every British power in the East incompetent to the acquisition or exchange of any territory in behalf of the company, to the time everything was anarchy and acceding person removed for misdemeanor, relating to the Zemindars, or native landholders, who were now to be secured by every nabob of Arcot and the rajah of Tanjore; disqualified proprietors themselves, endeavoured to promote the trade present for terminating the disputes between the former, he said, after his demission.

During the course of the debates on this bill, Mr Fox set forth the affairs of the company as in the year 1757, according to an account of the government for customs. He took notice also, that during for his friends.

On the other hand, the requisite assistance was a matter of very extensive consideration. It would be absolutely necessary to permit the acceptance of the bills to the above-mentioned amount; and to do this without regulating their affairs, and reforming the abuses of their government, would only be to throw away the public money.

The conduct of the company's servants, and of the company itself, was now arraigned by Mr Fox in the most severe terms; and their misconducts were pointed out under the following heads:

1. With regard to Mr Haftings.—The chairman of the committee had moved in the house of commons, that it was the duty of the company to recall that gentleman; to which motion the house had agreed. In obedience to this resolution, the directors agreed that Mr Haftings should be recalled: but supposing this to be a matter rather beyond their jurisdiction, they had submitted their determination to a court of proprietors, who refixed the resolution of the directors; and after this the whole affair came to be laid before the house of commons. In the mean time every thing was anarchy and confusion in the East, owing to this unsettled conduct with regard to the governor; as the whole continent had been made acquainted with the resolution of the house for recalling him, while that of the proprietors for continuing him in his office was kept a secret. The proprietors had also been guilty of another contradiction in this respect, as they had voted their thanks to Mr Haftings for his conduct in India. Hence Mr Fox was led to comment on the nature of the company's settlements. Mr Haftings, to send two gentlemen, Hastings, to Oude, the one to reside with the nabob of Oude, the other at Benares. Mr Haftings, however, refused to mend them: the directors transmitted the most positive orders to carry the vote of the supreme council into execution; but still Mr Haftings disobeyed; alleging in his defence, that he could not employ persons in whom he had no confidence. Afterwards, however, Mr Haftings seemed to contradict himself in a very curious manner. He granted Mr Fowke a contract, with a commiss of 15 per cent.; which, he observed, was a great sum, and might operate as a temptation to prolong the war.

"But (added he) the entire confidence I have in the integrity and honour of Mr Fowke, amounts to a full and perfect security on that head."

To this Mr Fox added some other instances of a similar kind; but though he supported these and the projected bill with all the argument and eloquence for which he is so remarkable, he found it impossible to make his scheme agreeable to the majority of the house. The strongest opponent was Mr William Pitt, who...
Company, who insisted chiefly on the two following topics. 1. its infringement, or rather annihilation of the company's charter; and, 2. The new and unconstitutional influence it tended to create.—He owned indeed, that India stood in need of a reform, but not such a one as broke through every principle of justice and reason. The charter of the company was a fair purchase from the public, and an equal compact for reciprocal advantages between the proprietors and the nation at large; but if it was infringed in the manner proposed by the bill, what security could other trading companies have that they should not be treated in the same manner? Nay, what security could there be for Magna Charta itself? The bill, he said, amounted to a confiscation of property. It had been suggested indeed, that it was not a bill of disfranchisement, because he did not take from the proprietors their right to an exclusive trade: but this was not the only franchise of the proprietors. A freehold might have a franchise annexed to it, the latter of which might be taken away, and yet the property of the former remain; in which case it could not be denied that the freeholders would have great cause to complain. The case was exactly parallel with the India lobby. Persons polluted of this to a certain amount, were invited to a vote upon every important question of the company's affairs: and on this account the purchase money was more considerable. But, by the bill in question, this privilege was to be taken away; which plainly amounted to a disfranchisement.

The great objection to this bill, however, seemed to be a suffocation it was a scheme of Mr Fox to gratify his own personal ambition as a politician, and the influence of which might overturn the crown and subvert the constitution of Britain. A petition was presented from the proprietors, and deputations from the directors of the company, representing the bill as subversive of their charter, and confiscating their property, without either charge of delinquency, trial, or conviction. They prayed, therefore, that the acts of delinquency prefixed against them might be stated in writing, and a reasonable time allowed them to deliver in their answer; and that they might be heard by counsel against the bill. About the same time the directors gave in a slate of the company's affairs, differing in the most extraordinary manner from that given by Mr Fox. In this they represented the creditor side of the account as amounting to £1,051,151,771, and they brought themselves in debtors to the amount of £10,284,000; so that of confluence there was a balance in their favour of £95,616,481. This was vehemently contested by the secretary, who said he could bring objections to the statement of the directors to the amount of more than £12,000,000 Sterling. He then entered into a particular discussion of the articles stated in the director's account, and made good his assertion. Objections to his method of calculation, however, were made on the part of the company; so that nothing could certainly appear to the public but that the company were at that time much distreßed, and would fail entirely unless powerfully supported by government.

Mr Fox now proceeded to a particular refutation of the arguments brought against the bill; in which indeed he displayed an astonishing force of argument and acuteness of reasoning. The objection drawn from the validity of the company's charter, he set aside, by showing that the company had abused their power, and that it was therefore necessary to take it from them. This he said always had been the case, and must be the case, in a free nation; and he brought the example of James II., who, on account of the abuse of his power, had been deprived of it by the nation at large. The case was the same with the company. They had made a bad use of their power, and therefore the nation at large ought to deprive them of it. It had been objected by the country gentlemen that the bill augmented the influence of the crown too much; and by Mr Dundas, that it reduced it to nothing. Both these objections, he said, were overturned by the circumstance of making the commissioners hold their office only during good behaviour. Thus, when conscious that they were liable to punishment if guilty, but secure in case they faithfully discharged their trust, they would be liable to no seduction, but would execute their functions with glory to themselves, and for the common good of their country and of mankind. He then drew a comparison between his own bill and that of Mr Dundas already mentioned. The bill of the latter, he said, had created a despotic authority in one man over some millions of his fellow-creatures; not indeed in England, where the remedy against oppression was always at hand; but in the East Indies, where violence, fraud, and mischief every where prevailed. Thus the bill proposed by Mr Dundas afforded the most extensive latitude for malversation, while his own guarded against it with every possible care; as was insinuated in its confiding in the crown. He affirmed that there was not in India a prince, state, or potentate, with whom the company had come into contact, whom they had not fold; that there was not a single treaty they had ever made which they had not broken; and that there was not a prince or state that had ever put any confidence in the company who had not been ruined. With regard to the first article Mr Burke insulted the fate of the Great Mogul himself; or the Robill; the nabob of Bengal; the polygars of the Mahratta empire; Ragobah the pretender to that empire; and the Subah of Deccan.

—The second article was proved by a review of the transactions from the beginning to the end of the Marlborough war. With regard to the third, viz. the ruin of such princes as put any confidence in the company or their servants, he desired them to look into the history and situation of the nabob of Oude. In the year 1779, this country had been visited by a famine; a calamity which had been known to relax the severity
Company
city even of the most rigorous government; yet in this situation the president of Bengal had put an absolute negative upon the representation of the prince; adding, That perhaps expedients might be found for affording him a gradual relief; but their effect must be distant. This distant relief, however, never arrived, and the country was ruined.

Our limits cannot allow a particular detail of the charges against the company on the one hand, or the defences on the other. In general, it must appear, that such severe and heavy charges could not be advanced without some foundation, though perhaps they may have been considerably exaggerated by the orators who brought them. The picture drawn by Mr Burke on this occasion indeed was shocking. "The Arabs, Tatars, and Persians, had conquered Indostan with vast effusion of blood; while the conquest of the English had been acquired by artifice and fraud, rather than by open force. The Asiatic conquerors, however, had soon abated of their ferocity; and the short life of man had been sufficient to repair the waste they had occasioned." But with the English the case had been entirely different. Their conquests were still in the same state they had been 20 years ago. They had no more society with the people than if they still resided in England; but, with the view of making fortunes, rolled on in one after another, wave after wave; so that there was nothing before the eyes of the natives but an endless prospect of new flights of birds of prey and passage, with appetites continually renewing for a food that was continually waiting. Every rupee gained by an Englishman in India was for ever lost to that country. With us there were no retributory superstitions, by which a foundation of charity compensated, for ages, to the poor, for the injustice and rapine of a day. With us no pride erected stately monuments, which repaired the mischiefs pride had occasioned, and adorned a country out of its own spoils. England had created no churches, no hospitals, no palaces, no schools (the trifling foundation at Calcutta excepted); England had built no bridges, made no high roads, cut no navigations, dug no reservoirs. Every other conqueror of every other description had left some monument either of state or beneficence behind him; but were we to be driven out of India this day, nothing would remain to tell that it had been pollied, during the inglorious period of our domination, by any thing better than the orient panting or the tiger?

All this eloquence, however, was at present entirely ineffectual, and the bill was finally rejected: much confusion and altercation ensued, which terminated in a change of ministry and dissolution of parliament. On the 26th of May 1784, a petition from the company was presented to the house of commons, praying for such relief as the nature of their affairs might seem to demand. This was followed on the 24th of June by a bill for allowing the company to divide four per cent, for the half year concluding with midsummer 1784. This having passed, after some debate, a new bill was proposed by Mr Pitt for relieving the company in the mean time, and regulating their affairs in time to come. A bill to this purpose had been brought in during the last session of the former parliament by the same gentleman, which he wished to bring to a comparison with that of Mr Fox, of which an account has already been given. In this bill he began with laying it down as a principle, that "the civil and military government of India, or, in other words, the imperial dominion of our territories in the East, ought to be placed under other control than that of the merchants in Leadenhall street; and this control could be no other than the executive branch of the constitution. The commerce of the company, however, ought to be left as free from restrictions as possible; and, lastly, capricious effects from the government of India upon the constitution of Britain, were to be carefully avoided. A control in the executive branch of the legislature over the government of India had indeed been established by the regulation bill of 1773; but the former interference of ministers had not been beneficial, because it had not been active and vigilant. He now proposed, therefore, that a board should be instituted expressly for the purpose. This board was to be appointed by the king, and to consist of the secretary of state for the home department, the chancellor of the exchequer, and a certain number of the privy council. To this board the dispatches of the company were to be committed, and were not to be sent to India until they were countersigned by them. To prevent questions concerning the commercial and political concerns of the company, it was proposed, that the dispatches upon the former subject should be submitted to the board; and that, in case of any difference, an appeal should be made to the king in council. Though he (Mr Pitt) had not thought proper to accept of the proposal of the company to yield the appointment of foreign councils to the crown, he was nevertheless clearly of opinion, that the commander in chief ought to be appointed by the king. He proposed also that this commander should have a vote in council next to the president; that the king should be empowered to below the reversion of his office; that the king might recall the governor-general, the presidents, and any members of their councils. He yielded the appointment of all officers, with the single exceptions he had stated to the court of directors, subject, however, to the approbation of the king; and that, in case of a negative, the directors should proceed to a second choice, and so on. He deprived the court of proprietors of their privilege of confirming or altering the proceedings of their court of directors; and with respect to the foreign government, he was of opinion, that their authority should comprise in it a considerable discretion, accompanied with the restraint of responsibility. He proposed, that there should be a revision of the establishments in India with a view to reformations; that appointments should take place by graduation; and that a new and summary tribunal should be erected for the trial of offences committed in that country. With regard to the Zemindaries, though he could not help paying a compliment to Mr Fox, on his intention of reforming them to their proper owners, he yet thought that a general and indiscriminate restitution was as bad as an indiscriminate confiscation. He therefore proposed, that an inquiry should be instituted for the purpose of reforming such as had been irregularly and unjustly deprived, and that they should in time to come be secured against violence.

In the bill of 1784 few alterations were made; and thefe
months after his arrival; one copy of which was to be kept in the court of exchequer, and the other at the India-office. The board of control, the court of directors, or any three of the proprietors whose stock should amount together to 10,000l. were allowed to move the court of exchequer to examine the validity of the account. In case of an apparently well-founded accusation, the court of exchequer were allowed to examine the party upon oath, and even to imprison him until the interrogatories proposed to him should be answered. The whole property of a person who should neglect to give in such an account within the time limited, or who should have been guilty of a misrepresentation in that account to the amount of 2,000l. sterling, was ordered to be confiscated; ten per cent. to be paid to the accuser, and the remainder to be equally divided between the public and the company. Every person who had once been employed in India, but had afterwards resided in Europe for five years, unless such residence had been expressly on account of his health, was declared incapable of being sent out to India again.

As a farther curb on the company's servants, the attorney-general or court of directors was authorized to file an information in the court of King's bench against any person for crimes committed in India. That court was empowered also to imprison or admit the accused to bail immediately. It was then ordered, that within 30 days a certain number of peers should be chosen by the house of lords, and of the members of the house of commons by that house, to constitute a court for the trial of the accused. The court was finally to consist of three judges appointed by the crown, four peers, and six members of the house of commons; and the accused had a right to a peremptory challenge. From this court there was no appeal; and it was empowered to adjudge the party incapable of ever serving the company; to punish by fine or imprisonment; and in order to proportion the fine to the property of the convict, the court of exchequer might, at the requisition of the attorney-general, or of the company, examine him upon oath concerning the sums he was worth. A refusal to answer was to be punished with confiscation of property, and imprisonment during pleasure.

With regard to the treatment of delinquents in India, Mr. Pitt observed, that at that time we had it not in our power to punish them. Either a new process must therefore be instituted, or offences, equally shocking to humanity, and contrary to every principle of religion and justice, must be permitted to continue unchecked. Every person therefore who went hereafter, would know the predicament in which he stood; and would understand, that by so doing he agreed to give up some of the most valuable privileges of an Englishman: yet in this he would do no more than a very numerous and honorable body of men, the military, did daily, without the least hesitation, or the slightest impeachment of their character.

This bill, so tremendous in its appearance to the company's servants, was vehemently opposed by the minority. Mr. Francis observed, that it went upon two principles, viz. the abuse of power abroad, and the want of it at home. To remedy there, Mr. Pitt had proposed to augment the power abroad, and to
for the purpose of receiving presents of power Company. supposed that there diminution that at home. He condemned the unlimited destruction that it was intended to fet aside the directors at home and the government abroad, in order to throw the whole power into the hands of a military commander. Though he approved of the clause by which schemes of conquest and extension of territory were condemned, he remarked, that it was essentially destructive in other respects; as alluding to facts and offences which were not described, and to criminals whom, so far from punishing, it did not venture to describe. With respect to the affair of precepts, he confided that his opinion was rather singular. He was for an unlimited prohibition to men in high stations; but in the ordinary transactions of business, he was of opinion that they were useful, without giving room for any just apprehensions. The government of India, as it was now constituted, was a government of favour, and not of justice; and nothing would be done for the natives unless the persons who forwarded their affairs were gratified. In the mean time, however, the exception in favour of precepts of ceremony was founded upon ideas which he knew to be fallacious, and was even calculated to render the prohibition itself useless and inefficient. For the purpose of receiving presents of ceremony, all occasions would be sufficiently solemn. He warmly cenfured also the power of imprisonment given to the respective prefidencies, and he condemned the institution of the new court of judicature as unnecessary, arbitrary, and dangerous.

By Mr Fox the bill was so highly disapproved of, that he objected to the house going into a committee upon it. He endeavoured to show, that instead of diminishing, it was calculated to increase the calamities of the East; and instead of reforming, to perpetuate the abuses so much complained of. The board of control, he said, provided for a weak government at home by a division of power; and if there were a receipt or a nootrom for making a weak government, it was by giving the power of contriving measures to one, and the nomination of the persons who were to execute them to another. The negative given to the commissioners operated as a complete annihilation of the company, and the chartered rights so much vaunted of. The bill was a scheme of dark and delusive art, and took away the rights of the company by slow and gradual sap. The first step was originally to contrive measures without the knowledge of the company; and the next, to convey order; secretly to India, at the very time perhaps that the commissioners were openly giving countenance to orders of a quite different tendency sent from the directors. With regard to the new tribunal, he confidered it as in truth a screen for delinquents; since no man was to be tried but on the accusation of the company or of the attorney-general; in which case he had only to conciliate government in order to remain in perfect security.

The opposition of Mr Fox's party against this bill proved as fruifef as their efforts had been in favour of the other. The house divided on the speaker's leaving the chair; when the motion was carried by a majority of 215. Still however, all parts of the bill were warmly debated. In the course of conversation upon this subject, Mr Dempfter expressed a with that Company, the king could be requested to send over one of his sons to become sovereign of that country. They might then enter into a federal union, and enjoy all the benefits that could be derived from the inhabitants of the East by europeans, viz. those of commerce. The clauses relative to the native princes and hereditary farmers were all withdrawn at the motion of Mr Dum-das; and under the head of presents, the exception in favour of those of ceremony was withdrawn. That clause, which insisted on all persons returning from India to give an account of the value of their certificates upon oath, was severely cenfured by Mr Dempfter and Mr Eden; and after some debate was entirely withdrawn, as was also the idea of making the person take the oath when required by the board of control. Mr Pitt then proposed, that persons who had passed five years in India, and accumulated no more than L. 5000 for that time, or double that sum for the next five years, should be exempted from all precaution on the score of their fortunes. But on a suggestion by Mr Atkinson, that, in case of default, it might not be practicable for a person arriving from India to give in an account upon oath in the space of two months; on which suggestion, a power was granted to the court of exchequer for extending the term from time to time as they should think proper. It had been the original idea of the chancellor, that this jurisdiction should take place in twelve months; and it had been objected, that thus persons would be deprived of the trial by jury, without being granted to them to choose whether they would submit to the condition. Mr Pitt now moved, that no account upon oath should be required of any person who should arrive from India before the first of January 1789. This amendment was likewise cenfured by opposition, as holding out an indemnity to peculators, and a warning for them to return within the assigned period. It was remarked by Mr Sheridan, that by the bill before the house, a person who took the oath would be liable all his lifetime to a prosecution for perjury. He could therefore make no settlement of his fortune; he could not sell or mortgage his estate, as nobody would have any thing to do with a property which was still liable to contain and forfeit. This representation produced another amendment limiting the commencement of a prosecution to the period of three years. The clause prohibiting the return of any person to India under certain conditions, was also mitigated by two amendments from the chancellor; one of them exempting the officers of the king from its operation; and the other permitting the restitution of any person with the consent of the directors, and three-fourths of the court of proprietors.

With these amendments the bill finally passed the house of commons on the 28th of July. On being carried up to the house of lords, it met with a very vigorous opposition; the principal speakers against it being Lord Stormont and the Earl of Carlavle. The former animadverted upon the principle of seniority establisht by it; which he laid was particularly ill-faied to the critical posture of their affairs at present in India; and he affirmed, that had such a clause been in effect at the time that Lord Clive first entered into the company's service, there would not
have been an inch of the territorial posessions at present belonging to Britain. It would damp the ardour of emulation, check the rising spirit of the youth now in Asia, and that at a time when the most extraordinary talents were necessary to raise them from their insipidous and ruined condition. He objected also to the power of recall in the board of control; which, he said, was by no means a sufficient check upon the company's servants in India. The dilance of time and place, he said, were so great, that a recall from India could not have the least effect. But these remonstrances had very little weight with the house; the bill being finally passed on the 9th of August.

Some years after this, however, a declaratory law was found necessary, in consequence of a controvery which had arisen between the board of control and the company. It had been resolved, in the month of October 1757, when his Majesty had reason to be alarmed, and to look with more than common anxiety to the safety and preservation of every part of the Britih dominions, to send four additional regiments for the better protection of their Indian posessions; nor was the design taken up as a temporary, but with a view to a permanent establishment of his Majesty's troops in India. At that time, no unwillingness to receive the regiments on board the company's ships, and provide for their support in India, had been intimated by the court of directors; but, on the contrary, the measure had been considered as a wise one, and the suggestion of it had given universal satisfaction. Since, however, the threatening form had been dispersed, far different sentiments prevailed. Some of the directors, at least, were of opinion, that unless they made a requisition to government for further military assistance, they had it in their option to bear, or to refuse to bear, the expense of any additional regiments of his Majesty's army which might be sent to India; and this opinion seemed to be, in a great measure, grounded on the act of 1751, by which the East India company were bound to pay for each of his Majesty's regiments as had, by their directors, been declared unfit to be trusted with them. Was it likely, that, when they provided for the better management of the political and military concerns, they had paid no attention to the circumstance upon which these concerns inseparably depended? The board of control had already proceeded to reduce the enormous establishments in India; their right of interference in that respect had never been questioned; and what indeed would be the consequence of denying this right? The court of directors, if they had it in their power, as the expiration of their charter drew near, and it was doubtful whether their monopoly would be renewed, would certainly make it their object to swell the amount of their imports, and would neglect the care of the territorial and political state of India. The duty of administration was to look, first, to the prosperity and happiness of the natives; secondly, to the security of the territorial posessions; thirdly, to the discharge of the debts due to the partners who had advanced their money, and enabled the company to struggle with their late difficulties; and, in the last place, to the commercial benefit of the proprietors. Was it probable that the court of directors would act upon that scale? Could it have been intended to confine in their discretion? It had been said, that the powers attributed to the board of control were the same in substance as had before been given to the secretaries of state and the lords of the treasury. But the fact was otherwise. The court of directors had been obliged to communicate their dispatches previous to their going to India; but there was no obligation upon the secretary of state to give any directions concerning them. The responsibility had ordinarily rested, under the former government, with the court of directors; under the present it was wholly vested with the board of control.

An
An objection had been stated, that the declaratory bill conveyed to the king the power of maintaining an army without the consent of parliament. No proposition (Mr Pitt opposed) could be more adverse to his intentions than that which was thus imposed to him. But in reality the troops in question had already been recognized by parliament when they voted the estimate for raising them; and the number of king's regiments served in India would always be to be ascertained by the company belonging to each, which remained in England for the purpose of recruiting, and the expense of which would be to be provided for by parliament.

Mr Pitt acknowledged, that it had been the object of the act of 1784 to assume the power of superintendence and control, without alluming the power of patronage. In the present bill he declared, that every thing had been done which his understanding had suggested for the diminution of patronage. The regiments in question belonged to the crown; and of course it could not be supposed that the sovereign could entirely depart from his prerogative of naming his own officers, but the king had acted with the most gracious attention to the company, and to the merits of the officers who had grown grey in their service; having relinquished nearly half the patronage of the regiments, and leaving the dispat of these commissions to the court of directors. The company indeed alleged that they had 600 officers unemployed; but the king could not forget that he had 2800 officers upon half-pay, not perhaps more meritorious, but certainly not less than those in the company's service, and many of whom had actually served with distinction in India. Such had been the forbearance he had thought it proper to exercise upon the subject of patronage. But if, by the objection that had been started, it was intended to refer to the great political patronage, this he did not deny that he had at all times intended to assume. Men who were responsible for the government of a country, ought undoubtedly to have the appointment of those whom they were to entrust with the execution of their orders. But it would be admitted that the patronage left to the company was very considerable, when the great extent of their military establishment was properly recollected. Mr Pitt added, that the objections that were started on this head would possibly throw difficulties in the way of the consolidation of the two armies in India; an object on many accounts desirable, and which in some way or other must be attempted. If it should be thought advisable to make the whole army royal, then undoubtedly the patronage of the crown would be greatly increased. He believed, however, that the measure was necessary; and there was scarcely any thing to which he would not assent, to remove the apprehensions of the nation respecting the undue use of this patronage. For the bill now before the house, Mr Pitt professed himself ready to propone clauses that should annihilate every suspicion of danger.

The speech of Mr Pitt produced a favourable effect upon the country gentlemen; and the clauses which he had alluded to being moved, were received without any debate. These provided, that no king's troops, beyond the number which was now proposed, should be sent to India under the authority of any existing law:

That no increase of salary should be given to any of the servants of the company, without the dispatches for that purpose being laid before both houses of parliament thirty days previous to their being sent; and that no emolument should be given, as a profit for which did not originate with the court of directors. A fourth clause was added to these by the mischief, which had not precisely the same object: it directed, that an account of the revenues and disbursements of the company should be laid before parliament at a certain assigned period in the course of every year.

The bill was carried up to the house of lords on the 14th of March, read a first time on the following day, which was Saturday, and proposed for a second reading on the ensuing Monday. This precipitation was made the subject of a petition, offered by certain proprietors, and presented to the house by the Duke of Norfolk, in which they requested a delay of three days, till a general meeting could be held of the proprietors of the East India company. To this suggestion it was objected by Lord Thurlow and Lord Hawkesbury, that the ships of the East India company were now detained in port at the enormous expense of three or four hundred pounds per diem. By Lord Stormont and Lord Loughborough it was replied, that no expense, however great, ought to weigh in the consideration of the present question. The bill decided upon a matter of private right, and parliament could not justly refuse to hear the petitioners. The house divided upon the question, contents 32, not contents 75. A motion of Lord Porchester was rejected by a similar majority, for referring a question to the twelve judges respecting the true meaning and intent of the act of 1784.

The Duke of Richmond said, that he was peculiarly circumstanced on the present occasion, since he had never beenpleased with any of the bills for the government of India that had yet been brought into parliament. He had ever been of opinion, that the concerns of the East were trusted in the best hands when they were vested in the company itself. He had opposed the bill of 1783, because it flagrantly violated the charter of the company, and placed an immense power in the hands of a commission, that was not responsible, so far as he could find, either to the king or the parliament. He had opposed the act of 1784, because it gave to the crown an enormous addition of power. But he could not admit that that act was in any degree so violent and despotical as the bill which preceded it. The declaratory measure now under consideration must necessarily have his complete approbation. It consisted of two distinct parts: its exposition of the act of 1784, and certain enabling clauses containing checks and restraints upon the extensive patronage that the government of the East naturally gave. To the former part he must inevitably agree. That the act of 1784 gave to the board of control complete authority, had always been his opinion. For that reason he had opposed it: but, entertaining that opinion, he must justify the present bill, which in his mind was a true declaration of the fact. He could not but equally approve of the restraints that were proposed upon the exercise of patronage. Patronage was inseparable from power. But when he saw the
Company with which it was limited, and ministers were tied down from the abuse of it; when he saw that it was not to be used otherwise than for the good of the service, he could not view the present measure with the same jealousy with which he was accustomed to regard propositions for extending the power of the crown.

The bill, however, underwent a severe discussion in this as it had done in the other house; but at length failed.

In May following a petition was presented to the house of commons by the company, stating certain pecuniary embarrassments which they apprehended to take place on the first of March 1790, owing to the arrears of the war, to the government claim of L. 500,000, to the debt incurred in China, and to the advances necessary to be made for the purposes of the China trade. In compliance with their petition, Mr Pitt moved on the following day that they should be empowered to borrow a sum not exceeding L. 1,200,000. He at the same time observed, that in all probability the company in 1791 would have upwards of L. 3,000,000 Sterling, more than sufficient to discharge their debts. The measure was carried thro' both houses without opposition.

3. Hudson's Bay Company. The vast countries which surround Hudson's Bay abound with animals whose furs and skins are excellent, being far superior in quality to those found in less northerly regions. In 1670, a charter was granted to a company, which does not consist of above nine or ten persons, for the exclusive trade to this bay; and they have acted under it ever since with great benefit to themselves. The company employ four ships and 150 seamen. They have several forts, viz. Prince of Wales's fort, Churchill river, Nelson, New Severn, and Albany, which stand on the west side of the bay, and are garrisoned by 186 men. The French, in May 1782, took and destroyed these forts, and the fortifications, &c. valued at 500,000l. They export commodities to the value of 16,000l. and bring home returns to the value of 29,340l. which yield the revenue 3374l. This includes the fisheries in Hudson's Bay. This commerce, small as it is, affords immense profits to the company, and even some advantages to Great Britain in general; for the commodities they exchange with the Indians for their skins and furs, are all manufactured in Britain; and as the Indians are not very nice in their choice, such things are sent of which they have the greatest plenty, and which, in the mercantile phrase, are drugs with them. Though the workmanship too happens to be in many respects so deficient that no civilized people would take it off their hands, it may be admired among the Indians. On the other hand, the skins and furs brought from Hudson's Bay, enter largely into the British manufactures, and afford materials for trading with many nations of Europe to great advantage. These circumstances tend to prove incontrovertibly the immense benefit that would redound to Great Britain, by throwing open the trade to Hudson's Bay, since even in its present restrained state it is so advantageous. This company, it is probable, do not find their trade so advantageous now as it was before the English got possession of Canada. The only attempt made to trade with Labrador has been directed towards the fisheries, the annual produce of which exceeds 40,000l.

The above are the principal trading companies presently subsisting in Great Britain; but to the number might have been added one of vast importance, the Scotch Darien Company, had it not been for the crooked and punnanimous policy of the English ministry at the time. For an account of which, see the article DARIEN.

Greenland Company. See Greenland.

Banking Companies. See Bank.

Of establishments similar to the above in other countries, the following, belonging to the Dutch and French, may be mentioned as the most important.

1. Dutch Companies. 1. Their East India company had its rise in the midst of the struggle which that people had for their liberty; for the Spaniards having forbidden all commerce with them, and that upon all their ports, necessity inspired some Zealanders to seek a new north-east passage to China. This enterprize proving unsuccessful to three several armaments in 1594, 1595, and 1596, a second company was formed under the name of the Company of remote Ports; which, in 1595, took the ordinary route of the Portuguese to the Indies, and returned in two years and a half's time with little gain but good hopes.

This company, and a new one just established at Amsterdam, being united, equipped other fleets; and these occasioned other companies at Amsterdam, Rotterdam, in Zealand, &c. infomuch that the states soon began to apprehend they might be prejudicial to each other. Under this concern, they called all the directors of the several companies together, who all consented to an union; the treaty whereof was confirmed by the states in 1602; a very remarkable epocha, as being that of the most solid and celebrated establishment of commerce that ever was in the world.

Its first capital was six millions fix hundred thousand gilders. It had sixty directors, divided into several chambers; twenty in that of Amsterdam, twelve in that of Zealand, fourteen in that of Delft and Rotterdam, and a like number in those at Sluys and Horn. As each grant expires, the company is obliged to procure a new one, which it has already done five times since the first, paying a considerable sum each time. The last application was in 1773, when the company, after stating that its trade had declined, solicited the states-general to grant a diminution of the sum formerly paid for the renewal of the charter. Upon this representation, their high mightiness, in order to have time to enquire into the matter, prolonged the charter for three years, upon the old establishment; and finding upon examination, that the company had really sustained great losses, and its trade considerably declined, they acted with the spirit of a wise commercial commonwealth, by complying with the company's request. They therefore, in 1776, granted them a new charter for 50 years, on the same terms as the former, on the immediate payment of 2,000,000 of florins, instead of 3,000,000 which they paid before; and the sum of 360,000 florins yearly; which annual pay-
payment they were allowed to make either in money or merchandise. In consequence of this indulgence, the flock of the company rose in a short time to less than 19 per cent.

Their factories, residences, &c. in the East Indies, are very numerous; reaching from the Persian gulf to the coast of China: the principal is that of Batavia, the centre of their commerce: here resides their general, with the state and splendor of a sovereign prince; making war and peace with the eastern kings and emperors at pleasure.

The other more considerable factories are, Tainan on the coast of China, Nagasaki in Japan, Malacca, Surat, Amboyna, Banda, Siam, Moluccas, &c. several on the coast of Coromandel, and at Ipanah, Cape of Good Hope, &c. in all, they number 40 factories and 25 fortresses. They have the whole trade of the spicery in their own hands.

2. Their West India Company was established in 1621, with an exclusive privilege to trade 24 years along the coasts of Africa, between the tropic of Cancer and the Cape of Good Hope; and in America from the south point of Newfoundland, through the straits of Magellan, that of Le Maire, or others, to the straits of Anian, both in the North and South Sea. The directors are divided into five chambers (as in the East India company), out of which 19 are chosen for the general direction of affairs. In 1647, the company renewed its grant for 25 years; but it was scarce able to hold out the term, on account of its great loaves and expenses in taking the bay of Todos los Santos, Fernambuc, and the greatest part of Brazil, from the Portuguese. The weakness of this company, which had several times in vain attempted to be joined to that of the East Indies, occasioned its dissolution at the expiration of its grant.

In 1674, a new company, composed of the ancient proprietors and their creditors, was settled in the same rights and establishment with the former; and still subsists, though considerably decayed. Their first capital was about six millions of florins. Its principal establishments are, one at Cape Verd, another on the Gold Coast of Africa, at Tobago, Carafao, &c. in America.

II. French Companies. 1. Their East India Company was established in 1664 with an exclusive privilege to trade for 50 years in all the seas of the East Indies and South Sea. No adventurer to be admitted without 1000 livres in stock; and foreigners who have 20,000 livres in stock to be reputed regicides.

The parent grants them the island of Madagascar; and the king to be at one-fifth of the expense of the three first armament, without interest: the principal to be refunded in ten years; or, if the company find it loses on the whole, the loss to fall on the king's side.

The capital fund of the company, which was most furnish of the king, was seven or eight million of livres, but was to have been fifteen millions.

In effect, though no means were wanting to support the company, yet it still drooped and still struggled: till having subsisted ten years without any change in its form, and being no longer able to discharge its engagements, there were new regulations concerted, but to little purpose. At length, things not being disposed for a new East India company, nor much good to be expected from the old one, in 1708 the ministry allowed the directors to treat with the rich traders of St Malo, and resign to them their privilege under certain conditions. In the hands of these last, the company began to flourish. See India Company, below.

Its chief factory is at Pondicherry, on the coast of Coromandel. This is the residence of the director-general; the other factories are inconsiderable. The mercantile which the company brings into France are, silk, cotton, spices, coffee, rice, nutmegs; several kinds of gums and drugs, wood, wax, printed calicoes, mullins, &c.

2. Their West India Company was established in 1664. Their charter gave them the property and feignory of Canada, Acadia, the Antilles islands, Isle of Cayenne, and the Terra Firma of America, from the river of the Amazons to that of Oroonoque; with an exclusive privilege for the commerce of those places, as also of Senegal and the coasts of Guinea, for 40 years, only paying half the duties. The stock of the company was so considerable, that in less than six months 45 vessels were equipped; wherewith they took possession of all the places in their grant, and settled a commerce: yet this only subsisted nine years. In 1674, the grant was revoked, and the countries above reunited to the king's dominions as before; the king reimbursing the actions of the adventurers. This revocation was owing partly to the poverty of the company, occasioned by its loites in the wars with England, which had necessitated it to borrow above a million, and even to alienate its exclusive privilege for the coasts of Guinea: and partly to its having in good measure answered its end; which was to recover the commerce of the West Indies from the Dutch, who had torn from them: for the French merchants, being now accustomed to traffic to the Antilles, by permission of the company, were so attached to it, that it was not doubted they would support the commerce after the dissolution of the company.

3. Their Mississippi Company was first established in 1684 in favour of the Chevalier de la Salle; who having projected it in 1669, and being appointed governor of the fort of Frontignac at the mouth of that river, travelled over the country in the year 1683, and returned to France to solicit the establishment. This obtained, he set sail for his new colony with four vessels laden with inhabitants, &c. but entering the Gulph of Mexico, he did not, it seems, know the river that had cost him so much fatigue, but settled on another river unknown, where his colony perished by degrees; so that in 1685 there were not 100 persons remaining. Making several expeditions to find the Mississippi, he was killed in one of them by a party who mistook him against him: whereupon the colony was deserted and lost. M. Filiberville afterwards succeeded better. He found the Mississippi, built a fort, and settled a French colony there; but he being poisoned, it is said, by the intrigues of the Spaniards, who feared such a neighbour, in 1712 M. Crozat had the whole property of trading to the French territories called Louisiana granted him for 15 years.

4. Company of the West. In 1717, the Sieur Crozat surrendered his grant; and in the same year a new
Company was erected under the title of Company of the West, to which, besides every thing granted to the former company, was added the commerce of beavers, enjoyed by the Canada company from the year 1706, but expiring in 1717. In this establishment, an equal view was had to the finances and the commerce of the nation, and accordingly, part of the conditions of its establishment regarded the settling of a colony, a trade, &c. the other the vending part of the bills, called bills of flate, which could no longer sublind on their present footing. The former are no more than are usual in such establishments: for the latter, the actions are fixed at 500 livres, each payable in bills of flate, the actions to be esteemed as merchandise, and in that quality to be bought, fold, and trafficked. The bills of flate, which make the fund of the actions, to be converted into yearly revenue. To put the finishing hand to the company, in 1717 its fund was fixed at an hundred millions of livres, which being filled, the cash was shut up.

5. India Company. The junction of the former company with that of Canada was immediately followed by its union with that of Senegal, both in the year 1716, by an arrest of council; which at the same time granted the new company the commerce of beavers, and made itself mistress of the negro or Guinea trade to the French colonies in America.

Nothing was now wanting to its perfection but an union with the East India company, and with those of China and St. Domingo; which was effected, with the two first in 1719, and with the third in 1720. This union of the East India and China company with the company of the West, occasioned an alteration of the name; and it was henceforth called the India Company.

The reasons of the union were, the inability of the two former to carry on their commerce; the immense debts they had contracted in the Indies, especially the East company, complaints whereof had been sent to court by the Indians, which did not think the company so that they dared not appear any longer at Surat; the care they tooke to discharge their engagements; and their having transferred their privilege to the private traders of St. Malo, in consideration of a tenth in the profits of the returns of their ships.

The ancient actions of the company of the West, which were not at par when this engratment was projected, before it was completed, were risen to 300 per cent.; which unexpected successes gave occasion to conclude the new actions of the united companies would not bear less credit. The concourse of subscribers was so great, that in a month's time there were above fifty millions subscribed for the first twenty-five million actions which were granted to the India company, beyond the hundred millions of stock allowed the company of the West, being filled as soon as the books were opened: to satisfy the earnestness of the subscribers, the stock was increased by several arrests to three hundred millions. Credit still increasing, the new actions rose to 1200 per cent. and those of the ancient company of the West to 1900 per cent.; an exorbitant price, to which no other company ever rose. Its condition was now so flourishing, that in 1719 it offered the king to take a leaf of all his farms for nine years, at the rate of three millions five hundred thousand livres; per annum; more than had been given since; and also to lend his majesty twelve hundred millions of livres to pay the debts of the state. These offers were accepted; and the king, in consideration hereof, granted them all the privileges of the several grants of the companies united to that company to the year 1770; on condition, however, of discharging all the debts of the old East India company, without any deduction at all. The loan of twelve hundred millions not being sufficient for the occasions of the state, was augmented three months afterwards, with three hundred millions more; which, with the former loan, and another of one hundred millions before, made sixteen hundred millions, for which the king was to pay interest at the rate of three per cent.

The Duke of Orleans, in February 1720, did the company the honour to preside in their assembly, where he made several proposals to them on the part of the king: the principal of these was, that they should take on them the charge and administration of the royal bank. This was accepted of; and Mr Law, comptroller-general of the finances, was named by the king inspector-general of the India company and bank united.

This union, which it was proposed, should have been a mutual help to both those famous establishments, proved the fatal point from whence the fall of both commenced: from this time, both the bank bills and the actions of the company began to fall. In effect, the first perished absolutely; and the other had been drawn along with it but for the prudent precautions taken for its support.

The first precaution was the revoking the office of inspector-general, and the obliging Mr Law to quit the kingdom; the ancient directors were discarded, and new ones substituted; and, to find the bottom of the company's affairs, it was ordered they should give an account of what they had received and disbursed both on the account of the company and of the bank, which they had had the management of near twenty years. Another precaution to come at the late of the company was by endeavouring to distinguish the lawful actions from the Mississippi extortioners; whose immense riches, as well as their criminal address in realizing their actions either into specie or merchandise, were become so fatal to the flate; in order, if possible, to secure the honest adventurers in their stock. To this end, an inquisition was made into their books, &c. by persons appointed by the king; and the new directors, or as they were called, regisseurs, began seriously to look about for their commerce abroad. Their affairs, however, declined, and at length sunk into a ruined and bankrupt state about the year 1760. The king immediately suspended their exclusive privileges, and laid the trade to the catt open to all his subjects; confining, at the same time, the affairs of the company to the care of the ministry to adjust and settle. But the various schemes which were then formed for the restoration of the old company and the establishment of a new one, were accompanied with such insurmountable difficulties, as to prove wholly ineffectual. Nor was the laying open of the trade attended immediately with the successes that was expected; the merchants being very slow in engaging in it, though the king, by way of en-
Company, encouragement, lent them some of his own ships to convey their commodities to the East; and the garrison and civil establishments continued to be supported in their existing form by the crown. The measure, however, proved in time unsuccessful; so that for a course of years previous to 1785, the annual importation from India was considerably greater than during any former period. But whether it were that they regarded this prosperity as precarious; or that they aimed at more extensive successes; or that they wished, in imitation of Britain, for territorial acquisitions in that climate, and believed an incorporated society the best instrument of obtaining them; the French court was induced to listen to proposals for establishing a new East India Company. Their privilege was for seven years, with the special proviso, that years of war which might occur in the interim should be excluded from the computation.

In the preamble of the act of the 14th April 1785, by which the scheme was adopted, it was alleged, "that the commodities of Europe not having of late years been regulated by any common standard, or proportioned to the demands of India, had on the one hand sold at a low price; while, on the other, the competition of the subjects of France had raised the price of the objects of importation: that, upon their return home, a want of system and arrangement had been universally complained of, the market being glutted with one species of goods, and totally defective of another; that these defects must necessarily continue as long as the trade remained in private hands; and that, on their account, as well as that of the capital required, the establishment of a new company was absolutely necessary."

These reasonings did not appear altogether satisfactory to the persons principally interested. France has been so far enlightened by the discourses of the excellent writers who have produced upon questions of politics and commerce, as not to be prepared to behold the introduction of monopolies with a very favourable eye. By many persons it was remarked, that the arguments of the preamble did not apply more to the trade of India than any other trade; and that, if they were admitted in their entire force, they were calculated to give a finishing blow to the freedom of commerce. The capital of the new company, which amounted to £820,000, was ridiculed as altogether inadequate to the magnitude of the undertaking. The privileges with which it, so far as it was indulged, were as enormous. The monopoly of East India goods imported into France from any part of Europe, was granted to them for two years, as well as the monopoly of East India goods imported from the place of their growth. It was said, that during that period they would fit out no adventures for India; that they hoped to obtain a prolongation of this injurious indulgence; and that, of consequence, their incorporation was in reality a conspiracy to prevent all future communication between France and the sources of commerce in Asia. A provision in the act, directing that the prices of East India goods in the islands of Mauritius and Bourbon should be regulated by a tariff to be fixed by the court of Verfailles, excited still louder exclamations. In this instance, it was said, the first principles of commerce were trampled upon in a manner the most wanton and absurd. Instead of suffering it to find its own level by the mutual collision of the wants of one party and the labour of another, it was arbitrarily to be fashioned by a power whose extreme distance must necessarily render its decisions ill-timed and inapplicable. The very mode in which the monopoly was introduced was a subject of complaint. It was determined by a resolution of the king in council; a proceeding totally inadequate to the importance of the subject, and which was to be regarded as clandestine and surreptitious. In all former instances such measures assumed the form of edicts, and were registered in the parliaments. It was the prerogative of these courts to verify them; that is, to inquire into the facts which had led to their adoption. The injured parties had an opportunity of being heard before the privilege assumed the form of a law; not privately by the ministers of the sovereign, but publicly by the most considerable bodies in the kingdom, and in the face of the nation.

The act of council establishing a new East India company, was followed on the tenth of July by another declaration, intended still farther to promote their interest; by which it was expressly forbidden to import cottons, printed linens, and muslins, except through the medium of the company. The arrest proceeds upon the same principles of monopoly as in the former instance. It sets out indeed with a declaration, "that nothing can appear more desirable to the king, or better accord with the sentiments of his heart, than a general liberty, that freeing at once the circulation of commodities from every species of restraint, should seem to make of all the people of the world but one nation with respect to commerce." But it adds, "that the period of this liberty is not yet arrived; that it must either be, with respect to the nations of Europe, unlimited and reciprocal, or that it cannot be admitted; that the revocation of their former indulgence respecting cottons and linens was become necessary on account of the opportunities it created for contraband trade; and because the competition of the East India company and private traders would occasion a surplus in the market, and the admission of foreign manufactures would increase and annihilate the national industry."

The provisions that were made for carrying this law into effect were considered as unjust and severe. The merchants petitioning any of the prohibited commodities were allowed twelve months to dispose of them; but upon the express condition, that the commodities were to bear a stamp, importing that they were vendible only to a certain period, a circumstance that must necessarily depreciate their value. It was also enacted, that the house of any trader might be entered by day or by night, at the solicitation of the directors, to search for prohibited goods, which were to be confiscated to the use of the company. These kinds of visits of the officers of revenue, hitherto unauthorised in France, were represented as peculiarly obnoxious, when they were made for the sole benefit of a privilege monopoly.

Company, in military affairs, a small body of foot, commanded by a captain, who has under him a lieutenant and ensign.
The number of centinels or private soldiers in a company is from 50 to 100; and a battalion or regiment consists of 9, 10, or 11, such companies: one of which is always gendarmers, and posted on the right; next them stands the colonel's company, and on the left the light infantry company. Companies not incorporated into regiments are called irregulars, or independent companies.

Artillery Company. See Artillery.

Company of ships, a fleet of merchantmen, who make a charter party among themselves; the principal conditions whereof usually are, that certain vessels shall be acknowledged admiral, vice-admiral, and rear admiral; that such and such signals shall be observed; that those which bear no guns shall pay so much per cent. of their cargo; and in case they be attacked, that what damages are sustained shall be reimbursed by the company in general. In the Mediterranean, such companies are called conferences.

COMPARATIVE ANATOMY,

It is that branch of anatomy which considers the secondary objects, or the bodies of other animals; serving for the more accurate distinctions of several parts, and supplying the defects of human subjects.

It is otherwise called the anatomy of beasts, and sometimes zoology; and stands in contradistinction to human anatomy, or that branch of the art which considers the human body the primary object of anatomy. See Anatomy.

INTRODUCTION.

The principal advantages of comparative anatomy are the following: First, it furnishes us with a sufficient knowledge of the different parts of animals, to prevent our being imposed upon by those authors who have delineated and described several parts from brutes as belonging to the human body. Secondly, it helps us to understand several passages in the ancient writers in medicine, who have taken many of their descriptions from brutes and reinvented from them. The third and great use we reap from this science, is the light it casts on several functions in the human economy, about which there have been so many disputes among anatomists.

In this view it is altogether needless to insist on those parts whose use is usually understood when once their structure is unravelled: Thus, for instance, if we be acquainted with the action of the muscles in general, it will not be difficult to determine the use of any particular muscle whose origin and insertion is known, if we at the same time consider the various connections of the bones to which it is fixed, and the different degree of mobility they have with respect to each other. In the same manner, if we know the use of the nerves in general, we can easily assign the use of those nerves which are distributed to any particular part.

There is then no occasion for a complete osteology, myology, &c. of the several animals we shall treat of, nor need we trouble ourselves about the structure of any of the parts, unless when it serves to illustrate some of the fore-mentioned purposes.

That the first use we proposed from examining the structure of the parts in brutes is real and of consequence, is evident from looking into the works of some of the earliest and greatest masters of anatomy, who for want of human subjects have often borrowed their descriptions from other animals. The great Ve-salius, although he justly reproves Galen for this fault, is guilty of the same himself, as is plain from his delineations of the kidneys, urterns, the muscles of the eye, and some other parts. Nor is antiquity only to be charged with this, since in Willis's Anatomia Cerebrj (the plates of which were revised by that accurate anatomist Dr Lower) there are several of the pictures taken from different brutes, especially the dog, besides those he owns to be such. We shall give several examples of the second use in the sequel of the work.

The animal kingdom, as well as the vegetable, contains the most surprising variety, and the defects in ty and uniformity observable in it are almost imperceptible. The bat and flying-squirrel, though quadrupeds, have wings to buoy themselves up in the air. Some birds inhabit the waters; and there are fishes that have wings, and are not strangers to the airy regions; the amphibious animals blend the terrestrial and aquatic together.

As there is then such a vast variety, it is not only needless, but impossible, to consider all of them particularly. We shall take only some of the most remarkable genera; and hope, from what will be said of them, any of the intermediate degrees may be understood.

In treating of quadrupeds, we shall divide them into Division of the carnivorous, i.e. those that feed indiscriminately on animal and vegetable substances, and granivorous: as an instance of these last we shall take the ruminant kind. The fowls we shall also divide into those that feed on grain, and those that feed on flesh. The distinction we shall make in treating of fishes, shall be of those that have lungs, and those that have them not. The first indeed are with difficulty procured, and at the same time differ very little from quadrupeds. The structure of insects and worms is so very minute, that little attention for the ends proposed by the present subject has been expected from their anatomical investigation. As they constitute, however, one of the great classes into which animals are divided, and as every advance in knowledge, with respect to the structure of any one animal, must either directly or indirectly cast some light on the structure of some part of every other, we have thought proper to add a few particulars concerning them.

In inquiring into the structure of different animals, we ought to be previously acquainted with the form of their body, manner of life, kind of food; or, in short, with their natural history; which will lead us to account for the reason of their different structure, and hence explain the actions of the human body. Of all those particulars a detail will be found under the titles of the different subjects in their alphabetical order.
A question has been started by some fanciful philosophers, "Whether man is naturally a biped or a quadruped?" much ingenuity has been employed to establish the latter opinion. But it is presumed that few of their readers have been made converts to such an opinion, and that not many of ours will require much argument to persuade them of their erect definition. It may therefore suffice to observe, that this erect position is best adapted to the conformation of the human head, and the ponderous quantity of human brains:—that the articulation of the occipital with the first vertebrae of the neck, is differently constructed from that of quadrupeds, with the obvious design that man should be able to move his head in every direction with the greatest facility:—that the human species (and also monkeys) are deficient of that strong ligament or tendinous aponeurosis, vulgarly called fascias, which quadrupeds possesses (as a kind of stay-tape), to prevent the head from sinking to the earth; to which, from its natural position, it must be very prone:—and that our eyes and ears are, fortunately, not placed as those of the quadrupeds. The axis of the human eye is nearly perpendicular with a vertical position of the head; whereas, in the brute creation (the larger ape excepted), the position of the eyes forms an acute angle:—nature has also furnished other animals with a softmenforiurn occuli, a mucle which the erect attitude renders needful, though highly necessary in the prone; consequently, whoever tries the experiment will find that, in the inclined direction, both his eyes and his ears are in the most unfavourable situation possible for quick hearing or extensive vision. In fine, the shape, breadth, strength of the vertebrae of the back and loins, are all coincident with the erect attitude of the trunk.

All quadrupeds have a covering of hair, wool, &c. to defend them from the injures of the weather, which varies in thickness according to the season of the year and difference of the climate: thus in Russia and the northern countries, the furs are very thick and warm, while the little Spanish lap-dogs, and Barbary cows, have little or no hair at all.

The cutis and cuticula in quadrupeds are disposed much in the same way as the human, only more elastic; immediately under this, there is a very thin cutaneous muscular substance called panniculus carnosus, which is common to all quadrupeds, the porcine kind excepted; this principally covers the trunk, serving to shrivel the skin, in order to drive off insects, their tails and heads not being sufficient for this purpose, while their extremities are employed in their support and progression.

It has probably been from observing some muscles of the human body, such as the platysma myoides, cremaster, and frontales, and the collapsed tunica celluloa of emaciated subjects, to resemble this thin muscle, that some of the older anatomists reckoned such a panniculus among the common teguments of the human body. This Carusus Stephanus has well observed.

Moist part of quadrupeds want clavicles, whereby their anterior extremities fall upon their chief, so as to make their thorax proportionally narrower than the human. This small distance of their anterior extremities is very necessary for their uniform progression: apes indeed and squirrels have clavicles to allow them a more full use of their extremities in climbing; but when they walk on all-fours, they move but indifferently.

While some philosophers, as above noticed, have endeavoured to level man to the rank of quadrupeds, others have attempted to elevate certain of the brute creation to the same class with their reputed lords. The orang outang is ranged by Linnæus as congenerous with man, (See Homo); and some theorists have even considered him as the original flock of the human race, pretending that he has been the rais of the woods for many ages before gardens were ever thought of. His claims to humanity are founded on his being able to walk upright occasionally, being furnished with a competent share of muscles requisite for the purpose. The form of his heart, lungs, breast, brains, intestines, are similar to those of men; the omentum has also its peculiar vermetiformis; he can sit upright with great ease; shows more dexterity in his pains than his associates in the forests, and can handle a stick on occasion with tolerable dexterity. His disqualifications are the following:—The position of the faradumo magnu mos occipitis, which is farther backward than in the human species, and the sockets of his lower jaw, made to receive the dentes inferiores of the upper, indicate his relationship to the monkey breed. He has also thirteen ribs on each side; his arms, feet, and toes, are much longer than those of the human species, &c. and although his foot does not so closely resemble a hand as that of the ape, yet the pollicis pedis, or the great toe, is placed at a greater distance from the other toes, which gives it the appearance and use of a thumb. These differences indicate, that, although the orang can occasionally act the biped, yet he is much better qualified to walk on his fore-foot, and to climb trees, than the generality of the modern race of men. But an objection to his claims, still weightier than any of the differences stated above, arises from his want of speech. For there is no nation of men, however savage, that is deficient of speech; though individuals, secluded from society, may in time lose the faculty. No infiances are known in which a company of ten or twelve men have been without a language; but upwards of thirty of the orang species have been found in a herd, without showing the smallest traces of this faculty. It has been suggested by Rouillé, that they may have lost the power from their neglect of using it; but it is very singular that they alone should lose this power, and not that race of men to whom they are supposed to be so nearly related. This point, however, has been completely decided by the discoveries of professor Camper; who in a paper in the Philosophical Transactions has demonstrated, by an anatomical dissection of the organ of the voice, that articulation is rendered impossible in these animals in consequence of the structure of that organ. From the nature and situation of those parts in the orang (as well as in the ape and in the monkey) he has proved, that no modulation of the voice resembling human speech can be produced in these creatures, because the air, passing through the
Chap. I. COMPARATIVE ANATOMY.

Of Quadrupeds.

Rima glutinis, is immediately lost in two ventricles or hollow bags in the neck (which are sometimes united into one), with which all these animals are furnished, and which have a communication with the mouth through the fadum or slit; so that the air might return from thence, without any force or melody, within the throat and mouth of these creatures.

Sect. III. The Anatomy of a Dog.

We may first observe of this animal, as indeed of most quadrupeds, that its legs are much shorter in proportion to its trunk than in man; the length of whose legs depends entirely upon the length of his inferior extremities; however, to balance this, the trunk of the animal is proportionally longer and smaller, his spine more flexible, by which he is able at each step to bring his posterior extremities nearer to his anterior. His common tendons are much akin to those of other quadrupeds, only they allow little or no passage for sweat; but when he is over heated, the superfluous matter finds an exit by the salivary glands, for he lolls out his tongue and flavers plentifully. We are not, however, to suppose, that because a dog does not sweat, he has no insensible perspiration. That a dog perspires is evident, because one of these animals can trace another by the scent of his foot-steps; but that could not happen if a large quantity of perspirable matter was not constantly going off.

The pyramidal muscles are wanting, to supply which the rectus is injected deeply into the os pubis. The omentum reaches down to the os pubis, which considering the position of the animal we will find to be a wise provision, since its ufe is to separate an oily liquor for lubricating the guts and facilitating their peristaltic motion; so in our erect posture the natural gravity of the oil will determine it downward, but in the horizontal position of these creatures, if all the intestines were not covered, there would be no favourable derivation of the fluid to the guts lying in the posterior part of the abdomen, which is the highest; and besides, had the omentum reached much farther down in us, it would not only have supplied too great a quantity of oil to the lower part of the abdomen, but we would have been in continual danger of herniae; and even at present the omentum frequently puffs down with some of the other viscera, and forms part of these tumours. To these, however, the dog is not subject, as his viscera does not press so much on the rings of the abdominal muscles, and besides are prevented from passing through by a pendulous flap of fat, mentioned No. 53. The inferior and anterior lamella of the omentum is fixed to the spleen, fundus of the stomach, pylorus, liver, &c. in the same way as the human; but the superior having no colon to pass over, goes directly to the back-bone. This serves to explain the formation of the small omentum in the human body; which is nothing but the large omentum, having lost its fat, passing over the stomach and colon, where it reallmes its pignudo, so proceeds, and is firmly attached to the liver, spine, &c. The size of fat are pretty regularly disposed through it, accompanying the distribution of the blood-veiels to guard them from the presure of the superincumbent viscera.

This animal’s stomach, though pretty much resembling the human in its shape, is somewhat differently situated. It lies more longitudinal, as indeed all the other viscera do, to accommodate themselves to the shape of the cavity in which they are contained; that ventriculus, his inferior orifice is much farther down with respect to the superior than the human; by this means the grossest food has an easier passage into the duodenum.

Again, the fundus of the human stomach, when distended, stands almost directly forwards, which is occasioned by the little omentum tying it so close down to the back-bone, &c. at its two orifices; but it not being fixed in that manner in the dog, the fundus remains always posterior; this also answers very well the shape of the different cavities, the distance between the cardia and fundus being greater than that between the two sides. It seems to be much larger in proportion to the bulk of the animal than the human, that it might contain a greater quantity of food at once; which was very necessary, since this animal cannot at any time get its full measure as men do. The turbilium is not so large, nor is there any contraction forming the aus tum Wulleli, as in the stomach of man. It is considerably thicker and more muscular than ours, for breaking the cohesion of their food, which they swallow without sufficient chewing. Hence it is evident the force of the stomach is not so great as some would have it, nor its contraction so violent; otherwise that of dogs would be undoubtedly wounded by the sharp bones, &c. they always take down; for the contraction here is still greater than in the human stomach, which is much thinner. The rugae of the tunica villosa are neither so large, nor situated transversely, as in the human, but go from one orifice to the other; the reason of which difference is, perhaps, that they might be in less danger of being hurt by the hard substances this creature frequently feeds upon; and for the same reason there is not the like coaction at their pylorus.

The intestines of this animal are proportionally much shorter than ours; for the food which these creatures mostly use, soon dissolves, and then putrifies; on which account there was no occasion for a long track of intestines, but on the contrary that it should be quickly thrown out of the body. The fame is to be observed of all the carnivorous animals. The muscular coat of the intestines is also thicker and stronger than the human, to protrude the contents quickly and accurately.

The valvulae conniventia are less numerous, and in a longitudinal direction; and the whole track of the alimentary canal is covered with a slime, which lubricates the intestines, saves them from the acrimony of the excrementitious part, and facilitates its passage.

The duodenum differs considerably in its situation from the human. For in man it first mounts from the num pylorus upwards, backwards, and to the right side; then pales down by the gall-bladder; and, marching over the right kidney and superior part of the psoas muscles, makes a curvature upwards; and pales over the back-bone and vena cava inferior, to the left hypochondrium, where it gets through the omentum, mesentery, and mesocolon, to commence the jejenum, being firmly tied down all the way, the biliary and pancreatic ducts entering at its most depending part: Whereas, in the dog, the duodenum is fixed at the pylorus to the concave
CONCISE SURFACE OF THE LIVER, AND HANGS LOOSE AND PENDULOUS WITH THE MEFENTERY BACKWARDS INTO THE CAVITY OF THE ABDOMEN; THEN TURNING UP AGAIN, IS FIXED TO THE BACK BONE, WHERE IT ENDS IN THE JEJUNUM; THE BILE AND PANCREATIC JUICE ARE POURED INTO IT AT THE MOST DEPENDING PART. THEREFORE THE SAME INTENTION SEEMS TO HAVE BEEN HAD IN VIEW IN THE FORMATION OF THIS PART IN BOTH VIZ. THE GIVING THE CHYLE, AFTER THE LIQUEORS OF THE LIVER AND PANCREAS ARE POURED INTO IT, A DISADVANTAGEOUS COURSE, THAT IT MIGHT BE THE MORE INTIMATELY BLENDED WITH THE HUMOURS BEFORE ITS ENTRY INTO THE JEJUNUM, WHERE THE LADLEALS ARE VERY NUMEROUS: AND THIS, BY REASON OF THEIR DIFFERENT POTTURE, THE SAME DESIGN (THO' BY A VERY DIFFERENT ORDER OF THE PARTS) IS BROUGHT ABOUT IN BOTH.

The other small guts are much the same with ours, only shorter. The great guts are also shorter and less capacious than in the human body; and we take it for a general rule, that all animals that live on vegetable food, have not only their small guts considerably longer, but also their great guts more capacious than such creatures as feed on other animals. Hence man, from this form of his intestines, and that of the teeth, seems to have been originally designed for feeding on vegetables chiefly; and still the most of his food, and all his drink, is of that class.

The reason of this difference seems to be, that as animal food is not only much more easily reduced into chyle, but also more prone to putrefaction, too long a remora of the juices might occasion the worst consequences. So it was necessary that the receptacles should not be too capacious; but on the contrary, being short and narrow, might conduct to the reasonable discharge of their contents. Whereas vegetable food being more difficulty dissolved and converted into an animal nature, there was a necessity for such creatures as fed on it to be provided with a long intestinal canal, that this food in its passage might be considerably retarded, and have time to change its indoles into one more agreeable to our nature. Besides which there is another advantage which accrues to man in particular, from having his great guts very capacious: for as he is a rational being, and mostly employed in the functions of social life, it would have been very inconvenient as well as unbecoming for him to be too frequently employed in such ignoble exercises; so that, having this large reservoir for his faces alwine, he can retain them for a considerable time without any trouble.

The appendix vermiformis justly enough deserves the name of an intestinum cecum in this subject, though in the human body it does not; and it has probably been from the largeness of this part in this and some other animals, that the oldest anatomists came to reckon this small appendicle in man as one of the great guts. On its internal surface we observe a great number of mucous glands. As all these throw out flime, their principal office would seem to be the procuring a sufficient quantity of that matter for the purposes abovementioned. Still, however, there seems to be some unknown use for this organ in other animals; for the appendicula vermiformis in them is either of a great size or of great length. In a rat, it is rather larger than the stomach; in others, as swine, and some of the animals which live on vegetables, it has long convolutions, so that the food must be lodged in it for a long time. Thus, probably, some change takes place in the food, which requires a considerable time to effectuate, and, though unknown to us, may answer very useful purposes to the animal.

The colon has no longitudinal ligaments; and consequently this gut is not purged up into different bags or cells as the human: nor does this intestine make any circular turn round the abdomen; but passes directly across it to the top of the os sacrum, where it gets the name of rectum.

At the extremity of the intestinum reatum, or verge of the anus, there are found two bags or pouches, which contain a most abominable fetid mucus of a yellow colour, for which we know no use, unless it serves to lubricate the straitened extremity of the rectum, and defend it against the apertures of the faces, or to separate some liquor that might otherwise prove hurtful to their bodies. There is nothing analogous to those faces in the human subject, unless we reckon on the mucilaginous glands that are found most frequent and largest about the lower part of the rectum.

The mefentery is considerably longer than in the human body; that, in his horizontal situation, the intestines may rest more securely on the soft cushion of the abdominal muscles. The fat is here disposed in the same way, and for the same reason, as in the omentum. The interfaces between the fat are filled with a fine membrane. Instead of a great number of glandulæ vage to be found in the human mefentery, we find the glands few in number, and those are closely connected together; or there is only one large gland to be observed in the middle of the mefentery of a dog, which, from its imagined resemblance to the pancreas and the name of its discoverers, is called pancreas affelli; but the resemblance, if there is any, depends chiefly on the connection, the structure being entirely different. The reason why this in man is as it were subdivided into many smaller ones, may possibly be, that as the guts of a human body are proportionally much longer than those of this creature, it would have been inconvenient to have gathered all the lactea prima et genus into one place; whereas, by collecting a few of these vessels into a neighbouring gland, the same effect is procured much more easily. Whether the food in this animal needs less preparation in its passage through these glands, is a matter very much unknown to us; though it is certain that some changes really do take place.

The pancreas in man lies across the abdomen, tied down by the peritoneum; but the capacity of this creature's abdomen not allowing of that situation, it is disposed more longitudinally, being tied to the duodenum, which it accompanies for some way. Its duct enters the duodenum about an inch and a half below the ductus communis.}

The spleen of this animal differs from ours very much, both in figure and situation. It is much more oblong and thin, and lies more according to the length of the abdomen, like the pancreas. Though the spleen of this creature is not firmly tied to the diaphragm (which was necessary in our erect posture to hinder it from falling downwards), yet by the animal's prone position,
Of Quadrupeds.

LIVER.

The human liver has no sulphures or divisions, unless you please to reckon that small one between the two pyli, where the large vessels enter: whereas in a dog, and all other creatures that have a large flexion in their spine, as lions, leopards, cats, &c. the liver and lungs are divided into a great many lobes by deep fissures, reaching the large blood vessels, which in great motions of the back-bone may easily shuffe over one another; and so are in much less danger of being torn or bruised, than if they were formed of one entire piece, as we really see it is in horses, cows, and such creatures as have their back-bone stiff and immovable. There is here no ligamentum tendineum connecting the liver to the diaphragm, which in our situation was necessary to keep the viscera in its place: whereas in this creature, it naturally gravitates forwards, and by the horizontal position of the animal is in no danger of preffing against the vena cava; the preventing of which is one use generally affigned to this ligament in man. Had the liver of the dog been thus connected to the diaphragm, the respiration must necessarily suffer for; as, we shall see afterwards, this muscle is here moveable at the centre as well as at the edges: but in man the liver is fixed to the diaphragm, mostly at its tendinous part; that is, where the pericardium is fixed to it on the other side; so that it is in no danger of impeding the respiration, being suspend- ed by the mediastinum and bones of the thorax. In consequence of this viscera being divided in so many lobes, it follows, that the hepatic ducts cannot possibly join into one common trunk till they are quite out of the substance of the liver; because a branch comes out from every lobe of the liver; all of which, by their union, form the hepatic duct: whence we are led to conclude, that the hepato-cylic ducts, mentioned by former authors, do not exist. The gall-bladder itself is wanting in several animals, such as the deer, the horse, the ass, &c. but in place of it, in such animals, the hepatic duct, at its beginning, is widened into a resevoir of considerable bigness, which may answer the same purpose in them that the gall-bladder does in others.

We come next, after having examined the chylopoetic visceræ, to discourse of those organs that serve for the secretion and excretion of urine. And first of the kidneys: Which in this animal are situate much in the same way as in the human subject; but have no fat on their inferior surface, where they face the abdomen, and are of a more globular form than the human. The reason of these differences will easily appear, if you compare their situation and posture in this animal with those in a man who walks erect. They are placed in this subject in the inferior part of the body, so are not subject to the preffure of the visceræ, which seems to be the principal cause of the fadness of those organs in us, and perhaps may likewise be the cause of our being more subject to the stone than other animals. Hence there is no need of any cellular substance to ward off this preffure where there would necessarily be fat collected; but the superior part of their kidneys is pretty well covered with fat, left they should suffer any compression from the action of the ribs and spine.

In the internal structure there is still a more confiderable difference: For the papilla do not here end in a transverse tube, but being all united, they hang down in form of a long pendulous flap in the middle of the pelvis, and form a kind of septum medium; so that a dog has a pelvis formed within the substance of the kidney. The only thing that is properly analogous to a pelvis in man is that fac or dilatation of the ureters formed at the union of the ductus urinifiri. The external part of the kidney of a dog somewhat resembles one of the lobes of the kidney of a human, but in a human adult the appearance is very different; because, in man, from the continual preffure of the surrounding visceræ, the lobes, which in the fæces are quite diffuse and separated, concrete, but the original cortical substance is still preserved in the internal parts of the kidney. The reason of these particularities may probably be, that the liquors of this animal, as of all those of the carnivorous kind, being much more acrid than those that live on vegetable food, its urine must incline much to an alkaliency, as indeed the smell and taste of that liquor in dogs, cats, leopards, &c. evidently show, being fetid and pungent, and therefore not convenient to be long retained in the body. For this end it was proper that the secreting organs should have as little impediment as possible by preffure, &c. in the performing their functions; and for that design, the mechanism of their kidneys seems to be excellently adapted: We have most elegant pictures in Buffon of the kidneys of brutes, delineated as such, with a view to show Vælius's error in painting and describing them for the human.

The glandulae or capsulae atrabilaria are thicker and Capulus a rounder than the human, for the same reason as the trabalariae kidneys.

The ureters are more muscular than the human, because of the unfavourable preffage the urine has through them; they enter the bladder near its fundus.

The bladder of urine differs considerably from the Vefica urina- human; and first in its form, which is pretty much maria. pyramidal or pyriform. This shape of the dog's bladder is likewise common to all quadrupeds, except the ape and those of an erect posture. In man it is by no means pyriform, but has a large fac at its posterior and inferior part: this form depends entirely on the urine gravitating in our erect posture to its bottom, which it will endeavour to protrude; but as it cannot yield before, being contiguous to the os pubis, it will naturally stretch out where there is the least resistance, that is, at the posterior and lateral parts; and were it not for this fac, we could not so readily come at the bladder to extract the stone either by the lower anal, or lateral operation of lithotomy. Most anatomists have delineated this wrong; so much, that I know of none who have justly painted it, excepting Mr Cowper in his Zoonomia, and Mr Buffon. It has certainly been from observing it in brutes and young children, that they have lecu led into this mistake. The same cause, viz the gravity of the urine, makes the bladder of a different form in brutes: In their horizontal position the cervix, from which the urethra is continued, is higher than its fundus; the urine must therefore dif-
Of Quadrupeds.

To this connection, it is fastened to the abdominal muscles by a process of the peritoneum, and that membrane is extended quite over it, whereas in us its superior and posterior parts are only covered by it: hence in man alone the high operation of lithotomy can be performed without hazard of opening the cavity of the abdomen. Had the peritoneum been spread over the bladder in its whole extent, the weight of the vesicles in an erect posture would have so borne upon it, that they would not have allowed any considerable quantity of urine to be collected there; but we must have been obliged to discharge its contents too frequently to be consistent with the functions of a social life: Whereas by means of the peritoneum, the urine is now collected in sufficient quantity, the vesicles not gravitating this way.

It may be taken for a general rule, that those creatures that feed upon animal-food have their bladder more muscular and considerably stronger, and less capacious, than those that live on vegetables, such as horses, cows, swine, &c. whose bladder of urine is perfectly membraneous, and very large. This is wisely adapted to the nature of their food: For in these, as all their juices are more acrid, so in a particular manner their urine becomes excited; which, as its remora might be of very ill consequence, must necessarily be quickly expelled. This is chiefly effected by its stimulating this vefiwm more strongly to contract, and so to discharge its contents, though the irritation does not altogether depend upon the stretching, but likewise arises from the quality of the liquor. That a stimulus is one of the principal causes of the excretion of urine, we learn from the common saline diuretic medicines that are given, which are dissolved into the serum of the blood, and carried down by the kidneys to the bladder: The same appears likewise from the application of caustic drugs; or without any of these, when the parts are made more flexible, as in an excoriation of the bladder, there is a frequent desire to make water.

Accordingly we find these animals evacuate their urine much more frequently than man, or any other creature that lives on vegetable food. And if these creatures, whose fluids have already a tendency to putrefaction, are exposed to heat or hunger, the liquids must for a considerable time undergo the actions of the containing vessels, and frequently perform the course of the circulation, without any new supplies of food; by which the fluids becoming more and more acrid, the creature is apt to fall into feverish and putrid diseases: And in fact, we find that fatal and melancholy distemper called the rabies canina, enplina, &c. frequent in these animals; whereas those that feed on vegetable food seldom or never contract those diseases but by infection.

That the causes commonly assigned for the rabies canina are insufficient to produce it in dogs and other animals of that kind, is denied in a dissertation on this disease by Dr Heylham. That heat is insufficient, he proves from the disease being totally unknown in South America, where the heat is much greater than in this country. Putrid aliment he also says is taken in great quantity by dogs without any inconvenience; and as it seems in this state to be most agreeable to them, the rabies canina cannot with any probability be ascribed to it. As to want of water, he observes that the disease often originates among dogs that are plentifully supplied with that element, while others long deprived of it have remained perfectly free. In short, Dr Heylham totally denies, not only the efficacy of the causes commonly assigned for the rabies canina, but the nature of the distemper itself; and conjectures that the cause of it is not a putrefaction but an acidity of the fluids.

Their spermatic vesicles are within the peritoneum, Vasa spermatique is spread over them, and from which they have matrices, a membrane like a memertery, so hang loose and pendulous in the abdomen: whereas, in us, they are contained in the cellular part of the peritoneum, which is tenely stretched over them. At their passage out of the lower belly, there appears a plain perforation, or the false holes; hence the adult quadruped, in this respect, resembles the human foetus. And from observing this in quadrupeds, has arisen the false notion of hernia or rupture among authors. This opening, which leads down to the testicle, is of no disadvantage to them, but evidently would have been to us; for from the weight of our vesicles, and our continually gravitating upon these holes, we must have perpetually laboured under enterocleses. These they are in no hazard of, since in them this passage is at the highest part of their belly, and, in their horizontal posture, the vesicles cannot bear upon it: And, to prevent even the smallest hazard, there is a loose pendulous feminin flap of fat; which serves two uses, as it both hinders the intestines from getting into the passage, and also the course of the fluids from being stopped in the vesicles, which is secured in us by the cellular substance and tenes peritoneum: And it may be worth while to observe, that this process remains almost unaltered, even after the animal has been almost exhausted of fat.

There is next a passage quite down into the cavity where the testicles lie. Had the same structure obtained in man, we should always have laboured under an hydrocele; but their posture secures them from any hazard of this kind: indeed the very fat lap-dogs, who, consequently have an overgrown omentum, are sometimes troubled with an epiplocele.

The foramen is shorter and not so pendulous as the scrotum in all the dog kind that want the vesicula fejminales, that the feed at each copulation might the sooner be brought from the testes, thus in some measure supplying the place of the vesicula fejminales; for the Venus of a dog in the course of the feed through the vasa deferentia is thus cut off from the feed supplied, by placing the secreting vesicles nearer the excreatory organs. Perhaps its passage is likewise quickened by the muscular power of the vasa deferentia, which is stronger in this creature than in man. The want of vesicula fejminales at the same time explains the reason why this creature is so tedious in copulation. But why these bodies are absent in the dog kind more than in other animals, is a circumstance we know nothing of.

The structure of the testicles is much the same with the human; as are likewise the corpus pyramidale, varicoscs, or prominiformes, and the epididymis or excreatory vessel of the testicle. The vasa deferentia enter the
COMPARATIVE ANATOMY.

Of Quadrupeds.

Chap. I.

Penis.

39. The preputium has two muscles fixed to it: one that arises from the spheniurum, and is inserted all along the penis; and this is called retrahor preputium: But the other, whose office is directly contrary to this, is cutaneous; and seems to take its origin from the muscles of the abdomen, or rather to be a production of their tunica carnosa. The corpora cavernosa rise much in the same way as in the human: but these soon terminate; and the root is supplied by a triangular bone, in the inferior part of which there is a groove for lodging the urethra. There are upon the penis two protuberant bulbous fleshy substances, resembling the glans penis in man, at the back of which are two veins, which by the ereclores penis and other parts are comprised in the time of coition; and the circulation being stopped, the blood diffends the large cavernous bodies. After the penis is thus swelled, the vagina by its contraction and swelling of its corpus cavernosum, which is considerably greater than in other animas, grips it closely; and so the male is kept in action some time contrary to his will, till time be given for bringing a quantity of seed sufficient to impregnate the female: and thus, by that operation, the seed of this animal, though not so convex as the human; whereby in respiration the motion forward will very little enlarge their thorax, which is compensated by the greater mobility of their diaphragm: so our thorax is principally enlarged according to its breadth and depth, and theirs according to its length. The want of clavicles, and the consequent falling in of the anterior extremities upon the chest, may contribute somewhat to the straightness of the ribs.

40. The uterus of multiparous animals is little else but a continuation of their vagina, only separated from it by a small ring or valve. From the uterus two long canals mount upon the loins, in which the foetuses are lodged: these are divided into different faces, which are strongly constricted between each foetus; yet these communicate in the way of birth. From these go out the tube Fallopia, so that the ovaria come to lodge pretty near the kidneys.

41. The profeta scems here divided into two, which are proportionally larger than the human, and afford a greater quantity of that liquid.

42. Of Uterus.

The uterus of multiparous animals is little else but a continuation of their vagina, only separated from it by a small ring or valve. From the uterus two long canals mount upon the loins, in which the foetuses are lodged: these are divided into different faces, which are strongly constricted between each foetus; yet these communicate in the way of birth. From these go out the tube Fallopia, so that the ovaria come to lodge pretty near the kidneys.

43. Diaphragm.

We ought next to examine the structure of the thorax and its contents. But first it may not be amiss to remark of the diaphragm in its natural situation, that it is in general more loose and free than the human; which is owing to its connection with the neighbouring parts in a different manner from ours. The human diaphragm is connected to the pericardium; which again, by the intervention of the mediastinum, is tied to the sternum, spine, &c. but here there is some distance between the diaphragm and pericardium. We observe further, that its middle part is much more moveable, and the tendinous parts not so large. And indeed it was necessary their diaphragm should be some what loose, they making more use of it in difficult respiration than man. This we may observe by the strong heaving of the flanks of an horse or dog when out of breath; which corresponds to the rising of the ribs in us.

44. Thorax.

The disposition and situation of the mammary vary as they bear one or more young. Those of the uniparous kind have them placed between the posterior extremities, which in them is the highest part of their bodies, whereby their young get at them without the inconvenience of kneeling; Nevertheless, when the creatures are number of great size, and the breasts large, as in sheep, the young ones are obliged to take this posture. In multiparous animals, they must have a great number of nipples, that their several young ones may have room at the same time, and these diploped over both thorax and abdomen; and the creatures generally lie down when the young are to be suckled, that they may give them the most favourable situation. From this it does not appear to be from any particular fits of the vessels at certain places for giving a proper nourishment to the child, that the breasts are so placed in women as we find them, but really from that situation being the most convenient both for mother and infant.

45. Mammary.

The sternum is very narrow, and consists of a great number of small bones, moveable every way; which always happens in creatures that have a great mobility in their spine. The ribs are straighter, and by no means so convex as the human; whereby in respiration the motion forward will very little enlarge their thorax, which is compensated by the greater mobility of their diaphragm: so our thorax is principally enlarged according to its breadth and depth, and theirs according to its length. The want of clavicles, and the consequent falling in of the anterior extremities upon the chest, may contribute somewhat to the straightness of the ribs.

46. Sternum.

47. Collar.

The mediastinum in this creature is very broad. Mediastinum.

The pericardium is not here contiguous to the diaphragm, but there is an inch of distance between them, in which place the small lobe of the lungs lodges; and by this means the liver, &c. of this animal, though continually pressing upon the diaphragm, yet cannot disturb the heart’s motion.

48. Cor.

The heart is situated with its point almost directly downwards, according to the creature’s posture, and is but very little inclined to the left side. Its point is much sharper, and its shape more conoidal, than the human. Here the names of right and left ventricles are proper enough, though not so in the human; which ought rather to be called anterior and posterior, or superior and inferior. The animal has the venae cavae of a Vena cava: considerable length within the thorax, having near the whole length of the heart to run over ere it gets at the fissus Lowerianus dexter. In men, as soon as it pierces the diaphragm, it soon enters the pericardium, which is firmly attached to it, and immediately gets into the fissus Lowerianus; whereas in the human subject, by the oblique situation of the heart is almost contiguous to the diaphragm: and by this we discover, that several authors have taken their delineations of the human heart from brutes; which is easily detected by the shape and situation of the heart, and long vena cava, within the thorax. This was one of the faults of the curious wax-work that were shewn at London and Paris, which were plainly taken from a cow.

This
COMPARATIVE ANATOMY.

This situation of the heart of the creature agrees best with the shape of its thorax, which is lower than the abdomen.

The egress of the large blood-vessels from the heart is, in the creature, different from the human; for here the subclavian comes off first; and as a large trunk runs some way upwards before it gives off the left carotid, and splits into the carotid and subclavian of the right side, then the left subclavian is sent off. So that neither here, properly speaking, is there an aorta ascendens, more than in the human; but this name has probably been imposed upon it from observing this in a cow, where indeed there is an ascending and descending aorta.

From this specialty of the distribution of the vessels of the right side, which happens, though not in so great a degree, in the human subject, we may perhaps in some measure account for the general greater strength, readiness, or facility of motion, which is observable in the right arm. Upon measuring the sides of the vessels, the surface of the united trunk of the right subclavian and carotid is less than that of the left subclavian and carotid, as they are separated. If so, the resistance to the blood must be less in that common trunk than in the left subclavian and carotid: But if the resistance be smaller, the absolute force with which the blood is sent from the heart being equal, there must necessarily be a greater quantity of blood sent through them in a given time; and as the strength of the muscles is, ceteris paribus, as the quantity of blood sent into them in a given time, those of the right arm will be stronger than those of the left. Now children, being conscious of this superior strength, use the right upon all occasions; and thus from use comes that great difference which is so observable. That this is a sufficient cause, seems evident from fact; for what a difference is there between the right and the left arm of one who has played much at tennis? View but the arms of a blacksmith and legs of a footman, and you will soon be convinced of this effect arising from using them. But if by any accident the right arm is kept from action for some time, the other from being used gets the better; and those people are left-handed: For it is not to be imagined, that the small odds in the original formation of the vessels should be sufficient to refit the effect of use and habit (influences of the contrary occur every day); it is enough for our present argument, that where no means are used to oppose it, the odds are sufficient to determine the choice in favour of the right. Now, because it is natural to begin with the leg corresponding to the hand we have most power of, this is what gives also a superiority to the right leg.

This difference is not peculiar to man, but is still more observable in those creatures in whom the same mechanism does obtain in a greater degree. Do but observe a dog at a trot, how he bears forward with his right side; or look at him when a-scaping up any thing, and you will presently see that he uses his right much oftener than he does his left foot. Something analogous to this may be observed in horses. It has been the opinion of some anatomists, that left-handed people, as well as those distinguished by the name of ambidexter (who use both hands alike), have the two carotid and subclavian arteries coming off in four distinct trunks from the arch of the aorta: but no appearance of this kind has ever been observed in such bodies as have been examined for this purpose; though indeed these have been but few, and more experience might throw greater light on the subject.

The thymus of this creature is proportionably much larger than ours: whereas the glandula thyroida is much less, and is divided into two distinct parts, or there are two separate glands; which is not the case in man. The reason of this difference is unknown, as is likewise the use of the gland itself. It is generally remarked, that these two glands do thus always supply the place of each other; that is, in such animals as have a large thymus, the glandula thyroida is smaller, and vice versa. Hence we are naturally led to ascribe the same use to both, viz. the separation of a thin lymph for diluting the chyle in the thoracic duct before it be poured into the blood; then if we consider the different formation of the thorax in both, we shall readily account for the variety in the bulk of these two glands.

Respiration being chiefly performed by the widening of the chest, the lungs at every inspiration must press upon the thymus, and consequently diminish it; but the diaphragm yielding more in the dog's inspiration, this gland is not so much pressed by the lungs, and so will be larger; and hence the glandula thyroida will be proportionably less. Again, from the posture of this creature, we shall see that it was much more convenient for a dog to have the most part of the diluting lymph supplied by the thymus, since the neck being frequently in a descending posture, the lymph of the thyroid gland would have a very disadvantageous course to get to the thoracic duct; whereas in the human body, the thymus is really below the laryngeal canal, where it makes its curvature before it opens into the subclavian; and consequently there is a necessity of a considerable share of the diluting liquor being furnished by the thyroid gland, which is situated much higher; so that its lymph has the advantage of a perpendicular descent.

We may here observe, that the thoracic duct in a dog Dugus has no curvature before it enters the subclavian vein, thoracica, the horizontal position of this animal allowing a favourable enough course to the chyle, so as not to need that turn to force its passage into the blood. It may likewise be observed, that such animals as walk horizontally have the valves of the thoracic duct fewer in number than others. The horse has only a single pair; while, on the contrary, the ape refembles man in having several valves. Thus the lymph is not only forwarded in its passage, but the weight of the column is diminished. The lungs of this creature are divided into more numerous lobes, and deeper, than they are in man, for the same reason as the liver. The left side of the thorax in this animal bears a greater proportion to the right than in man; the one being nearly as three to two, the other as four to three. In quadrupeds, as well as in man, the lungs are closely applied to the containing parts; although this has been denied by some.

We look on it as a general rule, that all quadrupeds, having occasion to gather their food from the ground, are provided with longer necks than man: but as a long neck not only gives the advantage of too long a lever to the weight of the head, but also, when the animal is gathering his food, makes the brain in danger of...
of being oppressed with too great a quantity of blood, by the liquor in these arteries having the advantage of a* deficient, while that in the veins must remount a con-
considerable way contrary to its own gravity; it was there-fore necessary that a part of the length of the neck should be supplied by the length of the jaws. Thus we see horses, cows, &c. who have no occasion for opening their mouths very wide, yet have long jaws. Bulldo-
ges, indeed, and such animals as have occasion for very strong jaws, must of necessity have them short; because the longer they are, the resistance to be overcome acts with a longer lever. Another exception to this general rule, is fuch animals as are familiar with something analogous to hands to convey their food to their mouths, as cats, apes, &c. The teeth of this creature plainly show it to be of the carnivorous kind; for there are none of them made for grinding its food, but only for tearing and dividing it. It has six remarkable sharp teeth before, and two very long tusks behind; both of which the ruminating animals want. These are evidently calculated for laying very firm hold of substan-ces, and tearing them to pieces; and the vast strength of the muscles inferred into the lower jaw, affords greatly in this action; while the molars have sharp cutting edges, calculated for cutting flesh, and breaking the hardest bones. Even its posterior teeth are not formed with rough broad surfaces as in horses, but are made considerably sharper, and pref on over one another when the mouth is shut, that so they may take the firmer hold of whatever comes between them.

The tongue, in consequence of the length of the jaws, is much longer than ours; and as this creature feeds with his head in a depending posture, the bolus would always be in danger of falling out of the mouth, were it not for several prominences or papillæ placed mostly at the root of the tongue, and crooked backwards in such a manner as to allow any thing to pass easily down to the jaws, but to hinder its return. By the papillæ also the surface of the tongue is increased, and a stronger impression is made on the sensation of taste. In some animals who feed on living creatures, the tongue-hooks are still more numerous, and theima-
er large fishes, where they are almost as large as their teeth in the forepart of their mouth, and near as firm and strong.

When we open the mouth, we see the amygdalæ very prominent in the posterior part of it; so that it would appear at first view, that those were inconve-\ieniently placed, as being continually exposed to injuries from the hard substances this creature swallows; but upon a more narrow scrutiny, we find this provided for by two membranous capillæ, into which the amygd-
æ, when prefixed, can escape, and remove themselves from such injuries.

The velum palatinum is in this creature consider-
derably longer than in man, to prevent the food from getting into his nose; which would happen more fre-
cently in this animal than in man, because of its situa-
tion while feeding.

In this subject, as well as in other quadrupeds, there is no uvula, but then the epiglottis, when prefixed down, covers the whole rima entirely, and naturally continues so: there is therefore a ligament, or rather nucle, that comes from the os hyoïdes and root of the tongue, that is inferred into that part of the epiglottis where it t is articulated with the cricoid cartilage, which serves to Of Qua-
drupeds.

It may be asked, however, Why the uvula is want-
ing here, and not in man? This seems to be, that the uvula in quadrupeds, who swallow their food in an horizon-
tal situation, have no occasion for an uvula, though it is necessary in man on account of its erect situa-

In the upper part of the pharynx, behind the cricoid cartilage, there is a pretty large gland to be found which serves not only for the preparation of a mucus liquor to lubricate the bolus as it passes this way, but also supplies the place of a valve, to hinder the food from regurgitating into the mouth, which it would be apt to do by reason of the descending situation of the creature's head. In man, the muscle of the epiglottis is wanting, its place being supplied by the elasticity of the cartilage.

The stomach is formed pretty much in the same way as the human. Authors indeed generally allege, that gus-
quadrupeds have their gullet composed of a double row of spiral fibres decussating one another; but this is pecu-
lar to ruminating animals, who have occasion for such a decussation of fibres. The action of these you may easily observe in a cow chewing her cud.

The nose is generally longer in man, and its ex-
ternal palate much narrower. The internal structure is also better adapted for an acute smell, having a larger convoluted surface on which the neophrænus is spread; and this is to be observed in most quadrupeds, who have the os spongiosum commonly large, and these two divided into a great number of exceedingly fine thin lamellæ. The sensibility seems to be increased in proportion to the surface; and this will also be found to take place in all the other senses. The elephant, which has a head pretty large in proportion to its body, has the greatest part of it taken up with the cavity of the nose and frontal sinuses; which last extend almost over their whole head, and leave but a small cavity for their brains. A very nice sense of smell is therefore peculiar to man, who has judgement and experience to direct himself in the choice of his food; whereas brutes, who have only their senses, must of necessity have those acute, some having one sense in greater perfection than others, according to their different way of life. We not only conclude a priori from the large expanded membranes theidentians, that their sense of smelling is very acute, but we find it so by cows and horses distinguishing readily be-
xixt noxious and wholesome herbs, which they do principally by this sense.

The external ear in different quadrupeds is differ-
ently framed, but always calculated to the creature's manner of life. In shape it commonly resembles the oblique section of a cone from near the apex to the base. Hares, and fuch other animals as are daily ex-
pended to insults from beasts of prey, have large ears directed backwards, their eyes warning them of any danger before; rapacious animals, on the other hand, have their ears placed directly forwards, as we see in the lion, cat, &c. The flow hounds, and other animals that are designed to hear most distinctly the sounds coming from below, have their ears hanging downwards; or their ears are flexible, because they move...
Of Quadrupeds.

their head for the most part with greater difficulty than man. Man, again, who must equally hear sounds coming from all quarters, but especially such as are sent from about his own height, has his external ear placed in a vertical manner, somewhat turned forward. In short, wherever we see a specialty in the make of this organ in any creature, we shall, with very little reflection, discover this form to be more convenient for that creature than another. The animal also has the power of directing the cone of the ear to the sonorous body without moving the head. There are some differences to be observed in the structure of the internal ear in different animals; but we know so very little of the use of the particular parts of that organ in the human subject, that it is altogether impossible to assign reasons for these variations in other creatures.

All quadrupeds have at the internal canthus of the eye a strong firm membrane with a cartilaginous edge, which may be made to cover some part of their eye; and this is greater or less in different animals as their eyes are more or less exposed to dangers in searching after their food. This membrane, as it is called, is not very large in this animal. Cows and hares have it so large as to cover one half of the eye like a curtain, and at the same time is transparent enough to allow abundance of the rays of light to pass through it. Fishes have a cuticle always over their eyes, as they are ever in danger in that inconvenient element. In this then we may also observe a sort of gradation.

All quadrupeds have a seventh muscle belonging to the eye, called falsenforius. It surrounds almost the whole optic nerve, and is fixed into the flectoric coat as the others are. Its use is to sustain the weight of the globe of the eye, and prevent the optic nerve from being too much stretched, without obliterating the four straight muscles to be in a continual contraction, which would be inconvenient: at the same time this muscle may be brought to assist any of the other four, by causing one particular portion of it to act at a time.

The next thing to be remarked is the figure of the pupil, which is different in different animals, but always exactly accommodated to the creature's way of life, as well as to the different species of objects that are viewed. Man has it circular, for obvious reasons; an ox has it oval, for the creature's way of life, as they have little occasion to lie on either side of their bodies, and to look forward while the brain at this time gravitating much on the bones while they are as yet soft, will gradually make impressions upon them at these places where it rives into eminences. This is prevented in man mostly by his erect posture.

The false is not near so large in quadrupeds as in man, as they have little occasion to lie on either side, and the two hemispheres of the brain are in a great measure hindered from jostling against one another in violent motions, by the brain's insinuating itself into the abovementioned pits. The second procès of the duramater, or corticium cerebellum super-expansum, is considerably thicker and stronger in most quadrupeds than in man; especially in fuch of them as are very swift of foot, as hares and rabbits, and that most when they are old. This membrane

Cerebrum.
The olfactory nerves are very large, and fully deserve the name of processus maxillaris. They are hollow, and consist of a medullary and chorineous substance, and at first sight appear to be the anterior ventricles of the brain produced; but in man they are small, and without any discernible cavity. The reason of this is pretty evident, if we consider how this animal's head is situated; for the lymph continually gravitating upon the inferior part of the ventricles, may thus elongate and produce them; but from this very inferior part the olfactory nerves rise, and are sent immediately through the os ethmoides into the nose. Hence the ancients, thinking they were continued hollow into the nose, believed they were the emunctories of the brain: in the brain of sleep, which by its firm texture is the best subject of any for searching into the structure of this part, we evidently see, that the name of the processus maxillaris was very properly applied by the ancients to the lateral ventricles of the brain; which are really of a greater extent than they are ordinarily painted by the anatomists, reaching farther backwards, and forwards again under the substance of the brain. The cortical and medullary parts, as well as the corpus callosum, are similar to those parts in man.

The nates and tympani deserve this name much better here than in the human body, with respect to each other. They are larger in the quadruped, and hence we conceive that there is no great reason for ascribing the different operations to any particular size or shape of these parts. They are here also of different colours; the nates being of the colour of the cortical, and the tympani of the medullary substance of the brain; whereas in man they are both of one colour. The reason of these differences, and others of the like nature to be met with, we shall not pretend to determine; for we have hitherto such an imperfect knowledge of the brain itself, that we are entirely ignorant of the various uses of its different parts. We may in general conclude, that the varying in one animal from what it is in another, is fitted to the creature's particular way of living.

The nates mirabilia Galeni, situated on each side of the fossa turricula, about which there has been so much dispute, is very remarkable in most quadrupeds. This plexus of vesicles is nothing else than a continuation of the internal carotid arteries, which, entering the skull, divide into a vast number of branches along the side of the fossa turricula; and, uniting afterwards, are sent on the brain in the common way. Galen feems with justice to suppose, that this plexus of vesicles serves for checking the impetuosity of the blood destined for the brain.

The structure of the brain differing but very little in all quadrupeds, it will be needless to examine it in any other.

The next species of quadrupeds we proposed to consider was the ruminant kind, of which we have an
Allantois. This is a fine transparent membrane contiguous to the former. It is not a general involucrum of the fetus in the mother, for it covers only a small part of the abdomen; forthly, that midwives have ever observed the placenta to the royal academy every year a preparation of it: On all these accounts it seems most probable, that there is such a membrane in the human body.

The third proper integument of the fetus is the amni
don. It is thinner and firmer than the chorion; it has numerous ramifications of the umbilical vessels spread upon it, the lateral branches of which separate a liquor into its cavity. This is the proper liquor of the amni-

to inject coloured liquors from the veins of the glands of the uterus into the placenta, seem to prove beyond a reply, that there can be here no anatomoses between the veins; on their coats run a great number of veins that are sent to the several placenta, on the external side next to the uterus; whereas in creatures that have but one placenta, as in the human subject, cats, dogs, &c. the adhesion is somewhat firmer: The placenta is likewise joined to the papillae in the cornua uteri. We shall next give the history of the allantois.

Of Quadrupeds.

The body. The great design of this mechanism is, that the whole mass of blood might pass through the collapsed lungs of the fœtus; but that part of it might pass through the foramen ovale and canalis arteriosus, without circulating at all through the lungs.

This was the opinion that universally prevailed till the end of the last century, when it was violently opposed by Monseur Mery, who is very singular in his opinions. He will not allow that the foramen ovale transmits blood from the right to the left auricle, but on the contrary from the left to the right; and that for no other reason but because he observed the pulmonary artery in a fœtus larger than the aorta. Mr Winnow endeavours to reconcile these two opinions, by saying that the blood may pass either way, and that it is here as it was blended; his reason is, that on putting the heart in water, the foramen ovale transmits it any way. Mr Rohault, professor of anatomy at Turin, and formerly one of Mery's scholars, strongly defends his matter, and criticizes Mr Winnow. What he principally builds on, is the appearance this foramen has in some dried preparations; this Mr Winnow would allow as a proof. After all, the common opinion seems most probable; and that for the following reasons: First, the pulmonary artery being larger signifies nothing, since its coats are not only thinner and will be more easily distended, but also the resistance to the blood in the pulmonary artery from the collapsed lungs is greater than the resistance to the blood in the aorta. Secondly, if we should allow any of these two uncommon opinions, we should have the right ventricle vastly more capacious than the left; for if we suppose the foramen ovale to be capable of transmitting one-third of the whole mass of blood in any given time, and the canalis arteriosus as much in the same time, then you will find, that, according to Mr Mery's opinion, the whole mass of blood being driven from the right ventricle into the pulmonary artery, one-third passes by the canalis arteriosus into the descending aorta, two-thirds passing through the lungs and returning into the left auricle; one-half of which portion, or one-third of the whole mass, passes by the foramen ovale into the right auricle; and the other, or the left third, will be sent into the left ventricle, and thence expelled into the aorta; which third, with that from the pulmonary artery by the canalis arteriosus, circulating through the body, are returned into the right auricle, where meeting with the other third from the foramen ovale, with it they are sent into the right ventricle to undergo the same course. Thus the whole mass is expelled by the right ventricle, and only one-third by the left. If this was the case, why is not the right ventricle three times as large and strong as the left?

Then, according to Mr Winnow's system, the foramen ovale transmits equal quantities from both auricles, this comes to the same as if there was no foramen ovale at all; that is to say, the whole mass going from the right auricle into the right ventricle and pulmonary artery, one-third of the whole mass passes into the aorta through the canalis arteriosus; the other two-thirds passing through the lungs, return to the left auricle and ventricle. Thus the right ventricle expels the whole mass; the left, only two-thirds.

But if, according to the common opinion, we suppose the foramen ovale to convey the blood from the right to the left auricle, then one-third passes this way into the left ventricle; the other two-thirds are sent by the right ventricle into the pulmonary artery: from whence one-third passes by the canalis arteriosus into the aorta descending; the other third circulates through the lungs, and is returned into the left ventricle; where meeting with that from the foramen ovale, it is therewith expelled into the aorta, and with the one-third transmitted by the canalis arteriosus; it will not allow that the right auricle can run the same race as before. Thus we conclude, that two-thirds are expelled by each ventricle, and the whole circulates through the body; and hence they come to be of pretty equal dimensions. In all this calculation no regard has been had to the blood discharged from the umbilical veins, but the greater quantity returned by the veins, than sent out by the arteries, still argues for the common opinion.

The kidneys in the fœtus are composed of different lobes, which serve to give us an idea of the kidneys neys, being a congeries of different glands; these lobes being kept contiguous by the external membrane, are divided by the other visceral, still at length they unite. They are called the kidneys, or the renal animal, as a ruminate animal.

There are no dentes incisores in the upper jaw: but the gums are pretty hard, and the tongue rough. This roughness is occasioned by the long thorns, pointed papilae with which the whole substance of it is covered. These papilae are turned towards the throat; so that by their means the food, having once got into the mouth, is not easily pulled back. The animals therefore supply the defect of teeth by wrapping their tongue round a tuft of grass; and so, pressing it against the upper jaw, keep it stretched, and cut it with the teeth of the under jaw; then, without chewing, through it down into the œsophagus, which in these creatures consists of a double row of spiral fibres decussating one another. All animals which ruminate must have more ventricles than one; some have two, some three; our present subject has no less than four. The food is carried directly down into the first, which lies upon the left side, and is the largest of all; it is called the œsophagus, ventriculus, and stom, by way of eminence. It is what is called by the general name of paunch by the vulgar. There are no rugae upon its internal surface; but instead of these there is a vast number of small blunt pointed processes, by which the whole has a general roughness, and the surface is extended to several times the size of the paunch itself. The food, by the force of its mucous coat, and the liquids poured in here, is sufficiently macerated; after which it is forced up hence by the œsophagus into the mouth, and there it is made very small by mastication; this is what is properly called chewing the cud, or rumination; for which purpose the dentes molares are exceedingly well fitted: for instead of being covered with a thin craft, the enamel on them consists of perpendicular plates, between which the bone is bare, and constantly wearing fatter than the enamel, so that the tooth remains good to extreme old age; and by means of these teeth, the rumination is carried on for a long time without any danger of spoiling them. After rumination, the food is sent down by the gullet into the second stomach; for the œsophagus opens differently into both. It ends exactly where the two stomachs meet; and there is a smooth gutter with ri-
C O M P A R A T I V E A N A T O M Y.

Of Quadrupeds.

The edges which lead into the second stomach, from thence to the third, and also to the fourth: however, the creature has a power to direct it into which it will. Some tell us, that the drink goes into the second; but that might easily be determined by making them drink before slaughter. The second stomach, which is the anterior and smaller, is called the duodenum, reticulum, honeycomb, the bennet, or king's hood. It consists of a great number of cells on its internal surface, of a regular pentagonal figure, like a honeycomb. Here the food is further macerated; from which it is protruded into the third, called the coagulum, vaga, or the many places, because the internal surface rises up into a great many placæ or folds, and from this figure, according to the length of this stomach. Some of these plicæ are further produced into the stomach, than others; i. e. first two long ones on each side; and within these two shorter in the middle, &c. There are numberless glandular grains like millet-feeds dispersed on its plicæ, from which some authors call this stomach the saffron. From this it passes into the fourth, whose names are vaginal, abdominal, caulis, or the red, which is the name it commonly has because of its colour. This much resembles the human stomach, or that of a dog; only the inner folds or plicæ are longer and looser; and it may also be observed, that in all animals there is only one digestive stomach, and that has the same coagulating power in the fist as the fourth stomach in this animal; whence this might not improperly be called the only true stomach. Caulis signifies curved; and hence the French have given that as a name to this fourth stomach, because any milk that is taken down by young calves is there curved. It is this fourth stomach, with the milk curved in it, that is commonly taken for making runnet; but after the bile and pancreatic juice enter, this coagulation is not to be found, which fews the use of these liquors. There are other creatures which use the same food, that have not such a mechanism in their digestive organs. Horses, ass, &c. have but one stomach, where grass is macerated, and a liquor for their nourishment extracted, and the remainder sent out by the anus. So very small a proportion of food in this creature not being so, the stomach is divided into three chambers or lobes, from which it is further macerated. The outside of these lobe stomachs, the stomach is not fitted for this; so that he requires a much greater quantity of food to extract the same nourishment.

The guts of these creatures are of a considerable length in proportion to the bulk of the body; and this confirms what we said formerly on the subject of the intestines of a dog, viz. that the length and capacity of the guts were different in different animals, according to the nature of their food.

The duodenum is formed here much the same way as in a dog, and the general intention kept in view with regard to the mixture of the bile and pancreatic lymph. The great guts here hardly deserve that name, their diameter differing very little from that of the small ones; but to compensate this they are much longer proportionally than a dog's are, being convoluted as the small guts are. The caecum is very large and long. The digestion of the cow, as well as some other animals, is accompanied with a peculiar kind of action called rumination; the intention of which seems to be, that the food may be sufficiently comminuted, and thus more fully acted upon by the stomach: for it is not observed that a calf ruminates as long as it is fed only upon milk, though the action takes place as soon as it begins to eat solid food. But it is to be observed, that as long as a calf feeds only upon milk, the food descends immediately into the fourth stomach (which, as has been already mentioned, seems only capable of performing the operation of digestion) without stopping in any of the first three. The rumination does not take place till after the animal has eaten a pretty large quantity: after which it lies down, if she can do it conveniently, and begins to chew; though the operation will take place in a standing posture, if she cannot lie down. In this action a ball is observed to rise from the stomach with great velocity, almost as if shot from a musket. This ball the animal chews very accurately, and then swallows it again, and so on alternately, till all the food she has eaten has undergone this operation. This is easily explained from the structure of the oesophagus, which has one set of fibres calculated for bringing up the grans, and another for taking it down.

By means of rumination, the cow extracts a much larger proportion of nourishment from her food than those animals which do not ruminate; and hence she is contented with much worse fare, and smaller quantities of it, than a horse; hence also the dung of cows, being much more exhausted of its fine parts than horse-dung, proves much inferior to it as a manure.

The spleen differs not much either in figure or situation from that of a dog; but it is a little more firmly fixed to the diaphragm, there not being here fo much danger of this viscus's being hurt in the flexions of the spine.

The liver is not split into so many lobes in this creature as either in a man or dog; which depends on the small motion this creature enjoys in its spine, which made such a division needless. This also confirms what we formerly advanced on this head. Their vesica urinaria is of a pyramidal shape. It is very large, and more membranaceous; for the urine of these creatures not being so acid as that of carnivorous animals, there was no such occasion for expelling it so soon.

The male is provided with a loose pendulous scrotum; and consequently with vesiculae seminales. The female Vesiculae organs differ from those of a bitch, mostly in the form of the cornua uteri, which are here contorted in form of a flail. In this, and all uniparous animals, they contain only part of the fccumines; but in bitches, and other multiparous animals, they run straight up in the abdomen, and contain the fetus themselves.

The situation of the heart is pretty much the same with that of a dog, only its point is rather sharper: In us, the heart beating continually against the ribs, and both ventricles going equally far down to the constiution
Chap. II.  

COMPARATIVE ANATOMY.

Of Fowls.

The situation of the apex, it is very obtuse; but here the apex is made up only of the left ventricle; so is more acute.

The aorta in this creature is justly divided into ascending and descending, though this division is ill-founded either in a dog or man; and it has certainly been from this subject that the older anatomists took their descriptions when they made this division; for here the aorta divides into two, the ascending and descending.

CHAP. II. Of Fowls.

The next class of animals we come to consider are of the feathered kind; which are divided into the granivorous and carnivorous. But before we go on to consider the specialties in the vifera of each kind, we must observe what both species agree in.

SECT. I. Of Fowls in general.

Fowls have a particular covering of feathers different from all other creatures, but exactly well suited to their manner of life; for it not only protects them from the injuries of the weather, but serves them in their progress through that thin aerial element they are for the most part employed in; and as some fowls live much in the water, their feathers being continually becaused with an oily liquor, keeps the water from foaking into their skins, and so prevents the bad effects which it would infallibly otherwise produce.

Fowls have the strongest muscles of their whole body inserted into their wings; whence by the way we may observe, that it is altogether impossible for man to buoy himself up into the air like birds, even though he had proper machines in place of wings, unless he were likewise provided with muscles strong enough for moving them, which he has not. In the next place, their wings are not placed in the middle of their bodies, but, a good deal further forwards; whence it would at first view appear, that their heads would be erect, and their posterior parts most depending when raised in the air; but by stretching out their heads which act upon the lever of a long neck, they alter their centre of gravity pretty much; and also by filling the faces or bladders in the inside of their abdomen with air, and expanding their tail, they come to make the posterior part of their bodies considerably higher; and thus they fly with their bodies nearly in an horizontal situation. Hence we find, that if their necks are kept from being stretched out, or if you cut away their tails, they become incapable of flying any considerable way.

The largeness of the wings in different fowls varies according to the occasions of the creature. Thus birds of prey, who must fly a considerable way to provide their food, have large strong wings; whereas domestic birds, who find their nourishment almost every where, have very short and but small wings. Their tail is of use in affluting to raise them in the air; though the chief purpose of it is to serve as a rudder in guiding their flight, whilst they use their wings as we do oars in putting forward a boat. The best account of this manner of progress of fowls is given by Alonius Borellus, in his treatise De Nota Animalium; and in the Religiosus Philopher we have Borelli's doctrine stripped pretty much of its mathematical form. The posterior extremities are situated so far back, as to make us at first think they would be in continual hazard of falling down forwards when they walk; but this is prevented by their holding up their heads and neck, so as to make the centre of gravity fall upon the feet; and when they have occasion for climbing up a steep place, they stretch out their heads and necks forward, especially if they are short-legged, the better to preserve properly the balance of the body. Thus we may observe a goose entering a barn-door, where generally there is an ascending step, to stretch out its neck, which before was raised, and incline its body forwards. This is laughed at by the common people, who ascribe it to a piece of folly in the goose, as if afraid of knocking its head against the top of the door.

Carnivorous animals are provided with strong crooked claws for the catching their prey; water-fowls use them for swimming; and, principally for this purpose, have a strong firm membrane interposed betwixt the toes. There is a beautiful mechanism to be observed in the toes of fowls, which is of considerable use to them. For their toes are naturally drawn together, or bended, when the foot is bended; this is owing to the shortenings of the tendons of the toes, which pass over them, which is analogous to our heel; and that the toes are set in the circumference of a circle, as our fingers are: Hence, when the foot is bended, the tendons must consequently be much stretched; and, since they are inerfed into the toes, must of necessity bend them when the foot is bent; and when the foot is extended, the flexors of the toes are again relaxed, and they therefore expanded. This is also of great use to different kinds of fowls: thus the hawk descending with his legs and feet extended, spreads his talons over his prey; and the weight of his body bending his feet, the toes are contracted, and the prey is seized by the talons. This is also of great use to water-fowls: for had there been no such contrivance as this, they must have lost as much time when they pulled their legs in as they had gained by the former stroke; but, as the parts are now framed, whenever the creature draws in its foot, the toes are at the same time bended and contracted, making it impossible for them to resist made against the water is not near so great as before; on the contrary, when they stretch their foot, their toes are extended, the membrane betwixt them expanded, and consequently a greater resistance made to the water. Again, such fowls as live mostly in the air, or have occasion to sustain themselves on branches of trees in windy weather, and even in the night-time when asleep, while all their muscles are supposed to be in a state of relaxation; such have no more to do but lean down the weight of their bodies, and their toes continue bended without any muscles being in action; and whenever they would disengage themselves, they raise up their bodies, by which their feet, and consequently their toes, are extended.

The rostrum, bill, or beak of fowls, is composed of the various two mandibles; and, as in quadrupeds, the upper one has no motion but what it possesses in common with the head. But parrots are an exception to this rule; for they can move the upper mandible at pleasure; this is exceeding convenient, as it enables them to lay hold of what ever comes in their way. Carnivorous fowls
fowls have their beaks long, sharp, and crooked; the
domestic fowls, such as the hen-kind, &c. have strong
short beaks, commodiously fitted to dig up and break
their food; the water-fowls, again, having very
broad fourchard beaks, which is most convenient for
them. The fternum of fowls is much larger propor-
tionally than the human, and has a ridge rising in its
middle for the more commodious origin of the muscles
that move the wings. It is also less movable than ours;
for had it been very moveable, a great deal of the
force employed for moving the wings would at
every contraction of the muscles have been loft, or
else some other muscles must have come in play to keep
firm the fternum; but this additional weight would
have been inconvenient for their progression.

What other things are most remarkable in the struc-
ture of the feveral vifera, we shall consider in that
common domestic animal the cock or hen, and after-
wards observe the difference of their vifera chylopoieti-
tica from a carnivorous fowl.

**Sect. II. Anatomy of the Domestic Cock.**

Though this kind of birds live upon food some-
what similar to that of man, yet as they have no teeth
to separate or break down this food, we would expect
to find something to compensate for the want of teeth,
something remarkable in the organs of digestion: we
shall therefore begin with these parts.

The **cajrophagus** of this creature runs down its neck,
somewhat inclined to the right side; and terminates in a
pretty large membranous fac, which is the ingluvies
or crop, where the food is macerated and disolved by a
liqour separated by the glands, which are easily ob-
erved every where on the internal surface of this bag.
The effect of this maceration may be very well obser-
vied in pigeons, who are sometimes in danger of being
suffocated by the peafe, &c. they feed upon, swelling
to such an immense bulk in their ingluvies, that they
can neither get upwards nor downwards. If it be a
faovourite fowl, it might be preferred by opening the
fac, taking out the peafe, and feewing up the wound.

The food getting out of this fac goes down by the
remaining part of the **cajrophagus** into the **verricularis
faccincturitatis, or infundibulum pyrleri**, which is a con-
tinuation of the gullet with more numerous glands,
which separate a liqour to dilute the food still more,
which at length gets into the true foomach or gizzard.
**vermicularis callofus**, which confists of two very strong
muscles covered externally with a tendinous capsulose
membrane, and lined on the inside by a very thick firm
membrane, which we evidently difcover to be a produc-
tion of the cuticula. This might have been proved in fome
measure a priori, from taking notice, that this mem-
brane, which in chucks is only a thin light pedicle, by
degrees turns thicker and stronger the more attrition it
suffers; but there is no other animal substance, fo far
as we know, which grows more hard and thick by be-
ing subjected to attrition, excepting the cuticula—

Hence may be drawn fome kind of proof of what
has been affirmed concerning the unicula vellon of the
fomach and intestines in the human body, viz. that it
was in part a continuation of the epidermis; nay, all
the hollow parts of the body, even arteries, veins, &c.
seem to be lined with a production of this membrane,
or one analougs to it. The ufe of the internal coat
of the fomach of fowls is to defend the more tender
parts of that viscus from the hard grains and little
stones those fowls eat; and it is well fitted for this purpoze from the great
strength it poifefls.

The digestion of these animals is performed merely
by attrition, as is evinced by many experiments; and
it is further aífifted by the hard bodies they swallow.
We fee them daily take down considerable numbers of
the moll solid rugged little fints they find; and these
can ferve for no other purpoze than to help the tritur-
tion of their aliments. After these pebbles, by be-
coming smooth, are unfit for this office, they are
thrown up by the mouth. Hence fowls that are long
continued, though ever fo well fed, turn lean for want
of these ftones to help their digestion. This was
put beyond all dispute by Mr. Tauvry, who gave a spe-
cies of metal to an oilrich convex on one fide and
concave on the other, but carved on both; and open-
ing the creature's body some time after, it was found,
that the carving on the convex fide was all obliterated,
while the engraved character remained the fame as be-
fore on the concave fide, which was not padded to the
fomach's preflure: which could not have happen-
ed had digestion been performed by a menftrum, or
any other way whatsoever; but may be easily folved
by allowing a fimple mechanical preflure to take place.

We are, however, by no means to conclude from this,
that some have too rashly done, that in the human body
digitation is performed by fimpler attrition; other-
wise we may, with equal strength of reafon, as good
arguments drawn from what is observed in fowls, prove
that the aliments are dissolved in our fomachs by the
action of a menftrum. But this method of reasoning
is very fanfty; nor can it ever bring us to the true
folution of any philosophical or medical problem. It
is very plain, that the ftructure of the parts of the
human fomach are fo very different from that of this
creature, that it is foolifh and unreasonable to imago
both of them capable of producing the fame effects.
At each end of the fomach, there are as it were two
particular faces of a different texture from the rest of
the fomach, not confiding of ftrong muscular fibres;
they seem to be receptacles for the ftones (efpecially at the end which is farthest from the ori-
cy), while the digefled aliments are protruded into the
intefines.

Spallanzani, however, has lately found, that pebbles
are not at all neceffary to the trituration of the food
of these animals. At the fame time, he does not de-
ny, that when put in motion by the gastric muscles,
they are capable of producing fome effed on the con-
tents of the fomach; but is inclined to believe, that
they are not fought for and flected by design, as ma-
ny fuppose, but because they frequently happen to be
mixed with the food.

The **duodenum** begins pretty near the fame place at Duode-
which the cajrophagus enters; yet notwithstanding the num-
}
Of Fowls.

The small guts are proportionally longer than those of carnivorous birds, for the general cause already signified. At the end of the ilium they have two large intestines caca, one on each side, four or five inches long, coming off from the side of the rectum, and ascending; and we find them containing part of the food: these serve as reservoirs to the feces; which, after some remora, there regurgitate into what hour becomes the rectum; which, together with the excretories, urine and organs of generation, empties itself into the common cloaca. The small intestines are connected by a long loofe meneftery, which has little or no fat accompanying the blood-veffils there; being no hazard of the blood's being stopped.

Pancreas.

The pancreas in the creature lies between the two folds of the duodenum, and sends two or three ducts into this gut pretty near the biliary.

The spleen.

The spleen is here of a round globular figure, situated between the liver and stomach; and betwixt these and the back-bone it enjoys the fame properties as in other animals, viz. large blood-veffils, &c. All its blood is sent into the vena portarum, and has a perpetual confluence. It has no excretory, as far as we know. Their liver is divided into two equal lobes by a pellucid membrane, running according to the length of their body: and hence we may observe, that it is not proper to that bowel to lie on the right side; which is still more confirmed by what we observe in fishes, where the greatest part of it lies in the left side.

Vena fellis.

The shape of their gall-bladder is not much different from that of quadrupeds; but is thought to be longer in proportion to the fize of the animal, and is further removed from the liver.

Cor.

The principal difference to be remarked in their heart, is the want of the valvula tricuspidae, and their place being supplied by one fleshy flap.

Pulmones, their structure and uses.

The lungs are not loose within the cavity of the thorax, but fixed to the bone all the way; neither are they divided into lobes, as in those animals that have a large motion in their spine. They are two red spongy bodies, covered with a membrane that is perruous, and which communicates with the large veffils or air-bags that are diffpeared over their whole abdomen; which veffils, according to Dr Monro, serve two very considerable uses. The one is to render their bodies specifically light, when they have a mind to ascend and buoy themselves up when flying, by diffpearing their lungs with air, and also straining their trachea articia, and to return the air. Secondly, they supply the place of a particular diaphragm and strong abdominal muscles; producing the same effects on the several contained viscer. as these muscles would have done, without the inconvenience of their additional weight, and conducing as much to the exclusion of the egg and feces.

The diaphragm.

Dr Hunter hath lately made some curious discoveries relative to these internal receptacles of air in the plied bodies of birds. Some of them are lodged in the fleshy parts, and some in the hollow bones; but all of them communicate with the lungs. He informs us, that the air-cells which are found in the soft parts have no communication with the cellular membrane which is common to birds as well as other animals. Some of them communicate immediately with each other; but all of them by the intervention of the lungs as a common centre. Some of them are placed in cavities, as the abdomen; others in the interstices of parts, as about the breast. The bones which receive air are of two kinds; some of them divided into innumerable cells; others hollowed out into one large canal. They may be distinguished from such as do not receive air, by having less specific gravity; by being less vascular; by containing little oil; by having no marrow nor blood in their cells; by having less hardness and firmness than others; and by the passage for the air being perceivable.

The mechanism by which the lungs are fitted for conveying air to these cavities is, their being attached to the diaphragm, and connected also to the ribs and sides of the vertebra. The diaphragm is perforated in several places by pretty large holes, allowing a free passage of air into the abdomen. To each of these holes is attached a distinct membranous bag, thin and transparent. The lungs open at their anterior part to membranous cells, which lie upon the sides of the pericardium, and communicate with the cells of the sternum. The superior parts of the lungs open into cells of a loose net-work, through which the trachea and oesophagus pass. When these cells are diffpeared with air, it indicates passion, as in the cafe of the turky-cock, pouting-pigeon, &c.

These cells communicate with others in the axilla, and under the large pectoral muscle; and those with the cavity of the os humeri, by means of small openings in the hollow surface near the head of that bone. Lastly, The posterior edges of the lungs have openings into the cells of the vertebrae, ribs, os sacrum, and other bones of the pelvis, from which the air finds a passage to the cavity of the thigh-bone.

Concerning the use of these cavities the doctor conjectures, that they are a kind of appendage to the lungs; and that, like the bags continued through the bellies of amphibious animals, they serve as a kind of reservoirs of air. They assist birds during their flight, which must be apt to render frequent respiration difficult. He farther intimates, that this construction of the organs of respiration may assist birds in singing: which he thinks, may be inferred from the long continuance of song between the breathing of a canary-bird. On tying the trachea of a cock, the animal breathed through a canula introduced into his belly; another through the os humeri, when cut across; and a hawk through the os femoris. In all these cases the animals soon died. In the first, the doctor ascribes the death to an inflammation of the bowels; but in the last, he owns it was owing to difficult breathing.
What took place, however, was sufficient to show that the animals really did breathe through the bone.

When we examine the upper end of the trachea, we observe a rima glottidis with muscular fides, which may act in preventing the food or drink from passing into the lungs; for there is no epiglottis as in man and quadrupeds.

The trachea arteria, near where it divides, is very much contracted; and their voice is principally owing to this coaction. If you liken attentively to a cock crowing, you will be sensible that the noise does not proceed from the throat, but deeper; nay, this very pipe, when taken out of the body, and cut off a little after its division, and blown into, will make a squeaking noise, something like the voice of these creatures. On each side, a little higher than this contraction, there is a nucleus arising from their sternum, which dilates the trachea. The cartilages, of which the pipe is composed in this animal, go quite round it; whereas in men and quadrupeds they are discontinued for about one-fourth on the back-part, and the intermediate space is filled up by a membrane. Neither is the trachea so firmly attached to their vertebrae as in the other creatures; we have examined the ftructure, and we shall find of great service to them, if we consider, that had the fame structure obtained in them as in us, their breath would have been in hazard of being stopped at every flexion or twitting of their neck, which they are frequently obliged to. This we may be sensible that they have escaped the notice of some, by their trachea fo firmly attached to the spine; whereas their trachea is better fitted for breathing; whereas their trachea is better fitted for breathing; whereas their trachea is better fitted for breathing; whereas their trachea is better fitted for breathing; whereas their trachea is better fitted for breathing; whereas their trachea is better fitted for breathing.

In place of a muscular diaphragm, this creature has nothing but a thin membrane connected to the pericardium, which separates the thorax and abdomen. But besides this, the whole abdomen and thorax are divided by a longitudinal membrane or mesodermum connected to the lungs, pericardium, liver, stomach, and to the fat lying over their ribs, and from which there is a lymphatic, which runs from the lymphatics of the abdomen, not near the thoracic veins, but deeper; nay, this very pipe, when taken out of the body, and cut off a little after its division, and blown into, will make a squeaking noise, something like the voice of these creatures.

The lymphatic system in birds consists, as in man, of lacteal and lymphatic vessels, with the thoracic duct.

The lacteals indeed, in the strictest fense, are the lymphatics of the small intestines; and, like the other lymphatics, carry only a transparent lymph; and instead of one thoracic duct, there are two, which go to the jugular veins. In these circumstances, it would seem that the ducts differ from the human subject, so far at least as we may judge from the diffention of a goose, the common subject of this inquiry, and from which the following description is taken.

The lacteals run from the intestines upon the mesenteric vessels: those of the duodenum pafs by the side of the pancreas; afterward they get upon the cæcal artery, of which the superior mesenteric is a branch. Here they are joined by the lymphatics of the liver, and then they form a plexus which surrounds the cæcal artery. Here also they receive a lymphatic from the gizzard, and soon after another from the lower part of the cæophagus. At the root of the cæcal artery they are joined by the lymphatics from the glandulae renales, and near the same part by the lacteals from the other small intestines, which vessels accompany the lower mesenteric artery; but, before they join those from the duodenum, receive from the rectum a lymphatic, which runs from the blood-vessels of that gut. Into this lymphatic some small vesseis from the kidneys seem to enter at the root of the cæaliac artery. The lymphatics of the lower extremities probably join those from the intestines. At the root of the cæaliac artery and contiguous part of the aorta, a net-work is formed by the vessels above described. From this net-work arise two thoracic ducts, of which one lies on each side of the spine, and runs obliquely over the lungs to the jugular vein, into the inside of which it terminates, nearly opposite to the angle formed by the vei of the vein and this subclavian one. The thoracic duct of the left side is joined by a large lymphatic, which runs upon the oesophagus. The thoracic ducts are joined by the lymphatics of the neck, and probably by those of the wings where they open into the jugular veins. The lymphatics of the neck generally convey two large branches, on each side of the neck, accompanying the blood-vessels; and these two branches join near the lower part of the neck, and form a trunk which runs close to the jugular vein, and opens into a lymphatic gland; from the opposite side of this gland a lymphatic comes out, which ends in the jugular vein.

On the left side, the whole of this lymphatic joins the thoracic duct of the same side: but, on the right one, part of it goes into the inside of the jugular vein a little above the angle; whilst another joins the thoracic duct, and with that duct forms a common trunk, which opens into the inside of the jugular vein, a little below the angle which that vein makes with the subclavian. This system in birds differs most from that of quadrupeds, in the chyle being transparent and colourless, and in there being no visible lymphatic glands, neither in the course of the lacteals, nor in that of the lymphatics of the abdomen, nor near the thoracic ducts.

The kidneys lie in the hollow excavated in the side Kidneys.

of the back-bone, from which there is sent out a bluish-coloured canal running along by the side of the vas deferens, and terminating directly in the common cloaca. This is the urerter which opens by a peculiar aperture of its own, and not at the penis. Birds having no vesica urinaria, it was thought by some they never passed any urine, but that it went to the nourishment of the feathers: but this is false; for that whitish substance that you see their greenish faces covered with, and which turns afterwards chalky, is their urine. Let us next consider the organs of generation of both sexes, and first those of the male.

The testicles are situated one on each side of the backbone; and are proportionally very large to the size of the creature's bulk. From these run out the vesica feminina, the coition being at the same time very short: These terminate in the penis, of which the cock has two, one on each side of the common cloaca, pointing directly forwards. They open at a distance from each other, and are very small and short; whence they have escaped the notice of anatomists, who have often denied their existence. In birds there is no prostate.
COMPARATIVE ANATOMY.

OF FOWLS. The raccatus velllorum, being analogous to the ovaria in the human subject, are attached by a proper membrane to the back-bone. This is very fine and thin, and continued down to the uterus. Its orifice is aperus with respect to the ovary; yet notwithstanding, by the force of the organis veneris, it is turned round and grasps the vitellus, which in its passage through this duct, called the infundibulum, receives a thick gelatinous liquor, secreted by certain glands. This, with what it receives in the uterus, composes the white of the egg. By this tube then it is carried into the uterus. The fistula is lined with a membrane; and in the large end there is a bag full of air, from which there is no outlet.

The uterus is a large bag, placed at the end of the infundibulum, full of wrinkles on its inside; here the egg is completed, receiving its last involucrum, and is at last pushed out at an opening on the side of the common cloaca. From these in the male being so very large in proportion to the body of the creature, there must necessarily be a great quantity of fermen seceded; hence the animal is false and becomes capable of impregnating many females. The want of the vesicula femoralis is in some measure supplied by the convolutions of the vagina deferentia, and by the small distance between the seceding and excretory organs. The two pences contribute also very much to their short cotion; at which time the opening of the uterus into the cloaca is very much dilated, that the effect of the fermen on the vitellum may be the greater.

A hen will of herself indeed lay eggs; but these are not impregnated, and yet appear entirely complete, except that the small black spot, which comes afterwards to be the rudiments of the chick, is not here to be observed. After having observed the contents of the abdomen and thorax, we next proceed to examine the parts about the neck and head.

These creatures, as was observed of fowls in general, have no teeth. Some, indeed, have an appearance of teeth; but these are only small proclives or ferra rising out from the mandible, without any socket, &c. which would be needes, as they swallow their food entire. But their tongues are made pretty firm, left it should be hurt by the sharp points of the grain they feed on. It is of a triangular figure, and pointed before; and as by their depending posture their meat is in hazard of falling out of their mouths, to prevent this there are several small pointed papillae standing out upon their tongue and palate, with their points inclined backwards, allowing an easy passage to the food, but hindering it to return.

We have here no velum palatinum, uvula, or epiglottis; and in place of two large holes opening into the nose, there is only a long narrow rima supplied with pretty strong muscles, and such another supplies the place of a glottis. The creature has a power of shutting both at pleasure; and the nature of their food seems not only to exempt them from the hazard of its getting into the nose or trachea, but its sharp points would hurt an uvula, or epiglottis, if they had any.

Hence we see with what difficulty they swallow dough or other sort of food that can be easily moulded into any form. When we examine the upper end of the trachea, we observe a rima glottidis with cellular sides, which may act in preventing the food or drink from passing into the lungs, for there is no epiglottis as in man and quadrupeds.

Their cranium is more cellular and cavernous than ours. By this means their heads are light, yet strong enough to resist external injuries; for the enlarging the diameter of bones contributes to their strength. By this cavernous cranium the organ of smelling is supposed to be considerably enlarged; and further, fishing birds, as is observed by Mr Ray and Mr Derham, have this cavernous structure of the brain still more observable: and we are told that the cavity of the tympanum communicates with the cells: but this seems rather founded on theory than matter of fact. Their brain is covered with the common membranes, but its external surface is not formed into so many gyres or convolutions as ours. Its anterior part is quite solid, of a cineritious colour, and so far has a resemblance of the corpora striata as to give rise to the olfactory nerves. The whole of it appears to us as imperfect, and we can scarce determine whether there be anything analogous to a third or fourth ventricle: neither corpus callosum, fornix, nates, or telae, &c. can be observed here; which parts therefore cannot be imagined as absolutely necessary for the functions of life, since we find these creatures perform them sufficiently well. We may perhaps think these serve a particular use in man, who is a rational creature; but then quadrupeds enjoy them in common with men. These protruberances, &c. seem rather to depend on the different disposition of the several parts, being variously connected and meeting in different directions in different places, than their being absolutely necessary for any particular use; and the uses that have been assigned to different parts of the brain by authors, seem to have no foundation but in the author's fancy.

Their organ of smelling is very large, and well provided with nerves; hence they have this sensation very acute. Ravens and other birds of prey give a fierce, painful, and proof of this, by their being able to find out their prey, though concealed from their sight and at a considerable distance.

These birds that grope for their food in the waters, mud, &c. have large nerves, which run quite to the end of their bills, by which they find out and distinguish their food.

The anterior part of their eyes (instead of having the sclerotic coat continued, so as to make near a sphere as in us) turns all of a sudden flat; so that here the sclerotic makes but half a sphere; and the cornea rises up afterwards, being a portion of a very small and distinct sphere so that in these creatures there is a much greater difference between the sclerotic and corneous than in us. Hence their eyes do not jut out of their heads, as in man and quadrupeds. As most of these creatures are continually employed in hedges and thickes. therefore, that their eyes might be secured from these injuries, as well as from too much light when flying in the face of the sun, there is a very elegant mechanism in their eyes. A membrane rises from the internal can-
thus, which at pleasure, like a curtain, can be made to cover the whole eye; and this by means of a proper muscle that rises from the sclerotic coat, and pulling round the optic nerves, runs through the musculus cilioli additiorius (by which however the optic nerves are not compressed) and palpebra, to be inserted into the edge of this membrane. Whenever this muscle ceases to act, the membrane by its own elasticity again discovers the eye. This covering is neither pelliculœ nor opaque, both which would have been equally convenient; but being somewhat transparent, allows as many rays to enter as to make any object just visible, and it is sufficient to direct them in their progression. By means of this membrane it is that the eagle is said to look at the sun.

Quadrupeds also, as we mentioned before, have a small membrane nictitans.

Besides, all fowls have another particularity, the use of which is not so well understood; and that is, a pretty long black triangular purse, rising from the bottom of each eye just at the entry of the optic nerve, and stretched out into their vitreous humour, and one would imagine it gave some threads to the crystalline. To this the French (who probably were the first who took notice of it in their dissections before the Royal Academy) gave the name of bouche noire. This may possibly serve to suffocate some of the rays of light, that they may see objects more distinctly without hurting their eyes. It has a connection with the vitreous, and seems to be joined also to the crystalline, humour. If we suppose it to have a power of contraction (which may be as well allowed as that of the iris), it may so alter the position of the vitreous and crystalline humours, that the rays from any body may not fall perpendicularly upon the crystalline; and this seems to be necessary in them, since they cannot change the figure of the anterior part of their eye so much as we can do: and as this animal is exposed often to too great a number of rays of light, so they have no tapetum, but have the bottom of their eye wholly black on the retina; and in consequence of this, fowls see very ill in the dark.

They have no external ear; but in place thereof a tuft of very fine feathers covering the meatus auditoreus, which easily allows the rays of sound to pass through, and likewise prevents dust or any insect from getting in. An external ear would have been inconvenient in their passing through thickets, and in flying, &c. A liquor is separated in the external part of the ear, or meatus auditoreus, to lubricate the passage, and further prevent the entrance of any insects, &c. The membrana tympani is convex externally; and no muscles are fixed to the bones of their ear, which are rather of a cartilaginous consistence: any tremulous motions impertinent on the air are communicated in these creatures merely by the spring and elasticity of the bones; so, probably, the membrane is not so stretched as in the human ear by muscles. The semicircular canals are very difficult, and easily prepared.

**Sect. III. Anatomy of a Carnivorous Bird.**

We come next to the birds of prey, and for an example shall take a falloon or small hawk. The principal difference to be observed in them, is in their chylopoetic viscera, which may be accounted for from their different way of life.

Immediately under their clavicles, you will observe of Aqueous the oesophagus expanded into their inguvius, which is proportionally less than in the granivorous kind, since their food does not swell so much by maceration; and Inguvius, for the same reason, there is a less quantity of a men­

strum to be found here.

They have also a neuritica succenturatus, plentifully Ventricle­

ly restored with glands, situated immediately above their lus succent­

um, which we see here is thin and muculo-men­

turatus, otherwise than in the granivorous kind: and this difference, which is almost the only one we shall find between the two different species of fowls, is easily accounted for from the nature of their food, which requires less attrition, being easier of digestion than that of the other kind; nevertheless, it seems requisite it should be stronger than the human, to compensate the want of abdominal muscles, which are here very thin.

The same mechanism obtains in this creature's eye; Intellina.
denm that we have hitherto observed. As being a carnivorous animal, its gus are proportionally shorter than those of the granivorous kind; for the reason first given, viz. its food being more liable to corrupt, therefore not proper to be long detained in the body; and for that reason it has no intellina cæca, of which the other species of fowls have a pair. The difference in their wings, beaks, and claws, are obvious; and have been already in some measure observed.

**Chap. III. The Anatomy of Aqueous Animals.**

**Sect. I. Of the Amphibious Tribe.**

Aqueous animals are generally divided into such as have lungs, and such as want them. The first species differ so inconsiderably from an ox or any other quadruped, that a few observations may be sufficient to give an idea of their internal structure; for this purpose, we shall first examine that species of them which most resembles man in the internal structure, the tortoises.

1. Tortoise. The covering of this animal is composed of a shell so remarkably hard and firm in its texture, or armour, that a loaded waggon may go over it without hurting the shell or the animal within it. In the young animal, this shell grows harder in proportion as its contents expand; and this creature never changes its shell as some others do; hence it was necessary for it to be made up of different pieces; and these are more or less distinct in different animals. Their feet are small and weak; and they are exceedingly slow in motion.

It has neither tongue nor teeth; to make up for which, their lips are so hard as to be able to break almost the hardest bodies.

The alimentary canal very much resembles that of the former clafs.

The principal difference is in the circulation of the blood. The heart has two distinct auricles, without any communication; and under these, there is the appearance of two ventricles similar in shape to those of the former clafs; but they may be considered as one cavity; for the ventricle sends out not only the pulmonary artery, but likewise the aorta: for there is a passage in the septum, by which the ventricles communicate freely, and the blood passes from the left into
COMPARATIVE ANATOMY.

142 Blood-vessels.

upwards, those vessels divide and subdivide, and are of aqueous afterwaters, joined by the lymphatics of the neck, which likewise form branches before they join those from below. So that between the thoracic duct and the lymphatics of the same side of the neck, a very intricate net-work is formed; from which a branch goes into the angle between the jugular vein, and the lower part or trunk of the subclavian. This branch lies therefore on the inside of the jugular vein, whilst another goes to the outside of it, and seems to terminate in it, a little above the angle, between that vein and the subclavian.

144

Into the above mentioned receptaculum the lymph-lymphatics of the thorax and duodenum likewise enter, &c.

Those of the duodenum run by the side of the pancreas, and probably receive its lymphatics and a part of those of the liver. The lymphatics of the thorax and duodenum have very numerous anastomoses, and form a beautiful net-work on the artery which they accompany. From this receptaculum likewise (besides the trunk already mentioned, which goes to the right side) arise two other trunks pretty equal in size; one of which runs upon the left side, and the other upon the right side of the left aorta, till they come within two or three inches of the left subclavian vein; where they join behind the aorta, and form a number of branches which are afterwards joined by the lymphatics of the left side of the neck; so that here a plexus is formed as upon the right side. From this plexus a branch issues, which opens into the angle between the jugular and subclavian vein.

145 Serpent and Crocodile. The circulation in these is similar to that of the turtle; but we find only one ventricle. The blood goes from the right auricle to the ventricle which sends out the pulmonary artery and aorta; the blood from the pulmonary artery returns to the left auricle, that from the aorta going to the right auricle, and both the auricles opening into the ventricle.

3. Frog and Lizard. These differ from the former animals, in having only one auricle and a ventricle; and besides, the ventricle sends out a single artery, which afterwards splits into two parts; one to supply the lungs, the other runs to all the rest of the body: from the lungs and from the other parts, the blood returns into the auricle.

Sect. II. Anatomy of Fishes.

Of these we may first observe, that they have a very strong thick cuticle, covered with a great number of scales laid one on another like the tiles of houses. This among other arguments is supposed to prove the human epidermis to be of a squamous structure: but the scales resemble the hairs, wool, feathers, &c. of the creatures that live in air; and below these we observe their proper cuticula and cilia.

The generality of fishes, particularly those shaped like the cod, haddock, &c. have a line running on each side. These lines open externally by a number of swimming ducts, which throw out a mucous or slimy substance by means of which they get to and from the surface, and seem to serve formed. The same purpose with the mucous glands or ducts which are placed within many of our internal organs.

In the next place, these creatures have neither anterior nor posterior extremities, as quadrupeds and fowls; air-bags for their progression is performed in a different way &c.
Teeth of Aquatic Animals.

In the form of large oblong fish, the spawls being observed stretched from the liver to the gall-bladder, but without any apparent cavity, the bile was supposed not to be carried into the gall-bladder, and the fluid thus secreted was supposed to pass into the small ducts of the liver, and to be regurgitated into the canals of the alimentary canal. It is certain, however, that hepatic-cylic ducts exist in fish and in birds.

The gall-bladder is situated a considerable way from their liver, and contains a canal, the cystic duct, which joins with the hepatic duct just at the entry into the gall-bladder. Some fibres are observed to stretch from the liver to the gall-bladder, but without any apparent cavity, the bile was supposed not to be carried into the gall-bladder in the usual way, but that it must either be secreted on the sides of the liver, or regurgitated into it from the canals of the alimentary canal. It is certain, however, that hepatic-cylic ducts exist in fish and in birds.

Teeth for what made, for breaking through which the food flows into smaller ducts, are kept with their backs always uppermost.

The abdomen is covered on the inferior part with a black-coloured thin membrane resembling our peritoneum. It is divided from the thorax by a thin membranous partition, which has no muscular appearance; so that we have now seen two different forms of animals that have no muscular diaphragm.

These creatures are not provided with teeth proper for grinding, but with sharp spurs, or with sharp spines, which the food they eat is generally small fish, or other animals that need no triturating in the mouth, but spontaneously and gradually disintegrate into a liquid chyle. Their teeth serve to grasp their prey, and hinder the creatures they have once caught from escaping again. For the same purpose, the internal cartilaginous latis of the bronchi, and the two rounded bodies situated in the posterior part of the jaws, have a great number of tender hooks fixed into them, in such a manner as that any thing can easily get down, but is hindered from getting back. The water that is excreta taken in along with their food in too great quantities to be received into their jaws in deglutition, passes betwixt the inter- 

""
The air-bladder, and its uses.

The air-bladder of fishes is an organ which is used for buoyancy in water. It is found in many aquatic animals and plays a role in their ability to navigate through the water. This structure is particularly interesting because it demonstrates how different animals have adapted to aquatic environments through evolution.

In fishes, the air-bladder is a sac-like organ that is often found near the collar of the gills. It is typically located under the diaphragm and is connected to the mouth and esophagus. By changing the volume of air in the air-bladder, fishes can adjust their buoyancy, allowing them to ascend or descend in the water column. This is crucial for finding food, escaping predators, and navigating through their aquatic habitats.

The air-bladder is not only a functional structure but also reveals insights into the evolutionary history of aquatic organisms. Its presence in various species of fishes indicates a common adaptation to living in water and highlights the importance of understanding these natural processes for the conservation and study of aquatic biodiversity.
carried through the liver from the intestines in man
and quadrupeds. The sorta in fishes sends off branches
cr which supply all the parts of the body excepting the
gills. From the extremity of those branches the blood
returns to the heart somewhat in the same manner as in
the former clas of animals; only there are two inferi-
ior veins cavae, whereas the former has but one.

Lymphatic vessels in Fishes. We shall take the had-
dock as a general example: for the other fishes, partic-
arily those of the same shape, will be found in gen-
eral to agree with it.

On the middle of the belly of a haddock, immedi-
ately below the outer skin, a lymphatic vessel runs up-
wards from the anus, and receives branches from the
parietes of the belly, and from the fin below the anus:
and having got above them, it receives their lymphatics.
It then goes under the lymphs of the two bones which form the thorax, where it opens
into a net-work of very large lymphatics, which lie
close to the pericardium, and almost entirely furrounds
the heart. This net-work, besides that part of it be-
hind the heart, has a large lymphatic on each side, which receives lymphatics from the kidneys, runs upon
the bones of the thorax backwards; and when it has got
as far as the middle of that bone, it sends off a large
branch from its infide to join the thoracic duct. After
detaching this branch, it is joined by the lymphatics of the thoracic fins, and soon after by a lymphatic
which runs upon the thoracic vessels. It then divides
into a net-work of very large lymphatics, which lie
behind the heart, and have a large lymphatic on each
side, which accompanies the ribs. After the large
network formed by these two branches lies on the
right side of the upper part of the gills, and is joined
by some lymphatics in that part, and also by some from the gills and gall-bladder, which in this fish ad-
heres to the receptaculum. This thoracic duct takes
its rise from the receptaculum, and lies on the right
side of the oesophagus, receiving lymphatics from that
part, and running up about half an inch, it divides
into two ducts, one of which passes over the oeso-
phagus to the left side, and the other goes straight
upon the right side, passes by the upper part of the
kidney, from which it receives some small branches,
and soon afterwards is joined by a branch from the OfAqueous
large lymphatic that lies above the bone of the tho-
rax, as formerly mentioned: near this part it like-
wise sends off a branch to join the duct of the oppo-
site side; and then, a little higher, is joined by those large
lymphatics from the upper part of the gills, and from
the faucies.

The thoracic duct, after being joined by these ves-
se, communicates with the net-work near the orbit,
where its lymph is mixed with that of the lymphatics
from the posterior part of the gills, and from the supe-
rior fins, belly, &c. and then from this net-work, a vef-
se goes into the jugular vein just below the orbit. This
left vessel, which may be called the termination of the
whole system, is very small in proportion to the net-
work from which it rises; and indeed the lymphatics of the part are so large, as to exceed by far the size of the fanguiferous vesels.

The thoracic duct from the left side, having passed
under the oesophagus from the right, runs on the in-
side of the vena cava of the left side, receives a branch
from its fellow of the opposite side, and joins the large
lymphatics which lie on the left side of the pericardium,
and a part of those which lie behind the heart; and
and afterwards makes, together with the lymphatics
from the gills, upper fins, and side of the fif, a net-
work, from which a vessel passes into the jugular vein
of this side. In a word, the lymphatics of the left side
agree exactly with those of the right side above descri-
ned. Another part of the system is deeper seated, ly-
ning between the roots of the spinal proceedes of the
back-bone. This part consists of a large trunk that be-
gins from the lower part of the side, and as it ascends
reaches branches from the dorsal fins and adjacent
parts of the body. It goes up near the head, and sends
a branch to each thoracic duct near its origin.

The brain in fishes is formed pretty much in the Cerebrum.

Their organ of smell is large; and they have an organ of
power of contralating and dilating the entry into their small
noze as they have occasion. It seems to be mostly by
their acute smell that they discover their food: for
their tongue seems not to have been designed for a
very nice sensation, being of a pretty firm cartilagi-
nous substance; and common experience evinces that
their sight is not of so much use to them as their small
in searching for their nourishment. If you throw a
fresh worm into the water, a fish shall distinguish it at
a considerable distance; and that this is not done by
the eye, is plain from observing, that after the same
worm has been a considerable time in the water and
laid its smell, no fishes will come near it: but if you
take out the bait, and make several little incisions into
it, so as to let out more of the odoriferous effluvia, it
shall have the same effect as formerly. Now it is cer-
tain, had the creatures discovered this bait with their
eyes, they would have come equally to it in both ca-
es. In consequence of their smell being the principal
means they have of discovering their food, we may fre-
quently observe their allowing themselves to be carried
down with the stream, that they may attend again
leisurely against the current of the water; thus the od-
oriferous particles swimming in that medium, being
Chap. III.

Comparative Anatomy.

The optic nerves in these animals are not confounded with one another in their middle progress between their origin and the orbit, but the one passes over the other without any communication; so that the nerve that comes from the left side of the brain goes distinctly to the right eye, and vice versa.

Indeed it would seem not to be necessary for the optic nerves of fishes to have the same kind of connection with each other as those of man have; for their eyes are not placed in the fore-part, but in the sides of their head; and of consequence they cannot so conveniently look at any object with both eyes at the same time.

The lens crystallina is here a complete sphere, and more dense than in terrestrial animals, that the rays of light coming from water might be sufficiently refracted. As fishes are continually exposed to injuries in the uncertain element they live in, and as they are in perpetual danger of becoming a prey to the larger ones, it was necessary that their eyes should never be shut; and as the cornea is sufficiently washed by the element they live in, they are not provided with palpebrae; but then, as in the current itself the eye must be exposed to several injuries, there was a necessity that it should be sufficiently defended; which in effect it is by a firm pellucid membrane, that seems to be a continuation of the cuticula, being stretched over here. The epidermis is very proper for this purpose, as being inelastic and destitute of vessels, and consequently not liable to obstructions, or, by that means, of becoming opaque. In the eye of the skate tribe, there is a digited curtain which hangs over the pupil, and may shut out the light when the animal reeds, and it is similar to the tunica adnata of other animals.

Although it was formerly much doubted whether fishes possessed a sense of hearing, yet there can be little doubt of it now; since it is found that they have a complete organ of hearing as well as other animals, and likewise as the water in which they live is proved to be a good medium. Fishes, particularly those of the skate kind, have a bag at some distance behind the eyes, which contains a fluid and a soft cretaceous substance, and supplies the place of vestibule and cochleæ. There is a nerve distributed upon it, similar to the porio mollis in man. They have three semicircular canals, which are filled with a fluid, and communicate with the bag; they have likewise, as the prefent professor of anatomy at Edinburgh has lately discovered, a meatus externus, which leads to the internal ear. The cod fish, and others of the same shape have an organ of hearing somewhat similar to the former; but instead of a soft substance contained in the bag, there is a hard cretaceous stone. In this kind of fish no meatus externus has been yet observed; And Dr. Monro is inclined to think that they really have not one, from the consideration that the common canal or vestibule, where the three semicircular canals communicate, is separated from the cavity of the cranium by a thin membrane only; so that this cavity, in the greater number of fishes, contains a watery liquor in considerable quantity; and that, by the thinnest of the cranium, the termed excited by a sonorous body may readily and easily be transmitted through the cranium to the water within it, and so to the ear.

Chap. IV. The Anatomy of Insects.

As insects and worms are so exceedingly numerous, it would be endless to examine all the different kinds, nor would it serve any useful purpose to the anatomist. We shall therefore be content with making a few general observations, and chiefly on the structure of their body; leaving the variety of their colour, shape, &c. to the naturalists. Insects differ from the former classes, by their bodies being covered with a hard crust or scale, by their having feelers or antennæ arising from their head, and many of them breathing the air through lateral pores. As to the shape of their bodies, though it somewhat differs from that of birds, being in general not so sharp before to cut and make way through the air, yet it is well adapted to their manner of life. The base of their bodies is not formed of bone, as in many other animals, but the hard external covering serves them for skin and bone at the same time. Their feelers, beside the use of cleaning their eyes, are a guard to them in their walk or flight. Their legs and wings are well fitted for their intended service; but the latter vary so much in different insects, that from them naturalists have given names to the several orders of the class. As, first, the Coleoptera, or beetle tribe, which have a cuticaceus elytra or shell, that thus together, and forms a longitudinal future down their back. Hymenoptera—as in cimex, cockroach, bug, &c. which have the upper wings half crullaceous and half membraneous; nor divided by a longitudinal future, but incumbent on each other. Lepidoptera—as the butterfly, have four wings, covered with fine scales in the form of powder. Neuroptera—as the dragon-fly, spring-fly, &c. have four membraneous transparent naked wings, generally reciliated. Hymenoptera—as wasps, bees, &c. have four membraneous wings, and a tail furnished with a sting. Diptera—as the common house-fly, have only two wings. Apida—as the robber, crab, scorpion, spider, &c. have no wings.

The structure of the eye in many insects is a most curious pieces of mechanism. The outer part is remarkably hard, to guard against injuries; and has commonly a reticular appearance, or the whole may be looked upon as an assemblage of smaller eyes; but whether they see objects multiplied before them, has not yet been determined.

Limæus, and several others following him, deny the existence of a brain in these creatures. But it is certain, that at least a number of the larger kinds, as the lobster, crab, &c. have a soft substance similar to the brain, from which the optic and other nerves take their rise; besides, when this substance is removed, the animal is thrown into convulsions; hence we would conclude, that insects have a brain as well as the former classes, although this is smaller in proportion to their bodies.

Their ear has been lately discovered to be placed at the root of their antennæ or feelers, and can be
COMPARATIVE ANATOMY.

Chap. V.

Of Insects, distinctly seen in some of the larger kinds, as the lobster.

They have a stomach, and other organs of digestion; and it is curious, that in some, as the lobster, the teeth are found in the stomach.

They have a heart and blood-veins, and circulation is carried on in them somewhat as in the former classes; but the blood is without red globules; or, as naturalists speak, is colourless. In the lobster, and others of the larger kind, when a piece of the flesh is broken, the pulsation of the heart is seen distinctly, and that sometimes for several hours after it has been laid bare.

Lungs. The existence of these by some has been denied. But late experiments and observations show, that no species want them, or at least something similar to them; and in many insects, they are larger in proportion than in other animals: in most of them they lie on or near the surface of their body; and send out lateral pores or tracheae, by which, if the animal is binseared with oil, it is instantly suffocated.

Generation. The same difference in sex exists in insects as in other animals, and they even appear more disposed to increase their species; many of them, when become perfect, seeming to be created for no other purpose but to propagate their like. Thus the fly-worm, when it arrives at its perfect or moth-state, is incapable of eating, and can hardly fly; it endeavours only to propagate its species: after which the male immediately dies, and so does the female as soon as it has deposited her eggs.

Besides those of the male and female, a third sex exists in some insects, which we call neuter. As these have not the distinguishing parts of either sex, they may be considered as eunuchs or infertile. We know of no instance of this kind in any other class of animals; and it is only found among those insects which form themselves into societies, as bees, wasps, and ants: and here these eunuchs are real slaves, as on them lies the whole burden of the economy. No hermaphrodites have as yet been discovered among insects.

Many have imagined that the generality of insects were merely the production of putrefaction, because they have been observed to arise from putrified substances: but a contrary opinion is now more generally adopted; and it is pretty certain, that if putrid bodies be shut up in a close vessel, no insects are ever generated unless their ova have been originally deposited there. They are oviparous animals, and lay their eggs in places most convenient for the nourishment of their young; some in water, others in flesh; some in fruit, and leaves: while others make nests in the earth or in wood, and sometimes even in the hardest stone. The eggs of all insects first become (larva) caterpillar or maggot; from which they are changed into (pupa) chrysalis or auraria, so named from their being enclosed in a case; and these dying, or seeming to die, the (imagio) fly, or butterfy or perfect state, succeeds; and during each of these changes their appearance differs wonderfully.

Some of those in the first order, as the common round worms, have a vascular and nervous system, with the parts of generation, which can be distinctly seen. Some, as the cattle fly, have a kind of connection between fishes and worms, in poulfelling gills but wanting fins, &c. while others, as those of the lowest order, or zoophyta, join the properties of the animal and vegetable kingdom together.

The class is divided by Linnaeus, &c. into the following orders, viz.

1. Intestina—as the earth worm, leech, &c. which are the most simple animals, being perfectly naked, and without limbs of any kind.

2. Mollusca—as the naked snail, sea-star, cuttle fish; which are likewise simple animals without any shell, but they are brachiated or furnished with a kind of limbs.

3. Teflacea—as the snail, oyster, &c. which have the same characters as the former order, but are covered with a shell, and include the greater part of what we commonly call shell-fishes.

4. Echinoidea—as corals, madrepors, &c. which are compound animals fixed upon a calcareous bafe, constructed by the creatures themselves.

5. Zoophyta—as the sponge, polypes, &c. These are likewise compound animals, furnished with a kind of flowers, and having a vegetating root and stem.

Some of these creatures inhabit the earth, others live on the reef of the animal or on the vegetable kingdom, and many are found in the hardest stones; while an innumerable tribe of them live in the waters. In general, they are said to be of the hermaphrodite and oviparous kind; while the lowest class, as the polyps, in a great measure resemble the vegetable kingdom in their manner of growth.
Comparisons may give pleasure by these various means: they have, probably, several ideas distinct enough; but cannot compare them farther than as to some sensible circumstances annexed to the objects themselves; the power of comparing general ideas, which we observe in men, we may probably conjecture they have not at all.

Comparison, in grammar, the infection of the comparative degree. See Grammar.

Comparison, in rhetoric, is a figure whereby two things are considered with regard to some third, which is common to them both.

Instruction is the principal, but not the only end of comparison. It may be employed with success in putting a subject in a strong point of view. A lively idea is formed of a man’s courage by likening it to that of a lion; and eloquence is excelled in our imagination by comparing it to a river overflowing its bank, and involving all in its impetuous course. The same effect is produced by contrast: a man in prosperity becomes more sensible of his happiness, by comparing his condition with that of a person in want of bread. Thus comparison is subservient to poetry as well as to philosophy.

Comparisons serve two purposes: when addressed to the understanding, their purpose is to instruct; when to the heart, their purpose is to pleasé. Various means contribute to the latter: 1st, the suggesting some unprofitable resemblance or contrast*; 2d, the feiting an object in the strongest light; 3d, the associating an object with others that are agreeable; 4th, the elevating an object; and 5th, the depriving it. And that comparisons may give pleasure by these various means, will be made evident by examples which shall be given, after premising some general observations.

Objects of different senses cannot be compared together; for such objects are totally separated from each other, and have no circumstance in common to admit either resemblance or contrast. Objects of hearing may be compared together, as sô of taste, of smell, and of touch: but the chief fund of comparison are objects of sight; because, in writing or speaking, they can only be compared in idea, and the ideas of sight are more distinct and lively than those of any other sense.

When a nation emerging out of barbarity begins to think of the fine arts, the beauties of language cannot long lie concealed; and when discovered, they are generally, by the force of novelty, carried beyond all bounds of moderation. Thus, in the earliest poems of every nation, we find metaphors and similes founded on the lightest and most distant analogies, which, losing their grace with their novelty, wear gradually out of repute; and now, by the improvement of taste, no metaphor nor simile is admitted into any polite composition but of the most striking kind. To illustrate this observation, a specimen shall be given afterward of such metaphors as we have been describing: with respect to similes take the following specimen:

“Behold, thou art fair, my love: thy hair is as a flock of goats that appear from Mount Gilboa; thy teeth are like a flock of sheep from the washing, every one bearing twins; thy lips are like a thread of scarlet: thy neck like the tower of

“David built for an armory, whereon hang a thousand shields of mighty men: thy two breasts like two young roes that are twins, which feed among the lilies: thy eyes like the daffy-pins in Hethlon, by the gate of Bath-rabbib: thy note like the tower Lebanon, looking toward Damascus.”

Song of Solomon.

“Thou art like snow on the heath, thy hair like the midst of Cromla, when it curls on the rocks and shines to the beam of the west: thy breasts are like two smooth rocks seen from Branno of the streams: thy arms like two white pillars in the hall of the mighty Fingal.”

Fingal.

It has no good effect to compare things by way of simile that are of the fame kind; nor to contrast things of different kinds. The reason is given in the article above cited on the margin, and shall be here illustrated by examples. The first is a comparison built upon a resemblance so obvious as to make little or no impression. Speaking of the fallen angels searching for mines of gold:

A numerous brigade hasten’d: as when bands of pioneers with spade an pick-ax arm’d, Forerun the royal camp to trench a field Or call a rampart.

The next is of things contrasted that are of different kinds.

Queen. What, is my Richard both in shape and mind
Transform’d and weak? Hath Bolingbroke depos’d Thine intellect? Hath he been in thy heart? The lion, dying, threeth forth his paw, And wounds the earth, if nothing else with rage To be o’erpower’d: and wilt thou, pupil like, Take thy correction mildly, kiss the rod, And fawn on rage with base humility?

Richard II. act. 5. sc. 1.

This comparison has scarce any power; a man and a lion are of different species, and therefore are proper subjects for a simile; but there is no such resemblance between them in general, as to produce any strong effect by contrasting particular attributes or circumstances.

A third general observation is, that abstract terms can never be the subject of comparison, otherwise than by being personified. Shakespeare compares adversity to a toad, and flander to the bite of a crocodile; but in such comparisons these abstract terms must be imagined sensible beings.

To have a just notion of comparisons, they must be distinguished into two kinds; one common and familiar, as where a man is compared to a lion in courage, or to a horse in speed; the other more distant and refined, where two things that have in themselves no resemblance or opposition, are compared with respect to their effects. There is no resemblance between a flower-plot and a cheerful song; and yet they may be compared with respect to their effects, the emotions they produce in the mind being extremely similar. There is as little resemblance between fraternal concord and precious ointment; and yet observe how successfully they are compared with respect to the impressions they make.

“Behold, how good and how pleasant it is for brethren to dwell together in unity. It is like

the
"...Compari­

...son.

For illustrating this fort of comparison, we shall add

some more examples:

"Delightful is thy presence, O Fingal! it is like

"the fun on Croata, when the hunter mourns his

"absence for a season, and fees him between the

"clouds.

"Did not Ossian hear a voice! or is it the sound

"of days that are no more! Often, like the evening-

"fun, comes the memory of former times on my

"fool.

"His countenance is settled from war; and is

"calm as the evening-beam, that from the cloud

"of the west looks on Coos'a silent vale." Fingal.

We now proceed to illustrate, by particular instan-

ces, the different means by which comparisons, whether of the one fort or the other, can afford pleasure; and, in the order above established, we shall begin with such instances as are agreeable, by suggesting some un

fiful resemblance or contrast.

Sweet are the uxes of Adversity,

Which, like the toad, ugly and venomous,

Wears yet a precious jewel in her head:

As you like it, ad ft. 2. fc. 1.

See how the Morning opens her golden gates,

And takes her farewell of the glorious fun.

How well it resembles the prime of youth,

Trim'd like a yonker prancing to his love.

Second Part Henry VI., ad ft. 2. fc. 1.

Thus they their doubtfull confidurations dark

Ended, rejoicing in their matchles officers:

As when from mountain tops, the dusky clouds

Ascend, while the North-wind sleeps, o'erspread

Heav'n's cheerful face, the lowering element

Scowls o'er the dark'en'd landscape, snow, and

shower;

If chance the radiant fun with farewell sweet

Extends his evening-beam, the fields revive,

The birds their notes renew, and bleating herds

Atteal their joy, that hill and valley rings.

Paradise Lost, book 2.

None of the foregoing similes tend to illustrate the principal subject: and therefore the chief pleasure they afford must arise from suggesting resemblances that are not obvious: for undoubtedly a beautiful subject introduced to form the simile affords a separate pleasure, which is felt in the similes mentioned, particularly in that cited from Milton.

The next effect of a comparison in the order men-
nioned, is to place an object in a strong point of view; which effect is remarkable in the following similes.

As when two scales are charg'd with doubtful loads,

From side to side the trembling balance nods,

(While some laborious matron, just and poor,

With nice exactness weighs her woolly flore),

Till pois'd aloft, the refting beam dupends

Each equal weight; nor this nor that defends;

So ftood the war, till Hector's matchles might,

With fates prevailing, turn'd the scale of fight.

Fierce as a whirlwind up the walls he flies,

And fires his bolt with loud repeated cries.

Iliad, b. xii. 521.

She never told her love;

But let concealment, like a worm i' th' bud,

Feed on her damask cheek: the pin'd in thought;

And with a green and yellow melancholy,

She figh like patience on a monument,

Smiling at grief. Twelfth Night, ad. 2. fc. 6.

"There is a joy in grief when peace dwells with

"the sorrowful. But they are wait'd with mourning,

"O daughter of Tofer, and their days are

"few. They fall away like the flower on which

"the sun looks in his strength, after the milde

"has pafted over it, and its head is heavy with the

"drops of night."

Fingal.

"Out, out, brief candle!

Life's but a walking shadow, a poor player,

That struts and frets his hour upon the stage,

And then is heard no more.

Macbeth, ad 5. fc. 5.

O thou godfess,

Thou divine nature! how thyfelf thou blazon'd

In these two princely boys! they are as gentle

As zephyrs blowing below the violet,

Not waging his sweet head; and yet as rough

(Their royal blood inchaf'd) as the rud'd wind,

That by the top doth take the mountain-pine,

And make it bow to th' vale.

Cymbeline, ad 4. fc. 4

"Why did not I pass away in secret, like the

"flower of the rock that lifts its fair head unseen,

"and throw's its withered leaves on the blast?"

Fingal.

As words convey but a faint and obscure notion of great numbers, a poet, to give a lively notion of the object he describes with regard to number, does well to compare it to what is familiar and commonly known. Thus Milton compares the Grecian army in point of number to a surf of bees: in another passage he compares it to that profusion of leaves and flowers which appear in the spring, or of infects in a summer's evening: And Milton,

As when the potent rod

Of Aram's son in Egypt's evil day

Wav'd round the coaft, up cal'd a pitchy cloud

Of locusts, warping on the eaftern wind,

That o'er the realm of impious Pharaoh hung

Like night, and dark'en'd all the land of Nile;

So numberles were those bad angels seen,

Hov'ring on wing under the cope of hell,

'Twixt upper, nether, and surrounding fires.

Paradise Lost, book 1.

Such comparisons have, by some writers, been con-
demned for the lowness of the images introduced; but surely without reason; for, with regard to numbers, they put the principal subject in a strong light.

The foregoing comparisons operate by resemblance; others have the same effect by contrast.

Ter. I am the last of noble Edward's sons,

Of whom thy father, prince of Wales, was first;

In war, was never lion rag'd more fierce;

In peace, was never gentle lamb more mild;

'Than was that young and princely gentleman.

His face thou hail, for even to look'd he,

Accomplish'd with the number of thy hours.
By the time the purpose of comparision, and the various impressions it makes on the mind, are sufficiently illustrated by proper examples. This was an easy work. It is more difficult to lay down rules about the propriety or impriropy of comparisons; in what circumstances they may be introduced, and in what circumstances they are out of place. It is evident that a comparision is not proper upon every occasion; a man in his cool and sedate moments, is not disposed to poetical flights, nor to sacrifice truth and reality to the delusive operations of the imagination: far less is he so disposed, when oppressed with care, or interested in some important transaction that occupies him totally. On the other hand, it is observable, that a man, when elevated or animated by any passion, is disposed to elevate or animate all his subjects: he avoids familiar names, exalts objects by circumlocution and metaphor, and gives even life and voluntary action to inanimate beings. In this warmth of mind, the highest poetical flights are indulged, and the boldest similes and metaphors relished. But without fparing to high, the mind is frequently in a tone to relieve chaste and moderate ornament; such as comparisions that set the principal object in a strong point of view, or that embellish and diversify the narration. In general, when by any animating passion, whether pleasant or painful, an impulse is given to the imagi-
nation; we are in that condition disposed to every
fort of figurative expression, and in particular to com-
parisons. This in a great measure is evident from
the comparisons already mentioned; and shall be fur-
ther illustrated by other instances. Love, for example,
in its infancy, routs the imagination, prompts the
heart to display itself in figurative language, and in
similes:

_Troilus._ Tell me, Apollo, for thy Daphne's love,
What Cressida is, what Pandar, and what we?
Her bed is India, there she lies a pearl;
Between our Ilium, and where the refuces,
Let it be call'd the wild and wandering flood;
Ourself the merchant, and this failing Pandar
Our doubtful hope, our convoy, and our bark.

_Troilus and Cressida, ad 1. sc. 1._

Again:

_Come, gentle night; come, loving black-brow'd
night!_
Give me my Romeo; and when he shall die,
Take him, and cut him out in little stars,
And he will make the face of heav'n so fine,
That all the world shall be in love with night,
And pay no worship to the garish sun.

_Romeo and Juliet, ad 3. sc. 4._

But it will be a better illustration of the present
head, to give examples where comparisons are improp-
erly introduced. Similes are not the language of a
man in his ordinary state of mind, disparching his
daily and usual work: for that reason, the following
speech of a gardner to his servant is extremely improp-
er:

Go bind thou up yon dangling apricots,
Which, like unruly children, make their fare
Stoop with oppression of their prodigal weight;
Give some succourance to the bending twig.
Go thou, and, like an executioner,
Cut off the heads of two-fail growing sprints,
That look too lofty in our commonwealth:
All must be even in our government.

_Richard II. ad 3. sc. 7._

The fertility of Shakespeare's vein betrays him fre-
quently into this error.

Rooted grief, deep anguish, terror, remorse, de-
despair, and all the severe dispiriting passions, are decla-
red enemies, perhaps not to figurative language in
general, but undoubtedly to the pomp and solemnity of
comparison. Upon this account, the finite pronounced
by young Rutland, under terror--of death from an
inveterate enemy, and praying mercy, is unnatural:

So looks the pent-up lion o'er the wretch
That trembles under his devouring paws;
And so he walks infulting o'er his prey,
And so he comes to rend his limbs asunder.
Ah, gentle Clifford, kill me with thy sword
And not with such a cruel threat'ning look.

_Third part, Henry VI. ad 1. sc. 5._

A man spent and dispirited after losing a battle, is
not disposed to heighten or illurdate his discourse by
similes:

_Tork._ With this we charged again; but out! alas,
We bodged' d again; as I have seen a lwan
With boodles labour swim against the tide,
And spend their strength with over-matching waves.
Ah! bark, the fatal followers do pounce;
Meanwhile the troops beneath Patroclus' care,
Invade the Trogans and commence the war.
As waps, provok'd by children in their play,
Pour from their mansions by the broad high-way,
In wars the guiltefs traveller engage,
Whet all their wings, and call forth all their rage;
All rise in arms, and with a general cry
Affert their waxen domes and burning progeny:
Thus from the tents the fervent legion swarms,
So loud their clamours, and so keen their arms.
Iliad, xvi. 312.

So burns the vengeful hornet (foul all o'er)
Relpa'd in vain, and thifty fill of gore;
(Bold fon of air and heat) on angry wings
Untam'd, untrim'd, he turns, attacks, and flings.
Flit'd with like ardour, fierce Atrides flew,
And sent his foul to the vengeful hornet (foul all o'er)
In swarms after Patroclos' care,
Invade the Trogans and commence the war.
And howl'd to find it.
Thus from the tents the fervent legion
Engage, with a general cry
As dwarfs upon knights-errant do.

Load as a bull makes hill and valley ring,
So roar'd the lock when it releas'd the spring.
Odyssey, xxi. 51.

Such a simile upon the simplicity of all actions, that of opening a lock, is pure burlesque.
A writer of delicacy will avoid drawing his comparisons from any image that is nauseous, ugly, or remarkably disagreeable; for however strong the resemblance may be, more will be lost than gained by such comparison. Therefore we cannot help condemning, though with some reluctance, the following simile, or rather metaphor.

O thou fond many! with what loud applause
Didst thou hear heav'n with bleffing Bolingbroke
Before he was what thou wouldst have him be?
And now being trimm'd up in thine own desires,
Thou, beaftly feeder, art fo full of him,
That thou provokst thyself to call him up.
And fo, thou common dog, didst thou disgorge
Thy gluton bosom of the Royal Richard,
And now thou wouldst eat thy dead vomit up,
And howl'd to find it.

Second Part Henry IV, act 1, fc. 6.

The strongest objection that can lie against a comparison is, that it consists in words only, not in fense. Such falfe coin, or baftard-wit, does extremely well in burlesque; but is far below the dignity of the epic, or of any serious composition.
The noble fitter of Poplicola,
The moon of Rome: chaife as the icicle
That's cur'dd by the frost from pureft snow,
And hangs on Dian's temple.
Coriolanus, act 5, fc. 3.

There is evidently no resemblance between an icicle
And a woman, chaife or meafe: but chaftity is cold
In a metaphorical fense, and an icicle is cold in a pro­
fper fense; and this verbal resemblance, in the hurry
and glow of compofing, has been thought a fufficient
foundation of the simile. Such phantom similes are
mere witcifins, which ought to have no quarter,
except where purpofely introduced to provoke laugh­
ter. Lucian, in his difciffion upon history, talking of
a certain author, makes the following comparifon,
which is verbal merely.

"This author's defcriptions are fo cold, that they
"farfafs the Caffian snow, and all the ice of the
"nordh."

—But for their spirits and souls
This word rebellion had froze them up
As fish are in a pond.

Second part Henry IV, act 1, fc. 3.
Pope has feveral similes of the fame stamp.
And hence one matter paffion in the breath,
Like Aaron's tertp, swallow'd up the refi.
Epif. 2. I. 131.

And again, talking of this fame ruling or matter paffion:
Nature its mother, Habit is its nurse;
Wit, spirit, faculties, but make it worfe;
Reason itself but gives it edge and pow'r;
As heav'n's blef'sd beam turns vinegar more four.
Ibid. I. 145.

Where the subject is burlesque or ludicrous, fuch
similes are far from being improper. Horace says
pleafantly,
Quaunguum tu levior cortice.
Lib. 3. ed. 9.

And Shakspeare,
In breaking oaths he's stronger than Hercules.
And this leads to obferve, that besides the foregoing comparisons, which are all serious, there is a species, the end and purpofe of which is to excite
gaiety and mirth. Take the following examples.

Falstaff speaking to his page:
"I do here walk before thee, like a sow
That's cmd'd by the froft from pureft snow.
Hudibras, canto 1.

"Books, like men, their authors, have but one
Way of coming into the world; but there are
ten thousand to go out of it, and return no more."
Tales of a Tub.

"The moft accomplished way of using books at
'prefent is, to ferve them as some do lords, learn
their titles, and then brag of their acquaintance."
Ibid.

"He does not confider, that finceny in love is
'as much out of fashion as sweet snuff; no body
'takes it now.'
Carlelft Huband.

COMPARTITION, in architecture, denotes the useful and graceful disposition of the whole ground-plot of an edifice, into rooms of office, and of reception or entertainment.
COMPARTMENT, in general, is a design composed of several different figures, disposed with symmetry, to adorn a parterre, a ceiling, &c.

A compartment of tiles or bricks, is an arrangement of them, of different colours, and varnished, for the decoration of a building. Compartments in gardening, are an assemblage of beds, plots, borders, walks, &c. disposed in the most advantageous manner that the ground will admit of. Compartments in heraldry, are otherwise called partitions.

COMPASS, or Navigator's Steering Compass, is an instrument used at sea by pilots to direct and ascertain the course of their ships. It consists of a circular brass box, which contains a paper card with the 32 points of the compass, fixed on a magnetic needle that always turns to the north, excepting a small declination variable at different places. See Variation.

The needle with the card turns on an upright pin fixed in the centre of the box. In the centre of the needle is fixed a brass conical cap or head by the card hanging on the pin turns freely round the centre.

The top of the box is covered with a glass, that the card's motion may not be disturbed by the wind. The whole is enclosed in another box of wood, where it is supported by brass hoops or gimlets, to preserve the card horizontal. The compass-box is to be so placed in the ship, that the middle section of the box, parallel to its sides, may be parallel to the middle section of the ship along its keel.

The compass being of the utmost consequence to navigation, it is reasonable to expect that the greatest attention should be used in its construction, and every attempt to improve it carefully examined, and, if proper, adopted. But so careless are the generality of commanders of this most useful instrument, that almost all the compasses used on board merchant-ships have their needles formed of two pieces of steel wire, each of which is bent in the middle, so as to form an obtuse angle; and their ends, being united together, make an acute one: so that the whole represents the form of a lozenge; in the centre of which, and of the card, is placed the brass cap. Now, if we examine a number of these cards, we shall rarely, if ever, find them all in the same direction, but they will all vary more or less, not only with regard to the true direction, but from one another.

These irregularities are owing to the structure of the needle; for the wire of which it is composed are only hardened at the ends; now, if these ends are not equally hard, or if one end be hardened up higher than the other, when they come to be put together, in fixing them to the card, that end which is hardest will destroy much of the virtue of the other; by which means the harder end will have the most power in directing the card, and consequently make it vary towards its own direction: and, as the wires are disposes in the form of a lozenge, these cards can have but little force, so that they will often, when drawn aside, stand at the distance of several degrees on either side the point from whence they are drawn: for all magnetic bodies receive an additional strength by being placed in the direction of the earth's magnetism, and act proportionately less vigorously when turned out of it; wherefore, when these kinds of needles are drawn aside from their true point, two of the parallel sides of the lozenge will converge, more directly than before, with the earth's magnetism; and the other two will be less in that direction: by which means the two sides will very much impede its return; and the two latter will have that impediment to overcome, as well as the friction, by their own force alone.

To remove these inconveniences, some needles are made of one piece of steel of a spring temper, and broad towards the ends, but tapering towards the middle, where a hole is made to receive the cap. At the ends they terminate in an angle, greater or less according to the skill or fancy of the workman. These needles, though infinitely preferable to the other, are, however, far from being perfect; for every needle of this sort hath six poles instead of two, one at each end, two where it becomes tapering, and two at the hole in the middle; this is owing to their shape; for the middle part being very slender, it has not substance enough to conduct the magnetic stream quite through, from one end to the other: all these poles appear very distinctly, when examined with a glass that is sprinkled over with magnetic sand. This circumstance, however, does not hinder the needle from pointing true; but as it has less force to move the card than when the magnetic stream moves in large curves from one end to the other, it is certainly an imperfection.

These inconveniences induced the ingenious Dr. Knight to contrive a new sea-compass, which came into use on board all the ships of war. The needle in this instrument is quite straight, and square at the ends; and consequently has only two poles, though about the hole in the middle the curves are a little confused. Needles of this construction, after vibrating a long time, will always point exactly in the same direction; and if drawn ever so little on one side, will return to it again, without any sensible difference. We may therefore conclude, that a regular parallel-fitted is the best form for a needle, as well as the simplest, the holes for the caps being as small as possible.

And as the weight should be removed to the greatest distance from the centre of motion, a circle of brass, of the same diameter of the card, may be added, which will serve also to support the card, which may then be made of this paper, without any thing to stiffen it. This ring being fixed below the card, and the needle above it, the centre of gravity is placed low enough to admit of the cap being put under the needle, whereby the hole in the needle becomes unnecessary.

The above observations will be easily understood from viewing the several parts of the instrument as represented on Plate CXLIV. where fig. 6. is the card, with the needle KL, and its cap M, fixed upon it, being one third of the diameter of the real card. Fig. 8. is a perspective view of the back side of the card, where AB represents the turning down of the brass edge, C the under part of the cap, D and E two sliding weights to balance the card, and F, G, two screws that fix the brass edge, &c. to the needle. Fig. 7. is the pedestal that supports the card, containing a screwing needle, fixed in two small grooves to receive it, by
...tion of the compass is usually ascribed to Flavio da Molis, or Flavio Gioia, a Neapolitan, about the year 1302; and hence it is, that the territory of Principato, which makes part of the kingdom of Naples, where he was born, has a compass for its arms. Others say that Marcus Paulus, a Venetian, making a journey to China, brought back the invention with him in 1200. What confirms this conjecture is, that at first they used the compass in the same manner as the Chinese still do; i.e. they let it float on a little piece of cork, instead of suspending it on a pivot. It is added, that their emperor Chiningus, a celebrated astrologer, had a knowledge of it 1120 years before Christ. The Chinese only divide their compasses into 24 points. Fauchette relates some verses of Guoyot de Provence, who lived in France about the year 1200, which seem to make mention of the compass under the name of marinette, or mariner's stone; which how it to have been used in France near 100 years before either the Melite or Venetian. The French even lay claim to the invention, from the fleur de lys whereby all nations shall distinguish the north point of the card. With as much reason Dr. Wallis ascribes it to the English, from its name compas, by which name most nations call it, and which he observes is used in many parts of England to signify a circle.

Though the mariner's compass has been long in use, the best construction of it was attended with many inconveniences, till the late improvement which it has received from the invention and experiments of Dr. Gowin Knight, and the farther emendation of Mr. Smeeaton, as has been described under the article Azimuth (Vol. II.).

The compasses have sometimes been observed to be disturbed by the electrity of its glass cover: and this from fio flight an application of the finger as was barely necessary to wipe off a little dust. The same glass, rubbed a little more with the finger, a bit of wax, or paper, would attract either end of the needle, so as to hold it to the glass for several minutes, in consequence of the attraction of that part of the glass which was most excited. And when the needle, after adhering to the glass, has dropped loose, and made vibrations, those would not be bisected as usual by that point where the needle should rest, but either be made all on one side, or be very unequally divided, by means of some remains of electrical virtue in that part of the glass which had attracted the needle, until at length, after 15 minutes or more, all the electricity being discharged, the magnetic power took place. The remedy for this inconvenience is to moisten the surface of the glass; a wet finger will do it immediately and-effectually. The mariner's compass with a chart is much less dangerously moved than the common compass with a bare needle: and the deeper, or farther distant, the needle hangs below the glass, the less disturbance is it likely to receive.

Notwithstanding the various contrivances that have been made to prevent the card from being much affected by the motions of the ship, they have always been found too delicate to encounter the shocks of a tempestuous sea. Improved sea-compasses have lately been constructed by Mr. M'Culloch of London, (and for which he has obtained a patent), that are reported to be the best of any yet used. The particulars are as follow.

Plate CXLV.

Fig. 1. is a section of the steering compass. Aaaa, The common wooden-box, with its lid. bb, The brass compass-box. cc, The glass cover to ditto. dd, The hollow conical bottom. e, The prop upon which the compass is supported instead of gimballs; the spherical top which is finely polished, and the apex of the hollow cone is fitted in a peculiar manner to receive it. ff, A quantity of lead run round the bottom and cone of the compass-box, to balance and keep it steadily horizontal. gg, The card, and the magnetic needle, bent in such a manner that the point of the conical pivot on which it moves and is supported, may be brought very near to the centre of gravity, as well as to the centre of motion. hh, Two guards, which by means of two pins, affixed to the compass-box, prevent it from turning round and deceiving the seaman.

Fig. 2. a perspective view of the steering compass, with the lid off and the front laid open. bb, The guards. e, The compass-box. f, The prop, &c. as in fig. 1.

Fig. 3. a view of the azimuth compass. b, The compass-box. e, One of the guards. f, The prop, as in fig. 1. and 2. with this difference, that in the azimuth compass, instead of being screwed to the bottom of the wood-box, it stands in a brass socket, and may be turned round at pleasure. 1. A brass bar, upon which the sight vanes are fixed. 2. A dark glass, which moves up or down on 3. the sight vane. 4. A magnifying glass, which is also moveable on the other vane. 5. The nonius or vernier. 6. A slide for moving the vernier so as to stop the card in taking the azimuth. 7. A double convex glass, by which the divisions on the vernier may be read with accuracy.

Fig. 4. is a section representing another application of the magnetic needle and card, constructed by Mr. M'Culloch. Aaaa, The common wood-box. bb, The brass compass-box. cc, The brass support for the circle and pendulum. d, The pendulum. e, The agate. ff, The magnetic needle and card. gg, The brass circle. hh, The glass cover and brass ring. i, The lead weight. N, B. All the centres of motion are in the same plane.

"In one particular this patent compass is considered as an improvement on the common compasses, in so far as the needle is both longer and broader; hence its magnetism must be stronger, and of course the line of its magnetic direction correspondent with the card. In another particular, in order to prevent the motions of the vellum from affecting the needle, which is the most desirable object, the patent compass-box, instead of swinging in gimballs at right angles to each other, is supported in its very centre upon a prop; and whatever motion the other parts of the box may have, this centre being in the vertex of the hollow cone, may be considered as relatively at rest; and therefore gives little or no disturbance to the needle. Again, the pivot or centre upon which the needle turns, is so contrived as to stand always perpendicular over the centre of the compass-box, or apex of the hollow cone, as upon a fixed point; and is therefore still less affected by
The centres of motion, gravity, and of magnetism, are brought almost all to the same point; the advantages of which will be readily perceived by any person acquainted with mechanical principles. Experience therefore will ascertain the utility of this improvement.”

Of Dr. Knight's Azimuth Compass, as improved by Mr. Smeaton. A description was given under the article Azimuth, and a figure in Plate LXXVII. The uie of the azimuth compass is for finding the sun's magnetic azimuth, or amplitude; and thence the variation of the compass. If the observation be for an amplitude at sun-rising, or for an azimuth before noon, apply the centre of the index on the west point of the card, within the box; so that the four lines on the edge of the card, and threeth on the inside of the box, may meet. If the observation be for the sun's amplitude setting, or an azimuth in the afternoon, turn the centre of the index right against the east point of the card, and make the lines within the box concur with those on the card: the instrument thus fitted for observation, turn the index be towards the sun, till the shadow of the thread ae fall directly on the fit of the right, and on the line that is along the middle of the index: then will the inner edge of the index cut the degree and minute of the sun's magnetic azimuth from the north or south. But note, that if, when the compass is thus placed, the azimuth is less than 45° from the south, and the index turned towards the sun, it will pass off the divisions of the limb: the instrument therefore in this case must be turned just a quarter of the compass, i.e. the centre of the index must be placed on the north or south point of the card, according as the sun is from you; and then the edge will cut the degree of the magnetic azimuth, or the sun's azimuth from the north, as before.

The sun's magnetic azimuth thus found, the variation of the needle is thus determined. Being out at sea the 15th of May 1717, in 45° north latitude, the tables give me the sun's latitude 19° north, and his azimuth 27° 25' north: by the azimuth compass, I find the sun's magnetic azimuth at his rising, 25° 5' north; and between the 62d and 63d degree, reckoning from the north towards the east point of the compass, i.e. between the 27th and 28th degree, reckoning from the east. The magnetic amplitude, therefore, being here equal to the true one, the needle has no variation; but if the sun at his rising should have appeared between the 52d and 53d degree from the north towards the east; his magnetic amplitude would then have been between 37 and 38 degrees, i.e. about 10 degrees greater than the true amplitude; therefore, the needle would vary about 10 degrees north-easterly. If the magnetic east amplitude found by the instrument should be less than the true amplitude, their difference would show the variation of the needle easterly. If the true east amplitude be southerly, as also the magnetic amplitude, and this last be the greater; the variation of the needle will be north-west; and vice versa.

What has been said of north-east amplitudes holds also of south-west; and what of south-east amplitudes holds of north-west amplitudes. Lastly, if amplitudes be found of different denominations, v. gr., if the true amplitude be six degrees north, and the magnetic amplitude five degrees south; the variation, which in this case is north-west, will be equal to the sum of the magnetic and true amplitudes: understand the same for west amplitudes.

The variation may likewise be found from the azimuth: but in that case, the sun's declination, latitude of the place, and his altitude, must be given; that his true azimuth may be found.

This instrument is also useful in settling the ship's wake, in order to find the lee-way; and also to find the bearings of head-lands, and other objects.

Compass is also an instrument of considerable use in surveying land, dialing, &c.

Its structure, in the main, is the same with that of the mariner's compass; consisting, like that, of a box and needle: the principal difference consists in this, that instead of the needle's being fitted into the card, and playing with it on a pivot, it here plays alone; the card being drawn on the bottom of the box, and a circle divided in 360 degrees on the limb. See fig. 5. Plate CXLIV This instrument is of obvious use to travellers, to direct them in their road; and to miners, to show them what way to dig, with other considerable uses.

1. To take the declination of a wall by the Compass. Apply that side of the compass whereto the north is marked along the side of the wall; the number of degrees over which the north end of the needle fixes will be the declination of the wall, and on that side; v. gr. if the north point of the needle tends towards the north, that wall may be shone on by the sun at noon; if it fix over sixty degrees, counting from the north towards the east, the declination is to many degrees from north towards east.

But since the needle itself declines from the north towards the west, with us, 15°; it must be noted, that to retrieve the irregularity, 15° are always to be added to the degrees shown by the needle, when the declination of the wall is towards the east; on the contrary, when the declination is towards the west, the declination of the needle is to be subtracted.

2. To take an angle with the Compass. Suppose the angle required be DAE, fig. 4. Apply that side of the compass whereto the north is marked along the side of the line AD; when the needle rests, observe the degrees at which its north point stands, which suppose 80°: so many degrees does the line decline from the meridian. In the same manner take the declination of the line AE, which suppose 215°; subtract 80° from 215, the remainder is 135; which subtracted from 180, there will remain 45°; the quantity of the angle required. But if the difference between the declination of the two lines exceed 180°; in that case, 180° must be subtracted from the difference: the remainder then is the angle required.

In measuring angles by the compass, there needs not any regard be had to the variation; that being supposed the same in all the lines of the angles.

3. To take a plot of a field by the Compass. Suppose the field A, B, C, D, &c. fig. 10; for the greater accuracy let there be two sights fitted to the meridian line of the compass, place it horizontal, and through the sights look along the side AB, or a line parallel to it; applying the eye to the sight at the south point of the compass. Draw a rough sketch of the field by the
Compafes, the eye, and on the corresponding line enter down the degree to which the needle points, which suppose 90, measure the length of the line, and enter that too, which suppose ten chains.

In this manner proceed with all the rest of the sides and angles of the field; the sides, which suppose 70, 65, 70, 44, 50 fathom; and the angles, which suppose 30, 100, 130, 240, 300, degrees. To protract the field, set down the several angles observed, one after another, and subtract the lesser from the next greater: thus will you have the quantity of the several angles, and the length of the lines that include them. For the rest, see Geometry.

Note. All the angles of the figure taken together, must make twice as many right angles; abating two if no mistake has been committed.

Azimuth Compass. See AZIMUTH.

Compases-Dials, are smooth horizontal dials, fitted in brass or silver boxes, for the pocket, to show the hour of the day, by the direction of a needle that indicates how to place them right, by turning the dial about till the cock or thistle stand directly over the needle; but these can never be very exact, because of the variation of the needle itself. See COMPASSES and DIALING.

COMPASSES, or Pair of COMPASSES, a mathematical instrument for describing circles, measuring figures, &c.

The common compasses consist of two sharp-pointed branches or legs of iron, steel, brass, or other metal, joined together at the top by a rivet, whereon they are riveted, or other materials. These compasses are of the kind for which they are intended; as, COMPASSES of three Legs, or Triangular COMPASSES, are, setting aside the excels of a leg, of the same figure with the common ones: their use being to take three points at once, and so to form triangles; to lay down three positions of a map, to be copied at once, &c.

Bear COMPASSES consist of a long branch, or beam, made of brass or wood, carrying two brass cursors, the one fixed at one end, the other sliding along the beam, with a screw to fasten it on occasion. To the cursors may be screwed points of any kind, whether steel for pencils, or the like. It is used to draw large circles, to take great extents, &c. To the fixed cursor is sometimes applied an adjusting or micrometer screw, by which an extent is obtained to extreme nicety. Mr Jones of Holborn has made beam compasses to adjust to the thickness of an inch.

Caliber COMPASSES. See CALIBER.

Clockmaker's COMPASSES are joined like the common compasses, with a quadrant, or bow, like the spring compasses; only of different use, serving here to keep the instrument firm at any opening. They are made very strong, with the points of their legs of well tempered steel, as being used to draw lines on plate-board COMPASSES or copper.

Cylindrical and Spherical COMPASSES, consist of four branches, joined in a centre, two of which are circular, and two flat, a little bent on the ends: their use is to take the diameter, thickness, or caliber of round or cylindric bodies; such as canons, pipes, &c.

Elliptic COMPASSES. Their use is to draw ellipses, Plate or ovals of any kind: they consist of a beam A B CXLIV. about a foot long, bearing three cursors; to one of fig. 9. which may be screwed points of any kind: to the bottom of the other two are riveted two sliding dovetails, adjusted in grooves made in the cross branches of the beam. The dovetail having a motion every way, by turning about the long branch, go backwards and forwards along the cross; so that when the beam has gone half way about, one of these will have moved the whole length of one of the branches; and when the beam has got quite round, the same dovetail has got back the whole length of the branch. Understand the name of the other dovetail.

Note. The distance between the two sliding dovetails is the distance between the two foci of the ellipsis; so that by changing this distance, the ellipsis will be rounder or flenderer. Under the ends of the branches of the cross are placed four steel points to keep it fast.

The use of this compass is easy: by turning round the long branch, the ink, pencil, or other point, will draw the ellipses required. Its figure shows both its use and construction.

German COMPASSES have their legs a little bent outwards, towards the top; so that when flush, the points only meet.

Hair COMPASSES are so contrived within side by side a small adjusting screw to one of the legs, as to take an extent to a hair's breadth.

Lapidary's COMPASSES are a piece of wood, in form of the shaft of a plane, cleft at top, as far as half its length; with this they measure the angles, &c. of jewels and precious stones, and cut the angles. There is in the cleft a little brass rule, fastened there at one end by a pin; but so that it may be moved in the manner of a brass level: with this kind of a square they take the angles of the angles, laying them on the shaft as they cut them.

Proportional COMPASSES are those whose joint lies between the points terminating each leg: they are either simple or compound. In the former the centre is fixed, so that one pair of these serves only for one proportion.

Compound proportional COMPASSES consist of two parts or sides of brass, which lie upon each other so nicely as to appear but one when they are flush. These sides slide easily open, and move about a centre, which is itself movable in a hollow canal cut through the greatest part of their length. To this centre on each side is affixed a sliding piece A of a small length, with a fine line drawn on it serving as an index, to be set against other lines or divisions placed upon the compasses on both sides. These lines are 1. A line of lines. 2. A line of superficies, areas, or planes. 3. A line of solids. 4. A line of circles, or rather of polygons to be inscribed in circles. These lines are all equally divided: the three first from 1 to 20, the last from 6 to 20. Their uses are as follow:

N 2
By the line of lines you divide a given line into any number of equal parts; for by placing the index A against 1, and ferewing it half, if you open the compasses, then the distance between the points at each end will be equal. If you place the index against 2, and open the compasses, the distance between the points of the longer legs B B, will be twice the distance between the shorter ones C C; and thus a line is bisected, or divided into two equal parts. If the index be placed against 3, and the compasses opened, the distances between the points will be as 3 to 1, and so a line is divided into three equal parts; and so you proceed for any other number of parts under 10.

The numbers of the line of planes answer to the squares of those in the line of lines; for because superficies or planes are to each other as the squares of their sides; therefore, if the index be placed against 2 in the line of planes, then the distance between the small points will be the side of a plane whose area is one; but the distance of the larger points will be the like side of a plane whose area is two; or twice as large as the side of the plane whose area is one, and the compasses opened, the distances between the points at each end will be the like side of planes whose area are as 1 to 3; and so of others.

The numbers of the line or solids answer to the cubes of those in the line of lines; because all solids are to each other as the cubes of their sides or diameters; therefore, if the index be placed to number 2, 3, 4, &c. in the line of solids, the distance between the lesser and larger points will be the like side of solids, which are to each other as 1 to 2, 1 to 3, 1 to 4, &c. For example: If the index be placed at 10, and the compasses opened so that the small points may make the diameter of a bullet whose weight is one ounce, the distance between the large points will be the diameter of a bullet or globe of 10 ounces, or which is 10 times as large.

Lastly, the numbers in the line or circles are the sides of polygons to be inscribed in a given circle, or by which a circle may be divided into the equal parts, from 6 to 20. Thus, if the index be placed at 6, the points of the compasses at either end, when opened to the radius of a given circle, will contain the side of a hexagon, or divide the circle into six equal parts. If the index be placed against 7, and the compasses opened so that the larger points may take in the radius of the circle, then the shorter points will divide the circle into seven equal parts for inscribing a heptagon. Again, placing the index to 8, and opening the compasses, the larger points will contain the radius, and the shorter points divide the circle into eight equal parts for inscribing an octagon or square. And thus you may proceed for others.

**Proportional Compasses with the sector lines.** The structure of these is so like that of the common proportional compasses, only a little nicer, that it needs no particular description. The lines on the first face are the line of lines, marked lines; it is divided into 100 equal parts, every tenth numbered: and the line of chords, which goes to 60°, is marked chords. On the other face are a line of lines to 90°, and a line of tangents to 45°. On one side are the tangents from 45° to 71° 34' 1; on the other, secants from 0° to 70° 30'.
of the compasses. The screw-pin of the beam passed through an adjuster, by means of which the mark on the slider might be brought exactly to any division. But the proportional compasses have been much out of use since the invention of the secteur.

Spring Compasses, or dividers; those with an armed head, which by its spring opens the legs; the opening being directed by a circular screw fastened to one of the legs, and let through the other, worked with a nut. These compasses are made of hardened steel.

Fitting Compasses consist of two central rules, and an arch of a circle of 120 degrees, immovable, with its radius; which is fastened with one of the central rules like the two legs of a secteur, that the central rule may be carried through all the points of the circumference of the arch. The radius and rule should be as thin as possible; and the rule fastened to the radius should be hammered cold, to attain the greater elasticity; and the breadth of the central rule should be triple that of the radius; there must also be a groove in this rule, with a dove-tail fastened on it for its motion, and a hole in the centre of each rule. The use of this instrument is to facilitate the trisection of angles geometrically; and it is said to have been invented by M. Tarragen for that purpose.

Turn-up Compasses. The body of this instrument is like the common compasses: but towards the bottom of the legs, without-tide, are added two other points besides the usual ones; the one whereof carries a drawing pen point, and the other a port-crayon, with a small head for those; and be in the way of use, or out of it, as occasion requires. These compasses have been contrived to save the trouble of changing the points.

Compassion, or compassion, in ethics, a mixed passion, compounded of love and sorrow, and excited by the sight or recital of distress. Hobbs makes this a merely selfish passion, and defines it, as being fear for ourselves; Hutcheson resolves it into affection; but Dr. Butler much more properly considers compassion as an original, distinct, particular affection in human nature.

Compatible, something that may suit or consent with another. See incompatible.

Compaigne, a handsome town of the isle of France, in the county of Senlis, with a palace, or castle, where the king often resided. The maid of Orleans was taken prisoner here in 1430. It is seated on the river Oise, near a large forest. E. long. 3. 12. N. Lat. 49. 25.

Compendium, in matters of literature, denotes much the same as epitome or abridgment. See abridgment.

Compensation, in a general sense, an action whereby any thing is admitted as an equivalent to another.

Compensation, in law. Where the same person is debtor and creditor to another, the mutual obligations, if they are for equal sums, are extinguished by compensation; if for unequal, the lesser obligation is extinguished, and the greater diminished, as far as the concourse of debt and credit goes.

Competence, or competency, in a general sense, such a quantity of any thing as is sufficient.

Competence, in law, the right or authority of a judge, whereby he takes cognizance of any thing. Competentes, an order of catechumens, in the primitive Christian church, being the immediate candidates for baptism. See Catechumen.

Competition, in a general sense, is the same with rivalry, or when two or more persons contend for the same thing.

Competition, in Scots law. In escheats, see law, part III. n. clxvi. 17, 18. In confirmations by the superior, in resignations, and in personal rights of lands, ibid. clxviii. 5—9. In inhibitions, in adjudications, amongst squires, serfes, and cottiers, ibid. clxvii. 6. clxvii. 3. clxvii. 2. clxvii. 8. 9. 10. Amongst creditors of a defunct, clxxi. 19.

Comitalia, or Comitality, feasts held among the ancients in honour of the lares. The word comes from the Latin compium, a cross-way; by reason the feast was held in the meeting of several roads. The Capitolia are more ancient than the building of Rome. Dionysius Halicarnassensis, and Pliny, indeed, say, they were instituted by Servius Tullus; but this only signifies that they were then introduced into Rome. The feast being moveable, the day whereon it was to be observed was proclaimed every year. It was ordinarily held on the 4th of the month of February, i.e. on the second of that month. Macrobius observes, that they were held not only in honour of the lares, but also of mania, madness. The priests who officiated at them were slaves and liberti, and the sacrifice a fowl. They were re-established, after a long neglect, by Tarquin the Proud, on occasion of an answer of the oracle, that they should sacrifice heads for heads; i.e. that for the health and prosperity of each family, children were to be sacrificed; but Brutus, after expelling the kings, in lieu of those barbarous victims substituted the heads of garlic and poppy; thus satisfying the oracle which had enjoined capture, heads. During the celebration of this feast, each family placed at the door of their house the image of the goddess Mania; they also hung up at their doors figures of wool, representing men and women; accompanying them with supplications that the lares and mania would be contented with those figures, and spare the people of the house.

Complement, in geometry, is what remains of the quadrant of a circle, or 90°, after any certain arch has been taken away from it. Thus, if the arch taken away be 40°, its complement is 50°; because 50° + 40° = 90°. The signe of the complement of an arch is called the co-sine, and that of the tangent the co-tangent, &c.

Compleatus Flos, in botany. A flower is said to be complete, which is provided with both the corona, viz. the calyx or flower-cup, and the petals. The term was invented by Vaillant, and is synonymous to calycatus flos in Linnaeus. Berkenhout erroneously confounds it with the calyx and calycatus calyx of the same author.

Complex, in a more general sense, a term synonymous with compound; though in strictness of speech there is some difference.

Complex is properly applied where a thing contains divers others, or confists of divers parts not really distinct from each other, but only imaginarily, or in our
COM [ 286 ]

Complex, our conceptions. In this sense the soul may be said to be complex, in respect to the understanding and will, which are two things that our reason alone distinguishes in it.

Complex Term or Idea, is a term compounded of several simple or complex ones. Thus in the proposition, A just God cannot leave crimes unpunished; the subject of this proposition, viz. a just God, is a complex term, or stands for a complex idea composed of two simple or in complex ones, viz. Cod and just.

Complexion, among physicians, the temperament, habit, and natural disposition, of the body; but more often the colour of the face and skin.

Few questions in philosophy have engaged the attention of naturalists more than the diversities among the human species, among which that of colour is the most remarkable. The great differences in this respect have given occasion to several authors to assert, that the whole human race have not sprung from one original; but that as many different species of men were at first created, as there are now different colours found among them. Under the particle America, n.8t —to, we have shown that all the arguments which can be brought for specific differences among mankind, whether drawn from a difference of colour, stature, or disposition, must necessarily be inconclusive. It remains, however, a matter of no small difficulty to account for the remarkable variations of colour that are to be found among different nations. On this subject Dr Hunter hath published a thesis, in which he considers the matter more accurately than hath commonly been done, and determines absolutely against any specific difference among mankind. He introduces his subject by observing, that when the question has been agitated, whether all the human race constitute only one species or not, much confusion has arisen from the sense in which the term species has been adopted. He therefore thinks it necessary to set out with a definition of the term. He includes under the same species all those animals which produce in the capable of propagating others resembling the original stock from whence they sprung. This definition he illustrates by having recourse to the human species as an example. And in this sense of the term he concludes, that all of them are to be considered as belonging to the same species. And as, in the case of plants, one species comprehends several varieties depending upon climate, soil, culture, and similar accidents; so he considers the diversities of the human race to be merely varieties of the same species, produced by natural causes. Of the different colours observable among mankind, he gives the following view:

Black. Africans under the line.
Inhabitants of New Guinea.
Inhabitants of New Holland.

Swarthy. The Moors in the northern parts of Africa.
The Hottentots in the southern parts of it.

Copper-coloured. The East Indians.

Red-coloured. The Americans.
Brown-coloured. Tartars.
Persians.
Arabs.

Brownish. The inhabitants of the souther parts of Europe; as
Sicilians,
Abyssinians,
Spaniards,
Turks, and likewise the Samoedea and Laplanders.

White. Most of the European nations; as
Swedes,
Danes,
English,
Germans,
Poles, &c.
Kabardiniki,
Georgians,
Inhabitants of the islands in the Pacific Ocean.

In attempting to investigate the causes of these differences, our author observes, that there can be no dispute of the seat of colour being placed in the skin; that it is not even extended over the whole of this, but confined to that part named the cuticle, consisting of the epidermis and reticulum; and that it chiefly occupies the latter of these. The cuticle is much thicker and harder in black people than in white ones; the reticulum in the latter being a thin membrane in the former a thick membrane. He concludes that this seat of colour in whites is transparent, and either totally deprived of vessels, or only furnished with very few; as the yellow colour appearing in jaundice vanishes on the cuticle of the diseased being removed; which is not the case with stains in the cuticle of gunpowder, or similar causes. He next points out three causes destroying the pellucidity of the cuticle, giving it a brown colour, and rendering it thicker. These are, access of air, saltiness, and the heat of the sun. The influence of each of these he proves by many examples; and from these he is inclined to consider the last as by much the most powerful. If, however, it be admitted that these causes have this effect, he thinks that all the diversity of colour which is to be observed among mankind, may be thus accounted for.

He remarks, that all the inhabitants of the torrid zone incline more or less to a black colour. When we observe the differences which occur amongst them, we must at the same time remember, that a black colour is not referred to heat alone, but to the other causes also; and when we attend to the diversity of temperature that occurs even in the torrid zone, the existence of a white nation there would by no means destroy the argument. He is farther of opinion, that the existence of a brown colour, and of considerable varieties from white, in the northern and cold parts of Europe, may very easily be explained. This he accounts for from the manner of life of the inhabitants, by which they are exposed to the inclemency of the air, or to constant saltiness from smoky houses.

Having thus attempted to account, from natural causes, for the varieties which occur among mankind with
with respect to colour, our author observes, that, to all this reasoning, an objection will naturally be made, from considering that infants bring these marks into the world along with them, before they can be exposed to any such causes. Dr. Hunter imagines, however, that this may readily be explained upon the supposition that many peculiarities acquired by parents are transmitted to their posterity; and of this, he thinks, no one can entertain the least doubt who attends to hereditary diseases. Thus, gout, feerophulins, mania, and many other affections, although at first induced by particular accidents, will continue to affect families for many generations. In the same manner, a parent exposed to causes destroying the natural whiteness of his complexion, will beget swarthy children; and the same causes continuing to operate upon the son, the blackness will be increased. Thus all the different shades may have been at first induced, and afterwards continued.

The objection here obviated, however, might have been shortly answered by denying the fact; for it is now generally known, that the children of the blackest negroes are absolutely born white, as will be afterwards noticed.

This subject of complexion has been very well illustrated by Mr. Clarkson, in a dissertation introduced in his Essay on the commerce and slavery of the human species. The first point that occurs to be ascertained, is, 'What part of the skin is the seat of colour?' The old anatomists usually divided the skin into two parts or laminae; the exterior or thinnefis, called by the Greeks epidermis, by the Romans cuticula, and hence by us cuticle; and the interior, called by the former dermis, and by the latter cutis, or true skin. Hence they must necessarily have supposed, that, as the true skin was in every respect the same in all human subjects, however, various their external hue, the seat of colour must have existed in the cuticle or upper surface.

Malpighi, an eminent Italian physician of the last century, was the first person who discovered that the skin was divided into three laminae or parts; the cuticle, the true skin, and a certain coagulated substance situated between both, which he distinguished by the name of rete mucosum. Which coagulated substance adhered so firmly to the cuticle, as, in all former anatomical preparations, to have come off with it; and, from this circumstance, to have led the ancient anatomists to believe, that there were but two laminae, or divisible portions in the human skin. See Anatomy, N° 74—76.

This discovery was sufficient to ascertain the point in question; for it appeared afterwards that the cuticle, when divided according to this discovery from the other lamina, was semi-transparent; that the cuticle of the blackest negro was of the same transparency and colour as that of the purest white; and hence the true skins of both being invariably the same, that the rete mucosum was the seat of colour.

This has been farther confirmed by all subsequent anatomical experiments; by which it appears, that, whatever is the colour of this intermediate coagulated substance, nearly the same is the apparent colour of the upper surface of the skin. Neither can it otherwise; for the cuticle, from its transparency, must necessarily transmit the colour of the substance beneath it, in the same manner, though not in the same degree, as the cornea transmits the colour of the iris of the eye. This transparence is a matter of obvious demonstration in white people. It is conspicuous in every blush; for no one can imagine that the cuticle becomes red as often as this happens: nor is it less discoverable in the veins, which are so easy to be discerned; for no one can suppose that the blue streaks, which he constantly sees in the fairest complexion, are painted, as it were, on the surface of the upper skin. From these, and a variety of other observations, no maxim is more true in physiology, than that on the rete mucosum depends the colour of the human body; or, in other words, that the rete mucosum being of a different colour in different inhabitants of the globe, and appearing through the cuticle or upper surface of the skin, gives them that various appearance which strikes us so forcibly in contemplating the human race.

As this can be incontrovertibly ascertained, it is evident, that whatever causes co-operate in producing this different appearance, they produce it by acting upon the rete mucosum; which, from the almost incredible manner in which the cuticle is perforated, is as accessible as the cuticle itself. These causes are probably those various qualities of things, which, combined with the influence of the sun, contribute to form what we call climate. For when any person considers, that the mucous substance before mentioned is found to vary in its colour, as the climates vary from the equator to the poles, his mind must be instantly struck with the hypothesis, and he must adopt it, without any hesitation, as the genuine cause of the phenomenon.

This fact, of the variation of the mucous substance, according to the situation of the place, has been clearly ascertained in the numerous anatomical experiments that have been made; in which subjects of all nations have come under consideration. The natives of many of the kingdoms and islands of Asia are found to have their rete mucosum black; those of Africa, situated near the line of the same colour; those of the maritime parts of the same continent, of a dusky brown, nearly approaching to it; and the colour becomes lighter or darker in direct proportion to the climate. To the equator is either greater or less. The Europeans are the fairest inhabitants of the world. Those situated in the most southern regions of Europe, have in their rete mucosum a tinge of the dark hue of their African neighbours; hence the epidemic complexion, prevalent among them, is nearly of the colour of the pickled Spanish olive; while in this country, and those situated nearer the north pole, it appears to be nearly, if not absolutely, white.

These facts which anatomy has established, and we acknowledge them to be such, that we cannot divest ourselves of the idea, that climate has a considerable share in producing a difference of colour.

The only objection of any consequence that has ever been made to the hypothesis of climate, is this, that people under the same parallels are not exactly of the same colour. But this is no objection in fact; for it does not follow that those countries which are at an equal distance from the equator, should have their climates the same. Indeed nothing is more contrary to experience than this. Climate depends upon a variety
ricity of accidents. High mountains in the neigbourhood of a place make it cooler, by chilling the air that is carried over them by the winds. Large spreading succulent plants, if among the productions of the soil, have the same effect; they afford agreeable cooling shades, and a moist atmosphere from their continual exhalations, by which the ardor of the sun is considerably abated. While the soil, on the other hand, if of a sandy nature, retains the heat in an uncommon degree, and makes the sunners considerably hotter than those which are found to exist in the same latitude where the soil is different. To this proximity of what may be termed burning sand, and to the sulphurous and metallic particles which are continually exhal­ling from the bowels of the earth, is ascribed the different degree of blackness by which some African nations are distinguishable from each other, though under the same parallels. To these observations, we may add, that though the inhabitants of the same parallel are not exactly of the same hue, yet they differ only by shades of the same colour; or, to speak with more precision, that there are no two people, in such a situation, one of whom is white and the other black.

To him up the whole—Suppose we were to take a common globe, to begin at the equator, and to paint every country along the meridian line in succession thence to the poles; and to paint them with the same colour which prevails in the respective inhabitants of each, we should see the black, with which we had been obliged to begin, insensibly changing to an olive, and the olive, through as many intermediate colours, to a white: and if, on the other hand, we should complete any one of the parallels according to the same plan, we should see a difference perhaps in the appearance of some of the countries through which it ran, though the difference would consist wholly in shades of the same colour.

To this argument may be added one that is uncontroversible, which is, that when the black inhabitants of Africa are transplanted to colder, or the white inhabitants of Europe to hotter climates, their children, born there, are of a different colour from themselves; that is, lighter in the first, and darker in the second instance.

As a proof of the first, we shall give the words of the Abbé Raynal, in his admired publication. "The children," says he, "which they (the Africans) procreate in America, are not so black as their parents were. After each generation the difference becomes more palpable. It is possible, that after a numerous succession of generations, the men come from Africa would not be distinguished from those of the country into which they may have been transplanted."

This circumstance we have had the pleasure of hearing confirmed by a variety of persons who have been witnesses of the fact; but particularly by many intelligent Africans who have been parents themselves in America, and who have declared, that the difference is so palpable in the northern provinces, that not only they themselves have constantly observed it, but that they have heard it observed by others.

Neither is this variation in the children from the colour of their parents improbable. The children of the blackest Africans are born white. In this state they continue for about a month, when they change to a pale yellow. In process of time they become brown. Their skin still continues to increase in darkness with their age, till it becomes of a dirty silvery black; and at length, after a certain period of years, glossy and shining. Now, if climate has any influence on the mucous substance of the body, this variation in the children from the colour of their parents is an event which must be reasonably expected: for being born white, and not having equally powerful canes to act upon them in colder, as their parents had in the hotter climates which they left, it must necessarily follow, that the same effect cannot possibly be produced.

Hence also, if the hypothesis be admitted, may be deduced the reason why even those children who have been brought from their country at an early age into colder regions, have been observed to be of a lighter colour than those who have remained at home till they arrived at a state of manhood. For having undergone some of the changes which we mentioned to have attended their countrymen from infancy to a certain age, and having been taken away before the rest could be completed, these farther changes, which would have taken place had they remained at home from either to have been checked in their progress, or weakened in their degree, by a colder climate.

We come now to the second and opposite case; for a proof of which we shall appeal to the words of Dr Mitchell in the Philosophical Transactions, n° 476. sect. 4. "The Spaniards who have inhabited America under the torrid zone for any time are become as dark coloured as our native Indians of Virginia, of which I myself have been a wit­ness; and were they not to intermarry with the Europeans, but lead the same rude and barbarous lives with the Indians, it is very probable, that, in a succession of many genera­tions, they would become as dark in complexion."

To this instance we shall add one, which is mentioned by a late writer, who, describing the African coast and the European settlements there, has the following passage. "There are several other small Portuguese settlements, and one of some note at Mombasa, a river in Sierra Leon. The people here called Portuguese, are principally persons bred from a mixture of the first Portuguese discoverers with the natives, and now become, in their complexion and woolly quality, of their hair, perfect negroes, retaining, however, a finning of the Portuguese language."

These facts with respect to the colonists of the Europeans are of the highest importance in the present case, and deserve a serious attention. For when we know to a certainty from whom they are descended, when we know that they were, at the time of their transplantation, of the same colour as those from whom they severally sprung; and when, on the other hand, we are credibly informed that they have changed it for the native colour of the place which they now inhabit; the
the evidence in support of these facts is as great as if a person, on the removal of two or three families into another climate, had determined to ascertain the circumstances; as if he had gone with them and watched their children; as if he had communicated his observations to his death to a successor; as if his successor had prolonged the plan: and thus an uninterrupted chain of evidence had been kept up from their first removal to any determined period of succeeding time.

But though these facts seem sufficient of themselves to confirm our opinion, they are not the only facts which can be adduced in its support. It can be shown, that the members of the same family, when divided from each other, and removed into different countries, have not only changed their family complexion, but that they have changed it to as many different colours as they have gone into different regions of the world. We cannot have, perhaps, a more striking instance of this than in the Jews. These people are scattered over the face of the whole earth. They have preserved themselves distinct from the rest of the world by their religion; and as they never intermarry with any but those of their own sect, so they have no mixture of blood in their veins that they should differ from each other: and yet nothing is more true, than that the English Jew is white, the Portuguese fbrthy, the Armenian olive, and the Arabian copper; in short that there appear to be as many different species of Jews as there are countries in which they reside.

To these facts we shall add the following observation, that if we can give credit to the ancient historians in general, a change from the darkest black to the purest white must have actually been accomplished. One instance, perhaps, may be thought sufficient. Herodotus relates, that the Colchi were black, and that they had crepied hair. These people were a detachment of the Asiatic army under Seleucus, who followed him in his expedition, and settled in that part of the world where Colchis is usually represented to have been situated. Had not the same author informed us of this circumstance, we should have thought it strange that a people of this description should have been found in such a latitude. Now as they were undoubtedly settled there, and as they were neither so totally destroyed, nor made any such rapid conquests, as that history should notice the event, there is great reason to presume that their descendants continued in the same, or settled in the adjacent country; from whence it will follow, that they must have changed their complexion to that which is observed in the inhabitants of this particular region at the present day; or, in other words, that the black inhabitants of Colchis must have been changed into the fair Circassians. Suppose, without the knowledge of any historian, they had made such considerable conquests as to have settled themselves at the distance of 1000 miles in any one direction from Colchis, still they must have changed their colour: For had they gone in an eastern or western direction, they must have been of the same colour as the Circassians; if to the north, whiter; if to the south, of a copper. There are no people within that distance of Colchis who are black.

From the whole of the preceding observations on the subject, we may conclude, that as all the inhabitants of the earth cannot be otherwise than the children of the same parents, and as the difference of their appearance must have of course proceeded from incidental causes, the causes are a combination of those qualities which we call climates: that the blackness of the Africans is so far engraven in their constitution, in a course of many generations, that their children wholly inherit it if brought up in the same spot; but that it is not so wholly interwoven in their nature, that it cannot be removed if they are born and settled in another.

The same principles with the above we find adopted and further illustrated by Professor Zimmerman of Brunswick, in his celebrated work The Geographical History of Man. He there proves in the most satisfactory manner, that the complexions of the human species is uniformly correspondent with the degree of heat or cold to which they are habitually exposed. In maintaining this position, he makes a very just distinction with regard to climate. By climates we are to understand, not simply or solely those distinguished by the geographical divisions of the globe, to the exclusion of what he terms physical climate, or that which depends on the changes produced in any given latitude by such adventitious circumstances as the lower or more elevated situations of a country, its being encompassed by water or large tracts of land, over spread or surrounded with forests, placed in an extensive plain, or environed by lofty mountains. Peculiarities of the like kind, as has been already noticed, frequently prevent the physical climate from corresponding entirely with the geographical, as a country influenced by them is often much warmer or colder than other regions placed under the same degree of latitude. The influence of the secondary or modifying circumstances has been already adverted to, and need not be further enlarged upon: we shall here only observe, that the erroneous reasonings of Lord Kames on this subject seems to have been owing to his inattention to the difference above mentioned. At Senegal, and in the adjacent lands, the thermometer is often at 112 or 117 degrees in the shade; and here we find the inhabitants as dark as the Abyssinians and inhabitants of Zara of as dark a complexion as the Moors on the coast of Guinea? M. Zimmerman answers, that these countries are much cooler. The deficit is not only farther from the equator, but the winds blowing over the Atlas mountains, which like the Alps covered with snow, and the westly wind coming from the sea, must considerably mitigate the heat. Nor is Abyssinia so warm as either Monomotapa or Guinea. The north-east winds from the face of Peru and Arabia are cooled by their passage over the Red Sea: the northern winds from Egypt lose much of their heat on the chain of mountains that is extended between the countries: the winds from the north and the west are sea-winds. Thus the only quarter from which they can derive excessive heat is from the west, as the air on this side must pass over tracks of heated lands." For a similar reason it is that negroes are not found either in Asia or South America.
merica under the equator. The situations of these countries, our author observes, expose them to heat and cooling winds from the continent. He confirms this hypothesis by observing, that the inhabitants of warm climates, as in Barbary and Ceylon, are much farther than the inhabitants of the valleys: that the Saracens and Moors, who conquered the north-east part of Africa in 700, from being brown, are become like the negroes near the equator: that the Portuguese, who settled at Senegal in 1400, became blacks; and Tudela the Jew affirms, that his countrymen in Abyssinia acquired the dark complexion of the original natives.

Upon the whole: Colour and figure may be styled habits of the body. Like other habits, they are created, not by great and sudden impressions, but by continual and almost imperceptible touches. Of habits both of mind and body, nations are susceptible as well as individuals. They are transmitted to offspring, and augmented by inheritance. Long in growing to maturity, national features, like national manners, become fixed only after a succession of ages. They become, however, fixed at last; and if we can ascertain any effect produced by a given state of weather or of climate, it requires only repetition during a sufficient length of time to augment and impress it with a permanent character. The fanguine countenance will, for this reason, be perpetual in the highest latitudes of the temperate zone; and we shall for ever find the swarthy, the olive, the tawny, and the black, as we descend to the south.

The uniformity of the effect in the same climate, and on men in a similar state of society, proves the power and certainty of the cause. If the advocates of different human species suppose that the beneficial Deity hath created the inhabitants of the earth of different colours, because these colours are best adapted to the respective zones; it surely places his benevolence in a more advantageous light to say, he has given to human nature the power of accommodating itself to every zone. This piousness of nature is favourable to the unions of the most distant nations, and facilitates the acquisition and the extension of science, which would otherwise be confined to few objects and to a very limited range. It opens the way particularly to the knowledge of the globe which we inhabit; a subject so important and interesting to man. It is verified by experience. Mankind are for ever changing their habitations by conquest or by commerce; and we find them in all climates, not only able to endure the change, but so assiduously by time, that we cannot say with certainty whose ancestor was the native of the clime, and whose the intruding foreigner.

All the foregoing observations have been well recapitulated, illustrated by new facts, and enforced by additional reasoning founded on experience, by the Reverend Dr S. S. Smith, professor of moral philosophy in the college of New Jersey, in his Essay on the Causes of the Variety of Complexion and Figure in the Human Species; to which the reader who wishes for further satisfaction on the subject is referred.

COMPLEXUS; and COMPLEXUS MINOR, or TRABEULO-MASSIDESUS: two muscles in the posterior part of the trunk. See Anatomy, Table of the Muscles.

COMPLICATION, in general, denotes the blending, or rather interweaving, of several different things together; thus, a person afflicted with several disorders at the same time, is said to labour under a complication of disorders.

COMPLINE, the last division of the Roman breviary. It was instituted to implore God's protection during the night, as the prime is for the day. It is recited after mass; and is so called, because it completes the office for the 24 hours.

COMPLETONIAN BIBLE. See BIBLE (Greek).

COMPONE, or COMPOSED, or Gobony, in heraldry. A border composed is that formed or composed of a row of angular parts, or chequers of two colours.

COMPONED, or COMPOSED, is also used in general for a bordure, a pale, or a fess, composed of two different colours or metals disposed alternately, separated and divided by fillets, excepting at the corners; where the junctures are made in the form of a goat's foot.

COMPOSITE, in general, denotes something compounded, or made up of several others united together: thus.

Composite Number, are such as can be measured exactly by a number exceeding unity; as 6 by 2 or 3, or 10 by 5, &c. so that 4 is the lowest composite number. Composite numbers between themselves, are those which have some common measure besides unity; as 12 and 15, as being both measured by 3.

Composite Order, in architecture, the last of the five orders of columns; so called because its capital is composed out of those of the other columns, borrowing a quarter-round from the Tuscan and Doric, a row of leaves from the Corinthian, and volutes from the Ionic. Its cornice has simple modillions or dentils. It is also called the Roman or Italic order, as having been invented by the Romans. By most authors it is ranked after the Corinthian, either as being the next richest, or the last invented. See Architecture, n° 48.

COMPOSITION, in a general sense, the uniting or putting together several things, so as to form one whole, called a compound.

Composition of Ideas, an act of the mind, whereby it unites several simple ideas into one conception or complex idea.

When we are provided with a sufficient flock of simple ideas, and have by habit and use rendered them familiar to our minds, they become the component parts of other ideas still more complicated, and form what we may call a second order of compound notions. This process may be continued to any degree of composition we please, mounting from one stage to another, and enlarging the number of combinations.

Composition, in grammar the joining of two words together; or prefixing a particle to another word, to augment, diminish, or change its significatio.

Composition in logic, a method of reasoning, whereby we proceed from some general self-evident truth to other particular and singular ones.

In disposing and putting together our thoughts, there are two ways of proceeding equally within our choice: we may so compose them as being relating to any part of knowledge, as they presented themselves to the mind in the manner of investigation; carrying on the series of proofs in a reverse order, till they at last terminate.
Compositions are either formed for the voice alone, or for instruments, or for voices and instruments joined. Full choruses and songs are the only compositions principally intended for the voice, though sometimes instruments are joined with it to support it. Compositions for instruments are intended to be executed by a band in the orchestra, and then they are called symphonies, concertos, or for some particular species of instruments, and then they are called pieces or sonatas.

Such compositions as are destined both for voices and instruments, have been generally divided into two capital species, vis. the sacred and the secular. The compositions destined for the church, whether psalms, hymns, anthems, or responsive, are in general distinguished by the name of church-music, and characterized by their intention to be sung with words. Secular music in general may likewise be divided into two kinds; theatrical and chamber music. Of the first kind that is found in the operas; the subdivisions of the second are endless. Solos, concertos, cantatas, songs, and airs, almost of every kind, which are not adapted to the church or the stage, may be included in the idea of chamber-music.

In general, it is thought, that sacred music requires deeper science, and a more accurate observation of rules; the secular species gives more indulgence to genius, and subsists in greater variety.

But we must here observe, that the ecclesiastical music now used, or rather profaned and murdered, amongst us, though regular in its harmony, is simple in its composition, and demands not that profound knowledge in the art, either to form or comprehend it, which Rondeau, whom till now we have followed in this article, seems to imagine. His affersion can only be applicable to the church-music of Italy. That which is now established amongst us seems not to be indigenous, but transferred with the Calvinistical liturgy from Geneva; and as it is intended for popular use, it can by no means be esteemed an high exertion of the musical art; yet, however simple, it is pleasing; and, when properly performed, might elevate the soul to a degree of devotion, and even of rapture, which
at present we are so far from feeling, that we rather seem to sleep or to howl, than to sing the praise of
God. Perhaps the clergy may find more advantage in
cultivating their farms; but they would thereby feel a
higher and diviner pleasure in cultivating the tastes and
voices of their people. The one, however, is not in-
compatible with the other. An hour of relaxation in
a winter evening might serve for the accomplishment
produce popular
fection.

of the ear alone; or otherwise he soars a nobler height;
arangements of

music; he endeavors to ren-
der the hearts and souls of his auditors ductile by his
art, and thus to produce the noblest emotions and most
salutary effects. In the first view, it is only neces-
Sary that he should look for beautiful sounds and
agreeable chords; but in the second, he ought to con-
sider music in its conformity with the accents of the
human voice, and in the expressive powers of notes
harmonically combined to signify or paint such objects
as are susceptible of imitation. In Rondeau’s article

Opera, some ideas may be found by which the art may be
enobled and elevated, by forming music into a
language more powerful and pathetic than eloquence
itself. See Opera.

Composition, in literature, the art of forming
and arranging sentiments, and clothed them with
language suitable to the nature of the subject or dif-
course. See the articles Language, Oratory, Po-
etry, Dialogue, Epistle, and History.

Composition, in chemistry, is the union and com-

bination of several substances of different natures, from
which a compound body results. From this union of
bodies of different natures, a body is formed, of a mix-
ed nature, which Becker and Stahl have called a mix-
ture, and which may be called a combination, or chemical
composition, to avoid the equivocal sense of the word
mixture. By this last, we understand only a mere ap-
portion of parts; and which would therefore give a
very false idea of chemical composition, in which a
mutual attraction takes place between the combined
fabstancies.

Composition, in painting, includes the invention
as well as disposition of the figures, the choice of at-
titudes, &c.

Composition, therefore, consists of two parts; one
of which finds out, by means of history, proper ob-
jects for a picture; and the other disposes them to ad-
Vantage. See Painting.

Composition, in pharmacy, the art or art of mixing
diverse ingredients together into a medicine so as
they may assist each other’s virtues, supply each other’s
defects, or correct any ill qualities thereof. See Phar-

macy.

Composition, in commerce, a contract between
an insolvent debtor and his creditors, whereby the
latter accept of a part of the debt in composition for
the whole, and give a general acquittance accord-

ingly.

Composition, in printing, commonly termed com-
posing, the arranging of several types or letters in the
composing-flick, in order to form a line; and of se-
various lines ranged in order, in the galley, to make a
page; and of several pages to make a form. See
Printing.

Composition, in botany. The name of a class in
Hermannus and Rosen; as likewise of an order in
Linnæus's fragments of a natural method, confituting
in general in the plants which have the flowers

farms; and thus to produce the

mixture. From this union of

compositions, of the whole: and

german. Compound

flowers are either ligulari, tubulofi, or radiati.

COMPOST, in agriculture, denotes a certain kind
of mixture designed to assist the soil in the way of ve-
getation, instead of dung. The requisites of the com-
post are: 1. That it ought to be cheaper than the
quantity of dung required for an equal extent of soil.
2. It ought to be less bulky; and, 3. It ought to pro-
duce equal effects.

Under the article Agriculture, we have ende-
vour'd to show, that the true vegetable food consists
in reality of the putrid effluvia proceeding from de-
cayed animal and vegetable substances. If this theory
is admitted, the hope of making composts as a succe-
deanum for dung is but very small, unless they are
made of putrefied animal and vegetable substances; in
which case, unless in very singular circumstances, they
will prove much dearer than dung itself. Several at-
tempts, however, have been made by those who had
other views concerning the nature of the true vege-
table food. An oil-compost is recommended in the
Georgical Essays, upon a supposition that the food of
vegetables is of an oily nature. It is made as fol-

gows: "Take of North American porab 12 lb. Break the fat
into small pieces, and put it into a convenient vessel
with four gallons of water. Let the mixture stand 48
hours; then add coarse train oil 14 gallons. In a few
days the fat will be dissolved, and the mixture, upon
flirring, will become nearly uniform. Take 14 buthels
of sand, or 20 of dry mold; upon these pour the above
liquid ingredients. Turn this composition frequently
over, and in six months it will be fit for use. When the
liquid ingredients are put to one or two hogheads of
water, a liquid compost will be formed, which must be
used with a water cart."

This compost, however, the inventor himself owns to
be inferior to rotten dung, as indeed may very na-
turally be supposed; yet in some cafes it seems ca-
Pable of doing service, as will appear from some of
the following experiments which we extract from the
effays above-mentioned.

Exp. 1. By the author of the essays. "I took four

defs, n° 1, 2, 3, 4. No 1. contained 12 lb. of barren

dand, with 1 oz. of the sand oil compost. No 2. con-
tained 12 lb. of sand without any mixture. No 3. had
12 lb. of sand with half an ounce of flaked lime. No 4.
had
had 12 lb. of fowl with 4 oz. of the land oil compost.

In the month of March, I put six grains of wheat into each pot, and during the summer, I occasionally watered the plants with filtrated water. All the time the plants were growing, the farina, I could observe very little difference in their appearance. But after one month's growth, I remarked that no. 1. was the best; no. 2. the next; no. 3. the worst; and no. 4. much the worst. The same differences were observed in August, when no. 1. the best, had five small ears, which contained a few poor grains of wheat.

Exp. II. By the same. "In the month of June, I selected four lands of equal goodness in a field intended for turnips. The soil was a light land, with a tolerable quantity of vegetable earth amongst it. It was ploughed out of land in November, and had not borne a crop for many years. I shall distinguish my experimental lands by no. 1., 2, 3. and 4. No. 1. was manured with rotten dung; no. 2. with oil-compost; no. 3. with lime; no. 4. was left without any dressing. On the 20th of June they were all sown with turnip-fed broad-cast, and during the course of the month were twice hoed. In November I viewed the field, and made the following remarks. No. 1. the best; no. 2. the next; no. 3. the worst; no. 4. better than no. 3." Here the oil-compost appears in a favourable light; but other trials, made with equal accuracy, seem rather to prove, that it is not proper for turnips, barley, or quick growing vegetables. It requires being meliorated by the atmosphere, and therefore is better adapted for winter crops.

Exp. III. By the same. "In the month of May, I planted 12 alleys that lay between my asparagus beds with cauliflower plants. Each alley took up about 30 plants. One of the alleys I set apart for an experiment with the oil-compost, prepared according to the directions already given. About an handful of the compost was put to the root of each cauliflower plant. In all other respects the alley was managed like the rest. The plants in general flowered very well; but those to which I applied the compost sprang up hastily with small stalks, and produced very poor flowers. I improved this unfavourable appearance to the freshness of the compost, which was only a few weeks old. In the September following this unsuccessful experiment, I planted the same alleys with early cabbages. The necessity of meliorating the compost was in this instance fully confirmed. For the cabbages that grew upon the alley, which in May had received the compost, were larger and in all respects finer than the others."

Exp. IV. By James Stow, Esq.; of Donecaster. "In the year 1769, I made the following trial with the oil-compost, prepared as above directed. One acre with barley, and manured with oil-compost at 5s. produced five quarters five bushels. An acre adjoining, with barley, and manured with 12 loads of rotten dung at 5l. produced four quarters three bushels and two pecks. The compost-barley was better and better corn than the other. In the year 1770, the dunged acre produced of rye, three quarters. The compost acre of ditto, two quarters six bushels. In the year 1771, the same lands were fown with oats, and the produce was greatly in favour of the dunged acre. These experimental lands were in a common field that had been long under the plough.

Exp. V. by Richard Townly, Esq. of Belfield. "In the spring 1770, I prepared a piece of ground for onions. It was laid out into six beds of the same size, and which were all fown at the same time. Over two of them, the oil compost was scattered in a very moderate quantity. Over other two, pigeon's dung; and over the remaining two, some of my weed-compost (formed of putrefied vegetables), which I esteem one of the best manures, for most vegetables, that can be made. The onions came up very well in all the beds; but, in about six weeks, those that were fed with the oil-compost, plainly discovered the advantage they had over the rest, by their luxuriance and colour, and at the end of the summer, the finest crop I had ever seen, being greatly superior to the others both in quantity and size. The same spring I made an experiment upon four rows of cabbages, set at the distance of four feet every way. Two were manured with oil-compost, and two with my own. All the plants were un luckily damaged, just before they began to form, by some turkeys getting into the field and plucking off the greatest part of the leaves. However, they far recovered, in the September following, from 22 to 28lb. a-piece. The rows proved so equal in goodness, that I could not determine which had the advantage. The same year, one part of a field of wheat exposed to the north-eaft winds, which, that spring, continued to blow for a month or five weeks, appeared very poor and languid; at the time of tillage. Over it I planted some of the oil-compost to be fown with the hand; which not only recovered, but also pushed forwards the wheat plants in that part of the field, so as to make them little inferior, if any, to the rest. The same spring, I made a comparative experiment, upon four contiguous lands of oats, between the oil-compost and my own weed-compost. The latter had manifestly the advantage, though the other produced a very large and fine crop. I also tried the oil-compost upon carrots, and it answered exceedingly well. I did the same this year (1771) both upon them and cabbages; and had the finest crops of these vegetables I ever saw any where upon the same compost of ground."

Exp. VI. by Mr. J. Broadbent of Berwick, in Elmet near Leeds. "On the first of October 1771, I sowed two acres of a light channelly soil with wheat, and harrowed in the compost with the grain. Being at a considerable distance from a large town, we find it very difficult and expensive to procure rotten dung in sufficient quantity for our tillage lands, for which reason we have recourse to land-dressings both for our winter and spring-corn. Rape-dust and foot are principally used; but the present price of both these articles is a heavy tax upon the farmer. To obviate that inconvenience, I resolved to make trial of the oil-compost; and from what I have observed in this one experiment, I am encouraged to make a more extensive use of it the next year. Being well acquainted with the nature and efficacy of foot, I am satisfied, that the above two acres produced as good a crop of wheat as if they had been dressed with that excellent manure."

On the supposition that vegetables are supported by matters...
Compost, matters of a saline nature, composites formed of different fods of faits have been contrived, but with less success than the one above treated of. A famous composition of this kind was lately fold by patent, under the name of Baron Van Haak's compost. The following experiment is mentioned in the Georgical Essays, as made with a view to determine the virtues of it compared with the oil-compost and foot mixed with ashes—'In the beginning of April 1773, an acre of land was fown with forward oats. I pitched upon one land in the middle of the piece, which I esteemed better than any of the rest, and upon this I scattered Baron Van Haak's compost, in the quantity directed in his instructions. On one side I manured a land with the oil-compost, but rather with a less quantity than directed; and, on the other side, I manured two lands with dry coal-ashes sifted fine, and an equal quantity of foot. The lands upon which this experiment was made, were much worn out with a long succession of animals are remarkably fond of whale-flesh. This animal compost may with great advantage be applied to all purposes where good rotten dung is required. I have used it with great success for cabbages, and find it an excellent dressing for meadow-ground. According to the best computation, one hoghead of whale refuse will make eight loads of dung, which, when we consider the great facility with which this basis of our dung-hill may be carried, is a momentous concern to such farmers as lie remote from a large town.' See Manure.

Compost, in gardening, is a mixture of several earths, earthy substances and dungs, either for the improvement of the general soil of a garden, or for that of some particular plants. Almost every plant delights in some peculiar mixture of soils or compost, in which it will thrive better than in others. The most remarkable and generally useful of these, are taken notice of under the description of the several botanical articles, as they occur in the order of the alphabet.

Compostella, a celebrated town of Spain, and capital of Galicia, with an archbishop's see, and an university. The public squares, and the churches, particularly the Metropolitan church, are very magnificent. It has a great number of monasteries, for both sexes, and about 2600 houses. It is pretended that the body of St James was first laid here, which draws a great number of pilgrims from most parts of Christendom. They walk in procession to the church, and visit his wooden image, which stands on the great altar, and is illuminated with 40 or 50 wax-candles. They kiss it three times with a very respectful devotion, and then put their hats on its head. In the church there are 30 silver lamps, always lighted, and six chandeliers of silver, five feet high. The poor pilgrims are received into an hospital, built for that purpose, which stands near the church; and round it are galleries of free stone, supported by large pillars. The archbishop is one of the richest prelates in Spain, having 70,000 crowns a-year. From this town the military order of St Jorge, or St James, had its origin. It is seated in a peninsula, formed by the rivers Tambre and Ulla, in a pleasant plain. W. Long. 7. 17. N. Lat. 42. 54.

New Compostella, a town of North America, in New Spain, and province of Xalisco, built in 1531.
COMPOUND, in a general sense, an appellation given to whatever is compounded or made up of different things; thus we say, a compound word, compound found, compound title, &c.—Compound differs from complex, and hands opposed to simple. See Complex and Simple.

Compound flower. See Compositus flos.

Compound interest, called also interest upon interest, is that which is reckoned not only upon the principal, but upon the interest itself forborn; which hereby becomes a sort of secondary principal. See Interest.

Compound motion, that motion which is effected by several confiring powers. Powers are said to confine if the direction of the one be not quite opposite to that of the other; as when the radius of a circle is conceived to revolve about a centre, and at the same time a point to move straight along it.

Compound numbers, those which may be divided by some other number besides unity, without leaving any remainder; such are 18, 20, &c. the first being measured by the numbers 2, 6, or 9; and the second by the numbers 2, 4, 5, 10.

Compound quantities. See Algebra.

Compound ratios, is that which the product of the antecedents of two or more ratios has to the product of their consequents. Thus, 6 to 72 is in a ratio compounded of 2 to 6, and of 3 to 12.

Compound (substantive), the result or effect of a composition of different things; or a mass formed by the union of many ingredients.

Comprehension, in English church-history, denotes a scheme proposed by Sir Orlando Bridgman in 1667-8, for relaxing the terms of conformity in behalf of protestant dissenters, and admitting them into the communion of the church. A bill for this purpose was drawn up by Lord Chief-Baron Hale, but disallowed. The attempt was renewed by Tillotson and Stillingfleet in 1674, and the terms were settled to the satisfaction of the non-conformists; but the bishops refused their assent. This scheme was likewise revived again immediately after the Revolution; the king and queen expressed their desire of an union; however the design failed after two attempts; and the act of toleration was obtained.

Comprehension, in metaphysics, is that act of the mind whereby it apprehends or knows any object that is presented to it, on all the sides whereon it is capable of being apprehended or known. To comprehend a thing is defined by the schoolmen, res aliquam totam et totaliter cognosce.

Comprehension, in rhetoric, a trope or figure whereby the name of a whole is put for a part; or that of a part for a whole; or a definite number of any thing for an indefinite.

Compress, in surgery, a bolster of soft linen cloth, folded in several doubles, frequently applied to cover a platter, in order not only to preserve the part from the external air, but also to better retain the dressings or medicines.

Compression, the act ofpressing or squeezing some matter together, so as to fet its parts nearer to each other, and make it poiffeis less space. Compreffion properly differs from condensation, in that the latter is performed by the action of cold, the former by some external violence.

Compromise, a treaty or contract, whereby two contending parties establish one or more arbitrators to judge of and terminate their difference in an amiable manner.

Compton (Henry), bishop of London, was the youngest son of Spencer Earl of Northampton, and born in 1632. After the restoration of Charles II., he became cornet of a regiment of horse; but soon after quitting the army for the church, he was made bishop of Oxford in 1674; and about a year after translated to the see of London. He was entreated with the education of the two princesses Mary and Anne, whom he also afterwards married to the princes of Orange and Denmark; and their firmness in the protestant religion was in a great measure owing to their tutor, whom, when popery began to prevail at court, it was imputed as an unpardonable crime. He was afflicted from his ecclesiastical function by James II., but was restored by him again on the prince of Orange's invasion. He and the bishop of Bristol made the majority for filling the vacant throne with a king; he performed the ceremony of the coronation; was appointed one of the commissioners for raising the livery; and laboured with much zeal to reconcile dissenters to the church. His spirit of moderation made him unpopular with the clergy, and in all probability checked his further promotion. He died in 1713; but, living in busy times, did not leave many writings behind him.

Compromizer. See Controller.

Compulsor, an officer under the Roman emperors, dispatched from court into the provinces, to compel the payment of taxes, &c. not paid within the time prescribed. The word is formed of the verb compellere, "to oblige, constrain." These were charged with so many exactions, under colour of their office, that Honorious enfranchised them by a law in 412.

The laws of the Visigoths mention military compulsors; which were officers among the Goths, whose business was to oblige the tardy soldiers to go into the fight, or to run to an attack, &c. Caflan mentions a kind of monastic compulsors, whose business was to declare the hours of canonical office, and to take care the monks went to church at those hours.

Comunction, in theology, an inward grief in the mind for having offended God. The word comes from compungere, of pungere, "to prick."—The Romanists own their confession insignificant unless attended with compunction or pricking of heart.

Among spiritualists, compunction bears a more extensive signification; and implies not only a grief for having offended God, but also a pious sensation of grief, sorrow, and displeasure, on other motives. Thus, the miseries of life, the danger of being lost in the world, the blindness of the wicked, &c. are to pious people motives of compunction.

Compurgator, one that by oath, justifyeth another perfon's innocence. Compurgators were introduced as evidences in the jurisprudence of the middle ages. Their number varied according to the importance of the subject in dispute, or the nature of the crime with which a perfon was charged.
COMPUTATION, in a general sense, the manner of estimating time, weights, measure, monies, or quantities of any kind.—The word is sometimes also used among mathematicians in the like sense as calculation.

COMUM (anc. geog.), a town of the Orobi, of an ancient founding, and formerly powerful, daring to dispute with the Romans: Comenses, the people; Comensis Ager, the epithet. It became afterwards no inconsiderable municipality, to which Julius Cæsar added 5000 new colonists (Sirah); whence it generally called Novocomum, and the people Novocomenses. But in time it recovered its ancient name, Comum; Pliny the Younger, a native of that place, calling it by no other name. Now Como, in the duchy of Milan, at the south end of the lake of that name. E. Long. 9. 35. N. Lat. 46.

COMUS, in mythology, the god of jollity or festivity. There is great reason to believe he was the Cham of the Moabites; Beel-Phegor, Baal-Peor, Praisus, and Baccus. He is represented under the appearance of a young man, with an infamed red countenance, his head inclined, and crowned with flowers; his air drowsy; leaning on a huntsman’s spear in his left hand, and holding an inverted torch in his right. His statue was placed at the chamber doors of new married persons; his pedestal crowned with flowers.

CON, or Con. See Cond.

CONANT (Dr John,) a learned English divine, born in 1608. He took his degrees at Exeter College Oxford; was, by the parliament, constituted one of the assembly of divines, though he fellon, if ever, far with them; and in 1657 was admitted vice-chancellor of the university. On the restoration he was one of the commissioners, and assisted at the conferences in the Savoy; but was deprived by the act of uniformity; after eight years he was confirmed, and was made arch-deacon of Norwich, and prebendary of Worcester. In 1688 he lost his sight; and died in 1693; leaving a number of admired sermons, afterwards published in six volumes.

CONARION, or Conoides, a name for the pineal gland. See Anatomy, n. 132.

CONATUS, a term frequently used in philosophy and mathematics, defined by some to be a quantity of motion, not capable of being expressed by any time or length; as the conatus rectius ad axem motus, is the endeavour which a body, moved circularly, makes to recede, or fly off from the centre or axis of its motion.

CONCA (Sebastiano), called Cavaliere, a celebrated history and portrait painter, was born at Gaeta in 1679, and placed as a disciple with Francesco Solimena, an incomparable master. Under his direction Conca exerted his utmost industry to obtain a proper knowledge of the true principles of the art of painting; nor did he permit any kind of amuement to withdraw his attention from his studies. Solimena soon perceived in his disciple such talents, and such a disposition, as would qualify him to make a very great progress; and on that account he conceived to strong an affection for him, that he not only afforded him the best instructions, but often employed him to sketch after his own designs; took him along with him to Monte Carlino, where he was to paint a chapel in fresco; and there made Conca acquainted with every thing relative to that manner of painting. At his return to Naples with Solimena, he was, if possible, still more ambitious to improve himself to the utmost; and entered on a project that might at once advance his income, and add to his experience in his profession. That project was, to paint portraits in a small size and at a low rate; by which scheme all ranks of persons crowded to him; and before the pecuniary advantages resulting from it, he acquired an extraordinary freedom of hand in pencilling and colouring; a good habit of imitating nature with an elegant choice; and likewise great diversity of sizes of heads, which were of extraordinary use to him in his future beautiful compositions. As he had a great desire to see Rome, he obtained permission from Solimena to indulge his inclination; and although he was near thirty years of age when he visited that city; yet he spent eight years in constant study after the antiques, after Boonoroli, Raphael, and the Caracci, and perfected himself in every part of his profession. The fame of his works soon spread throughout Rome, and procured him the patronage of Cardinal Ottoboni, who was a princely encourager of artists; and Conca having shown an elegant proof of his abilities in a composition representing Herod inquiring of the wife men the place of the birth of the Messiah, the figures being as large as life, the Cardinal thought it so excellent a performance that he rewarded him in a munificent manner, entertained him in his own palace, and introduced him to Pope Clement XI. who appointed Conca to paint the picture of the prophet Jeremiah in the church of St. John Lateran; which he executed with universal applause. On that occasion the pope was desirous to give him some particular mark of his esteem; and therefore, in a general assembly of the academicians of St Luke, i.e. conferred on him the order of knighthood, and the cardinal presented him with a rich diamond cross, which Conca, out of respect to his patron, always wore at his bosom. From that time he was incessantly employed, and his works were solicited by most of the princes of Europe. The churches and chapels of every part of Italy are enriched with some of his compositions; of which he painted an incredible number, as he lived to a very advanced age, and never discon­tinued his labours. He was ever­lastingly invited by Philip V. of Spain to visit his court, but he could not be prevailed on to leave Rome; and painted up admirable pictures for the king of Poland, with figures as large as life; in one was represented Alexander presenting Bucephalus to Philip, after he had managed him; a grand composition, with a multitude of figures, correctly designed, and charmingly grouped and disposed; the whole being adorned with most elegant architecture, in true and beautiful perspective. The other was the marriage of Alexander with Roxana, the daughter of Darius, which was in every respect equal to the former. He was at last so strongly pressed to go to Naples, that he undertook the journey; and was received in that kingdom with all the respect and honour due to his merit; and there he furnished several noble designs, as also at Gaeta his native city. While he continued at Naples, he received in the royal presence a snuff-box of very great value, presented to him in the king’s name by the marquis of Tanucci, at that time prime minister; and in the year 1757,
CONCALE, a town of France, in Bretagne, with a harbour and a caffle. E. Long. 3° 45. N. Lat. 47° 55.', 'CONCEPtion, in logic, the simple apprehension or preception which we have of any thing, without proceeding to affirm or deny any thing about it. Some writers, as Lord Kames, distinguish between conception and perception; making the latter to denote the conjunction of an object when present, or to include the reality of its object; whereas conception expresses the forming an idea of an object whether present or absent, or without any conviction of its reality.

CONCEPTION, in medicine, denotes the first formation of the embryo, or fetus, in the womb. Conception is no other than such a concurrency and commixture of the prolific seed of the male with that of the female, in the cavity of the uterus, as immediately produces an embryo.

The symptoms of conception or pregnancy are, when, in a few days after the conjugal act, a small pain is perceived about the navel, and is attended with some gentle convolutions in the bottom of the abdomen; and within one, two, three, or even four months, the menses cease to flow, or prove in less quantity than usual. Upon the first failure of this kind, the woman begins to count the series of her weeks, without taking any notice of the time before elapsed; after this, or between the second or third months, but generally about the third, the motions of the embryo become perceivable to the mother; who hereupon becomes troubled with a nausea, vomiting, listlessness, longings, &c. About this time the breasts begin to swell, grow hard and painful, and contain a little milk; the nipples also become larger, firmer, and darker coloured, a livid circle appearing round them; the eyes seem sunk and hollow. During the two first months of pregnancy, the woman grows thinner and slenderer; the abdomen being also depressed; though it afterwards swells, and grows gradually larger.

The manner wherein conception is effected is thus laid down by the modern writers: In the superficies of the ovaries of women, there are found little pellucid spherules, consisting of two concentric membranes filled with a lymphatic humour, and connected to the surface of the ovaria, underneath the tegument, by a thick calyx, contiguous to the extremities of the minute ramifications of the Fallopian tubes.

These spherules, by the use of venery, grow, swell, raise and dilate the membrane of the ovary into the form of papillae; till, the head propending from the stalk, it is at length separated from it; leaving behind it a hollow cicatrix in the broken membrane of the ovary, which, however, soon grows up again.

Now, in these spherules, while still adhering to the ovary, fructus have been frequently found; whence it appears, that these are a kind of ova, or eggs, deriving their structure from the vessels of the ovary, and their liquor from the humours prepared therein.

Hence also it appears, that the Fallopian tubes being swelled and stiffened by the act of venery, with their mucular fibres, like fingers, may embrace the ovaries, compress them, and by that compression expand their own mouths; and thus the eggs, now mature, and detached as before, may be forced into their cavities, and hence conveyed into the cavity of the uterus; where they may either be cherisht and retained, as when they meet with the male seed; or if they want that, again expelled.

Hence the phenomena of false conceptions, abortions, foetuses found in the cavity of the abdomen, the Fallopian tubes, &c. For in coition, the male seed, abounding with living animalculcs, agitated with a great force, a brisk heat, and probably with a great quantity of animal spirits, is violently impelled through the mouth of the uterus, which on this occasion is opened, and through the valves of the neck of the uterus, which on this occasion are laxer than ordinary, into the uterus itself; which, now, in like manner, becomes more active,turgescent, hot, inflamed, and moistened with the flux of its lymph and spirits, by means of the titillation excited in the nervous papillae by the attrition against the rugæ of the vagina.

The semen thus disposed in the uterus, is retained, heated, and agitated, by the convulsive contrition of the uterus itself; till meeting with the ova, the finest and most animated part enters through the dilated pores of the membranula of the ovum, now become glandulous; is there retained, nourished, dilated; grows to its umbilicus or navel; fills the other less lively animaluckles; and thus is conception effected.

Hence it appears, that conception may happen in any part where the semen meets with an ovum; thus
whether it be through the Fallopian tube to the ovary, and there cast upon the ovum; or whether it meet with it in some recess of the tube itself; or, lastly, whether it join it in the cavity of the uterus, it may still have the same effect, as it appears from observation actually to have done. But it is probable, that conception is most perfect when the two, viz. the semen and ovum, are carried at the same time into the uterus, and there mixed, &c.

Other anatomists choose to suppose the male seed taken up, before it arrives in the uterus, by the veins which open into the vagina, &c. and thus mixed with the blood; by which, in the course of circulation, it is carried, duly prepared, into the ovary, to impregnate the eggs.

It has been advanced by several writers, that women may possibly conceive in their sleep, and be with child without any knowledge of the occasion of it. As ridiculous and absurd as this doctrine may appear to the generality of the world, no less an author than Gentil has thought it worthy a particular demonstration. The immaculate conception of the Holy Virgin, is a feast established in honour of the holy virgin, particularly with regard to her having been conceived and born immaculate, i.e. without original sin, held in the Romish church on the 8th of December. The immaculate conception is the great head of controversy between the Scotists and Thomists; the former maintaining, and the latter impugning it. In the three Spanish military orders, of St James of the sword, Calatrava, and Alcantara, the knights take a vow at their admission to defend the immaculate conception. This resolution was first taken in 1652. Peter d’Alva has published 48 huge volumes in folio on the mysteries of the conception.

Conception, an episcopal town of Chili in South America. It is situated in W. Long. 79° 12' S. Lat. 36° 43'; and is the oldest European settlement in Chili, and the second in point of dignity. On their first settlement here, the Spaniards were repeatedly driven off by the Indians, so that they were obliged to take up their residence at St. Jago. Since that time both the cities of Conception and St. Jago have been frequently destroyed by earthquakes. In the year 1730 both of them were laid in ruins by a dreadful shock, the first concussions of which were attended with an unprofitable swelling of the sea, that overturned the few houses which had escaped the ravages of the earthquake. The harbour is good, and pretty much frequented; on which account the city is regarded as a place of consequence. The king allows annually 350,000 pieces of eight for the support of a garrison of 2500 men; a corps that is seldom complete. None of the fortifications are considerable; but those towards the land are wretched. The Spaniards now live in tolerable security with respect to the Indians, and have no notion of any attack from the land side. It is said indeed, that not only this but all the settlements in Chili and Peru would fall an easy prey to the attacks of a foreign enemy; the fortifications being in ruins, and the garrisons scarce half the number required by the king: owing to the avarice, ignorance, and supine negligence of the governors, who flufly nothing but to enrich themselves.

Conception, a town of North America, in New-Spain, and in the Audience of Guatimala. It is seated near the sea-coast, 100 miles west of Porto-bello, and a small river that runs into the sea. W. Long. 85°; N. Lat. 10°.

Concert, or concerto, in music, a number or company of musicians, playing or singing the same piece of music or song at the same time.

Concert ato intimates the piece of music to be composed in such a manner, as that all the parts may have their recitatives, be it for two, three, four, or more voices or instruments.

Concert grosst, the grand chorus of a concert, or those places where all the several parts perform or play together.

Concession, in general, signifies either the act of granting or yielding anything, or the thing itself which is so granted or yielded.

Concessio, in rhetoric, a figure, whereby something is freely allowed, that yet might bear dispute, to obtain something that one would have granted to him, and which he thinks cannot fairly be denied, as in the following concession of Dido, in Virgil:

"The nuptials he declines, I urge no more;"
"Let him pursue the promised Latian shore;"
"A short delay is all I ask him now;"
"A pause of grief, an interval from woe."

Concha, in zoology, a synonyme of the Mystus Solen, and other shell-fish.

Conches, a town of Normandy, with a Benedictine abbey, which carries on a considerable trade. It is seated on the top of a mountain, in the territory of Ouche, 45 miles north-west of Paris. E. Long. 0° 31'. N. Lat. 48° 38'.

Conchites Marmor, a name given by the ancients to a species of marble dug near Megara, and remarkable for containing a great number of sea-shells, and other marine bodies imbedded in it.

Conchoil, in geometry, the name of a curve, given to it by its inventor Nicomedes. See Fluxions.

Conchylia, a general name for all petrified shells, as limpets, cockles, nantilli, conches, lepades, &c.

Conciator, in the glass art, is, for the crystal-glass, what the founder is at the green-glass houses. He is the person that weighs and proportions the salt on ashes and sand, and works them with a strong fire till they run into lumps and become white; and if the metal be too hard, and consequently brittle, he adds salt or ashes, and if too soft, sand; still mixing them to a fit temper, which is only known by the working.

Concinnous Intervals, in music, are such as are fit for music, next to, and in combination with concords; being neither very agreeable nor disagreeable in themselves; but having a good effect, as by their opposition they heighten the more essential principles of pleasure: or as, by their mixture and combination with them, they produce a variety necessary to our being better pleased.

Concinnous System, in music. A system is said to be concinnous, or divided concinnously, when its parts, considered as simple intervals, are concinnous; and are besides placed in such an order between the extremes, as that the succession of sounds, from one extreme to the other, may have an agreeable effect.

Conclamatio, in antiquity, a shout raised by those present at burning the dead, before they set fire.
Conclave, or the place in which the cardinals of the Roman church meet, and are shut up, in order to the election of a pope.

The conclave is a range of small cells, to feet square, made of wainscot: these are numbered, and drawn for by lots. They stand in a line along the galleries and hall of the Vatican, with a small space between each. Every cell has the arms of the cardinal over it. The conclave is not fixed to anyone determinate place, but is removable, and then in Italian or Latin; even the priests who may have interest in the election of the pontiff.

Conclave is also used for the assembly, or meeting, of the cardinals shut up for the election of a pope.

Conclusion, in logic, the consequence or judgment drawn from what was affirmed in the premises; or the previous judgments in reasoning, gained from combining the extreme ideas between themselves.

Concoction, in medicine, the change which the food undergoes in the stomach, and then in the small intestine. See Chyle.

Concomitant, something that accompanies or goes along with another.

Concord, in grammar, that part of construction called syntax, in which the words of a sentence agree; that is, in which nouns are put in the same gender, number, and case; and verbs in the same number and person with nouns and pronouns. See Grammar.

Concord, in music, the relation of two sounds that are always agreeable to the ear, whether applied in succession or conformance.

Form of Concord, in ecclesiastical history, a standard-book among the Lutherans, composed at Torgau, in 1576, and thence called the Book of Torgau, and reviewed at Copenhagen by six Lutheran doctors of Germany, the principal of whom was Jan Arentz. This book contains in two parts, a symposium of doctrine, the subordination of which was a condition of communion, and a formal and very severe condemnation of all who differed from the compilers of it, particularly with respect to the majesty and omnipresence of Christ’s body, and the real manaculation of his flesh and blood in the eucharist. It was first imposed on the Saxons by Augustus, and occasioned great opposition and disturbance. The dispute about it was revived in Switzerland in 1579, when the magistrates of Bern published an order for adopting it as the rule of faith; the consequence of which was a concilium, that reduced its credit and authority.

Concordance, a dictionary or index to the Bible, wherein all the leading words, used in the course of the inspired writings, are ranged alphabetically; and the various places where they occur referred to; to assist in finding out passages, and comparing the several significations of the same word.

Cardinal Hugo de St Charo, is said to have employed 300 monks at the same time in compiling a Latin concordance: besides which, we have several other concordances in the same language; one, in particular, called the concordance of England, compiled by J. Darlington, of the order of Predicants; another more accurate one, by the Jesuit de Zamora.

R. Mordecai Nathan has furnished us with a Hebrew concordance, first printed at Venice in 1523, containing all the Hebrew roots branched into their various significations, and under each signification all the places in scripture wherein it occurs; but the best and most useful Hebrew concordance is that of Buxtorf, printed at Batai in 1672.

Dr Taylor published, in 1754, a Hebrew concordance in two volumes folio, adapted to the English Bible, and disposed after the manner of Buxtorf.

The Greek concordances are only for the New Testament: indeed we have one of Conr. Kircher’s on the Old; but this is rather a concordant dictionary than a concordance; containing all the Hebrew words in an alphabetical order; and underneath all the interpretations or sentences the LXX. give them; and in each interpretation, all the places where they occur in that version.

In 1718, Trommimius published his Greek concordance for the Septuagint at Amsterdam, in two volumes folio; and Schmidius improving on a similar work of H. Stephen, has given an excellent Greek concordance for the New Testament, the best edition of which is that of Leipzic, an. 1717.

Calafius, an Italian Cordelier, has given us concordances of the Hebrew, Latin, and Greek, in two columns: the first, which is Hebrew, is that of R. Mordecai Nathan, word for word, and according to the order of the books and chapters: in the other column is a Latin interpretation of each passage of scripture quoted by R. Mordecai; this interpretation is Calafius’s own; but in the margin he adds that of the LXX. and the vulgar, when different from his. The work is in 4 vols folio, printed at Rome in 1621.

We have several very copious concordances in English, as Newman’s, &c. but the last and best esteemed, is that in 400 by Alex. Cruden.

Concordant verses, such as have several words in common; but which, by the addition of other words, convey an opposite, at least a different meaning. Such are those, 

\[
\text{Et } \left\{ \begin{array}{l}
\text{canis} \\
\text{lupus}
\end{array} \right\} \text{ in filio } \left\{ \begin{array}{l}
\text{venatur} \\
\text{nutritur}
\end{array} \right\} \text{ et omnia } \left\{ \begin{array}{l}
\text{servat} \\
\text{vesitat},
\end{array} \right\}
\]

Concordat, in the Canon law, denotes a covenant or agreement concerning some beneficiary matter, as a renunciation, perpetuation, or the like.

The council of Trent, [f. vi. de reform. cap. 4. speaking of concordats made without the authority]
and approval of the pope, calls them concordias quae tantum fines obigant aulores, non successores. And the congregation of cardinals, who have explained this decree, declares also that a concordat cannot be valid so as to bind successors, unless confirmed by the pope.

Concordat is also used, absolutely, among the French, for an agreement concluded at Bologna in 1516, between pope Leo X. and Francis I. of France, for regulating the manner of nominating the pope.

The concordat serves in lieu of the Pragmatic sanction, which has been abrogated; or, rather, it is the pragmatic sanction softened and reformed. The concordat between the pope and the republic of Venice resembles the former.

There is also a German concordat, made between the emperor Frederic III. and the prince of Germany, in 1445, relating to beneficiary matters, confirmed by pope Nicholas V.

Concordia, a town of Italy, in the duchy of Mirandola, situated on the river Secchia, 5 miles west of Mirandola, and 15 miles south-east of Manna; also called to the house of Austria. E. Long. 11. 22. N. Lat. 44. 52.

Concordia (anc. geog.), a town of the Veneti, situated at the confluence of the rivers Romanus Major and Minor, 31 miles to the west of Aquileia, (Pliny, Ptolemy, Antonine); a colony furnamed Julia. Its ruins still go by the name of Concordia.—Another Concordia (Ptolemy), of Lucania, to the north-west of Trajan's bridge, on the Tagus.—A third of the Nemetes in Belgica, on the west side of the Rhine; a Roman fortress, situated between Brocogamus and Noviomagus. Now Drufenheim, in Allace. E. Long. 8°, Lat. 48° 40'.

Concordia, a pagan divinity of the Romans. She had a temple on the declivity of the Capitol; another in the portico of Livia; and a third on Mount Palatine, built of braifs by Cn. Flavius, on account of a vow made for reconciling the Senate and people. She was pictured with a cup in her right hand; in her left was sometimes a sceptre, and sometimes a cornu-oppia. Her symbols were two hands joined, as is seen in a coin of Aurelius Venus, and another of Nero; also two serpents twisting about a caduceus. She was addressed to promote the peace and union of families and citizens.

Concous, in botany, a name given by the people of Guinea to an herb, which is in great esteem among them for killing that troublesome sort of worm called the Guinea-worm, that breeds in their flesh. They bruise the leaves, and mixing them with oil, apply them in a form of a cataplasm.

Concrete, in the school-philosophy, an assemblage or compound.

Concrete, in natural philosophy and chemistry, signifies a body made up of different principles, or any mixed body: thus, soap is a fictitious concrete, mixed together by art; and antimony is a natural concrete, or a mixed body compounded in the bowels of the earth.

Congration, the uniting several small particles of a natural body into sensible masses or concretes, whereby it becomes so and so figured and determined, and is ended with such and such properties.

Congration is also the act whereby soft bodies are rendered hard; or an insensible motion of the particles of a fluid or soft body, whereby they come to a confluence. It is indifferently used for induration, concretion, congelation, and coagulation.

Concubinage sometimes expresses a criminal or prohibited commerce between the two sexes, in which sense it comprehends adulteries, incest, and simple fornication.

In its more restrained sense, concubinage is used for a man's and a woman's cohabiting together in the way of marriage, without having passed the ceremony thereof.

Concubinage was anciently tolerated: the Roman law calls it an allowed custom, licta confungtula. When this expression occurs in the constitutions of the Christian emperors, it signifies what we now call a marriage in conscience.

The concubinage tolerated among the Romans in the time of the republic, and of the heathen emperors, was that between persons not capable of contracting marriage together: nor did they even refuse to let inheritances descend to children which sprung from such a tolerated cohabitation. Concubinage between such persons looked on as a kind of marriage, and even allowed it several privileges; but then this concubinage was confined to a single person, and was of perpetual obligation as much as marriage itself. Hottoman observes, that the Roman laws had allowed of concubinage long before Julius Cæsar made that law whereby every one was allowed to marry as many wives as he pleased. The emperor Vespasian, Socrates tells us, allowed every man two.

Concubinage is also used for a marriage performed with less solemnity than the formal marriage; or a marriage with a woman of inferior condition, and to whom the husband does not convey his rank or quality. Cujus observes, that the ancient laws allowed a man to espouse, under the title of concubine, certain persons, such as were esteemed unequal to him, on account of the want of some qualities requisite to sustain the full honour of marriage. He adds, that though concubinage was beneath marriage, both as to dignity and civil effects; yet was concubine a reputable title, very different from that of mistresses among us. The commerce was esteemed lawful, that the concubine might be accused of adultery in the same manner as a wife.

This kind of concubinage is still in use in some countries, particularly in Germany, under the title of half-marriage, or marriage with the left hand; alluding to the manner of its being contracted, viz. by the man's giving the woman his left hand instead of the right. This is a real marriage, though without solemnity: the parties are both bound for ever; though the woman be thus excluded from the common rights of a wife for want of quality or fortune.

The children of concubines were not reputed either legitimate or bastards, but natural children, and were capable only of donations. They were termed to retain the low rank of the mother; and were on this ground unqualified for inheriting the effects of the father.

Concubinage, in a legal sense, is used as an exception against her that sith for dower, alleging there-
Concubine, a woman whom a person takes to cohabit with him, in the manner, and under the character, of a wife, without being authorized thereto by a legal marriage.

Concubine is also used for a real, legitimate, and only wife, distinguished by no other circumstance but a disparity of birth or condition between her and the husband. Du Cange observes, that one may gather from several passages in the epistles of the popes, that they anciently allowed of such concubines. The fourteenth canon of the first council of Toledo declares, that he who, with a faithfultul wife, keeps a concubine, is excommunicated; but that if the concubine served him as a wife, so that he had only one woman, under the title of concubine, he should not be rejected from communion; which shows that there were legitimate wives under the title of concubines.

In effect, the Roman laws did not allow a man to espouse whom he pleased; there was required a kind of parity, or proportion, between the conditions of the contracting parties: but a woman of inferior condition, who could not be espoused as a wife, might be kept as a concubine; and the laws allowed of it, provided the man had no other wife.

It is certain the patriarchs had a great number of wives, and that these did not all hold the same-rank; some being subaltern to the principle wife, which were what we call concubines or half wives. The Romans prohibited a plurality of concubines, and only had regard to the children issuing from a single concubine, because she might become a legitimate wife. Solomon had seven hundred wives and three hundred concubines: the emperor of China has sometimes two or three thousand concubines in his palace. Q. Curtius observes, that Darius was followed in his army by 365 concubines, all in the equipage of queens.

Concupiscence, according to divines, an irregular appetite, or lust after carnal things, inherent in the nature of man ever since the fall.

Conde, Con, or Conn, in sea language, signifies to guide or conduct a ship in her right course. He that cons her, stands aloof with a compass before him, and gives the word of direction to the man at the helm, how he is to steer. If the ship go before the wind, or, as they call it, betwixt the sheets, the word is either starboard, or port the helm: according as the concer would have the helm put to the right or left side of the ship, upon which the ship always goes the contrary way. If he says, helm a midship, he would have the ship to go right before the wind, or directly between her two sheets. If the ship fail by a wind, or on a quarter wind, the word is aloof, keep your luff, fall not off, veer no more, keep her to, touch the wind, have a care of the ice-latch: all which expressions are of the same import, and imply that the seafarer should keep the ship near the wind. On the contrary, if he would have her fall more large, or more before the wind, the word is cafe the helm, no near, bear up. If he cries steady, it means, keep her from going in and out, or making yaws (as they call it), however she fails, whether large or before a wind: and when he would have her go just as she does, he cries, keep her thus, thus, &c.

Condate (anc. geog.), a town of Armorica in Gaul: called Civitas Rhedum, in the Notitia; afterwards Redon; Redonica Regio, the district. Hence the modern name Renes, in Brittany. W. Long. 7. 45. Lat. 48. 5. Another Condate of Britain (Antonine) now thought to be Congleton, in Yorkshire; others say in Lancashire.

Conde (Lewis de Bourbon prince of), was born at Paris Sept. 7, 1621. He was styled Duke d’Enguien till he succeeded to the title of Prince of Conde by his father’s death in 1646. As he was of a tender and delicate constitution, the prince sent him to the castle of Montrond in Berry, that he might breathe a more pure and salutary air. Here he was educated in his infancy by some experienced and prudent citizens. When he was of a proper age, the prince took upon himself the talk of governor, and appointed for his amanuensis M. de la Boulriere, a private gentleman, a man of honour, fidelity, and good nature, and who made it a rule to observe inviolably the orders that were given him. Two Jesuits distinguished for their genius and knowledge were also given him for preceptors. He formed him a household of 15 or 20 officers, all men of the greatest virtue and discretion.

With these attendants the duke d’Enguien went to settle at Bourges, where he frequented the college of Jesuits. Here, besides the ordinary studies, he was taught ancient and modern history, mathematics, geography, declamation; also riding and dancing, in which last he soon excelled. He made such a surprising progress, that before the age of 12 he defended in public some questions in philosophy with incredible applause. At his return from Montrond, he had for his tutor M. de Merille; a man deeply versed in the law, fidelity, and good nature, and appointed the prince of Conde by his own will, and on the death of his father, he gave himself by yielding to it was so great, that he fell dangerously ill. It
The duke made two more campaigns as a volunteer; the one under the marshal de la Meilleraye, the other in the army of Louis XIII. which conquered Rouillon. In 1643, at the age of 22, he obtained from the king, at the persuasion of cardinal Mazarin, the command of the army defined to cover Champagne and Picardy; which command was confirmed to him after the king's death by the queen regent, Anne of Austria, to whose interest he was strongly devoted. In this station, though he never had been present at any battle, he soon gave such a specimen of his abilities as crowned him with glory. The Spaniards, who threatened France with an invasion, were defeated by him at Rocroi; and this signal victory made him from that time considered as the guardian genius of his country. He next formed the project of besieging Theonville, and proposed it to the council of regency. They consented with fear and difficulty; but the duke carried it into execution with such skill, activity, and courage, that he became justly the subject of general admiration. In two months time Theonville surrendered. At length, having covered Alsace and Lorraine from the enterprise of the Imperialists, the duke returned to Paris, where he obtained the government of Champagne, and of the city of Stenay.

The three following years were little more than a series of military operations. The three battles of Fribourg, in which the duke d'Enguicin triumphed over Velt Marithal count de Mercy, the greatest general in all Germany: the taking of Philippsbourg, and a great number of other places, which rendered him master of the palatinate, and of the whole course of the Rhine; the victory of Nortlingue, by which he revenged the vicount du Turenne's defeat at Mariendal; the siege and conquest of Dunkirk; the good and bad success of his arms in Catalonia, where, though he had resolved to raise the forces of the Spaniards in awe, and cut to pieces their garrisons; there are the principal events which distinguish the campaigns of 1644, 1645, and 1646.

The victories of the duke d'Enguicin, his great reputation and esteem with the people, began now to give umbrage to Mazarin. The cardinal's dislike to him appeared on the death of the duke de Breze, admiral of France. The prince of Conde earnestly demanded for his son the duke de Breze's places. But Mazarin, afraid of increasing the wealth and power of a prince whom his victories and the love and confidence of the people and the army had already rendered too formidable to him, evaded his requets, by persuading the queen to take the Admiralty to herself. On the death of his father, the minister's dislike to the young prince of Conde became still more apparent. By the minister's persuasion he had accepted of the command of the army in Catalonia; but, on his arrival at Barcelona, he found neither troops, money, artillery, provisions, nor ammunition. Enraged at this deception, he vented his resentment in bitter complaints and severe threats: but by the resources that he found in this dilemma, the prince added new lustre to his glory.

The campaign of 1648 was as glorious to Conde as those which preceded it had been. To divert him from once the projects of the arch-duke Leopold, the prince resolved to attack him even in the heart of the Low Countries; and notwithstanding the considerable difficulties which he had to surmount, he besieged the important city of Ypres, and took it in fight of all the enemies forces.

Notwithstanding this success, Conde saw himself at the point of experiencing the greatest reverie of fortune. His army was a prey to scarcity, to nakedness, contagious distempers, and distraction. For eight months it received no supply from the minister, but half a mufier. Every thing was supplied by the prince himself; he lavished his money, and borrowed more to supply his troops. When it was represented to him that he was in danger of ruining himself by such an enormous expense, he replied, that "since he every day ventured his life for the service of his country, he could very well sacrifice his fortune to it. Let but the government exist (added he), and I shall want for no thing."

The French army having been reinforced by 4000 of the troops of Weimar, Conde attacked the Spaniards advantageously encamped near Lens, and gained a complete victory over them, which disabled them from attempting anything more, and even from supporting themselves. Afterwards he besieged Fosse, the garrison of which, 500 men, surrendered themselves prisoners of war. But the prince was wounded there in the trenches by a musket shot above the right hip; and the contusion was so great, that he was forced to submit to several incisions.

The French court, animated with the victory at Lens, thought this a proper time to take vengeance on the factions which for some time had violently agitated the kingdom; and accordingly imprisoned Brouille and Blanchemini, two of the principal leaders of the country party. This vigorous proceeding, however, occasioned a general revolt of Loria, by the enthusiasm of which the Spaniards in awe, and cut to pieces their garrisons; there are the principal events which distinguish the campaigns of 1644, 1645, and 1646.

The minister's dislike to the young prince of Conde became still more apparent. By the minister's persuasion he had accepted of the command of the army in Catalonia; but, on his arrival at Barcelona, he found neither troops, money, artillery, provisions, nor ammunition. Enraged at this deception, he vented his resentment in bitter complaints and severe threats: but by the resources that
he took part openly with the court, though he thought it ungrateful, and protected the minister, though he did not esteem him.

The royal family, the duke of Orleans, Conde, and Mazarin, left Paris privately in the night between the 5th and 6th of January 1649, and went to St Germain. The parliament sent deputies to learn from the queen herself the reasons of her departure, and to beg her to name the citizens whom she suspected, that they might be tried. Mazarin had the imprudence to dismiss them without any answer. Exasperated at this, the people again took up arms in order to defend themselves against the enterprizes of the court, who had determined to block up and to starve the capital, in order to suppress the party of malcontents. With 7 or 8000 men, the broken relics of the last campaign, the prince of Conde formed a design of reducing above 500,000 entrenched behind walls. He had neither money nor magazines; he knew himself in the depth of a most severe winter; nevertheless he triumphed over Paris, and this great success completed his glory. It did him so much the more honour, as during the siege he constantly defeated the troops of the malcontents; he prevailed on the army that marched to their assistance under Turenne, to abandon that general; he stopped the progress of the duke de Longueville, who had caused an insurrection in Normandy; and got the start of the Spaniards, who were advancing to give him battle.

Conde de Reiz, co-adjutor of Paris, and afterwards cardinal, was the life and soul of the revolutionists, and directed all their motions. He had taken Catiline for his model; and was equally intrepid and capable of the greatest actions of an exalted genius, but governed by his ambition. He distinguished his hatred to Mazarin by arming the malcontents; and he himself raised at his own expense a regiment which he called the regiment of Corinth; as soon as this corps took the field during the blockade of Paris, it was defeated and dispersed. This check was called the first to the Corinthian. The peace was signed at St Germain; but neither party carried its point, and scarce any one but Conde acquired glory by this war. After the conclusion of the treaty, the prince repaired to the capital, and traversed all the streets in his coach alone. All persons of any consequence paid his compliments to him, and the parliament sent a solemn deputation to thank him for the peace to which he had so powerfully contributed. The people, however, made loud complaints on account of the king’s absence (for the court was not yet returned to Paris), and the malcontents gave reason to apprehend a new insurrection. Conde encouraged the king and queen to return; and at length brought them to Paris, amidst the acclamations and blessings of the public.

The important service which Conde had just done the court intimated him to the acknowledgments of the queen, and especially of Mazarin; but the dark soul of that cardinal only remembered it to punish a too fortunate and two powerful protector. He privately swore the prince’s destruction; at least that he should give the whole kingdom a pattern of submilion and dependence on his will. However, not to excite the public indignation, he still kept up appearances with the prince, while he secretly spread about him diftrusts, suspicions, snares of every kind, and the most heinous calumnies. The ungrateful minister deceived the prince by making him the most flattering proposals; and with the most alluring promises which he always found means to avoid fulfilling. The enraged prince defied the minister, and treated him with disdain. After this they were reconciled again only to be again at variance. Each of them in their turn courted the country party, in order to make it subservient to their designs. At last Mazarin thought of an expedient, which but too effectually answered his purpose, of making an irreconcilable quarrel between that party and the prince. There was among the malcontents one marquis de la Boulaiel, a man of an infamous character, who had obtained the confidence of the party by false appearances of hatred to the cardinal, but who secretly kept up a correspondence with him. It is pretended that he made him an offer of privately killing Conde. Mazarin was charmed with the proposal; yet he only required Boulaiel to exhibit all the proofs of an afflication, and to act in such a manner that every thing might concur to render the country party displeased of that crime. He was punctually obeyed; the coach was stopped; some pistols were fired at it; by which two of the footmen were dangerously wounded; and, after that shameful exploit, la Boulaiel took refuge in the hotel of the duke of Beaufort, who was the hero of the party, in order no doubt to counterbalance the prince’s perfidy of the malcontents. Luckily Conde was not in his coach when it was stopped; the cardinal had spread the report of his intended affillation; and in concert with the queen and the prince he had prevailed to have the coach sent away empty, to prove the reality of the attempt. Mazarin counterfeited a zeal for the prince’s life, he furiously denounced against the malcontents, who, he pretended, had made an attempt on a life so precious to the state; and he inflamed Conde’s resentment against the duke of Beaufort and the coadjutor, whom he supposed to be the authors of this heinous outrage. The prince was so strongly prejudiced, that he refused to hear them when they appeared before him to justify themselves. He demanded justice against them of the king; he formally accused them before the parliament, and remained inflexible in spite of the pains which the leaders of the party took to demonstrate to him that he had been imposed upon. However, the affair was brought before the parliament; the accused defended themselves, and the coadjutor, who had discovered the cardinal’s secret, unmasked him so well, that the prince agreed to a private negotiation with the malcontents; he required nothing more than the coadjutor’s leaving Paris; but with the rank of ambassador to Rome or Vienna. That prelate would have consented to it, to satisfy Conde, if Mazarin, some days after, had not given him the choice of any recompence, in order to engage his concurrence in the prince’s destruction. Affairs were now in such a dangerous situation, that the cardinal saw clearly it was necessary to hasten to the winding up of the plot. Matter of the queen’s mind, which he guided as he pleased; and sure of having inflamed against Conde all the resentment of the malcontents; he sought and obtained, by means of the duchess Chevreuse, the support of that powerful faction, which connected itself the
the more readily with him, in hopes that the prince’s ill would soon enable it to crush without difficulty the cardinal himself. The coadjutor had private conferences with the queen and the minister. Conde had notice of it; and in order to discover if it were true, he endeavoured to surprise it from Mazarin’s own mouth. “Cardinal (said he, one day), it is publicly reported that you have nightly meetings with the coadjutor, disguised like a trooper.” He accompanied this speech with a quick and penetrating look: but the cardinal, who was a perfect master of dissimulation, answered him in such a free, artless manner, that he entirely removed Conde’s apprehensions; and he flighted the information he had received, of the plot forming against him.

Mazarin wanted nothing but the support of the duke of Orleans; and at last found means, by the duchesses of Chevreuse, to inflame the jealousy of that fickle and inconstant prince, and to engage him to consent to the imprisonment of Conde. Having thus united all parties, and fearing no other obstacle, this ungrateful and perfidious minister made preparations for privately arresting the prince; the order for it was signed January 18th 1650. Conde having that day repaired as usual to the palais-royal, to assist at council with the prince of Conti and the duke of Longueville, the queen gave orders to arrest them all three, and convey them without any noise to the castle of Vincennes. She was instantly obeyed, and the princes were strictly guarded to that prison.

In this unexpected reverse of fortune, the fortitude and greatness of Conde’s mind appeared only the more remarkable. Confined with the other two princes in the tower of Vincennes, where neither supper, furniture, nor beds, were provided, he contented himself with two new laid eggs, and threw himself in his cloaths, on a truss of straw, where he slept 22 hours without waking. He still retained his cheerfulness, and dedicated the greatest part of his time to reading, the rest to conversation, playing at battle-door and shuttle-cock, to bodily exercises, and the cultivation of flowers.

Mazarin triumphed at the disgrace of the princes, prostrated all those who were attached to Conde, and behaved in the most insolent and arbitrary manner. The prince’s friends, however, notwithstanding their being strictly watched, found means to keep up a punctual correspondence with him. They made various attempts to release him: they raised troops; in order to obtain the province of Guienne to declare in his favour; they were coming to Paris, which he entered as happy, with the acclamations of the people, and the parliament, informed by the king’s army, he retired into the suburbs of Chartilley, where he was as much respected by the commonalty as by the king’s ministers. The coadjutor had signed the arrest, by which the prince was to be destined to the castle of Vincennes. There he was conformed, that he fled in the disguise of a trooper, and arrived at the gates of Richlieu, where a body of horse waited for him. The parliament, informed by the queen of his flight, thundered forth an arret, by which he was obliged to leave the kingdom, with his family and foreign servants, in the space of 15 days, under the penalty of being exposed to a criminal prosecution. The queen desired to follow him with the king; but the nobles and burghers invetered the palais-royal, and prevented the execution of this project, which would have kindled a civil war. Mazarin, therefore, perceiving that it was impossible for the queen to join him, determined to go himself to release the princes to their liberty, and to get the part of the deputies who were coming to acquaint them with it. On his arrival at Havre, he informed the princes that they were free; he entertained Conde’s friendship; and was so averse as to proftrate himself at the feet of him whom he had so falsely oppressed. Conde gave him a polite reception, and spoke to him in a free and cheerful tone; but tired with the mean submissions which the cardinal lavished upon him, he left him without making any promise, and set out on his return to Paris, which he entered as it were in triumph, amidst the acclamations of all orders of men, and the demonstrations of a most sincere and general joy.

After this a civil war ensued, in which the prince of Conde sided with the malcontents. Being pressed by the king’s army, he retired into the suburbs of St Anthony, where he behaved with the utmost bravery; when the citizens opened their gates and received him in; and a peace ensued soon after. His hatred of the cardinal, however, made him quit Paris, and take refuge among the Spaniards, who made him generalissimo of their forces; and he took Rochefort. The peace of the Pyrenees restored him to his country; and he again signalized himself at the head of the king’s armies. Being afflicted with the gout, he refused the command of the army in 1676, and retired to Chartilley, where he was as much esteemed for the virtues of peace, as he had been before for his military ones. He died in 1686, at Fontainebleau.

Conde, a town of the French Netherlands, in the province of Hainault, with the title of a principality, and a castle. It is one of the strongest towns in this country, and feated near the confluence of the rivers Haftine and Scheld. E. Long. 3. 29. N. Lat. 50. 27.

Conde, a town of France, in Normandy, and in the Beffin, which carries on a considerable trade; feated on the river Nereau. W. Long. 0. 37. N. Lat. 40. 50.

Condemnation, the act of giving judgment, passing or pronouncing sentence against a person subjected thereby to some penalty or punishment, either in respect of life, reputation, or fortune.
CONDENSATION, the act whereby a body is rendered more dense, compact, and heavy. The word is commonly applied to the conversion of vapour into water, by distillation, or naturally in the clouds. The way in which vapour commonly condenses, is by the application of some cold substance. On touching it, the vapour parts with its heat which it had before absorbed; and on doing so, it immediately loses the proper characteristics of vapour, and becomes water. But though this is the most common and usual way in which we observe vapour to be condensed, nature certainly proceeds after another method; since we often observe the vapours most plentifully condensed when the weather is really warmer than at other times. See the articles Cloud, Evaporation, &c.

CONDENSER, a pneumatic engine, or syringe, whereby an uncommon quantity of air may be crowded into a given space; so that sometimes ten atmospheres, or ten times as much air as there is at the same time in the same place, without the engine, may be thrown in by means of it, and its effects prevented by valves properly disposed. See Plate CXLVI.

It consists of a brass cylinder, wherein is a moveable piston; which being drawn out, the air rushes into the cylinder through a hole provided for the purpose; and when the piston is again forced into the cylinder, the air is driven into the receiver through an orifice, furnished with a valve to hinder its getting out.

The receiver or vessel containing the condensed air, should be made very strong, to bear the force of the air's spring thus increased; for which reason they are generally made of brass: its orifice is fitted with a female screw to receive the male screw at the end of the condenser.

If glass be used for a condenser, it will not suffer so great a degree of condensation; but the experiment will be more entertaining, since the subject may be viewed in the condensed air.

CONDITION, in the civil law, a clause of obligation stipulated as an article of a treaty or a contract; or in a donation of a thing. See its figure facilitates the separation of these substances according to their respective densities. The cone ought to be well heated before the melted mass is thrown into it; that it may not contain any moisture, which would occasion a dangerous explosion. It ought also to be greased internally with tallow, to prevent the adhesion of the fluid matter.

Cone of Rays, in optics, includes all the several rays which fall from any radiant point upon the surface of a glass.

CONF, in botany. See Conus.

CONESSI, a fort of bark of a tree, which grows on the Coromandel coast in the East Indies. It is recommended in a letter to Dr Monro, in the Medical Essays, as a specific in diarrheas. It is to be finely pulverized, and made into an electuary with syrup of oranges. The bark should be fresh, and the elec-
**CONFESS*ON**, among divines, the verbal acknowledgment which a Christian makes of his sins.

Among the Jews it was the custom, on the annual feast of expiation, for the high-priest to make confession of sins to God in the name of the whole people: besides this general confession, the Jews were enjoined, if their sins were a breach of the first table of the law, to make confession of them to God; but violations of the second table were to be acknowledged to their brethren. The confession of the primitive Christians were all voluntary, and not imposed on them by any laws of the church; yet private confession was not only allowed, but encouraged.

The Roman church requires confession not only as a duty, but has advanced it to the dignity of a sacrament: this confession is made to the priest, and is private and auricular; and the priest is not to reveal them under pain of the highest punishment.

**Confession of Faith**, a list of the several articles of belief in any church.

**Confessional**, or **Confessionary**, a place in churches under the great altar, where the bodies of deceased saints, martyrs, and confessors, were deposited.

This word is also used by the Romanists for a desk in the church where the confessor takes the confessions of the penitents.

**Confessor**, a Christian who has made a solemn and resolute profession of the faith, and has endured torments in its defence. A mere saint is called a confessor, to distinguish him from the roll of dignified saints: such as apostles, martyrs, &c. In ecclesiastical history, we frequently find the word confessors used for martyrs; in after-times, it was confined to those who, after having been tormented by the tyrants, were permitted to live and die in peace. And at last it was also used for those who, after having lived a good life, died under an opinion of sanctity. According to St. Cyprian, he who presented himself to torture, or even to martyrdom, without being called to it, was not called a confessor but a professor: and if any out of a want of courage abandoned his country, and became a voluntary exile for the sake of the faith, he was called extrius.

**Confessor is also a priest**, in the Roman church, who has a power to hear sinners in the sacrament of penance, and to give them absolution. The church calls him in Latin conatherls, to distinguish him from confessor, which is a name confecrated to saints. The confessors of the kings of France, from the time of Henry IV. have been constantly Jesuits; before him the Dominicans and Cordeliers shared the office between them. The confessors of the house of Austria have also, ordinarily, been Dominicans and Cordeliers; but the latter emperors have all taken Jesuits.

**Confirmation**, the outward figure which bounds bodies, and gives them their external appearance: being that which, in a great measure, constitutes the specific difference between bodies.

**Confirmation**, in a general sense, the act of ratifying or rendering a title, claim, or report, or the like more sure and indisputable.

**Confirmation, in law**, a conveyance of an estate, or right in estate, from one man to another, whereby a voidable estate is made sure and unavoidable, or a particular estate is increased, or a possession made perfect.
CONFLAQUETION, in theology, the ceremony of laying on of hands, for the conveyance of the Holy Ghost. The antiquity of this ceremony is by all ancient writers, carried as high as the apostles, and founded upon their example and practice. In the primitive church, it was given to Christians immediately after baptism, if the bishop happened to be present at the solemnity. Among the Greeks, and throughout the East, it still accompanies baptism; but the Romans make it a distinct independent sacrament. Seven years is the stated time for confirmation: however, they are sometimes confirmed before, and sometimes after, that age. The person to be confirmed has a godfather and godmother appointed him, as in baptism. The order of confirmation in the church of England, does not determine the precise age of the persons to be confirmed.

CONFISCATION, in law, the adjudication of goods or effects to the public treasury; as the bodies and effects of criminals, traitors, &c.

CONFULATIOR, the general burning of a city, or other considerable place.

This word is commonly applied to that grand period or catastrophe of our world, when the face of nature is to be changed by fire, as formerly it was by water. The ancient Pythagoreans, Platonists, Epicureans, and Stoics, appear to have had a notion of the confagration: though whence they should derive it, unless from the sacred books, is difficult to conceive; except, perhaps, from the Pythagoreans, who themselves had it from the Jews. Seneca says expressly, Tempus adventerit quo fisura sideribus incurrit, et omni flagrante materia uno igne, quiqueplae noue ex deposito lucet, ardebit. This general dilabution the Stoics call evopcap, cyypoLo. Mention of the confagration is also made in the books of the Sybils, Sophocles, Hylasides, Ovid, Lucan, &c. Dr Burner, after F. Tachard and others, relates that the Siamese believe that the earth will at last be parched up with heat; the mountains melted down; the earth's whole surface reduced to a level, and then consumed with fire. And the Bramins of Siam do not only hold that the world shall be destroyed by fire; but also that a new earth shall be made out of the cinders of the old.

Various are the sentiments of authors on the subject of the confagration: the cause whence it is to arise, and the effects it is to produce. Divines ordinarily account for it metaphorically; and will have it take its rise from a miracle, as a fire from heaven. Philosophers contend for its being produced from natural causes; and will have it effected according to the laws of mechanics. Some think an eruption of the central fire sufficient for the purpose; and add, that this may be occasioned several ways, viz. either by having its intention increased; which again, may be effected either by being driven into less space by the encroachments of the superficial cold, or by an increase of the inflammability of the fuel whereon it is fed; or by having the resistance of the imprisoning earth weakened; which may happen, either from the diminution of its matter, by the consumption of its central parts, or by weakening the cohesion of the constituent parts of the mafs by the excess of the defect of moisture. Others look for the cause of the confagration in the atmosphere; and suppose, that some of the meteors there engendered in unusual quantities, and exploded with unusual vehemence, from the concurrence of various circumstances, may effect it, without seeking any further. The astrologers account for it from a conjunction of all the planets in the sign Cancer; as the deluge, say they, was occasioned by their conjunction in Capricorn. Lastly, others have recourse to a still more effectual and flaming machine, and conclude the world is to undergo its confagration from the near approach of a comet in its return from the sun.

CONFLUENT, among physicians, &c. an appellation given to that kind of SMALL-POX wherein the pustules run into each other.

CONFLUENTES (anc. geog.), a place at the confluence of the Rhine and Meille, supposed to be one of the 50 forts erected by Drusus on the Rhine, in Gallia Belgica: Now Coblentz, a town of Trier. E. Long. 7. 15. Lat. 50. 30.

CONFORMATION, the particular consistence and texture of the parts of any body, and their disposition to compose a whole.

CONFORMATION, in medicine, that make and construction of the human body which is peculiar to every individual. Hence, a main conformation signifies some fault in the first rudiments; whereby a person comes into the world crooked, or with some of the vitreous cavities unduly framed or proportioned. Many are subject to incurable aithmas, from too small capacity of the thorax, and the like vitious conformations.

CONFORMITY, in the schools, is the congruency, or relation of agreement between one thing and another; as between the measure and the thing measured, the object and the understanding, the thing and the division thereof, &c.

CONFRONTATION, the act of bringing two persons in presence of each other, to discover the truth of some fact which they relate differently.

The word is chiefly used in criminal matters; where the witnesses are confronted with the accused, the accused with one another, or the witnesses with one another.

CONFUCIUS, a Chinese philosopher, who lived about 500 years before our Saviour's birth, in the kingdom of Lu, now called the province of Shantung. His wit and judgment got him a reputation from his very youth: and being a mandarin, and employed in the government of the kingdom of Lu, his profound knowledge of morals and politics made him be greatly admired. Notwithstanding his care, his prince's court was much disordered; and Confucius finding the king would not listen to his advice, quitted the court, and taught moral philosophy with such applause that he soon had above 3000 scholars, whereof '72 surpassed the rest in learning and virtue, for whom the Chinese have since a particular veneration. He divided his doctrine into four parts, and his scholars into four classes: the first order was of those who studied to acquire virtue; the 2d, those who learned the art of reasoning well; the 3d studied the government of the state and the duty of magistrates; the 4th were wholly taken up in noble discourses of all that concerned morals. In spite of all his pains to establish pure morality and religion, he was nevertheless the innocent cause of their corruption. It is said, that when
Confusion. he was complimented upon the excellency of his philosophy, he replied, that he felt greatly short of the perfect degree of virtue; but that in the west the most holy was to be found. This made a strong impression on the learned; and in the 66th year after Christ's birth, the emperor Mou-ti sent ambassadors toward the west to seek this holy man. They stopped at an island near the Red Sea, and found a famous idol named Fohi, representing a philosopher that lived 500 years before Confucius. They carried this idol back with them, with instructions concerning the worship rendered to it; and so introduced a superstition that abolished in several places the maxims of Confucius. His tomb is in the academy where he taught, near the town Xiu-fu, upon the banks of the river Xu. This philosopher has been in great veneration in China above 2000 years; and is still so esteemed, that each town has a palace consecrated to his memory. There was one of his descendants who was very considerable in the kingdom in 1646, whom Xanchi king of Tartary, who then conquered China, received with a great deal of honour. All those of his family are mandarins by birth; and have a privilege common with the princes of the blood, not to pay any posterity do not follow, &c.

In a physical sense, confusion is a sort of union or mixture by mere contiguity. Such is that between fluids of contrary nature, as oil and vinegar, &c.

Confusion, in a general sense, is opposed to order, in a perturbation whereof confusion consists; e. g. when things prior in nature do not precede, or posterior do not follow, &c.

In a logical sense, confusion is opposed to distinctness or perspicuity; and may happen either in words, as when misconstrued or misapplied; or in ideas, as when the idea of any thing presents something along with it, which does not properly belong to that thing. See Idea and Notion.

By *בְּרֵאשֵׁי* 12, Gen. xi. 1. and 8, which our translators render the whole earth, he understands every region and province. This confusion was occasioned, as it supposes, by a labial failure; so that the people could not articulate. Thus their speech was confounded, but not altered; for, as soon as they separated, they recovered their true tenor of pronunciation, and the language of the earth continued for some ages nearly the same. The interviews between the Hebrews and other nations, recorded in Scripture, were as constantly observed to remain stationary, or even to recede while the congealation went on. The principle on which the phenomenon depends is thus ascertained; but why this heat should be emitted, is a question which has not yet been thoroughly investigated. Some conjectures relative to this are indeed mentioned in the article Chemistry, when treating of elementary fire, though experiments are still to be wished for on the subject.

It is not known whether all kinds of fluids are naturally capable of congealation or not; though we are certain that there are very great differences among them in this respect. The most difficult of all those of which the congealation has been actually ascertained is quicksilver. This was long thought capable of refining any degree of cold whatever; and it is only within the last few years that its congealation by artificial means was ascertained to be possible, and still more lately that some climates were found to be so severe as to congeal this fluid by the cold of the atmosphere.

The congealation of quicksilver was first ascertained by Mr. Joseph Adam Braun, the professor of philosophy at Petersburg. He had been employed in making thermometrical experiments, not with a view to make the discovery he actually did, but to see how many degrees of cold he could produce. An excellent opportunity for this occurred on the 14th of December 1759, when the mercury stood at $-34$, which is now known to be only five or six degrees above its point of congealation. Mr. Braun having determined to avail himself of this great degree of natural cold, prepared a freezing mixture of aquafortis and pounded ice, by means of which his thermometer was reduced to $-60$. Part of the quicksilver had now really congealed; yet so far was Mr. Braun from entertaining any suspicion of the truth, that he had almost defulted from further attempts, being satisfied with having so far exceeded all the philosophers who went before him. Animated, however, by the hopes of producing a still greater degree of cold, he renewed the experiment; but having expended all his pounded ice, he was obliged to substitute snow in its place. With this fresh mixture the mercury funk to $-100$, $240$, and $325^\circ$. He then supposed that the thermometer was broken; but on taking it out to observe whether it was so or not, he found the quicksilver fixed, and continuing it for 12 minutes. On repeating the same experiment with another thermometer which had been graduated no lower than $-220$, all the mercury funk into the ball, and became solid as before, not beginning to recede till after a still longer interval of time. Hence the professor concluded that the quicksilver was really frozen, and prepared for making a decisive experiment. This was accomplished on the 25th of the same month, and the bulb of the thermometer broken as soon as the metal was congealed. The mercury was now converted into solid by the cold of the atmosphere.
ed into a solid and shining metallic mass, which extended under the strokes of a pestle, in hardcrust inferior to lead, and yielding a dull sound like that of metal. Professor AXMANN made similar experiments at the same time, employing both thermometers and tubes of a larger bore; in which last he remarked, that the quicksilver fell sensibly on being frozen, assuming a concave surface, and likewise that the congealed pieces sank in fluid mercury.

The fact being thus established, and fluidly no longer to be considered as an essential property of quicksilver, Mr Braun communicated an account of his experiments to the Peterburg Academy, on the 6th of September 1760; of which a large extract was inserted in the Philosophical Transactions, vol. iii. p. 156. Five years afterwards he published another treatise on the same subject, under the title of Supplements to his former dissertation. In thes he declared, that since his former publication, he had never suffered any winter to elapse without repeating the experiment of congealing quicksilver, and never failed of succefs when the natural cold was of a sufficient strength for the purpose. This degree of natural cold he supposed to be 

\[ \text{at } -10 \text{ of Fahrenheit, though some commen} 
\]

At the time of congelation might be perceived when the temperature of the air was as high as 

\[ +28^\circ \text{.} \]

The refults of all his experiments were, that with the abovementioned frigoric mixtures, and once with rectified spirits and snow, when the natural cold was at 

\[ -28^\circ, \]

he congealed the quicksilver, and discovered that it is a real metal which melts with a very small degree of heat. Not perceiving, however, the necessary conquence of its great contraction in freezing, he, in this work, as well as in the former, confounded its point of congelation with that of its greatest contraction in freezing, and thus marked the former a great deal too low; though the point of congelation was very uncertain according to him, various difficulties having occurred to his attempts of finding the greatest point of contraction while freezing.

The experiments of M. Braun were not repeated by any person till the year 1774, when Mr John Frederic Blumenbach, then a student of physic at Gottingen, performed them to more advantage than it appears M. Braun had ever done. He was encouraged to make the attempt by the excelente cold of the winter that year. Mr put (says he), at five in the evening of January 11th, three drachms of quicksilver into a small glass-glass, and covered it with a mixture of snow and Egyptia ammoniac. This mixture was put loose into the glass, so that the quicksilver lay perfectly free, being only covered with it as by pieces of ice: the whole, together with the glass, weighed somewhat above an ounce. It was hung out at a window in such a position as to expose it freely to the north-west; and two drachms more of sal-ammoniac mixed with the snow on which it floated. The snow and sal-ammoniac, in the open air soon froze into a mass like ice: no sensible change, however, appeared in the quicksilver that evening; but at one in the morning it was found frozen solid. It had divided into a large and four smaller pieces; one of the former was hemispherical, the other cylindrical, each seemingly rather above a drachm in weight: the four small bits might amount to half a scruple. They were all with their flat side frozen hard to the glass, and no where immediately touched by the mixture; their colour was a dull white with a bluish cast, like zinc, very different from the natural appearance of quicksilver.

Next morning about seven o'clock I found that the larger hemisphere began to melt, perhaps because it was more exposed to the air, and not so near as the others to the sal ammoniac mixture which lay beneath. In this state it resembled an amalgam, sinking to that side on which the glass was inclined; but without quitting the surface of the glasses, to which it was yet firmly congealed: the five other pieces had not yet undergone any alteration, but remained frozen hard. Toward eight o'clock the cylindrical piece began to soften in the same manner, and the other four soon followed. About eight they fell from the surface of the glasses, and divided into many fluid shining globules, which were soon lost in the interstices of the frozen mixture, and reunited in part at the bottom, being now exactly like common quicksilver. At the time this experiment was made, the thermometer stood at 

\[ -10^\circ \]

in the open air.

The circumstances attending this experiment are still unaccountable; for, in the first place, the natural cold was scarcely sufficient, along with that of the artificial mixture, which produces 32° more, to have congealed the quicksilver; which yet appears to have been very effectually done by the length of time it continued solid. 2. It is not easy to account for the length of time required for congealing the quicksilver in this experiment, since other frigoric mixtures begin to act almost immediately; and, 3. There was not at that even the appearance of action, which consists in a solution of the snow, and not in its freezing into wafes.

of Mr Blumenbach.
eight in the morning, made an experiment to try how low he could bring the thermometer by artificial cold, the temperature of the atmosphere being then \(+2^\circ\). He could not, however, bring it lower than \(-94^\circ\), at which point it froze immovably; and on breaking the thermometer, part of the quicksilver was found to have lost its fluidity, and was thickened to the consistence of an amalgam. It fell out of the tube in little bits, which bore to be flattened by pressure, without running into globules like the inner fluid part.

The experiment was repeated next day, when the thermometer stood at \(+8^\circ\), but the mercury could not then descend below \(-80^\circ\); and as the thermometer was not broken, it could not be known whether the mercury had congealed or not. All that could be inferred from the experiments therefore was, that the congealing point of mercury was not below \(-94^\circ\) of Fahrenheit's thermometer. The other who attempted the congelation of this fluid was the late Dr Anthony Fothergill; but it could not be determined whether he succeeded or not. An account of his experiment is inserted in the Philosophical Transactions, Vol. lxvi.

No other attempts were made to congeal quicksilver until the year 1781, when Mr Hutchins resumed the subject with great success, inasmuch that from his experiment the freezing point of mercury is now almost as well settled as that of water. Preceding philosophers, indeed, had not been altogether inattentive to this subject. Professor Braun himself had taken great pains to investigate it: but for want of paying the requisite attention to the difference between the contraction of the fluid mercury by cold and that of the congealing metal by freezing, he could determine nothing certain concerning it. Others declared it as their opinion, that nothing certain could be determined by merely freezing mercury in a thermometer filled with that fluid. Mr Cavendish and Dr Black first suggested the proper method of obviating the difficulties on this subject. Dr Black, in a letter to Mr Hutchins, dated October 5, 1779, gave the following directions for making the experiment with accuracy:

"Provide a few wide and short tubes of thin glass, sealed at one end and open at the other; the wideness of these tubes may be from half to three quarters of an inch, and the length of them about three inches. Put an inch or an inch and a half depth of mercury into one of these tubes, and plunging the bulb of the thermometer into the mercury, let the tube with the mercury and the thermometer in it into a freezing mixture, which should be made for this purpose in a common tumbler or water-glass: and, N. B. in making a freezing mixture with snow and spirit of nitre, the quantity of the acid should never be so great as to disolve the whole of the snow, but only enough to reduce it to the consistence of panada. When the mercury in the wide tube is thus set in the freezing mixture, it must be stirred gently and frequently with the bulb of the thermometer; and if the cold be sufficiently strong, it will congeal by becoming thick and brassy like an amalgam. As soon as this is observed, the thermometer should be examined without lifting it out of the congealing mercury; and I have no doubt that in every experiment thus made with the same mercury, the instrument will always point to the same degree, provided it has been made and graduated with accuracy."

The apparatus recommended by Mr Cavendish, and which Mr Hutchins made use of, consisted of a small mercurial thermometer, the bulb of which reached about 15 inches below the scale, and was inclosed in a glass cylinder swelled at the bottom into a ball, which when used was filled with quicksilver, so that the bulb of the thermometer was entirely covered with it. In this cylinder be immersed in a freezing mixture till great part of the quicksilver in it is frozen, it is evident that the degree shown at that time by the inclosed thermometer is the precise point at which mercury freezes; for as in this case the bulb of the thermometer must be surrounded for some time with quicksilver, part of which is actually frozen, it seems impossible that the thermometer should be sensibly above that point; and while any of the quicksilver in the cylinder remains fluid, it is impossible that it should sensibly below it. The diameter of the bulb of the thermometer was rather less than a quarter of an inch, that of the swelled part of the cylinder two-thirds, and it was easy to keep the thermometer constantly in the middle of the cylinder, the thickness of quicksilver being 1\(0\) in. and the glass could never be much less than the sixth part of an inch. The bulb of the thermometer was purposely made as small as it conveniently could, in order to leave a sufficient space between it and the cylinder, without making the swelled part larger than necessary, which would have caused more difficulty in freezing the mercury in it.

The first experiment with this apparatus was made on the 15th of December 1781; the thermometer had been filled with boiling water the evening before at \(-10^\circ\). A bottle of spirit of nitre was put on the house-top, in order to cool it to the same temperature. The thermometers made use of had been hung up in the open air for three weeks to compare their scales. On the morning of the experiment they were about \(23^\circ\) below 0. In making it, the thermometer of the apparatus was suspended in the bulb of the cylinder by means of some red worsted wound about the upper part of its stem, to a sufficient thickness to fill the upper part of its orifice; and a space of near half an inch was left empty between the quicksilver and worsted.

The apparatus was placed in the open air, on the top of the fort, with only a few deer skins sewed together for a shelter; the snow lay 18 inches deep on the works, and the apparatus was stuck into the snow in order to bring it the sooner to the temperature of the air. The instruments were afterwards placed in three fresh freezing mixtures, in hopes of being able by their means to produce a greater degree of cold, but without effect; nor was any greater cold produced by adding more spirit of nitre. The mercury, however, was very completely frozen, that in the thermometer defcinging to \(48^\circ\). On plunging the mercury into the freezing mixture, it is defceding in less than one minute to \(40^\circ\) below 0.

The second experiment was made the day following; and the same quantity of quicksilver employed that had been used in the former. As to the quantity of the freezing mixture, however, had been originally made, it was necessary to add more during the
the operation of congealation; by which means the
spirit of nitre, in pouring it upon the snow, sometimes
touched the bulb of the thermometer, and instantly
raised it much higher; nor did the mercury ever
descend below 206°, which was not half so far as it had
done the day before, though the temperature of the
atmosphere had been this day at — 4° before the
commencement of the operation. That in the appar­
atus, however sunk to — 95°. The apparatus was
taken out of the mixture for half a minute, in order
to examine whether the mercury was
congealed or not, and during that time it showed no sign of
liquefaction.

The third experiment was made the same day, and
with the freezing mixture used in the last. By it
the point of congealation was determined to be not be­
low 40°.

The fourth experiment was made January 7th
1782; and in it he observed, the thermometer in the
apparatus thermometer, after standing at 42 and 47°
for a considerable time fell to 77, not gradually, but
at once as a weight falls.

In the fifth experiment the weather was excelle­
tly severe, so that it ought to have frozen the metal in the
open air; but this did not then happen.

At the time of making the sixth experiment, the
quicksilver in the open air fell at 44 below 0°; and
Mr Hutchins resolved to make use of this opportunity
to observe how far it was possible to make it descend
by means of cold, observing the degrees at the same
time with a spirit thermometer made by Nairne and
Broun, with which he had been furnished by the
royal society in 1774. In this, however, he did not
succeed; for the mercury never fell below 45°, nor
the thermometer 48°. It fell at 57°; at the begin­
ing of the experiment. The reason of this was sup­
posed to be, that the atmosphere was too cold for
making this kind of experiments, by reason of its
freezing the thread of quicksilver in the stem of the
thermometer, so that it became incapable of contrac­
tion along with that in the bulb. In other experiments,
though the metal in the bulb became solid, yet
that in the stem always remained fluid; and solid
was enabled to contract a great degree by the diminu­
tion of bulk in the solid mercury. That this was real­ly the case, appeared from the quicksilver falling at
once from — 85 to — 34°, when the cold of the freez­
ing mixture diminished, and the temperature of the air
becoming about the same time somewhat milder, nel­
ed the congealed part in the stem, which thus had li­berty to descend to that point.

In this experiment, also, the mixtures were made in
double quantity to those of the former: these being
only in common tumblers, but the mixtures for this
experiment in pint basins. It was observed that they
liquefied faster than in other experiments. He had
usually made them of the confidence of paper; but
though he added snow at different times, it had very
little effect in augmenting the cold, but rather de­
creased it. The congealed pieces of metal fell to the
bottom as might naturally have been expected from
its great contraction in becoming solid.

From this experiment Mr Hutchins concluded, that
the nearer the temperature of the atmosphere ap­
proached to the congealing point of mercury (so that
a great degree of cold might be communicated to the
bulb of a thermometer, and yet the quicksilver in the
tube remain fluid), he might make the experiment of
aftertaining the greatest contraction of mercury to
more advantage. With this view, he made another ex­
periment, when the temperature of some of his ther­
mometers stood as low as — 37°; and after an hour's
attendance he perceived the mercury had fallen to
— 36°; but the thermometer unluckily was broken,
and its bulb thrown away with the mixture. Professors
for Braun had likewise observed, that his thermometers
were always broken when the mercury descended be­
low 60°.

The eighth experiment was made with a view to
try whether quicksilver would congeal when in con­
tact with the freezing mixture. For this purpose, he
did not use the apparatus provided for other experi­
m ents, but filled a gallipot made of flint stone (as be­
ing thinner than the common foundation) containing
about an ounce, half full of quicksilver, into which he
inserted a mercurial thermometer, employing another
as an index. Thus he hoped to determine exactly
when the quicksilver was congealed, as he had free
access to it at all times, which was not the case when
it was inclosed in the cylindrical glass, the worsted
wound round the tube of the thermometer to exclude
the air being equally effectual in excluding any in­
strument from being introduced to touch the quick­
silver. He then made a kind of skewer, with a flat
blunt point, of dried cedar wood, on account of its
lightness, which he found would remain in the gelat­
inous freezing mixture at any depth he chose; but,
when inserted into the quicksilver, the great difference
between the specific gravity of it and that ponderous
fluid, made it always rebound upward; and by the
degree of resistance, he could always know whether
it proceeded from fluid or solid metal. At this time,
however, the experiment did not succeed; but, at
another trial, having employed about 17 of a pound
of metal, and let it remain a considerable time immersed
in the same mixture which had just been sup­posed to
fail, he found that part of it was congealed; and,
on pouring off the fluid part, no less than two-thirds
remained fixed at the bottom.

The last experiment which has been published con­
cerning the congealation of quicksilver by means of dirt's ex­
snow is that of Mr Cavendish, and of which he gives
an account in the Phil. Trans. Vol. lxxiii. p. 325. Here,
speaking of the cold of freezing mixtures, he says, "There is the utmost reason to think that Mr
Hutchins would have obtained a greater degree of cold
by using a weaker nitrous acid than he did. I found Heatfome­
(fays he) by adding snow gradually to some of this times pre­
acid, that the addition of a small quantity produced
heat instead of cold; and it was not until so much was
added as to increase the heat from 28 to 51°, that
the spirit of nitre at the addition of more snow began to produce cold; the nitre.
quantity of snow required for this purpose being pret­
ically exactly one quarter of the weight of the spirit of
nitre, and the heat of the snow, and air of the room,
as well as of the acid, being 28°. The reason of this
is, that a great deal of heat is produced by mixing wa­
per with spirit of nitre; and the stronger the spirit is,
the greater is the heat produced. Now it appears
from this experiment, that before the acid was di­
uted,
The experiment made by Mr Walker, in which he congealed quicksilver by means of spirit of nitre and Glueber's salt, without any snow, concludes the history of the artificial congelation of mercury. See the article Con. I. It now remains that we try something of the congelation of it by the natural cold of the atmosphere.

Dr. Halley, from whose paper in the Philosophical Transactions, vol. lxxiii. this account is taken, observes, that it was not till near the year 1730 that thermometers were made with any degree of accuracy; and in four or five years after this, the first observations were made which prove the freezing of quicksilver. On the accession of the Empress Anne Ivanoua, to the throne of Russia, three professors of the Imperial academy were chosen to explore and describe the different parts of her Asiatic dominions, and to inquire into the communication between Asia and America. These were Dr John George Gmelin, in the department of natural history and chemistry; M. Gerard Frederic Muller, as general historiographer; and M. Louis de l'Isle de la Croyere, for the department of astronomy; draughtsmen and other proper assistants being appointed to attend them. They departed from Peterburgh in 1733; and such as survived did not return till ten years after. The thermometrical observations were communicated by Professor Gmelin, who first published them in his Flora Siberica, and afterwards more fully in the Journal of his Travels. An abstract of them was likewise inferred in the Peterburgh Commentaries for the years 1756 and 1765, taken, after the professor's death, from his original dispatches in possession of the imperial academy.

In the winter of 1734 and 1735, Mr Gmelin being at Yenoeisja in 58° N. Lat., and 92° E. Long. from Greenwich, first observed such a defect of the mercury, as we know must have been attended with congelation. "Here (says he) we first experienced the truth of what various travellers have related respecting the extreme cold of Siberia; for, about the middle of December, such severe weather fell in, as we were sure had never been known in our time at Peterburgh. The air seemed as if it were frozen, with the appearance of a fog, which did not suffer the smoke to ascend as it usually did from the chimneys. Birds fell down out of the air as dead; and froze immediately, unless they were brought into a warm room. Whenever the door was opened, a frost instantly formed round it. During the day, short as it was, parhelia and haloes round the sun were frequently seen; and in the night mock moons, and haloes about the moon. Finally, our thermometer, not subject to the same deception as the fencos, left us no doubt of the excessive cold; for the quicksilver in it was reduced, on the 5th of January O. S. to —120° of Fahrenheit's scale, lower than it had ever hitherto been observed in nature."

The next instance of congelation happened at Yakutsk, in N. Lat. 62. and E. Long. 150. The weather here was unusually mild for the climate, yet the

(a) This was a small mercurial thermometer, made by Nairne and Blount, on an ivory scale, divided at every five degrees, and reaching from 215° above to 250° below the cypher.

(b) This is to be understood of a spirit thermometer, whose —29° = 40° of Fahrenheit's mercurial.
thermometer fell to \(-73^\circ\); and one person informed the professor by a note, that the mercury in his barometer was frozen. He hastened immediately to his house to behold such a surprising phenomenon; but though he was witness to the fact, the prejudice entertained against the possibility of the congelation, would not allow him to believe it. “Not feeling, (says he), by the way, the same effects of cold as I had experienced at other times in less distances, I began, before my arrival, to entertain suspicions about the congelation of his quicksilver. In fact, I saw that it did not continue in one column, but was divided in different places as into little cylinders, which appeared frozen; and, in some of these divisions between the quicksilver, I perceived like the appearance of frozen moisture. It immediately occurred to me, that the mercury might have been cleaned with vinegar and salt, and not sufficiently dried. The person acknowledged it had been purified in that manner. The same quicksilver, taken out of the barometer, and well dried, would not freeze again, though exposed to a much greater degree of cold, as shown by the thermometer.

Another set of observations, in the course of which the mercury frequently congealed, were made by Professor Gmelin at Kirsear fort, in 57° N. Lat. 108° E. Long. His thermometer, at different times, standing at \(-108^\circ\), \(-86^\circ\), \(-100^\circ\), \(-115^\circ\), and many other intermediate degrees. This happened in the winter of 1777 and 1778. On the 27th of November, after the thermometer had been standing for two days at \(-46^\circ\), he found it sunk to 108°. Suspecting some mistake, after he had noted down the observation, he instantly ran back, and found it at 102°; but ascending with such rapidity, that in the space of half an hour it had risen to \(-15^\circ\). This phenomenon, which appeared so surprising, undoubtedly depended on the expansion of the mercury frozen in the bulb of the thermometer, and which now melting, forced upwards the small thread in the item.

A similar appearance was observed at the same fort a few days after, and on the 29th of December, O. S. he found the mercury, which had been standing at \(-40^\circ\) in the morning, sunk to \(-100^\circ\) at four in the afternoon. At this time, he says, he “saw some air in the thermometer separating the quicksilver for the space of about six degrees.” He had taken notice of a similar appearance the preceding evening, excepting that the air, as he supposed it to be, was not then collected into one place, but lay scattered in several.

These appearances undoubtedly proceeded from a congelation of the mercury, though the prejudice entertained against the possibility of this phenomenon would not allow the professor even to inquire into it at all. Several other observations were made; some of which were loft, and the rest contain no farther information.

The second instance where a natural congelation of mercury has certainly been observed, is recorded in the transactions of the Royal Academy of Sciences at Stockholm. The weather, in January 1760, was remarkably cold in Lapland; so that, on the 5th of that month, the thermometers fell to \(-76^\circ\), \(-125^\circ\), or lower; on the 24th and following days they fell to \(-58^\circ\), \(-79^\circ\), \(-92^\circ\), and below \(-23^\circ\) entirely into the ball. This was observed at Tornaa, Sombio, Jakasferf, and Ufiekki, four places in Lapland, situated between the 65th and 78th degrees of N. Lat. and the 21st and 28th of E. Long. The person who observed them was M. Andrew Hellant, who makes the following remarks, of themselves sufficient to show that the quicksilver was frozen. “During the cold weather at Sombio (says he), as it was clear sun-shine, though scarcely the whole body of the sun appeared above the low woods that covered our horizon, I took a thermometer which was hanging before in the shade, and exposed it to the rising sun about eleven in the forenoon, to see whether, when that luminary was low, it would have any effect upon the instrument. But to my great surprise, upon looking at it about noon, I found that the mercury had entirely suffused into the ball, though it was standing as high as \(61^\circ\) at 11 o’clock, and the scale reached down to \(238^\circ\) below c.” On bringing the instrument near a fire, it presently rose to its usual height; and the reason of its suffusion before was its being somewhat warmed by the rays of the sun; which, feeble as they were, had yet sufficient power to melt the small thread of congealed mercury in the item of the thermometer, and allow it to subside along with the rest. Mr Hellant, however, so little understood the reason of this phenomenon, that he frequently attempted to repeat it by bringing the thermometer near a fire, when the cold was only a few degrees below the freezing point of water, but could never succeed until it fell to \(-58^\circ\), or lower, that is, until the cold was sufficiently intense to congeal the metal. The only seeming difficulty in his whole account, is, that when the mercury had suffused entirely into the ball of the thermometer, a vacuum or empty spot appeared, which run round the cavity like an air bubble, on turning the instrument: but this proceeded from a partial liquefaction of the mercury, which must necessarily melt first on the outside, and thus exhibit the appearance just mentioned.

The most remarkable congelation of mercury, which Remark has ever yet been observed, was that related by Dr Peter Simon Pallas, who had been sent by the Empress of Russia, with some other gentlemen, to make a tour through Siberia. The cure one very cold evening, in the winter \(1772\), he found the mercury, kept in the instrument, so congealed, that it was apparent to the eye, that the quicksilver would not descend. The instrument being touched with the finger, the quicksilver rose; and it could plainly be seen that the solid columns stuck fast in the tube. “During the cold weather, as it hung in the open air, was warmed by being touched with the finger, the quicksilver rose; and it could plainly be seen, that the solid columns stuck and refirled a good while, and were at length pulled upward with a fort of violence. In the mean time,
time I placed upon the gallery, on the north side of my house, about a quarter of a pound of clean and dry quicksilver in an open bowl. Within an hour I found the edges and surface of the liquid silver still fluid, and in some minutes afterwards the whole was confused by the natural cold into a soft mass, very much like tin. While the inner part was still fluid, the frozen surface exhibited a great variety of branched wrinkles. But in general it remained pretty smooth in freezing, as did also a larger quantity which afterwards exposed to the cold.

The congealed mercury was more flexible than lead; but on being bent short, it was found more brittle than tin, and when hammered out thin, it seemed somewhat granulated. If the hammer had not been perfectly cooled, the quicksilver melted away under it in drops; and the same thing happened when the metal was touched with the finger, by which also the finger was immediately benumbed.

In our warm room it thawed on its surface gradually, by drops, like wax on the fire, and did not melt all at once. When the frozen mass was broken to pieces in the cold, the fragments adhered to each other and to the bowl on which they lay. Although the froth seemed to abate a little towards night, yet the congealed quicksilver remained unaltered, and the experiment with the thermometer could still be repeated.

On the 7th of December, I had an opportunity of making the same observations all day; but some hours after sunset, a northwest wind sprung up, which raised the thermometer to —46°, when the mass of quicksilver began to melt.

In the beginning of the year 1780, M. Von Elterlein, of Vytegra, a town of Russia, in Lat. 61°, E Long. 36°, froze quicksilver by natural cold, of which he gives the following account. "On the 4th of January 1780, the cold having encroached to —24° that evening at Vytegra, I exposed to the open air three ounces of very pure quicksilver in a china tea-cup, covered with paper, pierced full of holes. Next day, at eight in the morning, I found it solid, and looking like a piece of cast lead, with a considerable depression in the middle. On attempting to loosen it in the cup, my knife raised shavings from it as if it had been lead, which remained sticking up; and at length the metal separated from the bottom of the cup in one mass. I then took it in my hand to try if it would bend: it was still like glue, and broke into two pieces; but my fingers immediately lost all feeling, and could scarcely be relieved in an hour and a half by rubbing with snow. At eight o'clock a thermometer, made by Mr. Laxmam of the Academy, stood at —57°; by half an hour after nine it was risen to —40°; and then the two pieces of mercury which lay in the cup had lost so much of their hardness, that they could no longer be broken, or cut into shavings, but resembled a thick amalgam, which though it became fluid when pressed by the fingers, immediately afterwards refumed the consistence of paste.

With the thermometer at —39°, the quicksilver became fluid. The cold was never less on the 5th than —28°, and by nine in the evening it had increased again to —33°.

An instance of the natural congelation of quicksilver also occurred in Jemland, one of the provinces of Sweden, on the 1st of January 1782; and, lastly, on the 26th of the same month, Mr. Hutchins observed the same effect of the cold at Hudson's bay. "The subject of this curious phenomenon (says he), was quicksilver put into a common two-ounce vial, and corked. The vial was about a third part full, and had constantly been filling by the thermometer for a month past. At eight o'clock this morning I observed it was frozen rather more than a quarter of an inch thick round the sides and bottom of the vial, the middle part remaining fluid. As this was a certain method of finding the point of congelation, I introduced a mercury and a spirit thermometer into the fluid part, after breaking off the top of the vial, and they rose directly and became stationary; the former 40° or 40½°, the latter at 29½, both below the cypher. Having taken these out, I put in two others, G a mercurial one formerly described, and a spirit thermometer, the former of which became stationary at 40°, and the latter at 36°. I then decanted the fluid quicksilver, to examine the internal surface of the frozen metal, which proved very uneven, with many radii going across; some of which resembled pin-heads, Urgent business called me away an hour. On my return I found a small portion only had liquefied in my absence. I then broke the vial entirely, and the hammer repeatedly struck the quicksilver. It beat out flat, yielded a deadish sound, and became fluid in less than a minute afterwards.—It may be worth remarking, that the quicksilver in one of the thermometers, which had sunk to very near 500, and was then at 444, very readily run up and down the tube by elevating either end of the instrument."

These are all the well authenticated accounts of the congelation of mercury by the natural cold of the atmosphere. Some others have been published; but being either less important, or not so well authenticated, we forbear to mention them. A very considerable confirmation is obtained from the above history, of the theory of congelation delivered by Dr. Black, and which is fully explained under the article CHEMISTRY. Mr. Hutchins's experiments, and on congelation in general, Mr. Cavendish makes many valuable remarks; the substance of which is as follows.

"If a vessel of water, with a thermometer in it, be exposed to the cold, the thermometer will sink several degrees below the freezing point, especially if the water be covered up so as to be defended from the wind, and care taken not to agitate it; and then on dropping in a bit of ice, or on mere agitation, specula of ice shoot suddenly through the water, and the inclosed thermometer rises quickly to the freezing point, where it remains stationary." In a note he says, that though in conformity to the common opinion he has allowed that "mere agitation may set the water a freezing, yet some experiments lately made by Dr. Blagden seem to shew, that it has not much, if any, effect of that kind, otherwise than by bringing the water in contact with some substance colder than itself. Though in general also the ice shoots rapidly, and the inclosed thermometer rises very quick; yet he once observed it to rise very slowly, taking up not less than half a minute, before it ascended to the freezing point; but in this experiment the water was exposed not more than one or two degrees below freezing; and it should seem, that the more the water is cooled below the freezing point, the more rapidly the ice shoots and the enclosed thermometer rises."
Mr Cavendish then observes, "that from the foregoing experiments we learn that water is capable of being cooled considerably below the freezing point, without any congelation taking place; and that, as soon as by any means a small part of it is made to freeze, the ice spreads rapidly through the whole of the water. The cause of this rite of the thermometer is, that all, or almost all bodies, by changing from a fluid to a solid state, or from the state of an elastic to that of an unelastic fluid, generate heat; and that cold is produced by the contrary process. Thus all the circumstances of the phenomenon may be perfectly well explained: for, as soon as any part of the water freezes, heat will be generated thereby in consequence of the addition of the same quantity of water rather more than would be at a time when the cold of the mixture was only 2° below that point: so that it appears, that the contraction of quicksilver by freezing, must be at least equal to its expansion by 404 degrees of heat. (A) This however is not the whole contraction that it suffers; for it appears by an extract from a meteorological journal kept by Mr Hutchins at Albany fort, that his thermometer once sunk to 490° below zero; though it was known by a spirit thermometer, that the cold fearfully exceeded the point of freezing quicksilver. There are two experiments also of Professor Braun, in which the thermometer sunk to 545° and 550° below zero; though it was observed without the ball being cracked. It is not indeed known how cold his mixtures were; but from Mr Hutchins's experiments, there is great reason to think they could not be many degrees below 40°. If so, the contraction which quicksilver suffers in freezing, is not much less than its expansion by 500° or 510° of heat, that is, almost five times its whole bulk; and in all probability is never much more than that, though it is probable that this contraction is not always determinate: for a considerable variation may frequently be observed in the specific gravity of the same piece of metal cast different times over; and almost all cast metals become heavier by hammering. Mr Cavendish observed on cast iron the following variation. A piece of iron three times over, its density varied from the density of metals of different matters of metal of different times; and of metal of different metals of different melting metal of different metals of different times. It is not unusual that those metals, as well as water and quicksilver, may bear being cooled a little below the freezing or hardening point (for the hardening of melted metals, and freezing of water, seems exactly the same process), without beginning to lose their fluidity."

The experiments of Mr Hutchins prove, that quicksilver contracts or diminishes in bulk by freezing; and that the very low degrees to which the thermometers have been made to sink, is owing to this contraction; and not to the cold having been in any degree equal to that shown by the thermometer. In the fourth experiment, one of the thermometers sunk to 490°, though it appeared, by the spirit thermometers that the cold of the mixture was not more than five or six degrees below the point of freezing quicksilver. In the first experiment also, it sunk to 448°, but at a time when the cold of the mixture was only 2° below that point: so that it appears, that the contraction of quicksilver by freezing, must be at least equal to its expansion by 404 degrees of heat. (A) This however is not the whole contraction that it suffers; for it appears by an extract from a meteorological journal kept by Mr Hutchins at Albany fort, that his thermometer once sunk to 490° below zero; though it was known by a spirit thermometer, that the cold fearfully exceeded the point of freezing quicksilver. There are two experiments also of Professor Braun, in which the thermometer sunk to 545° and 550° below zero; though it was observed without the ball being cracked. It is not indeed known how cold his mixtures were; but from Mr Hutchins's experiments, there is great reason to think they could not be many degrees below 40°. If so, the contraction which quicksilver suffers in freezing, is not much less than its expansion by 500° or 510° of heat, that is, almost five times its whole bulk; and in all probability is never much more than that, though it is probable that this contraction is not always determinate: for a considerable variation may frequently be observed in the specific gravity of the same piece of metal cast different times over; and almost all cast metals become heavier by hammering. Mr Cavendish observed on cast iron the following variation. A piece of iron three times over, its density varied from the density of metals of different matters of metal of different times; and of metal of different metals of different melting metal of different metals of different times. It is not unusual that those metals, as well as water and quicksilver, may bear being cooled a little below the freezing or hardening point (for the hardening of melted metals, and freezing of water, seems exactly the same process), without beginning to lose their fluidity."

(A) "The numbers here given are those shown by the thermometer without any correction; but if a proper allowance is made for the error of that instrument, it will appear, that the true contraction was 2° less than here set down; and from the manner in which thermometers have been usually adjusted, it is likely that in the 5th experiment of Mr Hutchins, as well as in those of Professor Braun, the true contraction might equally fall short of that by observation."
Congelation. — sasser that to freeze, as is the case with solutions of common salt; so that if the cold of the materials before mixing is equal to this, no additional cold can be produced. If the cold of the materials is less, some increase of cold will be produced; but the total cold will be less than in the former case, since the additional cold cannot be generated without some of the fluid being dissolved, and thereby weakening the acid, and making it less able to dissolve more fluid; but yet the cold of the materials is, the greater will be the additional cold produced. This is conformable to Mr Hutchins’s experiments; for, in the fifth experiment, in which the cold of the materials was 40°, the additional cold produced was only 5°. In the first experiment, in which the cold of the materials was 23°, an addition of at least 190° of cold was obtained; and by mixing some of the same spirit of nitre with snow in this climate, when the heat of the materials was 19°, Mr Cavendish was able to sink the thermometer to —29°, so that an addition of 55 degrees of cold was produced.

It is remarkable, that in none of Mr Hutchins’s experiments the cold of the mixture was more than 6° of the spirit thermometer below the freezing point of quicksilver, which is so little, that it might incline one to think that the spirit of nitre used by him was weak. This, however, was not the case; as its specific gravity at 58° of heat was 1.4923. It was able to dissolve 1/1.42 its weight of marble, and contained very little mixture of the vitriolic or marine acid: as well as could be judged from an examination of it, it was as little phosphatized as acid of that strength usually is.

Acids, especially those of the mineral kind, powerfully refuse congelation. There is, however, a peculiarity with regard to that of vitriol. Mr Chaptal, a foreign chemist, observed that it congealed by the cold of the atmosphere, and the crystals began to melt only at 47° of his thermometer; which, if Reaumur’s, corresponds to about 47° of Fahrenheit. The crystals were anachronous from the melting acid, and they felt warmer than the neighbouring bodies: the form was that of a prism of six fides, flattened and terminated by a pyramid of six fides, but the pyramid appeared on one end only; on the other, the crystal was lost in the general mass. The pyramid resulted from an assemblage of six isosceles triangles: the oil when the crystal was melted was of a yellowish black; on redissolving it in a proper apparatus, no peculiar gas came over. M. Chaptal repeated his experiments with the highly concentrated acid, but found that it did not freeze; that the density of the acid which he thought froze most easily was to the oil, of the usual strength for sale, as from 63 and 65 to 66; and the necessary degree of cold about 19° of Fahrenheit. Oil of vitriol once melted will not crystallize again with the same degree of cold.

M. Moré, a considerable manufacturer of oil of vitriol at Hadmont near Vervier, in the duchy of Limbourg in Germany, attributes this congelation to the addition of nitrates of the air. The acid of vitriol is usually separated from sulphur by burning it in close vessels; and the air is supplied by adding to the sulphur a little nitre. He found, that by mixing the acid, capable of being congealed, with water, or employing it for other purposes, orange-coloured fumes, and the smell of the true nitrous acid, were very evident. When this gas was destroyed, no degree of cold would congeal the acid, whatever was its degree of concentration; and the congelation was generally observed immediately after the process by which the acid was obtained.

Mr Macquer relates, in the second edition of his Chemical Dictionary, article Vitriolic Acid, that the Duke d’Ayen had observed the congelation of concentrated vitriolic acid, which had been exposed to a cold expressed by 13 or 14 degrees below 0 on Reaumur’s thermometer; but that mixtures, consisting of one part of the abovementioned concentrated acid, with two or more parts of water, could not be frozen by the cold to which he exposed them, till he had diluted the acid so much that its density was to that of water as 1845 to 96; in which latter case of congelation it is probable that the water only was frozen, as the other in the dilution of the fall. Similar experiments were made by M. de Morveau, and with equal success. Having produced an intense cold by pouring spirit of niter on pounded ice, he congealed a part of some vitriolic acid which had been previously concentrated; but he observed, that though a very intense cold had been made use of to congeal the acid at first, it nevertheless remained congealed in much smaller degrees of cold, and that it thawed very slowly. This coincides with the observations of M. Chaptal; though the latter observes, that there is some difference between strong oil of vitriol lowered with water, and that produced of a given strength by rectification. The latter always has some colour; and it will not dissolve indigo in such a manner as to carry the colour into the fluid, though the stronger oil, diluted to the same degree, succeeds very well. Some observations were also made by Mr M’Nab at Hudson’s Bay, an account of which is given in the Phil. Trans. for 1786 by Mr Cavendish, at whose desire they had been made. From them it appears, that a vitriolic acid, whose specific gravity was to that of water as 1843 to 1000, froze when exposed to a cold of —15° of Fahrenheit’s scale; that another more dilute vitriolic acid, consisting of 626 parts of the former concentrated acid, and 374 parts of water, congealed in a temperature of —36°; and that, when further diluted, it was capable of sustaining a much greater degree of cold without freezing at all. In these experiments, as well as in those of Mr Moré, it appeared that the whole of the acid did not congeal, but that part of it retained its fluidity; and on examining the strength of that which remained fluid, Mr Cavendish found that there was very little difference between it and the other; whence he was led to suppose, that the reason of this congelation does not arise from any difference in strength, but on some less obvious quality, and such as constitutes the difference between common and icy oil of vitriol.

In all the experiments hitherto made, however, Mr Cavendish had found some uncertainty in determining the point of easiest freezing; neither could he determine whether the cold necessary for congelation does not increase without any limitation in proportion to the strength of the acid. A new set of experiments were...
were therefore made by Mr Kier to determine this point. He had observed, after a severe frost at the end of the year 1774 and beginning of 1775, that some vitriolic acid, contained in a corked phial, had congealed, while other bottles containing the same, some stronger and some weaker, retained their fluidity. As the congelation was naturally imputed to the extremity of the cold, he was afterwards surprised to find, when the fruit ceased, that the acid remained congelated for many days, when the temperature of the atmosphere was sometimes above 40° of Fahrenheit; and when the congealed acid was brought into a warm room on purpose to thaw it, a thermometer placed in contact with it during its thawing continued stationary at 40°. Hence he concluded, that the freezing and thawing point of this acid was nearly at 40°: and accordingly, on exposing the liquor which had been thawed to the air at the temperature of 30°, the congelation again took place in a few hours. From the circumstance of other parcels of the same acid, but of different strengths, remaining fluid, though they had been exposed to a much greater degree of cold, he was led to believe that there must be some certain strength at which the acid is more disposed to congeal than at any other. The specific gravity of the acid which had frozen was that of water nearly as 1800 to 1000, and that of the stronger acid which had not frozen was as 1846 to 1000, which is the common density of that usually sold in England; and there was not the least difference, excepting in point of strength, between the acid which had frozen and that which had not; Mr Kier having taken the acid some weeks before with his own hands from the bottle which contained the latter, and diluted it with water, till it became of the specific gravity of 1800.

To render the experiment complete, Mr Kier immersed several acids of different strengths in melting snow, instead of exposing them to the air; the temperature of which was variable, whereas that of melting snow was certain and invariable. Those which would not freeze in melting snow were afterwards immersed in a mixture of common salt, snow, and water; the temperature of which, though not so constant and determinate as that of melting snow, generally remained for several hours at 18°, and was sometimes several degrees lower. The intention of adding water to the snow and salt was to lessen the intensity of the cold of this mixture, and to render it more permanent than if the snow and salt alone were mixed. The acids which had frozen in melting snow were five in number; which being thawed and brought to the temperature of 60°, were found on examination to have the following specific gravities, viz. 1786, 1784, 1780, 1778, 1775. Those which had not congealed with the melting snow, but which did so with the mixture of snow, salt, and water, were found, when brought to the temperature of 60°, to be of the following specific gravities, viz. 1814, 1810, 1804, 1794, 1790, 1770, 1759, 1750. Those which remained, and would freeze neither in melting snow nor in the mixture of snow, salt, and water, were of the gravities 1846, 1829, 1815, 1745, 1720, 1700, 1610, 1551. From the first of these it appears, that the medium density of the acids which froze with the natural cold was 1780; and from the second, that at the densities of 1750 and 1770 the acid had been incapable of freezing with that degree of cold. Hence it follows, that 1780 is nearly the degree of strength of easiest freezing, and that an increase or diminution of that density equal to 1780 of the whole, renders the acid incapable of freezing with the cold of melting snow, though this cold is not congealing about the freezing point of the most congealable acid. From the second it appears, that by applying a more intense cold, viz. that produced by a mixture of snow, salt, and water, the limits of the densities of acids capable of congelation were extended to about 1780 above or below the point of easiest freezing; and there seems little reason to doubt, that, by greater augmentations of cold, these limits may be further extended; but in what ratio these augmentations and extensions proceed, cannot be determined without many observations made in different temperatures.

"But (says Mr Keir) though it is probable that the most concentrated acids may be frozen, provided the cold be sufficiently intense, yet there seems reason to believe, that some of the congelations which have been observed in highly concentrated acids, have been effected in consequence of the density of these acids being reduced nearly to the point of eaisest freezing by their having absorbed moisture from the air: for the Duke d'Ayen and M. de Morveau exposed their acids to the air in cups or open vessels; and the latter even acquaints us, that on examining the specific gravity of the acid which had frozen, he found it to that of water as 120 to 74; which density being less than that of eaisest freezing, proves that the acid he employed, and which he had previously concentrated, had been actually weakened during the experiment. I have several times exposed concentrated oil of vitriol in open vessels in frothy weather; and I have sometimes, but not always, observed a congelation to take place. Upon separating the congealed part, and on examining the specific gravity of the latter after it had thawed, I found that it had been reduced to the point of easiest freezing. When the congealed acid was kept longer exposed it gradually thawed, even when the cold of the air increased; the reason of which is not to be imputed to the heat produced by the moisture of the air mixing with the acid, but principally to the diminution below the point of easiest freezing, which was occasioned by the continued abstraction of moisture from the air, and which rendered the acid incapable of continuing frozen without a great increase of cold.

"It appears, then, that the concentration of M. de Morveau's acid, at the time of its congelation, from which circumstance Mr Cavenèth inures generally that the vitriolic acid freezes more easily as it is more dense, is not a true premise; and that therefore the inference, though justly deduced, is invalid. On the contrary, there seems every reason to believe, that as the density of the acids increases beyond the point of easiest freezing, the facility of the congelation diminishes; at least to as great density as we have ever been able to obtain the vitriolic acid; for it was possible to divide it entirely of water, it would probably assume a solid form in any temperature of the air.

"The
The crystallization of the vitriolic acid is more or less distinct, according to the slowness of the formation of the crystals and other favourable circumstances. Sometimes they are very large, distinctly shaped, and hard. Their shape is like those of the common mineral alkali and felenite spar, but with angles different in dimensions from either of these. They are solid, consisting of ten faces; of which the two largest are equal, parallel, and opposite to each other; and are oblique-angled parallelograms or rhomboids, whose angles are, as near as could be measured, of 103 and 75 degrees. Between these two rhomboidal faces are placed eight of the form of trapeziums; and thus each crystal may be supposed to be compounded of two equal and similar fractums of pyramids joined together by their rhomboidal bases. They always sunk in the fluid acid to the bottom of the vessel, which showed that their density was increased by congelation. It was attempted to determine their specific gravity by adding to this fluid some concentrated acid, which should make them float in the liquor; the examination of whose specific gravity should ascertain that of the floating crystals; but they were found to sink even in the most concentrated acid, and were consequently denser. Some of the soluble acid previously brought to the freezing temperature was then poured into a graduated narrow cylindrical glass, up to a certain mark, which indicated a space equal to that occupied by 200 grains of water. The glass was placed in a mixture of snow, salt, and water; and when the acid was frozen, a mark was made on the part of the glass to which it had sunk. Having thawed the acid and emptied the glass, it was filled with water to the mark to which it had sunk by freezing; and it was then found that 13 grains more of water were required to raise it to the mark expressing 200 grains; which shows, that the diminution of bulk sustained by the acid in freezing had been equal to $\frac{1}{13}$ of the whole. Computing from this datum, we should estimate the specific gravity of the congealed acid to have been 1924; but as it evidently contained a great number of bubbles, its real specific gravity must have been considerably greater than the above calculation, and cannot easily be determined on account of these bubbles. By way of comparison, Mr Keir observed the alteration of bulk which water contained in the same cylindrical vessel would suffer by freezing; and found that its expansion was equal to about 1/10th of its bulk. The water had been previously boiled, but nevertheless contained a great number of air bubbles; so that in this respect there is a considerable difference between the congealations of water and the vitriolic acid; though perhaps it may arise principally from the bubbles of effusive fluid being in greater proportion in the one than the other.

"Greater cold is produced by mixing snow or pounded ice with the congealed than with the fluid vitriolic acid, though the quantity is not yet determined. The greatest cold produced by Mr McNab at Hadson's Bay, was effected by mixing snow with a vitriolic acid which had been previously congealed; and to this circumstance Mr Cavendish imputes the intensity of the cold, as the liquefaction both of the acid and the snow had concurred in producing the same effect; while in mixing fluid acids with snow, the thawing of the snow is probably the only productive cause.

"To compare the times requisite for the liquefaction of ice and of congealed oil of vitriol, two equal and similar glasses were filled, one with the congealable vitriolic acid, the other with water; and after having immersed them in a freezing mixture till both were congealed and reduced to the temperature of $3^o$, the glasses were withdrawn, wiped dry, and placed in a room where the thermometer stood at $62^o$. The ice thawed in 40 minutes, and the acid in 9 1/2 at the end of which time the thermometer, which floated near the glasses, had risen to $62^o$. Hence it appears that the congealed acid requires more than twice the time for its liquefaction that ice does, though it cannot thence be fairly inferred, that the cold generated by the liquefaction of the ice and of congealed acid are in the above proportions of the times, from the following considerations, viz. that, during the liquefaction of the ice, its temperature remains stationary at $32^o$, and during the liquefaction of the acid, its temperature remains about $44^o$ or $45^o$. It appears, that the ice being considerably colder than the acid, will take the heat from the contiguous air much faster. By this experiment, however, we know that a considerable quantity of cold is generated by the liquefaction of the acid; and hence it appears probable, that in producing cold artificially, by mixing snow with acids in very cold temperatures, it would probably be useful to employ a vitriolic acid of the proper density for congelation, and to freeze it previously to its mixture with snow. It must not, however, be imagined, that the cold generated by the mixture of these two frozen substances is nearly equal to the sum of the colds generated by the separate liquefactions of the congealed acid and ice, when singly exposed to a thawing temperature; for the mixture resulting from the liquefaction, congealing of the vitriolic acid and the water of the snow, appears from the generation of heat which occurs from the mixture of these ingredients in a fluid state, to be subject to different laws than those which rule either of the ingredients separately.

"The vitriolic acid, like water and other fluids, is capable of retaining its fluidity when cooled considerably below its freezing point. A phial containing some congealable vitriolic acid being placed in a mixture of salt, snow, and water, a thermometer was soon afterwards immersed in it while the acid was yet fluid, on which it quickly sunk from 50 to 200. On moving the thermometer in the fluid, to make it acquire the exact temperature, the mercury was observed suddenly to rise; and on looking at the acid, numberless small crystals were observed floating in it, which had been suddenly formed. The degree to which the mercury then rose was $46^o$; and at another time, while the acid was freezing, it stood at $45^o$.
however, to be observed, that this degree is inferred from the temperature indicated by the thermometers immered in the freezing and thawing acids; but the congelation of the fluid acid could never be accomplished without exposing it to a greater degree of cold, either by exposing it to the air in frosty weather or to the cold of melting snow. 4. Like water, this acid possesses the property of retaining its fluidity when cooled several degrees below the freezing point; and of rising suddenly to it when its congelation is promoted by agitation, or by contact even with a warmer thermometer. 5. That, like water and other congealable fluids, the vitriolic acid generates cold by its liquefaction, and heat during its congelation, though the quantity of this heat and cold remains to be determined by future experiments. 6. That the acid, by congelation, when the circumstances for distinct crystallization are favourable, assumes a regular crystalline form, a considerable solidity and hardness, and a density much greater than that possessed in its fluid state.

Besides this species of congelation, the vitriolic acid is subject to another, probably the same described by Bafli Valentine and some of the older chemists. This is effected in the ordinary temperature of the air, even in summer; and, according to Mr Keir, is peculiar to that species of oil of vitriol which is distilled from green vitriol, and which is possessed of a smoking quality in a high degree; "for not only the authors (says Mr Keir), by whom this congelation has been observed, have given this description of the acid employed, but also the late experiments of Mr Dollfus, seem to show that this smoking quality is essential to the phenomenon: for neither the acid obtained from vitriol, when deprived by rectification of its smoking quality, nor the English oil of vitriol, which is known to be obtained by burning sulphur, and which does not smoke, were found by his trials to be susceptible of this species of congelation. It may, however, be worth the attention of those chemists who have an opportunity of seeing this "oil of vitriol," as it is called, to observe more accurately than has yet been done, the freezing temperature and the density of this congealable acid; and to examine whether the density of this smoking acid also is connected with the glacial property. It seems also farther deserving of investigation, whether there be not some analogy between the congelation of the smoking oil of vitriol and the very curious crystallization which Dr Priestley observed in a concentrated vitriolic acid saturated with nitrous acid vapours; and whether this smoking quality does not proceed from some marine or other volatile acid, which may be contained in the natural vitriol whence the vitriolic acid is distilled."  

Mr Keir also observes, that M. Cornoyer has effected the crystallization of vitriolic acid, by distilling it with nitrous acid and charcoal; and we can add from our own experience, that a crystallization instantly takes place on allowing the fumes of the nitrous and vitriolic acids to mix together; and this, whether the former be procured from natural vitriol or sulphur, and whether it be in a phlogificated state or not, concentration in both acids is the only requisite.

CONGER, in zoology. See MURRANA.  
CONGERIES, a Latin word, sometimes used in our language for a collection or heap of several particles or bodies united into one mass or aggregate.

CONGESTION, in medicine, a mass or collection of humours, crowded together and hardened in any part of the body, and there forming a preternatural tumor.

Congestion is effected by little and little; in which it differs from defluxion, which is more sudden.  
CONGRIUM, CONGIARY, among medalists, a gift or donation represented on a medal. The word comes from the Latin congius; because the first presents made to the people of Rome consisted in wine and oil, which were measured out to them in congiis. The congeries was properly a present made by the emperors to the people of Rome. Those made to the soldiers were not called congeries but donations. The legend on medals representing congeries is, Congarium or Liberalitas. Tiberius gave a congeries of three hundred pieces of money to each citizen: Calligula twice gave three hundred fessaries a head: Nero, whole congeries are the first that we find represented on medals, made four hundred.

CONGIUS, a liquid measure of the ancient Romans, containing the eighth part of the amphora, or the fourth of the urna, or six sextarii. The congius in English measure contains 2,070,676 solid inches; that is, four pints, 4,494 solid inches. 

CONGLOBATE GLAND. See Anatomy.  
CONGLOMERATE. See Geology.  
CONGLOMERATE FLOWERS, are those growing on a branching foot-stalk, to which they are irregularly but closely connected. This mode of inflorescence, as Linnaeus terms it, is opposed to that in which the flowers are irregularly and loosely supported on their foot-stalks, hence termed a disjunct pande
tus. The term is exemplified in several of the grapples, particularly in some species of the *poa, fescue graps, and a
gro
ty.

CONGLOMUTATION, the gluing or fastening any two bodies together by the intromission of a third, whose parts are unctuous and tenacious, in the nature of glue. See GLUE.  

CONGO, a kingdom of Africa, bounded on the north by the river Zair, or Zarah, which divides it from Loanga; on the south by the river Danda, which separates it from Angola; on the east by the kingdoms of Fungono and Metamba, and the burnt mountains of the sun, those of chrysfal or salt-petre and silver, or (according to Anthony Cavazzi, a late traveler into those parts) by the mountains of Bomanza, Hertza, and the great mountain of Chidaria or Aquilonda; and on the west by that part of the Atlantic ocean called the Ethiopic sea, or the sea of Congo. According to these limits, Congo Proper extends about three degrees from north to south; lying between 6° and 9° S. Lat.; but widens in its breadth inland, by the course of the river Zair, which runs winding above two degrees more to the north. Its length from east to west is very uncertain, as no observations have been taken of the exact situation of those mountains which bound it.

The history of this kingdom affords but few interesting particulars. Before its discovery by the Portuguese, the history is altogether uncertain and fabulous, as the inhabitants were totally unacquainted with letters

---

* Phil. Trans. vol. lxvii. p. 467.
letters and learning. So little were they acquainted with chronology, that it is said they did not even distinguish between day and night; much less could they compute their time by moons or years; and therefore could remember past transactions only by saying they happened in such a King's reign.

The country was discovered by the Portuguese in 1484. The discoverer was named Diego Cam, an expert and bold seaman. He was very well received by the natives, and sent some of his men with presents to the king; but they being detained by unexpected accidents beyond the promised time of their return, Cam was obliged to sail away without them, and took with him four young Congolese, as hostages for the safety of his countrymen. These he taught the Portuguese language, in which they made such progress that king John was highly pleased, and sent them back next year to Congo with rich presents; charging them to exhort their monarch, in his name, to become a convert to the Christian religion, and to permit it to be propagated through his dominions. A firm alliance was concluded between the two monarchs, which continues to this day, though not without some interruptions, to which the Portuguese themselves have given occasion more than the natives.

Any particular account we have of this kingdom, rests almost entirely on the credit of Anthony Cavazzi, the traveller above-mentioned. He was a capuchin-friar, a native of the duchy of Modena, and was sent missionary into those parts de propaganda fide, in the year 1654, and arrived at Congo the same year. During his stay there, his zeal to make converts made him travel through all these different kingdoms; and the credit he gained, as well as the great employments he was intrusted with, gave him an opportunity of informing himself of every thing relating to them with great exactness. The extent and situation, however, he could not possibly ascertain, for want of instruments, nor hath this defect been since supplied. According to him, the dominions of Congo extended a great deal further eastward and southward before the introduction of Christianity than afterwards; a great number of the states that were under the Congolese monarchs, either as subjects, or tributary, having withdrawn their allegiance out of dislike to them on that account. Not content with oppressing the officers and troops that came annually to raise the tribute imposed by the king, they made frequent and powerful incursions into his dominions, that they obliged him to draw his forces nearer the centre of Congo to prevent an invasion; by which means the kingdom, from an extent of 600 leagues, was reduced to less than one half.

Cavazzi's account of Congo.

Congo Proper being situated within the torrid zone, is liable to excessive heats: as it lies on the southern side of the equinoctial, the seasons are of course opposite to ours. They reckon only two principal seasons, the summer and winter; the former begins in October, and continues till February or March; during which time the sun's rays dart with such force, that the atmosphere appears to an European to be in a flame. The excessive heat, however, is mitigated by the equal length of the days and nights, as well as by the winds, breezes, rains, and showers. The climate takes up the other part of the year; and is said by the natives to be proportionally cold, though to an European it would appear hot. These two seasons they divide into six letter ones, viz. Masfanza, Nafiri, Econdi, Quibibio, and Quibangala.

Masfanza begins with the month of October, which is the beginning of their spring. The rains begin to fall at that time, and continue during the next two, and sometimes three, months. When they do so, the low lands are commonly overflowed by the extraordinary floods, and all their corn carried off. A deficiency of this kind is sometimes followed by a famine; for the lazy inhabitants take no care to lay up any provisions, although such misfortunes happen very frequently. This first season they reckon commences at the time the plants begin to spring.

The second season, Nafiri, begins about the end of January, when the produce of their lands has arrived at its full height, and wants but a few days of being ripened for harvest. This first crop is no sooner gathered in, than they sow their fields afresh, their land commonly yielding them two harvests.

The third and fourth seasons, called Econdi and Quibangala, are frequently blended together towards the middle of March, when the more gentle rains begin to fall, and continue till the month of May. These two seasons are distinguished by the greater or lesser quantity of rain that falls during that interval. During the rest of the time, the air is either very clear, hot, and dry; or the clouds being overcharged with electric matter, burst out into the most terrible thunders and lightnings, without yielding the least drop of rain, though they seem loaded with it.

The two last, viz. the Quibibio and Quibangala, make up their short winter, which consists not in frost or snow, but in dry, blasting winds, which stir the earth of all its verdure, till the next Masfanza begins to restore them to their former bloom.

They now divide their year into twelve lunar months, and begin it in September. They have also weeks consisting of four days only, the last of which is their Sabbath; and on it they religiously abstain from every kind of work. This practice, the compilers of the Universal History conjecture to have arisen from the extreme laziness for which this people, and indeed all the African nations, are so remarkable. To doleut.

Natives ex- ceptively indolent.

This shameful indolence also is to be ascribed the little produce they reap from their lands, while the Portuguese settled among them, who are at more pains in the cultivation of theirs, enjoy all manner of plenty. The natives, however, had rather run the risk of the most terrible famines, than be at the tenth part of the labour they see the Portuguese take. They seem to think it below them to use any other exercises than those of dancing, leaping, hunting, shooting, &c.; the rest of their time they spend in smoking, and downright idleness, committing the laborious part of their household affairs to their slaves, or, in want of them, to their wives. Nothing is more common than to see these poor creatures toiling in the fields and woods, with a child tied to their backs, and fainting under their excessive labour and heavy burdens, or (which is still worse) hunger and thirst. What is yet more surprizing is, that though they have plenty of domestic animals which they might easily make use of for cultivating their grounds, and for other labori-
Trees, useful both useful and to the people. They cultivate also a variety of the pea and bean kind: but what they chiefly live upon, as most suitable to their lazy disposition, is a kind of nut, like our filberts, which fall to the ground themselves, and are to be found everywhere; every nut that falls to the ground produces a new shrub next year. They have scarcely any fruit-trees but what have been brought thither by the Portuguese. They have various sorts of palm-trees, useful both by their fruit, leaves, and their juice, which is easily converted into wine: also by affording a kind of oil, with which they dress their victuals, though the Europeans use it only to burn in their lamps. They have also a vast number of plants and shrubs, which it would be impossible to describe or enumerate. Wheat is the only tree, or defending one's self by fire-arms or other weapons. In such emergencies, the natives have a much better chance than the Europeans; the former being able to climb trees with surprising swiftness; while the latter must be assisted with rope-ladders, which they commonly cause their blacks to carry about with them, and to go up and fasten to one of the branches.

Vegetables produced in Congo.

The ground produces variety of grain, but no corn or rice except what is cultivated by the Portuguese. Their maize, or Indian wheat, grows very strong, and is well laden. This, being well ground, they make into bread, or boil with water into a kind of porridge. Of this they have four kinds; one of which resembling what we call French wheat, is produced in plenty, and makes some amends for the want of industry in the people. They cultivate also a variety of the pease and bean kind: but what they chiefly live upon, as most suitable to their lazy disposition, is a kind of nut, like our filberts, which fall to the ground themselves, and are to be found everywhere; every nut that falls to the ground produces a new shrub next year. They have scarcely any fruit-trees but what have been brought thither by the Portuguese. They have various sorts of palm-trees, useful both by their fruit, leaves, and their juice, which is easily converted into wine: also by affording a kind of oil, with which they dress their victuals, though the Europeans use it only to burn in their lamps. They have also a vast number of plants and shrubs, which it would be impossible to describe or enumerate. Wheat is the only
downy, and their fibre, which is strong, is used in their African settlements, it might perhaps have been attended with the fame success.

In the low lands the grass grows so high, rank, and thick, that it becomes one of the most dangerous receptacles for wild beasts, serpents, and other venemous insects: on this account travelling is exceedingly hazardous, as they have few beaten roads in the whole country, and travellers are obliged to march over it through vast plains, in continual danger of being devoured or flung to death; to say nothing of the manifold dangers produced by the unwholesome dews with which the grass is covered during some part of the day. The only method of guarding against all these evils effectually, is by setting fire to the grass in the hot weather, when it is quite parched by the heat of the sun: but even this cannot be done without the greatest danger; because both the wild beasts and venomous reptiles, being rooted out of their places of retirement, will fly furiously at those who happen to be in the way. In this case there is no possibility of escaping, but by climbing up the highest trees, or defending one's self by fire-arms or other weapons. In such emergencies, the natives have a much better chance than the Europeans; the former being able to climb trees with surprising swiftness; while the latter must be assisted with rope-ladders, which they commonly cause their blacks to carry about with them, and to go up and fasten to one of the branches.

The flowers are here exceedingly beautiful and numerous. Almost every field and grove yields a much richer prospect than the European gardens can boast of, notwithstanding the pains bestowed on their cultivation. The flowers are remarkable, not only for the prodigious variety of their colours, but the vast quantity of heads which grow upon one stalk. In the day-time, indeed, they seem to have lost their natural fragrance; but being in some measure exalted by the heat of the sun: but this is amply compensated after its setting, and more especially a little before its rising, when their sweetnees is again condensed, and revived by the coldnefs and dews of the night, after which they exhale various refreshing fragrants in a much higher degree than ours. The lilies, which there grow naturally in the fields, valleys, and woods, except those of our gardens, not only in their extreme white­ness, but much more in a delightful fragrance, without offending the head, as the European lilies do by their faffle sweetnees. The tulips which there grow wild, though generally called Perfian, have something so surpassingly charming in the variety and combination of their colours, that they dazzle the eyes of an intense beholder; neither do their flowers grow singly as with us, but ten or twelve upon one stalk; and with this double advantage, that they diffuse a very reviving and agreeable sweetnees, and continue much longer in their full bloom. Of the same nature are the tuberoses, hyacinths, and other native flowers; which spring up in vast groups of 100 and 200 from one root, though somewhat smaller than ours; some of them finely variegated, and all of them yielding an agreeable sweetnees. The rotes, jellamines, and other exotics brought thither from Europe or America, come up like wildflowers in the perfection; but require a constant supply of water, and diligent attendance, to prevent them from degenerating. The American jellamine, in particular, instead of single flowers, will grow up by dozens in a bunch: some of them of an exquisite white, and others of the colour of the most vivid fire.

A vast variety, of animals of different kinds are found in the kingdom of Congo; the chief of which is the elephant. This creature is mostly found in the province of Bamba, which abounds with woods, pasture, and plenty of water; the elephants delighting much to bathe themselves during the heat of the day. They commonly go in troops of an hundred or more; and some of them are of such a monstrous size, that we are told the print of their hoof hath measured four, nay, seven, spans in diameter. From the hair of their tails, and that of some other animals, the natives, especially the women, weave themselves collars, bracelets, girdles, &c. with variety of devices and figures, which denote their quality; and are in such esteem, that the hair of two elephants tails is sufficient to buy a slave. The reason of this is, that the natives have not the art of taming them, but are obliged to send some of their bravest and stoutest men to hunt them in the woods; which is not done without great labour and danger, they being here exceedingly fierce. The most common way of hunting them
CONGO. [323] CONG.

them is by digging deep holes in the ground, the top of which they cover with branches and leaves, as is practised in most parts of Asia.

Lions, leopards, tigers, wolves, and other beasts of prey, abound here in great plenty, and do much damage. Here are also a vast variety of monkeys of all sizes and shapes. The zebra, well known for its extreme beauty and prettiness, is also met with in this country. They have also a variety of buffaloes and wild oxen; but the dantes seems to be an animal peculiar to this kingdom. It is shaped and coloured much like an ox, though not so large. Its skin is commonly bought by the Portuguese, and sent into Germany to be tanned and made into targets, which are then called dantes. The natives make use of their raw hide dried to make their shields; which are so tough that no arrow or dart can pierce them; and they are also large enough to cover the whole body. The creature is very swift; and when wounded, will follow the scent or fange of the gu-powder with such fury, that the hunter is obliged to climb up a tree with all possible speed; and this retreat he always takes care to secure before he ventures to fire. The wounded beast finding its enemy out of its reach, stays for him at the foot of the tree, and will not stir from it; of which the hunter taking the advantage, dispatches it with repeated shots. The forests of Congo also swarm with wild dogs, who, like the wolves, prey upon the tame cattle, and are so fierce that they will attack armed men. Their teeth are exceeding keen and sharp; they never bark, but make a dreadful howling when famished or in pursuit of their prey.

This country also abounds with all the different kinds of birds that are to be found in other warm climates. One fort, which they call birds of music, is greatly esteemed, infomuch that persons of the highest rank have from time immemorial taken the greatest delight in keeping them in cages and aviaries for the sake of their surprising melody. On the other hand, as the Congolese are superstitious to the last degree, there are several kinds of birds which they look upon as ominous, and are so terrified at the sight or hearing of them, that if they were going to enter upon ever so momentous an expedition, if they were met in council, or going to engage an enemy with ever so great an advantage, the sight or cry of such birds would throw them into a general panic, and disperse them in the utmost haste and confusion. The most dreadful of the ominous kind are the crows, ravens, bats, and owls. The great owl is the most terrible of all, and to him they give the name of kariem penna, by which words they likewise denote the devil.

Fish of different kinds abound on the coasts of Congo in great numbers; but the inland parts are infested with such numbers of serpents, scorpions, and other venomous insects as are perhaps sufficient to overbalance every natural advantage we have yet mentioned. The most pernicious and dangerous kind are the ants; of which they reckon no less than six several species of different colours and sizes; all of them formidable on account of their prodigious numbers, and the mischief they do not only to the fruits of the earth, but to men and beasts; whom they will surround in the night time, and devour even to the very bone. It is a common practice, we are told, to condemn persons guilty of

From atrocious crimes to be stripped naked, tied hand and foot, and thrown into a hole where these insects swarm; where they are sure to be devoured by them in less than 24 hours to the very bone. But criminals are not the only persons who are in danger from the jaws of these little devouring insects. People may be attacked by them, as we have already hinted, in the night time, and while they are sleeping in their beds. This obliges the natives to be careful where they lie down, and to kindle a small fire, or at least to have a circle of burning hot embers round their beds. This caution is still more necessary in the country villages and hamlets, where persons are otherwise in danger of being attacked by millions of them in the dead of the night. In such a case, the only expedient to save one's self is to jump up as soon as one feels the bite, to brush them off with all possible speed, and then at once to set the house on fire. He danger is still greater in travelling through the country, where a person is often obliged to take up his lodging on the bare ground; and may be overtaken during the heat of the day with such profound sleep, as not to be wakened by these diminutive animals till they have made their way through the skin; and in such a case nothing will prevent their devouring a man alive, though there were ever so many hands to assist him. In such incredible quantities do these creatures abound, notwithstanding the great numbers of monkeys who are continually terrorizing the ants out of their retreats, and feed upon them with the utmost avidity. This can only be ascribed to the natural laziness and indolence of the inhabitants; which is such, that they not only neglect to rid their lands of them by proper cultivation, but will suffer their hou...
Earth, in which their combs are not found in great quantities.

With respect to the populousness of the kingdom of Congo, some authors, writing either from mere conjecture, or at best precarious inferences, have represented it as thinly peopled. The accounts of the missionaries and Portuguese, however, are directly opposite to this. They found the country for the most part covered with towns and villages, and these swarming with inhabitants; the cities well filled with people, particularly the metropolis, which is said to contain above 50,000 souls. The provinces, though not equally populous, yet in the whole make up such an amount, as plainly proves, that what is wanting in one is amply made up by the other. We are told, that the duchy of Bamba is still able to raise 200,000 fighting men, and was formerly in a condition to raise double that number; and that the army of the king of Congo, in the year 1665, consisted of 900,000 fighting men, who were attended by an infinite number of women, children, and slaves. The numbers of the Congolese will appear the more credible, when we consider the immense fertility of their women, the hardiness with which they bring up their children, and the thriftiness and industry of their men. In some villages, if the missionaries are to be credited, the number of children was raised, that the number of slaves they fell abroad seldom amounts, communibus annis, to less than 15,000 or 16,000.

There is scarce a nation on earth that have a higher opinion of themselves or their country, than the Congolese, or that is more hardened against all conviction to the contrary, from reason, experience, or the most impartial comparison with other countries in Europe or Asia. Indeed, it is impossible they should think otherwise, when it is one of the fundamentals of their belief, that the rest of the world was the work of angels, but that the kingdom of Congo, in its full and ancient extent, was the handywork of the Supreme Architect; and most of course have vast prerogatives and advantages over all others. When told of the magnificence of the European and Asiatic courts, their immense revenues, the grandeur of their palaces and edifices, the richness and happiness of their subjects, the great progress they have made in the arts and sciences, to which their country is wholly a stranger, they coolly answer, that all this comes vapidly short of the dignity and splendor of the kings and kingdom of Congo; and that there can be but one Congo in the world, to the happiness of whose monarch and people all the rest were created to contribute, and to whose treasury the seas and rivers pay their constant tribute of 'zimba (or shells, which are their current coin); whilst other princes must confend to enrich themselves by digging through rocks and mountains, to come at the extremities of the earth, so they flye gold and silver which are in such request among other nations. Accordingly, they imagine, that the nations which come to traffic with them, are forced to that servile employment by their poverty and the baseness of their country, rather than induced to it by luxury or avarice; whilst they themselves can indulge their natural indolence or sloth, though attended with the most pinching poverty, rather than disgrace the dignity of their blood by the least effort of industry, which, how laudable and beneficial forever, is looked upon by them as only a lesser degree of slavery. But though they generally esteem it so much below their dignity to apply to any useful work, they think it no disgrace to beg or steal. With respect to the first, they are said to be the most shameless and importunate beggars in the world. They will take no denial, spare no crouching, lying, praying, to obtain what they want, nor curseth and ill language when sent away without it. With regard to the last, they deem no theft unlawful or scandalous, except it be committed in a private manner, without the knowledge of the person wronged. It is esteemed a piece of bravery and gallantry to wrench any thing from another by violence; and this kind of theft is so common, not only among the vulgar, but also among the great ones, that they make no scruple, in their travels from place to place, to seize not only upon all the provisions they meet with in towns and villages, but upon every thing else that falls in their way. These violence oblige the poor people to conceal the few valuable things they have, in some secure place out of the knowledge and reach of those harpies; and they think themselves well off if they can escape a severe harrassing, or other cruel usage frequently inflicted upon them, in order to make them discover the place of their concealment.

The complexion of the natives, both men and women, is black, though not in the same degree; some have a much deeper black than others. Their hair is black and finely curled; some have it also of a dark sandy colour: their eyes are mostly of a fine lively black; but some are of a dark sea colour. They have neither flat noses nor thick lips like the Nubians and other negroes. Their stature is mostly of the middle size; and, excepting their black complexion, they much resemble the Portuguese. In their temper they are misanthropic, envious, jealous, and treacherous; and where they once take a dislike or affront, will spare no pains, nor flick at any means, however base, to be avenged of, and crush their enemy under their feet. There is no such thing among them as natural affection. A husband, if an heathen, may take as many wives as he pleases; and if a Christian, may have any number of concubines, whom he may divorce at pleasure, or even sell them though with child. So little regard have they for their children, that there is scarce one among them who will not sell a son or a daughter, or perhaps both, for a piece of cloth, a collar or girdle of coral or beads, and often for a bottle of wine or brandy.

The religion of the Congolese in many parts is downright idolatry, accompanied with the most ridiculous superstitions, and the most absurd and detestable rites invented by their gangs or priests; and even in those parts where Christianity is professed, it is so darkened by superstititions of one kind or other, that we may justly question whether the people are any gainers by the exchange.

The government of this kingdom is monarchical, and despotic as any in Asia or Africa. The kings are the sole proprietors of all the lands within their dominions; and ife they can dispose of to whom they
they please, upon condition they pay a certain tribute out of them; upon failure of the payment of which, or any other neglect, they turn them out. Even the princes of the blood are subjected to the same law; so that there is no perogov of any rank or quality whatever that can bequeath a foot of land to his heirs or successors; and when these owners under the crown die, the lands immediately return to it again, whether they were in their possession, or had been left to ever so many tenants under them; so that it entirely depends on the prince whether these lands shall be continued in the same, or be disposed into other hands. The Portuguese, however, since their settling in these parts, have prevailed upon the monarchs to permit the heirs and successors to continue in the quiet possession of such lands, in order to avoid the confusions, or even rebellions, which the alienation and deprivation of them frequently occasioned, and to oblige the tenants of them to pay their tribute more exactly and readily than they did before.

20

Commerce. St Salvador is the chief place of traffic the Portuguese and other Europeans have in this country. There are thought to be about 4000 of them settled here, who trade with most parts of the kingdom. The chief commodities they bring thither are either the product of Brazil or European manufactures. The former consist chiefly of grains, fruits, plants, &c.; the latter of Turkey carpets, English cloth, and other fluffs; copper, brazs vessels, some kinds of blue earthenware, rings, and ornaments of gold, silver, and other bader metals; coral, glass beads, bugles, and other trinkets; light fluffs made of cotton, woolen, and linen for clothing; and a great variety of tools and other utensils. In return for these, they carry off a great number of slaves, amounting to 15,000 or 16,000 annually, as we have already observed. Formerly they used also to carry away elephants teeth, furs, and other commodities of the country; but these branches of commerce are now greatly decayed, and the slave-trade is what the Portuguese merchants principally depend on.

CONGO, a term applied to tea of the second quality.

CONGREGATION, an assembly of several ecclesiastics, united so as to constitute a body. The term is principally used for assemblies of cardinals appointed by the pope, and distributed into several chambers, for the discharge of certain functions and jurisdictions, after the manner of our offices and courts. The first is the congregation of the holy office, or the inquisition: the second, that of jurisdiction over bishops and regulars; the third, that of councils; this has power to interpret the council of Trent: the fourth, that of customs, ceremonies, precedences, canonizations, called the congregation of rites; the fifth, that of St Peter's fabric, which takes cognizance of all causes relating to piety and charity, part whereof is due to the church of St Peter: the sixth, that of waters, rivers, roads: the seventh, of fountains and streets: the eighth, that of the index, which examines the books to be printed or corrected: the ninth, that of the council of state, for the management of the territories belonging to the pope and church (see CAMERLINGO): the tenth, de bono regimine: of which two last the cardinal-nephew is chief; the eleventh, that of money: the twelfth, that of bishops, wherein those who are to be promoted to bishoprics in Italy are examined; this is held before the pope: the thirteenth, that of confessional matters; the chief whereof is the cardinal-dean: the fourteenth, a congregation for propagating the faith (see COLLEGE): and the fifteenth, that of ecclesiastical immunity, for settling suits against churchmen. There is also a congregation of alms, which takes care of every thing that relates to the subsistence of Rome and the state of the church. CONGREGATION is also used for a company or society of religious cut out of this or that order; and making, as it were, an inferior order, or a subdivision of the order itself. Such are the congregations of the oratory, and those of Cluny, &c. among the Benedictines.

The word is also used for assemblies of pious persons in manner of societies, frequent among the Jesuits in honour of the Virgin, &c. It is likewise applied to the audience in a church, particularly as consisting of the inhabitants of the same parish.

CONGREGATIONALISTS, in church history, a sect of Protestants who reject all church government, except that of a single congregation under the direction of a pastor.

CONESS, in political affairs, an assembly of commissioners, envoys, deputies, &c. from several courts meeting to concert matters for their common good.

CONGRESS, in America, is the assembly of delegates from the United States. See AMERICA.

CONGRESS, in a judicial sense, the trial made by appointment of a judge before surgeons and matrons, in order to prove whether or no a man be impotent, before sentence is passed for the dissolution of a marriage solicited upon such a complaint.

Neither the civil nor canon law makes any mention of the trial of virility by congress. It had its origin in France from the boldness of a young fellow, who, in open court, having been hard pressed by his wife demanded the congress. The judge, surprised with the novelty of the demand, found it could not be denied, as being the safest evidence that the cause could admit of. In time it became a branch in the French jurisprudence, and was authorized by decrees and arrests. It obtained for about 120 years; and was annulled by an arrest of parliament in 1677, as being found precarious; some having failed under the experiment out of mere modesty and shame, which is found to have the same effect with actual impotency.

CONGREVE (William), a younger brother of an ancient family in Staffordshire. His father was employed in the stewardship of the great estate of the Earl of Burlington in Ireland, where he resided many years; and our author was born there in 1672. Mr Congreve entered into the Middle-Temple when he came to England, and began to study the law; but his bias was toward polite literature and poetry. His first performance was a novel, intitled, Incognita, or Love and Duty reconciled. He soon after began his comedy of the Old Bachelor; which was the amusemen of some leisure hours during a slow recovery from a fit of illness soon after his return to England; yet was in itself fo perfect, that Mr Dryden, on its being shown to him, declared he had never in his life seen such a first play.

When
When brought on the stage in 1695, it met with such universal approbation, that Mr. Congreve, though he was but 19 years old at the time of his writing it, became now considered as a prop to the declining stage, and a rising genius in dramatic poetry. The next year he produced the Double Dealer, which, for what reason it is not obvious, did not meet with so much success as the former. The merit of his first play, however, had obtained him the favour and patronage of Lord Halifax, and some peculiar mark of distinction from Queen Mary; on whose death, which happened in the close of this year, he wrote a very elegant elegiac pastoral. In 1695, when Betterton opened the new house in Lincoln's-Inn Fields, Mr. Congreve, joining with him, gave him his comedy of Love for Love, with which the company opened their campaign; and which met with such success, that they immediately offered the author a share in the management of the house, on condition of his furnishing them with one play yearly. This offer he accepted; but whether through indolence, or that correctness which he looked upon as necessary to his works, his Mourning Bride did not come out till 1697, nor his Way of the World till two years after that. The indifferent success this last mentioned play, though an exceedingly good one, met with from the public, completed that disgust to the theatre, which a long contest with Jeremy Collier, who had attacked the immorality of the English stage, and more especially for his pieces, had begun; and he determined never more to write for the stage. However, though he quitted dramatic writing, he did not lay down the pen entirely; but occasionally wrote many little pieces both in prose and verse, all of which stand on the records of literary fame. It is very possible, however, that he might not so soon have given way to this disgust, had not the easiness of his circumstances rendered any submission to the opinions and caprice of the town absolutely unnecessary to him. For his abilities having very early in life raised him to the acquaintance of the Earl of Halifax, who was then the Maecenas of the age; that nobleman, deputies of raising so many of his pieces, had begun, and had determined to carry them in hand. He soon after bestowed on him a place in the pipe-office; and not long after gave him a post in the censors worth 600 l. per annum. In the year 1718, he was appointed secretary of Jamaica; so that, with all together, his income towards the latter part of his life was upwards of 1200 l. a-year.

The greatest part of the last 20 years of his life was spent in ease and retirement; and he either did not, or affected not to give himself any trouble about reputation. Yet some part of that conduct might proceed from a degree of pride, to which perhaps, T. Cibber, in his life of the poets, Vol. IV, p. 92, relates the following anecdote of him: "When the celebrated Voltaire was in England, he waited upon Mr. Congreve, and passed some compliments upon the merit and reputation of his works. Congreve thanked him; but at the same time told that ingenious foreigner, that he did not choose to be considered as an author, but only as a private gentleman, and in that light expected to be visited. Voltaire answered, that if he had never been any thing but a private gentleman, in all probability he had never been troubled with that visit." He observes, in his own account of the transaction, that he was not a little disgraced with so unreasonable a piece of vanity.

Towards the close of his life he was much afflicted with the gout; and making a tower to Bath for the benefit of the waters, was unfortunately overturned in his chariot; by which, it is supposed, he got some inward bruise, as he ever after complained of a pain in his side; and, on his return to London, continued gradually declining in his health, till the 19th of January 1729, when he died, aged 57; and, on the 26th following, was buried in Westminster Abbey, the pall being supported by persons of the first distin­ction.

**CONGRUITY**, a suitableness or relation of agreement between things.

The terms **congruity** and **propriety** are not applicable to any single object: they imply a plurality, and obviously signify a particular relation between different objects. Thus we currently say, that a decent garb is suitable or proper for a judge; modest behaviour for a young woman; and a lofty style for an epic poem; and, on the other hand, that it is unsuitable or incongruous to see a little woman flank an overgrown farthingale, a coat richly embroidered covering coarse and dirty linen, a mean subject in an elevated style, a friar minifier darning his wife's stocking, or a reverend prelate in lawn sleeves dancing a hornpipe.

The perception we have of this relation, which seems peculiar to man, cannot proceed from any other cause, but from a *fence* of congruity or propriety; for, supposing us destitute of that fence, the terms would be to us unintelligible.

It is a matter of experience, that congruity or propriety, wherever perceived, is agreeable; and that incongruity or impropriety, wherever perceived, is disagreeable. The only difficulty is, to ascertain what are the particular objects that in conjunction suggest these relations; for there are many objects that do not: the sea, for example, viewed in conjunction with a picture, or a man viewed in conjunction with a mountain, suggest not either congruity or incongruity. It seems natural to infer, what will be found true by induction, that we never perceive congruity nor incongruity but among things that are connected together by some relation; such as a man and his actions, a principal and his accessories, a subject and its ornaments. We are indeed so framed by nature, as among things so connected, to require a certain suitableness or correspondence, termed congruity or propriety; and to be displeased when we find the opposite relation of incongruity or impropriety.

If things connected be the subject of congruity, it is reasonable before-hand to expect, that a degree of congruity should be required proportioned to the degree of the connection. And upon examination we find this to hold in fact: where the relation is intimate, as between a cause and its effect, a whole and its parts, we require the strictest congruity; where the relation is slight, or accidental, as among things jumbled together in the same place, we require little or no congruity: the strictest propriety is required.
Congruity.

A man is connected with these by the relation of cause and effect: the relation between an edifice and the ground it stands upon, is of the most intimate kind; and therefore the situation of a great house ought to be lofty; its relation to neighbouring hills, rivers, planes, being that of propriety only demands but a small share of congruity: among members of the same club, the congruity ought to be considerible, as well as among things placed for show in the same niche: among passengers in a stage-coach, we require very little congruity: and less still at a public spectacle.

Congruity is so nearly allied to beauty, as commonly to be held a species of it; and yet they differ so essentially as never to coincide: beauty, like colour, is placed upon a single subject; congruity upon a plurality: further, a thing beautiful in itself, may, with relation to other things, produce the strongest sense of incongruity.

Congruity and propriety are commonly reckoned synonymous terms; but they are distinguishable; and the precise meaning of each must be ascertained. Congruity is the genus of which propriety is a species; for we call nothing propriety, but that congruity or suitableness which ought to subsist between suitable beings and their thoughts, words, and actions.

In order to give a full view of these secondary relations, we shall trace them through some of the most considerible primary relations. The relation of a part to the whole, being extremely intimate, demands the utmost degree of congruity; even the slightest deviation is difficult.

Examples of congruity and incongruity are furnished in plenty by the relation between a subject and its ornaments. A literary performance intended merely for amusement, is susceptible of much ornament, as well as a music-room or a play-house; for in gaiety, the mind hath a peculiar relish for show and decoration. The most gorgeous apparel, however improper in tragedy, is not inadmissible to opera-actors: the truth is, an opera, in its present form, is a mighty fine thing; but as it deviates from nature in its capital circumstances, we look not for nature nor propriety in those which are accessory. On the other hand, a serious and important subject admits not much ornament; nor a subject that of itself is extremely beautiful: and a subject that fills the mind with its loveliness and grandeur, appears best in a dress altogether plain.

To a person of a mean appearance, gorgeous apparel is unsuitable; which, besides the incongruity, has a bad effect; for by contrast it shows the meanness of appearance in the strongest light. Sweetness of look and manner, requires simplicity of dress, joined with the greatest elegance. A flaty and mejecif air requires sumptuous apparel, which ought not to be gaudy, nor crowded with little ornaments. A woman of consummate beauty can bear to be highly adorned, and yet shows best in a plain dress:

For loveliness needs not the foreign aid of ornament, but is when unadorn'd, adorn'd the more.

Thomson's Autumn, 208.

Congruity regulates not only the quantity of ornament, but also the kind. The ornaments that embellish a dancing-room ought to be all of the gayest. No picture is proper for a church but what has religion for its subject. All the ornaments upon a shield ought to relate to war; and Virgil, with great judgment, confines the carvings upon the shield of Aeneas to the military history of the Romans; but this beauty is overlooked by Homer; for the bulk of the decoration upon the shield of Achilles, is of the arts of peace in general, and of joy and festivity in particular: the author of Telemachus betrays the same inattention, in describing the shield of that young hero.

In judging of propriety with regard to ornaments, we must attend, not only to the nature of the subject that is to be adorned, but also to the circumstances in which it is placed: the ornaments that are proper for a ball, will appear not altogether so decent at public worship; and the same person ought to dress differently for a marriage-feast and a burial.

Nothing is more intimately related to a man, than his sentiments, words, and actions; and therefore we require here the strictest conformity. When we find what we thus require, we have a lively sense of propriety: when we find the contrary, our sense of improbility is not less lively. Hence the universal delight of affectation, which consists in making a show of greater delicacy and refinement than is suited either to the character or circumstance of the person.

Congruity and propriety, wherever perceived, appear agreeable; and every agreeable object produces in the mind a pleasant emotion: incongruity and improbility, on the other hand, are disagreeable; and of course produce painful emotions. These emotions, whether pleasant or painful, sometimes vanish without any consequence; but more frequently occasion other emotions, which we proceed to exemplify.

When any slight incongruity is perceived in an accidental combination of persons or things, as of passengers in a stage-coach, or of individuals dining at an ordinary; the painful emotion of incongruity, after a momentary existence, vanishes without producing any effect. But this is not the case of propriety and improbility: voluntary acts, whether words or deeds, are imputed to the author: when proper, we reward him with our esteem; when improper, we punish him with our contempt. Let us suppose, for instance, a generous action suited to the character of the author, which raises in him and in every spectator the pleasant emotion of propriety: this emotion generates in the author both self-esteem and joy; the former when he considers the relation to the action; and the latter when he considers the good opinion that others will entertain of him: the same emotion of propriety produces in the spectators esteem for the author of the action; and when they think of themselves, it also produces, by means of contrariety, an emotion of humility. To discover the effects of an improper action, we must invert each of these circumstances: the painful emotion of improbility generates in the author of the action both humility and shame; the former when he considers his relation to the action, and the latter when he considers what others will think of him: the same emotion of improbility produces in the spectators contempt for the author of the action; and it also produces, by means of contrariety, when they think of themselves.
Congruity, themselves, an emotion of self-esteem. Here then are many different emotions, derived from the same action, considered in different views by different persons; a machine provided with many springs, and not a little complicated. Property of action, it would seem, is a chief favourite of nature, when such care and solicitude is bestowed upon it. It is not left to our own choice; but, like justice, is required at our hands; and, like justice, is enforced by natural rewards and punishments: a man cannot, with impunity, do any thing unbecoming or improper; he suffers the chafisement of contempt inflicted by others, and of blame inflicted by himself. An apparatus so complicated, and so singular, ought to rule our attention: for nature doth nothing in vain; and we may conclude with great certainty, that this curious branch of the human constitution is intended for some valuable purpose.

A gross impropriety is punished with contempt and indignation, which are vented against the offender by corresponding external expressions: nor is even the slightest impropriety suffered to pass without some degree of contempt. But there are improprieties, of the fhihter kind, that provoke laughter: of which we have examples without end, in the blunders and absurdities of our own species: such improprieties receive a different punishment, as will appear by what follows. The emotions of contempt and of laughter occasioned by an impropriety of this kind, uniting intimately in the mind of the spectator, are expressed externally by a peculiar fort of laugh, termed a laugh of derision or scorn. An impropriety that thus moves not only contempt, but laughter, is distinguished by the epithet of ridiculous; and a laugh of derision or scorn is the punishment provided for it by nature. Nor ought it to escape observation, that we are so fond of inflicting this punishment, as sometimes to exert it even against creatures of an inferior species: wise men a turky cock dwelling with pride, and laughing with displayer feathers; a ridiculous object, which in a gay mood is not improvidently a laugh of derision.

We must not expect, that those different improprieties are separated by distinct boundaries: for of improprieties, from the slightest to the most gross, from the most trivial to the most serious, there are degrees without end. Hence it is, that in viewing some unbecoming actions, too fihle for anger, and too fihle for derision, the spectator feels a sort of mixt emotion, partaking both of derision and of anger; which accounts for an expression, common with respect to the impropriety of those actions, that we know not whether to laugh or be angry.

It cannot fail to be observed, that in the case of a fihle impropriety, which is always slight, the contempt which we have for the offender is extremely faint, tho’ derision, its gratification, is extremely pleasant. This disproportion between a passion and its gratification, seems not conformable to the analogy of nature. In looking about for a solution, we must reflect upon what is laid down above, that an improper action not only moves our contempt for the author, but also, by means of contrariety, stas the good opinion we have of ourselves. This contributes, more than any other article, to the pleaure we have in ridiculing follies and absurdities; and accordingly, it is well known, that they who put the greatest value upon themsevles are the most prone to laugh at others. Pride, which is Congruity, a vivid passion, pleasant in itself, and not least so in its gratification, would fihlly be sufficient to account for the pleaure of ridicule, without borrowing any aid from contempt. Hence appears the reason of a noted observation, That we are the most disposed to ridicule the blunders and absurdities of others, when we are in high spirits; for in high spirits, self-conceit displays itself with more than ordinary vigour.

With regard to the final causes of congruity and impropriety; one, regarding congruity, is pretty obvious, that the sense of congruity, as one principle of the fine arts, contributes in a remarkable degree to our entertainment. Congruity, indeed, with respect to quantity, coincides with proportion: when the parts of a building are nicely adjusted to each other, it may be said indifferently, that it is agreeable by the congruity of its parts, or by the proportion of its parts. But propriety, which regards voluntary agents only, can never be the same with proportion: a very long note is disproportioned, but cannot be termed improper. A some instances, it is true, propriety coincides with disportion in the same subject, but never in the same respect; for example, a very little man buckled to a long toledo: considering the man and the sword with respect to size, we perceive a disproportion, confiderng the sword as the choice of the man, we perceive an impropriety.

The sense of impropriety with respect to mistakes, blunders, and absurdities, is happily contrived for the good of mankind. In the spectators, it is producive of mirth and laughter, excellent recreation in an interval from business. But this is a trifle in respect of what follows. It is painful to be the subject of ridicule; and to punish with ridicule the man who is guilty of an absurdity, tends to put him more upon his guard in time coming. Thus even the most innocent blunder is not committed, with impunity; because, were errors licensed where they do no hurt, inattention would grow into a habit, and be the occasion of much hurt.

The final caufe of propriety as to moral duties, is of all the most illustrious. To have a just notion of it, the moral duties that respect others muft be distinguished from those that respect ourselves. Fidelity, gratitude, and the forbearing injury, are examples of the first; temperance, modesty, firmness of mind, are examples of the other: the former are made duties by the sense of justice; the latter by the sense of propriety. Here is a final caufe of the sense of propriety, that must rule our attention. It is undoubtedly the interest of every man, to suit his behaviour to the dignity of his nature, and to the station allotted him by Providence; for such rational conduct contributes in every respect to happiness, by preserving health, by procuring plenty, by gaining the esteem of others, and, which of all is the greatest blessing, by gaining a justly-founded self-esteem. But in a matter so essential to our well-being, even self-interest is not relied on: the powerful authority of duty is superadded to the motive of interest. The God of nature, in all things essential to our happiness, hath observed one uniform method: to keep us steady in our conduct, he hath fortified us with natural laws and principles, which prevent many aberrations, that would daily happen were we totally surrendered to fallible a guide as human
CONIC SECTIONS

ARE curve lines formed by the intersecions of a cone and plane.

If a cone be cut by a plane through the vertex, the section will be a triangle ABC, Plate CXLVI. fig. 1.

If a cone be cut by a plane parallel to its base, the section will be a circle. If it be cut by a plane DEF, fig. 1, in such a direction, that the line AC of a triangle falling through the vertex, and having its base BC perpendicular to EF, may be parallel to DP, the section is a parabola; if it be cut by a plane DR, fig. 2, meeting AC, the section is an ellipse; and if it be cut by a plane DMO, fig. 3, which should meet AC extended beyond A, it is an hyperbola.

If any line HG, fig. 1, be drawn in a parabola perpendicular to DP, the square of HG will be to the square of EP, as DG to DP; for let LHK be a section parallel to the base, and therefore a circle, the rectangle LGK will be equal to the square of HG, and the rectangle BKC equal to the square of EP; therefore these squares will be to each other as their rectangles; that is, as BP to LG, that is DP to DG.

SECT. I. Description of Conic Sections on a Plane.

1. PARABOLA.

Let AB, fig. 4, be any right line, and C any point "without it, and DKF a ruler, which let be placed in "the same plane in which the right line and point are, "in such a manner that one side of it, as DK, be applied "to the right line AB, and the other side KF "coincide with the point C; and at F, the extremi-"ty of the side KF, let be fixed one end of the thread "FNC, whose length is equal to KF, and the other "extremity of it at the point C, and let part of the "thread, as FG, be brought close to the side KF by "a small pin G; then let the square DKF be moved "from B towards A, so that all the while its side DK "be applied close to the line BA, and in the mean "time the thread being extended will always be applied "to the side KF, being from going from "it by means of the small pin; and by the motion of "the small pin N there will be described a certain "curve, which is called a semi-parabola.

And if the square be brought to its first given po-sition, and in the same manner be moved along the "line AB, from B towards H, the other semi-para-bola will be described.

The line AB is called the directrix; C, the focus; any line perpendicular to AB, a diameter; the point "where it meets the curve, its vertex; and four times "the distance of the vertex from the directrix, its latus redctum or parameter.

2. ELLIPSE.

If any two points, as A and B, fig. 5, be taken "in any plane, and in them are fixed the extremities "of a thread, whose length is greater than the dis-tance between the points, and the thread extended "by means of a small pin C, and if the pin be moved "round from any point until it return to the place "from whence it began to move, the thread being "extended during the whole time of the revolution; "the figure which the small pin by this revolution "describes is called an ellipse."

The points AB are called the foci; D, the centre; EF, the transverse axis; GH, the lesser axis; and any other line passing through D, a diameter.

3. HYPERBOLA.

If to the point A, fig. 6, in any plane, one end "of the rule AB be placed, in such a manner, that "about that point, as a centre, it may freely move;
Conic Sections.

Sect. II.

“and if to the other end B, of the rule AB, be fixed “the extremity of the thread BDC, whose length is “smaller than the rule AB, and the other end of the “thread, being fixed in the point C, coinciding with “the side of the rule AB, which is in the same plane “with the given point A; and let part of the thread, “as BD, be brought close to the side of the rule AB,” by the help of a small pin, then let the rule be “moved about the point A, from C towards T, the “thread all the while being extended, and the re­ “main­ing part coinciding with the side of the rule “being flopped from going from it by means of the “small pin, and by the motion of the small pin D, a “certain figure is described which is called the semi­ “hyperbola.”

The other semi-hyperbola is described in the same way, and the opposite HKF, by fixing the ruler to “C, and the thread to A, and describing it in the same manner. A and C are called foci; the point G, which “bifec­ks AC, the centre; KE, the tranverse axis; a line “drawn through the centre meeting the hyperbola, a “transverse diameter; a line drawn through the centre, perpendicular to the tranverse axis, and cut off by “the circle MN, whose centre is E, and radius equal to “CG, is called the second axis.

If a line be drawn through the vertex E, equal and “parallel to the second axis GP and GO be joined, they “are called asymptotes. Any line drawn through the “centre, not meeting the hyperbolas, and equal in “length to the part of a tangent parallel to it, and in­ “tercepted between the asymptotes, is called a second “diameter.

An ordinate to any section is a line bisected by “a diameter and the abscissa, the part of the diameter cut “off by the ordinate.

Conjugate diameters in the ellipse and hyperbola “are such as mutually bisect lines parallel to the other; “and a third proportional to two conjugate diameters “is called the latus rectum of that diameter, which is “the first in the proportion.

In the parabola, the lines drawn from any point to “the focus are equal to perpendiculars to the directrix; “being both equal to the part of the thread separated “from the ruler.

In the ellipse, the two lines drawn from any point “in the curve to the foci are equal to each other, being “equal to the length of the thread; they are also equal “to the transverse axis. In the hyperbola the difference “of the lines drawn from any point to the foci is equal, “being equal to the difference of the lengths of the ru­ “ler and thread, and is equal to the transverse axis.

From these fundamental properties all the others “are derived.

The ellipse returns into itself. The parabola and “hyperbola may be extended without limit.

Every line perpendicular to the directrix of a pa­ “rabola meets it in one point, and falls afterwards “within it; and every line drawn from the focus meets “it in one point, and falls afterwards without it. And "every line that passes through a parabola, not perpen­ “dicular to the directrix, will meet it again, but only “once.

Every line passing through the centre of an ellipse “is bisected by it; the transverse axis is the greatest of “all these lines; the lesser axis the least; and these nearer “the transverse axis greater than those more remote.

In the hyperbola, every line passing through the “centre, is bisected by the opposite hyperbola, and the “transverse axis is the least of all these lines; also the “second axis is the least of all the second diameters. “Every line drawn from the centre within the angle “contained by the asymptotes, meets at once, and falls “afterwards within it; and every line drawn through “the centre without that angle, never meets it; and “a line which cuts one of the asymptotes, and cuts the “other extended beyond the centre, will meet both the “opposite hyperbolas in one point.

If a line GM, fig. 4, be drawn from a point in a “parabola perpendicular to the axis, it will be an ordi­ “nate to the axis, and its square will be equal to the “rectangle under the abscissa MI and latus rectum; for, “because GMC is a right angle, GM² is equal to the “difference of GC² and CM²; but GC is equal to GE, “which is equal to MB; therefore GM² is equal to “BM²–CM²; which, because CI and IB are equal, is “(En. 2.) equal to four times the rectangle under MI “and IB, or equal to the rectangle under MI and the “latus rectum.

Hence it follows, that if different ordinates be “drawn to the axis, their squares being each equal to “the rectangle under the abscissa and latus rectum, “will be to each other in the proportion of the abscissas, “which is the same property as was shown before to “take place in the parabola cut from the cone, and “proves those curves to be the same.

This property is extended also to the ordinates “of other diameters, whose squares are equal to the rec­ “tangle under the abscissa and parameters of their re­ “pective diameters.

In the ellipse, the square of the ordinate is to “the rectangle under the segments of the diameter, as “the square of the diameter parallel to the ordinate to “the square of the diameter to which it is drawn, or as “the first diameter to its latus rectum; that is, LK² “fig. 5. is to EKF as EF² to GH².

In the hyperbola, the square of the ordinate is “to the rectangle contained under the segments of the “diameter between the vertices, as the square of the “diameter parallel to the ordinate to the square of the “diameter to which it is drawn, or as the first “diameter to its latus rectum; that is, SX² is to “EXK as MN² “to KE².

Or if an ordinate be drawn to a second diameter, “its square will be to the sum of the squares of the se­ “cond diameter, and of the line intercepted between “the ordinate and centre, in the same proportion: that “is, RZ² fig. 6. is to ZG² added to GM², as KE² “to MN². These are the most important properties of “the conic sections; and, by means of these, it is de­ “monstrated, that the figures are the same described on “a plane as cut from the cone; which have demon­ “strated in the case of the parabola.

Sect. II. Equations of the Conic Sections

Are derived from the above properties. The equa­ “tion of any curve, is an algebraic expression, which “denotes the relation between the ordinate and abscissa; “the abscissa being equal to x, and the ordinate equal to “y. If
If \( p \) be the parameter of a parabola, then \( y^2 = px \); which is an equation for all parabolas.

If \( a \) be the diameter of an ellipse, \( p \) its parameter; then \( y^2 + ax = px \); and \( y^2 = \frac{p}{a}x^2 - ax \); an equation for all ellipses.

If \( a \) be a transverse diameter of a hyperbola, \( p \) its parameter; then \( y^2 + ax = px \); and \( y^2 = \frac{p}{a}x^2 + ax \); which are equations for all hyperbolas.

As all these equations are expressed by the second powers of \( x \) and \( y \), all conic sections are curves of the second order; and conversely, the locus of every quadratic equation is a conic section, and is a parabola, ellipse, or hyperbola, according as the form of the equation corresponds with the above ones, or with some other deduced from lines drawn in a different manner with respect to the section.

Sect. III. General Properties of Conic Sections.

A tangent to a parabola bisects the angle contained by the lines drawn to the focus and directrix; in an ellipse and hyperbola, it bisects the angle contained by the lines drawn to the foci.

In all the sections, lines parallel to the tangent are ordinates to the diameter passing through the point of contact; and in the ellipse and hyperbola, the diameters parallel to the tangent, and those passing through the points of contact, are mutually conjugate to each other. If an ordinate be drawn from a point to a diameter, and a tangent from the same point which meets the diameter produced; in the parabola, the part of the diameter between the ordinate and tangent will be biseected in the vertex; and in the ellipse and hyperbola, the semi-diameter will be a mean proportion between the segments of the diameter between the centre and ordinate, and biseects the centre and tangent.

The parallelogram formed by tangents drawn through the vertices of any conjugate diameters, in the same ellipse or hyperbola, will be equal to each other.

Sect. IV. Properties peculiar to the Hyperbola.

As the hyperbola has some curious properties arising from its asymptotes, which appear at first view almost incredible, we shall briefly demonstrate them: 1. The hyperbola and its asymptotes never meet; but, if not, let them meet in \( S \), fig. 6.; then by the property of the curve the rectangle \( KXE \) is to \( SX^2 \) as \( GE^2 \) to \( GM \) or \( EP \); that is, as \( GX^2 \) to \( SX^2 \); wherefore, \( KXE \) will be equal to the square of \( GX \); but the rectangle \( KXE \), together with the square of \( GE \), is also equal to the square of \( GX \); which is absurd.

2. If a line be drawn through a hyperbola parallel to its second axis, the rectangle, by the segments of that line, biseects the point in the hyperbola and the asymptotes, will be equal to the square of the second axis.

For if \( SZ \), fig. 6, be drawn perpendicular to the second axis, by the property of the curve, the square of MG, that is, the square of PE is to the square of GE, as the squares \( ZG \) and the square of \( MG \) together, to the square of \( SZ \) or \( GX \); and the squares of \( RX \) and \( GX \) are in the same proportion, because the triangles \( RXG \), \( PEG \) are equiangular; therefore the squares \( ZG \) and \( MG \) are equal to the square of \( RX \); from which, taking the equal squares of \( SX \) and \( ZG \), there remains the rectangle \( RSV \), equal to the square of \( MG \).

3. Hence, if right lines be drawn parallel to the second axis, cutting an hyperbola and its asymptotes, the rectangles contained between the hyperbola and points where the lines cut the asymptotes will be equal to each other; and through them, they are severally equal to the square of the second axis.

4. If from any points, \( d \) and \( S \), in a hyperbola, there be drawn lines parallel to the asymptotes \( da \) \( SQ \) and \( SB \) \( dc \), the rectangle under \( da \) and \( dc \) will be equal to the rectangle under \( SQ \) and \( SB \); also the parallelograms \( da \), \( Gc \), and \( SQ \), \( b \), which are equiangular, and consequently proportional to the rectangles, are equal.

For draw \( YW \) parallel to the second axis, and the rectangle \( Yd \) \( W \) is equal to the rectangle \( RSV \); wherefore, \( WD \) is to \( VS \) as \( RS \) is to \( dY \). But because the triangles \( RQS \), \( AYD \), and \( GSV \), \( dW \), are equiangular, \( Wd \) is to \( VS \) as \( c \) to \( SB \), and \( RS \) is to \( dY \) as \( SQ \) to \( da \); wherefore, \( d \) \( e \) is to \( b \) as \( SQ \) to \( da \); and the rectangle \( dc \) \( da \) is equal to the rectangle \( SQ \), \( SB \).

5. The asymptotes always approach nearer the hyperbola, for, because the rectangle under \( SQ \) and \( SB \) or \( QG \), is equal to the rectangle under \( da \) and \( dc \), or \( AG \), and \( QG \) is greater than \( a \); therefore \( a \) is greater than \( QG \).

6. The asymptotes come nearer the hyperbola than any appaenible distance.

Let \( X \) be any small line. Take any point, as \( d \), in the hyperbola, and draw \( da \), \( dc \), parallel to the asymptotes; and as \( X \) is to \( da \), so let \( a \) \( G \) be to \( GQ \). Draw \( QS \) parallel to \( a \), \( d \), meeting the hyperbola in \( S \); then \( QS \) will be equal to \( X \). For the rectangle \( SQG \) will be equal to the rectangle \( da \) \( G \); and consequently \( SQ \) is to \( da \) as \( AG \) to \( GQ \).

If any point be taken in the asymptote below \( Q \), it can easily be shown that its distance is less than the line \( X \).

Sect. V. Areas contained by Conic Sections.

The area of a parabola is equal to the area of a circumscribed parallelogram.

The area of an ellipse is equal to the area of a circle whose diameter is a mean proportional between its greater and lesse axes.

If two lines \( a \) \( d \) and \( QS \), be drawn parallel to one of the asymptotes of an hyperbola, the space \( a \) \( QS \) \( d \), bounded by these parallel lines, the asymptotes and the hyperbola will be equal to the logarithm of \( a \), \( Q \), whose module is \( a \), \( d \), supposing \( a \) \( G \) equal to unity.

Sect. VI. Curvature of Conic Sections.

The curvature of any conic section, at the vertices of its axis, is equal to the curvature of a circle whose diameter is equal to the parameter of its axis.
If a tangent be drawn from any other point of a conic section, the curvature of the section in that point will be equal to the curvature of a circle to which the same line is a tangent, and which cuts off from the diameter of the section, drawn through the point, a part equal to its parameter.

**Sect. VII. Uses of Conic Sections.**

Any body, projected from the surface of the earth, describes a parabola, to which the direction wherein it is projected is a tangent: and the distance of the director is equal to the height from which a body must fall to acquire the velocity wherewith it is projected: hence the properties of the parabola are the foundation of gunnery.

All bodies acted on by a central force, which decreases as the square of the distances increases, and impressed with any projectile motion, making any angle with the direction of the central force, must describe conic sections, having the central force in one of the foci, and will describe parabolas, ellipses, and hyperbolas, according to the proportion between the central and projectile force. This is proved by direct demonstration.

**Sect. VIII. Uses of Conic Sections in the Solution of Geometrical Problems.**

Many problems can be solved by conic sections that cannot be solved by right lines and circles. The following theorems, which follow from the simpler properties of the sections, will give a specimen of this.

A point equally distant from a given point and a given line, is situated in a given parabola.

A point, the sum of whose distances from two given points is given, is situated in a given ellipse.

A point, the difference of whose distances from two given points is given, is situated in a given hyperbola.

---

**CONICHTYODONTES,** or **Plectonites,** in natural history, one of the three names the fosse teeth of fishes are known by.

**CONIFERÆ,** in botany, an order of plants in the Fragments methodi naturatis of Linnaeus, containing the following genera, viz. cupræsus, ephedra, equifetum, juniperus, pinus, taxus, thuja.

**CONIFERÆ TREES,** such as bear hard dry seed-vessels of a conical figure; consisting of several woody parts, being mostly faly, adhering closely together, and separating when ripe.

**CONIMBÍRICA** (anc. geog.), a town of Lusitania, on the south side of the river Monda; from the ruins of which arose Coimbra, in its neighbourhood, a city of Portugal. W. Long. 9° 5'. Lat. 40° 16'.

**CONINGÉCK,** a town of Suisse in Germany, and capital of a county of the same name. E. Long. 9° 23'. N. Lat. 47° 50'.

**CONJOINT,** in a general sense, signifies united or connected.

**CONJOINT Degrees,** in music, two notes which follow each other immediately in the order of the scale, as ut and re.

**CONJOINT Tetrachords,** two tetrachords, or fourths, where the same chord is the highest of one and the lowest of the other.

**CONISSALÆ,** in natural history, a class of foosses naturally and essentially compounded, not inflammable, nor soluble in water, found in detached maffes, and formed of crystalline matter debased by earth.

Of this class there are two orders, and of each of these only one genus. Conisalæ of the first order are found in form of a naturally regular and uniform powder, all the genuine particles of which are nearly of one determinate shape, appearing regularly concreted, and not fragments of others once larger. Conisalæ of the second order are found in form of a rude, irregular, and shapeless powder, the particles of which are never of any determinate figure, but seem broken fragments of once larger masses.

To the former genus belong the different kinds of sand; to the latter the sabbure, or grits.

**CONJOINT Diameter,** or **Axis,** of an Ellipsis, the shortest of the two diameters, or that bisecting the axis.

**CONJUGATE DIAMETER,** in grammar, a regular distribution of the several inflexions of verbs in their different voices, moods, tenses, numbers, and persons, so as to distinguish them from one another. See **Grammar and Language.**

**CONIUM, HEMLOCK:** A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, Umbellatae. The partial involucra are halved, and mostly triphyllous; the fruit subglobose and quinque-ferrated, the frisae crenated on each side. The species are three; 1. The maculatum, or greater hemlock, grows naturally on the sides of banks and roads in many parts of Brittain. It is a biennial plant which perishes after it has ripened its seeds. It hath a long taper root like a parsnip, but smaller. The stalk is smooth, spotted with purple, and rises from four to upwards of six feet high; branching out toward the top into several smaller stalks, garnished with decomposed leaves, whose lobes are cut at the top into three parts; these are of a lucid green, and have a disagreeable smell. The stalks are terminated by umbels of white flowers, each being composed of about ten rays or small umbels, and have a great number of flowers, which spread open, each sitting upon a distinct footstalk; the seeds are small and channelled, and like those of anilfeed. It flowers in June, and the seeds ripen in autumn.

2. The
2. The *conium*, with fricated seeds, differs from the first in having taller stalks, which are not so much spotted. The leaves are much narrower, and of a paler green; and this difference is constant. It is a biennial plant, and grows naturally in Germany. 3. The *africanum*, with prickly seeds, is a native of the Cape of Good Hope. The plant rarely grows above nine inches high: the lower leaves are divided like those of the small wild rue, and are of a greyish colour, those upon the stalk are narrower, but of the same colour; these are terminated by umbels of white flowers, each of the larger umbels being composed of three small ones; the involucrum hath three narrow leaves satuated under the umbel. This flowers in July and ripens seed in autumn, soon after which the plants decay.

**Medicinal Uses.** The first species is sometimes applied externally, in a form of decoction, infusion, or poultice, as a ict. These are apt to excoriate, and their vapour is some particularly disagreeable and hurtful. The stalks are insignificant, and the roots very virulent. With regard to its virtue when taken internally, it has been generally accounted poisonous; which it doubtless is, in a high degree, when used in any considerable quantity. But Dr. Markham has lately found, that anise certain small doses it may be taken with great safety; and that, without at all disordering the constitution, or even producing any sensible operation, it sometimes proves a powerful solvent in many obdurate disorders. In febrifus, the internal and external use of hemlock has been found useful, but then mercury has been generally used at the same time. In open cancer, it often abates the pains, and is free from the confligating effects of opium. It is likewise used in serophous tumours and ulcers, and in other ulcers that are only defined by the term ill-conditioned. It is also recommended by some in chin-cough, and various other diseases. Its common, and perhaps best form, is that of the powdered leaves, in the dose at first of two or three grains a-day, which in some cases has been gradually increased to upwards of two ounces a-day, without producing giddines. An extract from the seeds is laid to produce giddiness sooner than that from the leaves. Hence, while both the London and Edinburgh colleges have given a place to the succus *spilatus* cicuta, into the pharmacopœia of the latter an extractum feminin cicuta is also introduced.

**CONJUNCT,** in a general sense, signifies conjoined, concurrent, or united.

**CONJUNCTOR Rights,** in Scots law. See Law, Part III. no clxxx. 15, &c.

**CONJUNCT, or Confident Persons,** in Scots law. Ibid. no clxxxiiii. 8.

**CONJUNCTION,** in astronomy, the meeting of two or more stars or planets in the same degree of the zodiac.

**CONJUNCTION,** in grammar, an indeclinable word or particle, which serves to join words and sentences together, and thereby shows their relation or dependence upon one another. See Grammar.

**CONJURATION,** magic words, characters, or ceremonies, whereby evil spirits, tempests, &c. are apposed to be raised, or driven away. The Romish priests pretend to expel devils, by preparing holy wa-

Some authors make the difference between conjuration and witchcraft to consist in this, that the former effects its end by prayers and invocation of God's name, &c. to compel the devil to do what is desired, so that the conjurer is supposed to be at war with the devil, and that evil spirit to act merely out of constraint: whereas the latter attains its end by an immediate application to the devil himself; and the devil's compliance is supposed to be the consequence of some compact between them, so that the devil and the witch have a good understanding together. Both thefe, again, differ from enchantment and forcery; in that these latter operate secretely and slowly by spells, charms, &c. without ever calling on the devil, or having any conference with him.

**CONN See CON.**

**CONNAUGHT,** one of the four provinces of Ireland, bounded on the east by that of Leinster, on the west by the ocean, on the north and north-west by part of the ocean and province of Ulster, and on the south by Munster. It is about 350 miles in length, and 84 in breadth. It has no rivers of any great note besides the Shannon. It has several convenient bays and creeks, and is fertile in many places. It had several dangerous bays, over-run with woods, which are now in some measure cleared away. This province produces abundance of cattle, sheep, deer, hawks, and honey; but the inhabitants being lazy, it is the least cultivated of all the four provinces. It contains 1 archbishopric, 5 bishoprics, 6 counties, 7 market-towns, 8 places of trade, 17 boroughs that send members to parliament, 47,356 houfe, 24 old caffles, besides fortresses that have been erected of late, and 330 parishes. The principal town is Galway.

**CONNADUS, CRYLON SUMACH:** A genus of the decandria order, belonging to the monadelphia class of plants; and in the natural method ranking with those of which the order is doubtvul. The stigma is simple, the capsule bivalved, uninocular, and monosperous. There is but one species, viz. *The monocarpus*. This is a native of India, and rifes with a ligneous stalk eight or ten feet high, which is hard, rigid, and covered with a black bark, and divides upward into two or three branches garnished with trifoliate leaves, having long footstalks placed alternate. It is propagated by cutting, and is to be treated in the same manner as other tender exotics.

**CONNECTICUT,** a large river which gives name to one of the five states of New England, (see the next article). It rises in a swamp on the height of land, in Lat. 45° 10 Long. 4° 8. After a steep course of eight or ten miles, it tumbles over four separate falls, and turning west keeps close under the hills which form the northern boundary of the vale through which it runs. The Amonoosuck and Issac rivers, two principal branches of Connecticut river, fall into it from the east, between the latitudes 44° and 45°. Between the towns of Walpole on the east, and Welfmifler on the west, side of the river, are the great Falls. The whole river, comprising between two rocks scarcely 30 feet asunder, foows with amazing rapidity into a broad baflion below. Over thes
These falls, a bridge 160 feet in length, was built in 1784, under which the highest floods may pass without detriment. This is the first bridge that was ever erected over this noble river. Above Deerfield in Massachusetts it receives Deerfield river from the west, and Miller's river from the east, after which it turns westly in a famous course to Fighting falls, and a little after tumbles over Deerfield falls, which are impassable by boats. At Windsor in Connecticut it receives Farmington river from the west, and at Hartford the tide. From Hartford it passes on in a crooked course, until it falls into Long Island Sound, between Saybrook and Lyme.

The length of this river, in a straight line, is nearly 300 miles. Its general course is several degrees west of south. It is from 80 to 100 rods wide, 120 miles from its mouth. At its mouth is a bar of sand which considerably obstructs the navigation. Ten feet water at full tides is found on this bar, and the same depth to Middleton. The distance of the bar from this place, as the river runs, is 36 miles. Above Middleton are several flats which fretch quite across the river. Only six feet water is found on the flats at high tide, and here the tide ebbs and flows but about eight inches. About three miles below Middleton the river is contracted to about 40 rods in breadth by two high mountains. Almost every where else the banks are low, and spread into fine meadows. In the spring floods, which generally happen in May, these meadows are covered with water. At Hartford the water sometimes rises 20 feet above the common surface of the river, and having all to pass through the abovementioned strait, it is sometimes two or three weeks before it returns to its usual bed. These floods add nothing to the depth of water on the bar at the mouth of the river; this bar lying too far down the river to Middleton. The distance of the bar from this place, as the river runs, is 36 miles. Above Middleton are the towns of Saybrook, Haddam, Middle-

don
cut.

Sturgeon, salmon, and shad, are caught in plenty Connecticut in their season, from the mouth of the river upwards, excepting sturgeon, which do not ascend the upper falls; besides a variety of small fish, such aspike, eel, perch, &c.

From this river are employed three brigs of 180 tons each, in the European trade; and about 60 sail from 60 to 150 tons, in the West India trade; besides a few fishermen, and 40 or 50 coating vessels.

Connecticut, one of the five states of New England in America; bounded on the north by Massachusetts; on the east by Rhode Island; on the south, by the found, which divides it from Long Island, and on the west, by the state of New York.

The divisional line between Connecticut and Massachusetts, as settled in 1713, was found to be about 72 miles in length. The line dividing Connecticut from Rhode Island was settled in 1728, and found to be about 45 miles. The sea coast, from the mouth of Pawcatuck river, which forms a part of the eastern boundary of Connecticut, in a direct southwardly line to the mouth of Byram river, is reckoned at about 90 miles. The line between Connecticut and New York runs from latitude 41° 40′ to latitude 42° 2′; 72 miles. Connecticut contains about 4674 square miles; equal to about 3,960,000 acres.

This state is watered by several fine rivers, the principal of which are, Connecticut, described in the preceding article, Housatonic, and the Thames. One branch of the Housatonic rises in Landborough, the other in Windsor, both in Berkshire county in Massachusetts. It passes through a number of pleasant towns, and empties into the Sound between Stratford and Milford. It is navigable 12 miles, to Derby. A bar of shells, at its mouth, obstructs its navigation for large vessels. In this river, between Salisbury and Canaan, is a cataract, where the water of the whole river, which is 150 yards wide, falls about sixty feet perpendicularly, in a perfectly white sheet. A copious mist arises, through which floating rainbows are seen in various places at the same time, exhibiting a scene exceedingly grand and beautiful.

The Thames empties in Long Island Sound at New London. It is navigable 14 miles, to Norwich Landing. Here it loses its name, an branches into Shetucket on the east, and Norwich or Little river on the west. The city of Norwich stands on the tongue of land between these rivers. Little river, about a mile from its mouth, has a remarkable and very romantic cataract. A rock 10 or 12 feet in perpendicular height, extends quite across the channel of the river. Over this the whole river pitches, in one entire sheet, upon an abed of rocks below. Here the river is compressed into a very narrow channel between two craggy cliffs, one of which towers to a considerable height. The channel descends gradually, is very crooked, and covered with pointed rocks. Upon these the water swiftly tumbles, foaming with the most violent agitation, 15 or 20 rods, into a broad bason which spreads before it. At the bottom of the perpendicular falls, the rocks are curiously excavated by the constant pouring of the water. Some of the cavities, which are all of a circular form, are five or six feet deep. The smoothness of the water above its descent—the regularity and beauty of the perpendicular fall—the tremendous
cut.
Connecticut. - Roughness of the other, and the craggy, towering cliff which impends the whole, present to the view of the spectator a scene indefinably delightful and majestic. On this river are some of the finest mill feats in New England, and those immediately below the falls, occupied by Lathrop's mills, are perhaps not excelled by any in the world. Across the mouth of this river is a broad, commodious bridge, in the form of a wharf, built at a great expense.

Shetucket river, the other branch of the Thames, four miles from its mouth, receives Quinnabog, which has its source in Brimfield in Massachusetts; thence passing through Strubridge and Dadvly in Massachusetts, it crosses into Connecticut, and divides Pomfret from Killingly, Canterbury from Plainfield, and Lisbon from Preston, and then mingles with Shetucket. In passing through this hilly country, it tumbles over many falls, and affords a vast number of mill feats. The source of the Shetucket is not far from that of Quinnabog. It has the name of Williamakt while passing through Stafford, and between Tolland and Willington, Coventry and Mansfield. Below Windham it takes the name of Shetucket, and empties as above. These rivers are fed by numberless brooks from every part of the adjacent country. At the mouth of Shetucket is a bridge of timber 124 feet in length, supported at each end by pillars, and held up in the middle by braces on the top, in the nature of a commodious bridge, entirely secure and commodious for large ships. New Haven harbour is greatly inferior to that of New London. It is a bay which sets up northerly from the found about four miles. Its entrance is about half a mile wide. It has very good anchorage, and two and a half fathoms at low water, and three fathoms and four feet at common tides. The whole of the sea coast is indented with harbours, many of which are safe and commodious, but are not sufficiently used to merit a description.

Connecticut, though subject to the extremes of heat and cold in their seasons, and to frequent sudden changes, is very healthful. As many as one in 46 of the inhabitants of Connecticut, who were living in 1774, were upwards of 70 years old. From accurate calculation it is found, that about one in eight live to the age of 70 years and upwards; one in 13 to the age of 80 years, and one in about 30 to the age of 90.

In the maritime towns the weather is variable, according as the wind blows from the sea or land. As you advance into the country, the sea breezes have less effect upon the air, and consequently the weather is less variable. The shortest day is 8 hours and 58 minutes, and the longest 15 hours. The winds, in winter, are often extremely severe and piercing, occasioned by the great body of snow which lies concealed from the dissolving influence of the sun in the immense forests north and northwest.

2 Harbours.

The two principal harbours are at New London and New Haven. The former opens to the south. From the light-house, which stands at the mouth of the harbour, to the town, is about three miles; the breadth is three quarters of a mile, and in some places more. The harbour has from five to six fathoms water—a clear bottom—tough ooze, and as far as one mile above the town is entirely secure and commodious for large ships. New Haven harbour is greatly inferior to that of New London. It is a bay which sets up northerly from the found about four miles. Its entrance is about half a mile wide. It has very good anchorage, and two and a half fathoms at low water, and three fathoms and four feet at common tides. The whole of the sea coast is indented with harbours, many of which are safe and commodious, but are not sufficiently used to merit a description.

3 Climate, soil, and productions.

Connecticut, though subject to the extremes of heat and cold in their seasons, and to frequent sudden changes, is very healthful. As many as one in 46 of the inhabitants of Connecticut, who were living in 1774, were upwards of 70 years old. From accurate calculation it is found, that about one in eight live to the age of 70 years and upwards; one in 13 to the age of 80 years, and one in about 30 to the age of 90.

In the maritime towns the weather is variable, according as the wind blows from the sea or land. As you advance into the country, the sea breezes have less effect upon the air, and consequently the weather is less variable. The shortest day is 8 hours and 58 minutes, and the longest 15 hours. The winds, in winter, are often extremely severe and piercing, occasioned by the great body of snow which lies concealed from the dissolving influence of the sun in the immense forests north and northwest.

The clear and serene temperature of the sky, however, makes amends for the severity of the weather, and is favourable to health and longevity. Connecticut is generally broken land, made up of mountains, hills, and valleys; and is exceedingly well watered. Some small parts of it are thin and barren. It lies in the fifth and sixth northern climates, and has a strong fertile soil. Its principal productions are Indian corn, rye, wheat in many parts of the state, oats and barley, which are heavy and good, and of late buck-wheat—flax in large quantities—some hemp, potatoes of several kinds, pumpkins, turnips, peas, beans, &c. and fruits of all kinds, which are common to the climate. The soil is very well calculated for pasture and mowing, which enables the farmers to feed large numbers of neat cattle and horses. Actual calculation has evinced, that any given quantity of the best mowing land in Connecticut, produces about twice as much clear profit as the same quantity of the best wheat land in the state of New York. Many farmers, in the eastern part of the state, have lately found their advantage in raising mules, which are carried to the ports of Norwich and New London to the West India islands, and yield a handsome profit. The beef, pork, butter, and cheese of Connecticut, are equal to any in the word.

The trade of Connecticut is principally with the West India islands, and is carried on in vessels from 60 to 140 tons. The exports consist of horsetires, mules, oxen, oak flaves, hoops, pine boards, oak planks, beans, Indian corn, fish, beef, pork, &c. Horsetires, live cattle, and lumber, are permitted in the Dutch, Danish, and French ports. Beef and fish are liable to such heavy duties in the French islands, as that little profit arises to the merchant who sends them to their ports. Pork and flour are prohibited. As the ordinance making free ports in the French West India islands extends to all foreigners, the price of molasses and other articles, has been greatly enhanced by the English purchases for Canada and Nova Scotia; so that the trade of Connecticut with the French West India islands is not profitable. Cotton, cocoa, indigo and fugar, are not permitted to be brought away by Americans. The severity with which these prohibitory laws are administered is such, as that these articles cannot be smuggled.

Connecticut has a large number of coasting vessels employed in carrying the produce of the state to other states--To Rhode Island, Massachusetts, and New Hampshire, they carry pork, wheat, corn, and rye. To North and South Carolina and Georgia, butter, cheese, salted beef, cider, apples, potatoes, hay, &c. and receive in return rice, indigo, and money. But as New York is nearer, and the state of the market always well known, much of the produce of Connecticut, especially of the western parts, is carried there; particularly pot and pearl ashes, flax-seed, beef, pork, cheese, and butter, in large quantities. Most of the produce of Connecticut river, from the parts of Massachusetts, New Hampshire, and Vermont, as well as of Connecticut, which are adjacent, goes to the same market. Considerable quantities of the produce of the eastern parts of the state are marketed at Boston and Providence.

The value of the whole exported produce and commodities from this state, before the year 1774, was then estimated at about £200,000 lawful money annually,
In 1774, the number of shipping in Connecticut was 180; their tonnage 10,317; seafaring men 1,623; besides upwards of 20 sail of coasting vessels, which employed about 90 seamen. This state has not yet fully recovered the confusion in which it was involved by the late war; so that the number of shipping, &c. has not, at any period since 1774, been ascertained with accuracy. It is probable, however, considering the losses sustained by the war, the decay of the ship-building business, and the number of unfortunate shipwrecks, and losses by hurricanes in the West Indies, that the shipping and seamen are not now so numerous as in 1774.

The number of shipping from the port of New London employed in 1788 in the European and West India trade, was four ships, one sloop, 54 brigantines, 32 schooners, and 45 sloops. The number of horses and cattle exported from the district round New London, from the 10th of January 1787 to the 10th of January 1788, was 6917; besides jack-asses imported and exported, not included. From 1786 to 1787, the number was 6671; so that the last year exceeded the other 246. From March 1787 to January 1788, 1454 horses, 700 oxen, and 23 cows, were exported from the port of Middleton.

The farmers in Connecticut and their families are mostly clothed in plain, decent, home-spun cloth. Their linens and woollens are manufactured in the family way; and although they are generally of a coarser kind, they are of a stronger texture, and much more durable than those imported from France and Great Britain. Many of their clothes are fine and handsome.

In New Haven is a linen manufacture which flourishes, and one for cotton is about to be established. In East Hartford is a glass-work, a snuff and powder mill, and an iron-work and flitting-mill. Iron works are established also at Salisbury, Norwich, and other parts of the state. At Stafford is a furnace at which is made large quantities of hollow ware and other ironmongery, sufficient to supply the whole state. Paper is manufactured at Norwich, Hartford, New Haven, and in Litchfield county. Nails of every size are made in almost every town and village in Connecticut; so that considerable quantities can be exported to the neighbouring states, and at a better rate than they can be had from Europe. Ironmongery, hats of the best kinds, candles, leather, shoes, and boots, are manufactured in this state. We must not omit to mention wooden dishes and other wooden ware, which are made in vast quantities in Suffield and some few other places, and sold in almost every part of the eastern states. Oil-mills, of a new and very ingenious construction, have been erected in several parts of the state.

It appears from experiments made formerly in this state, that a bushel of sunflower seed yields a gallon of oil, and that an acre of ground planted with the seed at three feet a part, will yield between forty and fifty bushels of the seed. This oil is as mild as sweet oil, and is equally agreeable with tallow, and as a medicine. It may, moreover, be used with advantage in paints, varnishes, and ointments. From its being manufactured in our own country, it may always be procured and used in a fresh state. The oil is pressed from the seed in the same manner that cold drawn linseed oil is obtained from flax-seed, and with as little trouble. Sweet olive oil sells for fix shillings a quart. Should the oil of the sunflower sell for only two-thirds of that price, the produce of an acre of ground, supposing it to yield only 40 bushels of the seed, will be L. 32, a sum far beyond the produce of an acre of ground in any kind of grain. The seed is raised with very little trouble, and grows in land of moderate fertility. It may be gathered and shelled, fit for the extraction of the oil, by women and children.

Connecticut is divided into eight counties, viz. Hartford, New London, New Haven, New York, Waterbury, Fairfield, Windham, and Litchfield, Middlesex, and Tolland. The counties are subdivided into upwards of 80 townships; each of which is a corporation, invested with power to hold lands, choose their own town-officers, to make prudential laws, the penalty of transgression not to exceed 20s. and to choose their own representatives to the general assembly. The townships are generally divided into two or more parishes, in each of which is one or more places for public worship.

Connecticut is the most populous, in proportion to its extent, of any of the thirteen states. It is laid out in small farms from 50 to 300 or 400 acres each, which are held by the farmers in fee simple; and are generally cultivated as well as the nature of the soil will admit. The state is chequered with innumerable roads or highways, crossing each other in every direction. A traveller in any of these roads, even in the most unsettled parts of the state, will seldom pass more than two or three miles without finding a house or cottage, and a farm under such improvements as to afford the necessaries for the support of a family. The whole state resembles a well-cultivated garden; which, with that degree of industry that is necessary to happiness, produces the necessaries and conveniences of life in great plenty.

In 1786, the number of inhabitants in Connecticut was 136,611; in 1774, there were 167,864 souls. In 18 years, the increase was 67,245; from 1774 to 1792, the increase was but 11,924 persons. This comparatively small increase of inhabitants may be factually accounted for from the destruction of the war, and the numerous emigrations to Vermont, the western parts of New Hampshire, and other states.

The inhabitants are almost entirely of English descent. There are no Dutch, French, or Germans, and very few Scotch or Irish people, in any part of New England.

In addition to what has been already said on the subject of Connecticut, particularly under New England, it may be observed, that the people of Connecticut are remarkably fond of &c. having all their disputes, even those of the most trivial kind, settled according to law. The prevalence of this litigious spirit affords employment and support for a numerous body of lawyers. The number of actions entered annually upon the several dockets in the state, justify the above observations. That party spirit, however, which is the bane of political happiness, has not raged with such violence in this state as in Massachusetts and Rhode-Island. Public proceedings have been conducted, generally, and especially of late,
sylvania are well informed in regard to their rights, and judicious in the methods they adopt to secure them. 

The clergy, who are numerous, and, as a body, very respectable, have hitherto preserved a kind of aristocratical balance in the very democratical government of the state; which has happily operated as a check upon the overbearing spirit of republicanism. It has been lamented that the unhappy religious disputes which have too much prevailed among some of the clergy, and the too great attention that others have paid to their temporal concerns, to the neglect of their flocks, and an inattention to the qualifications of those who have been admitted to the sacred office, have, heretofore, considerably diminished their influence. It is a pleasing circumstance that the rage for theological disputation is abating; and greater strictness is observed in the admission of candidates to the ministry. Their influence is on the increase; and it is no doubt to be attributed, in part, to their increasing influence, that an evident reformation in the manners of the people of this state has taken place. In regard to learning and abilities, the clergy, at the present day, are equal to their predecessors at any former period.

8 Religion. As to ecclesiastical government and discipline, each church is a separate jurisdiction, and claims authority to choose their own minister, to exercise government, and to enjoy gospel ordinances within itself. The churches, however, are not independent of each other; they are associated for mutual benefit and convenience. The associations have power to licence candidates for the ministry, to consult for the general welfare, and to recommend measures to be adopted by the churches, but have no authority to enforce them. When disputes arise in churches, councils are called, by the parties, to settle them; but their power is only advisory. There are as many associations in the state as there are counties; and they meet twice in a year. These are all combined in one general association, who meet annually. All religions that are consistent with the peace of society are tolerated in Connecticut; and a spirit of liberality and catholicism is increasing. There are very few religious sects in this state; the bulk of the people are congregationalists. Besides these there are episcopalian and baptists; and formerly there was a society of Sandimanians at New-Haven; but they are now reduced to a very small number. The episcopalian churches are respectable, and are under the superintendence of a bishop. There were 29 congregations of the baptists in 1784. These congregations, with those in the neighbouring states, meet in associations, by delegation, annually.

There are a great number of very pleasant towns, both maritime and inland, in Connecticut. It contains five incorporated towns or cities. Two of these, Hartford and New Haven, are the capitals of the state. The general assembly is held at the former in May, and at the latter in October, annually. See Hartford and New Haven.

10 Colleges, academies, and schools. In no part of the world is the education of all ranks of people more attended to than in Connecticut. Almost every town in the state is divided into districts, and each district has a public school kept in its greater or its part of every year. Somewhat more than one third of the monies arising from a tax on the polls and rateable estate of the inhabitants, is appropriated to the support of schools, in the several towns, for the education of children and youth. The law directs that a grammar school shall be kept in every county town throughout the state. There is a grammar school at Hartford, and another at New Haven, supported by a donation of governor Hopkins. This venerable and benevolent gentleman, in his last will, dated 1657, left in the hands of Theophilus Eaton, Esq.; and three others, a legacy of L. 1324, "as an encouragement, in these foreign plantations, of breeding up hopeful youths both at the grammar school and college." In 1664, this legacy was equally divided between New Haven and Hartford; and grammar schools were created, which have been supported ever since.

At Greenfield there is a respectable academy, under the care and instruction of the Rev. Dr. Dwight. At Plainfield is another, under the care of the Rev. Mr. Benedict. This academy has flourished for several years, and furnished a number of students for Yale and Dartmouth colleges. At Norwich and Windham, likewise, are academies furnished with able instructors; each of these academies have 60 or 70 scholars.

Yale College was founded in 1700, and remained at Killingworth until 1707—then at Saybrook until 1716, when it was removed and fixed at New Haven. See New Haven.

On the bank of Connecticut river, two miles from Mines, middleton, is a lead mine, which was wrought during the war, at the expense of the state, and was productive. It is too expensive to work in time of peace. Copper mines have been discovered and opened in several parts of the state, but have proved unprofitable, and are much neglected. Iron mines are numerous and productive. Steel ore has been found in the mountains between Woodbury and New Milford. Tales of various kinds, white, brown, and chocolate coloured crystals, zink or spelter, a semimetal, and several other foils and metals, have been found in Connecticut.

All freeholders in the state are required by law to give in lots of their polls and rateable estate, to per­levy­ing­re­ lev­ons­in­t­ town­s­to­ receive­them.­ On­or­before­the­20th­of­August­annually. These are valued according to law, arranged in proper order, and sent to the general assembly annually in May.

The sum total of the lift of the polls and rateable estate of the inhabitants of Connecticut, as brought into the general assembly in May 1787, were as follows:

<table>
<thead>
<tr>
<th>Description</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>Sum total of the single lift</td>
<td>L. 1,484,901 6 43</td>
</tr>
<tr>

</tr>
</tbody>
</table>

On this sum taxes are levied, so much on the pound, according to the sum proposed to be raised. A tax of two-pence on the pound would raise L. 12,782, 45. The ordinary annual expense of government before the war amounted to near L. 4000 Sterling, exclusive of that which was appropriated to the support of schools. The expences have since increased.
At Stafford is a medicinal spring, which is said to be a sovereign remedy for scrofulous, cutaneous, and other disorders. At Guilford is a spring, whose water, it is said, when separated from the fountain, will evaporate even when put into a bottle and tightly corked.

It is difficult to say what is the constitution of this state. Contended with the form of government which originated from the charter of Charles II., granted in 1662, the people have not been disposed to run the hazard of framing a new constitution since the declaration of independence. They have tacitly adopted their old charter as the ground of civil government, so far as it is applicable to an independent people.

Agreeable to this charter, the supreme legislative authority of the state is vested in a governor, deputy-governor, twelve assistants or counsellors, and the representatives of the people, styled the General Assembly. The governor, deputy governor, and assistants, are annually chosen by the freemen in the month of May. The representatives (their number not to exceed two from each town) are chosen by the freemen twice a year, to attend the two annual sessions, on the second Thursdays of May and October. This assembly has power to create judicatures, for the trial of causes civil and criminal, and to ordain and establish laws for settling the forms and ceremonies of government. By these laws the general assembly is divided into two branches, called the upper and lower houses. The upper house is composed of the governor, deputy-governor, and assistants; the lower house, of the representatives of the people. No law can pass without the concurrence of both houses. The judges of the superior court hold their offices during the pleasure of the general assembly. The judges of the county courts, and justices, are annually appointed. Sheriffs are appointed by the governor and council, without limitation of time. The governor is captain-general of the militia, the deputy-governor lieutenant-general. All other military offices are appointed by the assembly, and commissioned by the governor.

The mode of electing the governor, deputy governor, assistants, treasurer, and secretary, is as follows: The freemen in the several towns meet on the Monday next after the first Tuesday in April, annually, and give in their votes for the persons they choose for the said offices respectively, with their names written on a piece of paper, which are received and sealed up by a constable in open meeting, the votes for each office by themselves, with the name of the town and office written on the outside. Thrice votes, thus sealed, are sent to the general assembly in May, and there counted by a committee from both houses. All freemen are eligible to any office in government. In choosing assistants, twenty persons are nominated, by the vote of each freeman, at the freemen's meeting for choosing representatives in September annually. These votes are sealed up, and sent to the general assembly in October, and are there counted by a committee of both houses, and the twenty persons who have the most votes stand in nomination; out of which number the twelve who have the greatest number of votes, given by the freemen at their meeting in April, are in May declared assistants in the manner abovementioned. The qualifications of freemen are, maturity in years, quiet and peaceable behaviour, a civil conversation, and the freedom to be at the value of forty shillings per annum, or forty pounds personal estate in the town, certified by the select men of the town; it is necessary also that they take the oath of fidelity to the state. Their names are enrolled in the town clerk's office, and they continue freemen for life, unless disfranchised by sentence of the superior court, on conviction of misdemeanor.

The courts are as follows: The justices of the peace, of whom a number are annually appointed in each town by the general assembly, have authority to hear and determine civil actions, where the demand does not exceed four pounds. If the demand exceeds forty shillings, an appeal to the county is allowed. They have cognizance of small offences, and may punish by fine not exceeding forty shillings, or whipping not exceeding ten stripes, or sitting in the stocks.

There are eight county courts in the state, held in the several counties by one judge and four justices of the quorum, who have jurisdiction of all criminal cases, arising within their respective counties, where the punishment does not extend to life, limb, or banishment. They have original jurisdiction of all civil actions which exceed the jurisdiction of a justice. Either party may appeal to the superior court, if the demand exceeds twenty pounds, except on bonds or notes warded by two witnesses.

There are several courts of probate in each county, consisting of one judge. The peculiar province of this court is, the probate of wills, granting administration of intestate estates, ordering distribution of them, and appointing guardians for minors, &c. An appeal lies from any decree of this court to the superior court.

The superior court consists of five judges. It has authority in all criminal cases extending to life, limb, or banishment, and other high crimes and misdemeanors, to grant divorces, and to hear and determine all civil actions brought by appeal from the county courts, or the court of probate, and to correct the errors of all inferior courts. This is a circuit court, and has two sessions in each county annually. The superior and county courts try matters of fact by a jury, or without if the parties will agree.

There is a supreme court of errors, consisting of the deputy governor and the twelve assistants. Their sole business is to determine writs of error brought on judgments of the superior court, where the error complained of appears on the record. They have two sessions annually, viz. on the Tuesdays of the weeks preceding the sessions of the general assembly.

The county court is a court of chancery, empowered to hear and determine cases in equity, where the matter in demand does not exceed one hundred pounds. The inferior court has cognizance of all cases where the demand exceeds that sum. Errors may be brought from the county to the superior court, and from the superior court to the supreme court of errors, on judgment in cases of equity as well as of law.

The general assembly only have power to grant pardons and reprieves, to grant commissions of bankruptcy, or protect the persons and estates of unfortunate debtors.
The common law of England, so far as it is applicable to this country, is considered as the common law of this state. The reports of adjudication in the courts of king's bench, common pleas, and chancery, are read in the courts of this state as authorities; yet the judges do not consider them as conclusively binding, unless founded on solid reasons which will apply in this state, or sanctioned by concurrent adjudications of their own courts.

The feudal system of descent was never adopted in this state. All the real estate of intestates is divided equally among the children, males and females, except that the eldest son has a double portion. And all estates given in tail, must be given to some person then in being, or to their immediate issue, and shall become fee-simple estates to the issue of the first donee in tail. The widow of an intestate is entitled to a third part of the personal estate for ever, and to her dower, or third part of the houses and lands belonging to the intestate at the time of his death, during her life.

The practice of law in this state has more simplicity, but less precision, than in England. Attorneys and judges are impowered to issue writs through the state, and justices through their respective counties. In these writs, the substance of the complaints or the declarations must be contained; and if neither of the parties show good reason for delay, the causes are heard and determined the same term to which the writs are returnable. Few of the fictions of law, so common in the English practice, are known in this state. The plaintiff always has his election to attach or summon the defendant. Attorneys are admitted and qualified by the county courts. Previous to their admission to the bar, they must study two years with a practising attorney in the state, if they have had a college education, and three years if they have not; their morals must be good, and their character unblemished; and they must sustain an examination by the attorneys of the court of the county where they are admitted, and be by them recommended to the court. When admitted to the county court, they can practice, without other qualifications, in any court in the state.

There are upon an average about thirteen attorneys to each county, one hundred and four in the state; a very great proportion for the real exigencies of the people. Yet from the literal spirit of the citizens, the most of them find employment and support. There is no attorney general, but there is one attorney to the state in each county.

The present territory of Connecticut, at the time of the first arrival of the English, was possessed by the Pequot, the Mohegan, Podunk, and many other smaller tribes of Indians.

The Pequots were numerous and warlike. Their country extended along the sea coast from Pankatuck to Connecticut river. About the year 1630, this powerful tribe extended their conquests over a considerable part of Connecticut, over all Long Island, and part of Narragansett. Saffacs, who was the grand monarch of the whole country, was king of this nation. The seat of his dominion was at New London; the ancient Indian name of which was Pequots.

The Mohegans were a numerous tribe, and their territory extensive. Their ancient claim, which was surveyed and settled by commissioners from queen Anne Connecticu```
The English thus obtained the country east of the Connecticut, Dutch settlements, by right of conquest. The pursuit of the Indians led to an acquaintance with the lands on the sea coast from Saybrook to Fairfield. It was reported to be a very fine country. This favourable report, induced Meliss Eaton and Hopkins, two very respectable London merchants, and Mr Davenport, a man of distinguished piety and abilities, with their company, who arrived this year (1637) from London, to think of this part of the country as the place of their settlement. Their friends in Massachusetts, forry to part with so valuable a company, dissuaded them from their purpose. Influenced, however, by the promising prospects which the country afforded, and flattering themselves that they should be out of the jurisdiction of a general governor, with which the country was from time to time threatened, they determined to proceed. Accordingly, in March 1638, with the consent of their friends on Connecticut river, they settled at New Haven, and laid the foundation of a flourishing colony, of which Quinipiak, now New Haven, was the chief town. The first public worship, in this new plantation, was attended on Lord's day, April 18, 1638, under a large spreading oak. The Rev. Mr Davenport preached from Matt. iii. 1 on the temptations of the wilderness. Both colonies, by voluntary compact, formed themselves into distinct commonwealths, and remained so until their union in 1662.

In 1639, the three towns on Connecticut river, already mentioned, finding themselves without the limits of any jurisdiction, formed themselves into a body politic, and agreed upon articles of civil government. These articles were the foundation of the Connecticut charter, which was granted in 1662. The fabric of the articles, so far as they respect the holding of assemblies, the time and manner of electing magistrates and other civil officers (except that in the old confederation no person was to be chosen governor more than once in two years), and the extent of legislative powers, was transferred into, and established in said charter.

The first church was gathered in New Haven this year, and consisted of seven members. These were chosen by the settlers after Mr Davenport had preached from the words of Solomon, ' Wisdom had builded her house, the hath hewed out her seven pillars.' These men were indeed the pillars of the church, to whom the rest were added as they became qualified. They were also the court to try all civil actions.

The first settlers in New Haven had all things common; all purchases were made in the name and for the use of the whole plantation; and the lands were apportioned out to each family according to their number and original stock.

At their first election, in October 1639, Mr Theophilus Eaton was chosen governor for the first year. Their elections, by agreement, were to be annual, and the word of God their only rule in conducting the affairs of government in the plantation.

In 1643, the articles of confederation between the four New England colonies, mentioned under the article New England, were unanimously adopted by the colonies of New Haven and Connecticut.

The English settlement on Delaware, which was under
under the jurisdiction of New Haven, was surprized 
by the Swedes, and the people put in irons, under a 
false pretence that they were entering into a conspica 
y with the Indians to extirpate the Swedes.

The general court of New Haven, this year, esta-
blished it as a fundamental article not to be disputed, 
that none be admitted as free burgesses but church 
members, and that none but such should vote at elec-
tions. They also ordained, that each town choose 
from among themselves judges (church members) to be 
a court, to have cognizance of all civil actions not ex-
ceeding twenty pounds; and of criminal causes, where 
the punishment was, flogging in the stocks, whipping, 
and fining not exceeding five pounds. There was li-
berty of appeal from this to the court of magistrates. 
The court of magistrates consisted of all the magis-
trates throughout the colony, who were to meet twice 
year at New-Haven, for the trial of all capital 

The court of magistrates consisted of all the magis-
trates throughout the colony, who were to meet twice 
year at New-Haven, for the trial of all capital cau-

Six made a quorum. The general court was to 
consist of the governor, deputy-governor, magistrates, 
and two representatives from each town. The annual 
election of officers of government was at this time es-
tablised, and has ever since continued.

The unsettled state of the colony had hitherto pre-
vented their establishing a code of laws. To supply 
this defect, the general court ordered, 'That the ju-
dicial laws of God, as they are delivered to Moses, 
and as they are a fence to the moral, being neither 
typical nor ceremonial, nor having any reference to 
Canaan, shall be accounted of moral equity and gen-
erally bind all offenders, and be rule to all the courts 
in this jurisdiction in their proceedings against offen-
ders, until they be branched out into particulars here-
after.'

About this time a war broke out between the Mo-
hegan and Narragansett Indians. A personal quarrel 
between Myantonomo, sachem of the Narragansetts, 
and Uncas, sachem of the Mohegans, was the founda-
tion of the war. Myantonomo raised an army of 900 
warriors, and marched towards the Mohegan country. 
Uncas by his spies received timely notice of their ap-
proach. His seat of residence was in some part of 
Norwich. He quickly collected 600 of his bravest 
warriors, and told them, 'The Narragansetts must 
not come into our town; we must meet them.' They 
accordingly marched about three miles to a large plain, 
where the two armies met, and halted within bow-shot 
of each other. A parley was proposed by Uncas, and 
agreed to by Myantonomo. The sachems met, and 
Uncas addressed his enemy as follows. 'You have a 
great many brave men: so have I. You and I have 
quarrelled; but these warriors, what have they done? 
Shall they die to avenge a private quarrel between us? 
No. Come like a brave man, as you pretend to be, 
and let us fight. If you kill me, my men shall be 
yours; if I kill you, your men shall be mine.' Myan-
tonomo replied: 'My men came to fight, and they 
shall fight.' Uncas, like an experienced warrior, 
aware of the result of the conference from the superior 
force of his enemy, had previously signified to his men, 
that if Myantonomo refused to fight him in single 
combat, he would immediately fall, which was to be 
the signal for them to begin the attack. Therefore as Myantonomo had finishted his laconic 
speech, Uncas dropped; his men instantly obeyed the 
signal, and poured in a shower of arrows upon the un-
suspecting Narragansetts, and rushing on with their 
horrid yells and savage howls, put them to flight. 
Many were killed on the spot, the rest were closely 
pursued, and some were precipitately driven down 
craggy precipices, and dashed in pieces. At a place 
called, from this event, Sachem's Plains, Uncas over-
took and seized Myantonomo by the shoulder, and 
with a hoop called in his men, and the battle ceased. 

Loudly what to do 
with the royal prifoner, Uncas and his warriors, in 
council, determined to carry him to the governor and 
council at Hartford, and be advised by them. Thither 
he was accordingly conducted. The governor having 
adviced with his council, told Uncas, that the English 
were not then at war with the Narragansetts, and of 
course that it was not proper for them to intermeddle 
in the matter. Uncas was left to do with him as he pleased. 
Myantonomo was conducted back to the plain where 
he was taken, and put to death by Uncas himself. 
The tragic scene did not end with his death. Uncas, 
without the manner of the Indians, with hatchet's cut off a large piece of flesh from the shoulder of his 
slaughtered enemy, broiled and eat it, saying, with 
an air of savage triumph, 'It is the sweetest meat I 
ever eat. It makes me have a stout heart.' His body 
was afterwards buried, and a pillar erected over it, 
the remains of which are visible to this day.

The Narragansetts were greatly enraged at the death 
of their prince, and resolved to take vengeance on the 
Mohegans. The united colonies interposed to pre-
vant a war between them, but in vain. The Narra-
gansetts reluctantly declared, they would continue the 
war until they had Uncas's head. But as Uncas had 
ever been a friend to the English, they joined him a-
gainst his enemies, and were victorious. Such, how-
ever, was the enmity of the Narragansetts to the Eng-
lish, that they afterwards sent some of their men to 
Uncas, with large presents, to induce him to join with 
them in a war with the colonies. Uncas replied, 
"Go tell your king that I will go to Norwich, and 
advice with Major John Mason and Mr. Fitch; if they 
tell me to join him and fight against the English, I 
will join him." In the war that happened soon after, 
Uncas afflicted the English, and the Narragansetts were 
shamed, and never after were formidable.

In consideration of the successes and increase of the 
New England colonies, and that they had been of no 
charge to the nation, and in prospect of their being 
in future very serviceable to it, the English parlia-
ment, March 17, 1643, granted them an exemption 
from all customs, subsidies, and other duties, until 

In 1644, the Connecticut adventurers purchased of 
Mr. Fenwick, agent for Lord Say and Seal, and Lord 
Brook, their right to the colony of Connecticut, for 
L. 1600.

The history of Connecticut is marked with traces 
of the same spirit which appears to be cha-
acteristic of the Massachusetts, in different ages 
of their history. Indeed, as Massachusetts was the flock 
whence Connecticut proceeded, this is to be expect-
ed.

The colonies of Connecticut and New Haven, from 
their first settlement, increased rapidly; tracts of land
Connecticut were purchased of the Indians, and new towns settled from Stamford to Stonington, and far back into the country, when, in 1661, Major John Mason, as agent for the colony, bought of the natives all lands which had not before been purchased by particular towns, and made a public surrender of them to the colony, in the presence of the general assembly. Having done these things, the colonies petitioned King Charles II. for a charter, and their petition was granted. His Majesty, on the 23d of April 1662, ilixed his letters patent under the great seal, ordaining that the colony of Connecticut should for ever hereafter be one body corporate and politic, in fact and in name, confirming to them their ancient grant and purchase, and fixing their boundaries as follows, viz. "All that part of his patent remaining the corporate and politic, in them their ancient

Such was the ignorance of the Europeans respecting the geography of America, when they first assumed the right of giving away lands which the God of nature had long before given to the Indians, that their patents extended they knew not where, many of them were of doubtful construction, and very often covered each other in part, and have produced innumerable disputes and miscarriages in the colonies, some of which are not settled to this day. Connecticut confirmed her charter literally, and palling over New York, which was then in possession of the subjects of a Christian prince, claimed, in latitude and breadth mentioned therein, to the South Sea. Accordingly purchases were made of the Indians, on the Delaware river, west of the western bounds of New York, and within the supposed limits of Connecticut charter, and settlements were made thereon by people from, and under the jurisdiction of Connecticut. The charter of Pennsylvania, granted to William Penn, in 1681, covered these settlements. This laid the foundation for a dispute, which for a long time was maintained with warmth on both sides. The matter was at last submitted to gentlemen chosen for the purpose, who decided the dispute in favor of Pennsylvania. Many, however, still affect the justice of the Connecticut claim. The state of Connecticut has lately ceded to Congress all their lands west of Pennsylvania, except a reserve of 20 miles square. This cession Congress have accepted, and thereby indubitably established the right of Connecticut to the reserve.

The colony of New Haven, though unconnected with the colony of Connecticut, was comprehended within the limits of their charter, and, as they concluded, within their jurisdiction. But New Haven renounced against their claim, and refused to unite with them until they should hear from England. It was not until the year 1665, when it was believed that the king's commissioners had a design upon the New England Charters, that these two colonies formed a union, which has ever since amicably subsisted between them.

In 1672, the laws of the colony were revived, and the general court ordered them to be printed; and also, that "every family should buy one of the law books; such as pay in silver, to have a book for 12d. such as pay in wheat, to pay a peck and half a book; and such as pay in peafe, to pay 2s. a book, the pease at 3s. the bushel." Perhaps it is owing to this early and universal spread of law books, that the people of Connecticut are to this day fo fond of the law. In 1750, the laws of Connecticut were again revived, and published in a small folio volume of 258 pages. Dr. Douglass observes, that they were the most natural, equitable, plain, and concise code of laws for plantations hitherto extant." There has been a revision of them since the peace, in which they were greatly and very judiciously simplified.

The years 1675 and 1676 were distinguished by the wars with Philip and his Indians, and with the Narragansetts, by which the colony was thrown into great distress and confusion. The inroads of the enraged savages were marked with cruel murders, and with fire and devastation.

In 1664, the charter of Massachusetts bay and Plymouth were taken away, in consequence of their warrant, which had been inflicted against them. The charter of Connecticut would have shared the same fate, had it not been for Wadsworth, Esq.; who, having very artfully procured it when it was on the point of being delivered up, buried it under an oak tree in Hartford, where it remained until all danger was over, and then was dug up and reaffirmed.

Connecticut has ever made rapid advances in population. There have been more emigrations from this than from any of the other states, and yet it is at present full of inhabitants. This increase, under the divine benediction, may be ascribed to several causes. The bulk of the inhabitants are industrious, frugulous husbandmen. The farmers furnish them with all the necessaries, most of the conveniences, and but few of the luxuries of life. They are generally temperate, and, if they choose, can subsist with as much independence as is consistent with happiness. The subsistence of the farmer is substantial, and does not depend on incidental circumstances, like that of most other professions. There is no necessity of serving an apprenticeship to the husfint, nor of a large stock of money to commence it to advantage. Farmers, who deal much in barter, have less need of money than any other class of people. The ease with which a comfortable subsistence is obtained, induces the husbandman to marry young. The cultivation of his farm makes him strong and healthful. He toils cheerfully through the day—eats the fruit of his own labour with a gladsome heart—at night devoutly thanks his bountiful God for his daily blessings, and when his end is come, his sleep is sweet. Such circumstances as these have greatly contributed to the amazing increase of inhabitants in this state.

Besides, the people live under a free government, and have no fear of a tyrant. There are no overgrown estates, with rich and ambitious landlords, to have an undue and pernicious influence in the election of civil office. Property is equally enough divided, and must continue
A man who wishes to be chosen into office, he who has the most merit, not he who has the most money, is generally chosen into public office. As in instances of this, it is to be observed, that many of the citizens of Connecticut, from the humble walks of life have arisen to the first offices in the state, and filled them with dignity and reputation. That safe business of electioneering, which is so directly calculated to introduce wicked and designing men into office, is yet but little known in Connecticut. A man who wishes to be chosen into office, acts wisely for that end, when he keeps his desires to himself.

A thirst for learning prevails among all ranks of people in the state. More of the young men in Connecticut, in proportion to their numbers, receive a public education, than in any of the states. Dr Franklin and other literary characters have honoured this state by saying, that it is the Athens of America.

The revolution, which so essentially affected the governments of most of the colonies, produced no very perceptible alteration in the government of Connecticut. While under the jurisdiction of Great Britain, they elected their own governors, and all subordinate civil officers, and made their own laws in the same manner and with as little control as they now do. Connecticut has ever been a republic, and perhaps as perfect and as happy a republic, as has ever existed. While other states, more monarchical in their government and manners, have been under a necessity of undertaking the difficult task of altering their old, or forming new constitutions, and of changing their monarchical or republican manners. Connecticut has uninterruptedly proceeded in her old track, both to government and manners; and by these means has avoided those convulsions which have reared other states into violent parties.

Connection, connexion, the relation or dependence of one thing upon another.

Connection, of connexion, in the drama, consists in the joining of the several scenes together. The connection is said to be observed, when the scenes of an act succeed one another immediately, and are so joined as that the stage is never left empty.

Connectives, in grammar, one of the four species under which, according to Mr Harris, all words may be included. They are of two kinds; and as they connect sentences or words, are called by the different names of conjunctions and prepositions. See Grammar.

Convenient values, in anatomy, those wrinkles, cellulose, and vacuoles, which are found in the inside of the two intertines ilium and jejunum. See Anatomy, No. 92. et seq.

Connosseur, a French term, of late used in English; it literally denotes a person well versed in any thing; being formed of the verb connître, to know, understand. Hence it comes to be used in our language for a critic, or a person who is a thorough judge or master in any way, particularly in matters of painting and sculpture.

Connor (Bernard), a learned physician, was born in the county of Kerry, in Ireland, about the year 1666. Having determined to apply himself to the study of physic, he went to France, and resided sometime in the university of Montpellier. Afterward he went to Paris; where he obtained great skill in medicine, anatomy, and chemistry. From thence he traveled to Venice, with the two sons of the high-chancellor of Poland; and then taking a tour through great part of Germany, went to Warsaw, where he was made physician to king John Sobieski. In 1695, he came to England, read a course of lectures in London and Oxford, and became member of the Royal Society and College of Physicians; afterwards, being invited to Cambridge, he read public lectures there, and made various experiments in chemistry. He has rendered himself memorable for a philosophical and medical treatise in Latin, entitled, Evangelium Reditus, i.e. "the Physician's Gospel," tending to explain the miracles performed by Christ as natural events, upon the principles of nature philosophy. He wrote also a history of Poland; and died in 1698, aged 32.

Connor, a city of Ireland, in the county of Antrim, and province of Ulster. W. Long, 6. 30. N. Lat. 54. 50.

Conocarpus, button-wood: A genus of the monogynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 48th order, Aggregate. The corolla is pentapetalous; the seeds naked, solitary, inferior; the flowers aggregate. There are two species, the eretica and procumbens, both natives of the West Indies. They grow to the height of about 6 feet, but are trees of no beauty, nor is the wood of them used for any mechanic purposes in the countries where they grow naturally. They are, however, preferred in some botanic gardens in Britain for the sake of variety.

Conoid, in geometry, a solid body, generated by the revolution of a conic section about its axis. See Conic Sections.

Conoides, in anatomy, a gland found in the third ventricle of the brain, called pinealis, from its resemblance to a pine-apple. See Anatomy, No. 132.

Connor, the renowned Athenian general and admiral, flourished 394 years before Christ. See Artica, No. 162. 163. After his defeat by Lyxander, he fled to Evagoras king of Cyprus; after which he put himself under the protection of Artaxerxes king of Persia; with whose army he delivered Athens from the oppression of strangers, and rebuilt its walls. In the 360th year of Rome, he beat the Macedonians in a sea-fight near Cnidus upon the coast of Asia, deprived them of the sovereign right they had on sea ever since the taking of Athens, and had some other considerable advantages over them; but falling into the hands of Teribazus a Persian, who envied his glory, he was put to death.

Conops, in zoology; a genus of insects belonging to the order diptera, the characters of which are: The rostrum is perforated, and jointed like a knee. The antennae terminate by a flat and solid articulation, resembling the bowl of a spoon, with a lateral bristle, which when closely examined appears to be very hairy. Of this genus there are several species. 1. The calamistrum is to be found everywhere, especially in autumn, when it harases the horse, and draws blood from them with its stings. 2. The mercipedia might at first sight be mistaken for a species of whip.
CONOVUM. (anc. geog.) a town of the Ordovices, in Britain. From its ruins arose, at the distance of four miles, Aberconwy, the mouth of the Conway, in Caernarvonshire; and on the spot where Conovum stood is a hamlet, called Corwen, the old town, (Camden.)

CONQUEST, in civil jurisprudence, is the acquisition of property in common by a number of persons.

In some countries they confound acquisition with conquest; but according to the most general acceptation, the former is the regaining of unappropriated goods before the establishment of a community: whereas by the term conquest, is ordinarily intended whatever is acquired by a number of persons in community; or by some one for all the others.—As it is more especially in the union of persons by marriage, that a community of property takes place; so it is in reference to them that we frequently use the word conquest. There are nevertheless conquests also among other persons who are in a tacit community or society; such as obtain by particular local customs. According to this sense of the word, it has been contended by several, that William I. claimed Britain; that is, not by right of arms, but by right of conquest or acquit; under promise of succession made by Edward the Confessor, and a contract entered into by Harold to support his pretensions to that succession: and by old writers, conquistus, acquistus, and perquisitus, are frequently used as synonymous terms.

CONQUEST, in the law of nations, as the acquisition of sovereignty by force of arms, by some foreign prince: who reduces the vanquished under his empire. The right of conquest is derived from the laws of war; and when a people is subdued, the conduct of the conqueror is regulated by four kinds of law. First, the law of nature, which dictates whatever tends to self-preservation; secondly, our reason, which teaches us to use others, as we would be treated ourselves; thirdly, the laws of political society, to which nature has not assigned any precise boundary; lastly, the law which is derived from the particular circumstances attending the conquest. Thus, a state conquered by another will be treated in one of the four methods following: Either the conqueror will continue it under its own laws; and will only claim the exercice of civil and ecclesiastical sovereignty: or he will impose a new form of government; or he will destroy the frame of their society, and incorporate the inhabitants with others: or he will exterminate them.

CONRAD II., elected emperor of Germany in 1004. He was obliged to take the field against most of the German dukes who had revolted from him; and he put Ernest duke of Saxony under the ban of the empire. This being one of the earliest instances of such a prescription, the formula is inferred here for its singularity. "We declare thy wife a widow, thy children orphans; and we send thee, in the name of the devil, to the four corners of the world." It was in the reign of this prince that the German feecs became hereditary, he died in 1039.

CONRAD III., emperor of Germany in 1138. The duke of Bavaria opposed his election, and being put under the ban of the empire, and deprived of his dukedom, he could not survive his disgrace. The march of Austria was ordered by the Emperor to take possession of Bavaria; but Welser, uncle to the deceased duke, attacked him, and was defeated near the castle of Winzburg: the battle fought upon this occasion is famous in history, as having given rise to the party names of Guelphs and Gibelins, afterwards assumed in Italy. The parole of the day with the Bavarians was Welser, from the name of their general; that of the Imperials. Welbingen, from a small village where Frederic Duke of Swabia, their commander, had been murdered; by degrees these names spread to the engaged the two parties: and the Italians, who could not cut themselves to such rough words, formed from them their Guelphs and Gibelins. He died in 1152.

CONRAD of Lichtenau, or Abbas Ufergenus, was author of an Universal Chronology from the creation to 1229, continued by an anonymous writer to Cha. V. He collected a fine library, and died about the year 1240.

CONRADIN, or CONRAD, junior, son of Conrad IV., was acknowledged Emperor by the Gibelines, who received him in triumph at Rome: but Pope Alexander IV. had published a crusade against this orphan; and Urban VII. his successor, gave the empire to Charles of Anjou, brother to Louis IX., king of France; and the unfortunate youth, though supported even by the Turks, lost a battle, in which he was taken prisoner, and was beheaded by order of his base opponent, publicly at Naples in 1229, in the 18th year of his age. In him ended the race of the Dukes of Swabia, which had produced several kings and emperors.

CONSANGUINITY, or Kindred, is defined by the writers on these subjects to be, vinculum perfonae, ab eodem foete descendentium: the connection or relation of persons descended from the same flock or common ancestor. This confanguinity is either lineal or collateral.

Lineal consanguinity is that which subsists between persons of whom one is descended in a direct line from the other, as between John Stiles (the propositus in the table of confanguinity) and his father, grandfather, great-grandfather, and so upwards in the direct ascending line; or between John Stiles and his son, grand-son, great-grand-son, and so downwards in the direct descending line. Every generation, in this direct lineal consanguinity, confutes a different degree, reckoning either upwards or downwards: the father of John Stiles is related to him in the first degree, and so likewise is his son; his grandfathers and grandsons, in the second; his great-grandfathers and great-grandsons, in the third. This is the only natural way of reckoning
The doctrine of lineal consanguinity is sufficiently plain and obvious; but it is, at the first view, absurd to consider the number of the lineal ancestors which every man has, within so great a number of degrees: and so many different beings is a man said to contain in his veins, as he hath lineal ancestors. Of these he hath two in the first descending degree; his own parents: he hath eight in the second; the parents of his father, and the parents of his mother: he hath eight in the third, the parents of his two grandfathers, and of his two grandmothers; and, by the same rule of progression, he hath 128 in the seventh; 1024 in the tenth; and at the 20th degree, or the distance of 20 generations, every man hath above a million of ancestors, as common arithmetic will demonstrate (A). This lineal consanguinity, we may observe, falls distinctly within the definition of "ancestorum parentearum ab eodem ipsius descendit," since lineal relations are such as descend one from the other, and both of course from the same common ancestor.

Collateral kindred answers to the same description: collateral relations agreeing with the lineal in this, that they descend from the same stock or ancestor; but differing in this, that they do not descend the one from the other. Collateral kinship, then, are such as lineally spring from one and the same ancestor, who is the father, or "root," the mother, "trunk," or common stock, from whence these relations are branched out. As if John Stiles hath two sons, who have each a number of issues; both these issues are lineally descended consanguinely from John Stiles as their common ancestor, and they are collateral kin from each other, because they are all descended from this common ancestor, and all have a portion of his blood in their veins, which denominates them consanguineous.

We must be careful to remember, that the very being of collateral consanguinity consists in this, that one and the same common ancestor. Thus Titius and his brother are related; why? Because both are derived from one father: Titius and his first cousin are related; why? Because both descend from the same grandfather; and his second cousin's claim to consanguinity is this, that they are both derived from one and the same great-grandfather. In short, as many ancestors as a man has, so many common stocks he has from which collateral kinmen may be derived. And as we are taught by holy writ, that there is one couple of common ancestors belonging to us all, from whom the whole race of mankind is descended, the obvious and undeniable consequence is, that all men are in some degree related to one another. For, indeed, if we only suppose each couple of our ancestors to have left, one with another, two children; and each of those children to have left, on an average, two more (and without such a supposition the human species must be daily diminishing); we shall find that all of us (if we now subsist near 250 millions of kindred in the 15th degree, at the same distance from the several common ancestors as we ourselves are; besides those that are one or two degrees nearer to or farther from the common stock, who may amount to as many more.

(A) This will seem surprising to those who are unacquainted with the increasing power of progressive numbers; but it is palpably evident from the following table of a geometrical progression, in which the first term is 2, and the denominator also 2: or, to speak more intelligibly, it is evident, for that each of us has two ancestors in the first degree, the number of whom is doubled at every remove; because each of our ancestors has also two immediate ancestors of his own.

A shorter way of finding the number of ancestors at any even degree, is by squaring the number of ancestors at half that number of degrees. Thus, 16, the number ancestors at 4 degrees, is the square of 4, the number ancestors at two; 256 is the square of 16; 65536 of 256; and the number of ancestors at 40 degrees would be the square of 1,048,576, or upwards of a million of millions.
Con.

If this calculation would appear incompatible with the number of inhabitants on the earth, it is because, by intermarriages among the several descendants from the same ancestor, a hundred or a thousand modes of consanguinity may be consolidated in one person; or he may be related to us a hundred or a thousand different ways.

The method of computing these degrees in the canon law, which we have adopted, is as follows. We begin at the common ancestor, and reckon downwards; and in whatever degree the two persons, or the most remote of them, is distant from the common ancestor, that is the degree in which they are related to each other. Thus, Titius and his brother are related in the first degree; for from the father to each of them is counted only one; Titius and his nephew are related in the second degree; for the nephew is two degrees removed from the common ancestor, *viz.* his own grandfather, the father of Titius; or (to give a more illustrious instance from the English annals) King Henry VII., who slew Richard III. in the battle of Bosworth, was related to that prince in the fifth degree. Let the *propositus*, therefore, in the table of consanguinity, represent King Richard III. and the class marked *e*, King Henry VII. Now their common flock or ancestor was King Edward III. the *abens* in the consanguinity table: from him to Edmund Duke of York, the *pater* is one degree; to Richard Earl of Cambridge, the *avus*, two; to Richard Duke of York, the *pater* three; to King Richard III. the *propositus*, four; and from King Edward III. to John of Gant (*a*) is one degree: to John Earl of Somerset (*c*) two; to John Duke of Somerset (*c*) three; to Margaret Countess of Richmond (*b*) four; to King Henry VII. (*k*) five. Which last-mentioned prince, being the farthest removed from the common flock, gives the denomination to the degree of kindred in the canon and municipal law. Though according to the computation of the civilians (who count upwards from either of the persons related, to the common flock, and then downwards again to the other; reckoning a degree for each person both ascending and descending) these two princes were related in the ninth degree: for from King Richard III. to Richard Duke of York is one degree; to Richard Earl of Cambridge two; to Edmund Duke of York three; to King Edward III. the common ancestor, four; to John of Gant five; to John Earl of Somerset six; to John Duke of Somerset seven; to Margaret Countess of Richmond eight; to King Henry VII. nine. See the Table of Consanguinity.

(§) This will swell more considerably than the former calculation: for here, though the first term is but *i*, the denominator is 4; that is, there is one kinman (a brother) in the first degree, who makes, together with the *propositus*, the two descendants from the first couple of ancestors; and in every other degree, the number of kindred must be the quadruple of those in the degree which immediately precedes it. For since each couple of ancestors has two descendants who increase in a duplicate ratio, it will follow, that the ratio in which all the descendants increase downwards, must be double to that in which the ancestors increase upwards: but we have seen that the ancestors increase in a duplicate ratio: therefore the descendants must increase in a double duplicate; that is, in a quadruple ratio.

This calculation may also be formed by a more compendious process, *viz.* by squaring the couples, or half the number of ancestors, at any given degree; which will furnish us with the number of kindred we have in the same degree, at equal distance with ourselves from the common flock, besides those at unequal distances. Thus, in the tenth collateral degree, the number of ancestors is 1024; its half, or the couples, amount to 512; the number of kindred in the tenth collateral degree amounts therefore to 262144, or the square of 512. And if we will be at the trouble to recollect the state of the several families within our own knowledge, and observe how far they agree with this account; that is, whether, on an average, every man has not one brother or sister, four first-cousins, sixteen second-cousins, and so on; we shall find, that the present calculation is very far from being overcharged.
CON

Confangui-

CONSCIENCE, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil. See Moral Philosophy.

A man of integrity will never listen to any reason, or give way to any measure, or be misled by any inducement, against conscience. — The inhabitants of a great town offered Marshal de Turenne 100,000 crowns, upon condition he would take another road, and not march his troops their way. He answered them, “As your town is not on the road I intend to march, I cannot accept the money you offer me.” — The Earl of Derby, in the reign of Edward III, making a descent in Guenee, carried by the town of Berberac, and gave it up to be plundered. A Welsh knight happened by chance to light upon the receiver’s office. He found there a quantity of money that he thought himself obliged to acquaint his general with, imagining that to great a booty naturally belonged to him. But he was agreeably surprised when the earl told him, with a pleasant countenance, that he wished him joy of his good fortune; and that he did not make the keeping of his word to depend upon the great or little value of the thing he had promised. — The fiend of Fallici by Camillus general of the Romans, the schoolmaster of the town, who had the children of the senators under his care, led them abroad under the pretext of recreation, and carried them to the Roman camp, saying to Camillus, that by this artifice he had delivered Fallici into his hands. Camillus abhorring this treachery, observed, “That there were laws for war as well as for peace; and that the Romans were taught to make war with integrity not less than with courage.” He ordered the schoolmaster to be stripped, his hands to be bound behind his back, and to be delivered to the boys to be lashed back into the town. The Faliceni, formerly obdurate in refiitsance, struck with an act of justice so illustruous, delivered themselves up to the Romans; convinced that they would be far better to have the Romans for their allies than their enemies.

It is a saying, That no man ever offended his own conscience, but first or last it was avenged upon him. The power of conscience indeed has been remarked in all ages, and the examples of it upon record are innumerable. The following is related by Mr Fordecy, in his Dialogues on Education, as a real occurrence which happened in a neighbouring state not many years ago. A jeweller, a man of good character and considerable wealth, having occasion in the way of his business to travel at some distance from the place of his abode, took along with him a servant, in order to take care of his portmanteau. He had with some of his best jewels, and a large sum of money, to which his servant was likewise privy. The man being occa-

CONSCRIPT; in Roman antiquity, an appellation given to the senators of Rome, who were called con-
CONSECRATION, the act of devoting anything to the service and worship of God. The Mosaic law ordained, that all the first-born, both of man and beast, should be sanctified or consecrated to God. We find also, that Joshua consecrated the Gibeonites, as Solomon and David did the Nethinims, to the service of the temple; and that the Hebrews sometimes consecrated their firstborn and cattle to the Lord, after which they were no longer in their power.

Among the ancient Christians, the consecration of churches was performed with a great deal of pious solemnity. In what manner it was done for the three first ages, is uncertain; the authentic accounts reaching no higher than the fourth, when, in the peaceable reign of Constantine, churches were every where built, and dedicated with great solemnity. Some think the consecration consisted in letting up the sign of the cross, or in placing a communion-table in the church; and others, that no more was done than speaking a panegyrical sermon in commemoration of the founder, and that then they proceeded to prayers, one of which was composed on purpose for the church to be consecrated. The Romanists have a great deal of pious consecration, water, oil, blessed on by the words of consecration; which they consider as the instrument of that particular and extraordinary content between those parts. Hence it is, that a favour thing seen or smelt excites the appetite, and affects the glands and parts of the mouth; and a shameful thing seen or heard affects the cheeks with blushes; on the contrary, if it please, it affects the praecordia, and excites the muscles of the mouth and face to laughter; if it grieve, it affects the glands of the eyes, so as to occasion tears, and the muscles of the face, putting them into an affect of crying. Dr Willis, quoted by Mr Derham, imputes the pleasure of killing, and its effects, to this pair of nerves; which being branched both to the lips and the genital parts, when the former are affected an irritation is occasioned in the latter. See Sympathy.

CONSENTES, the name which the Romans gave to the 12 superior gods, the Dii majorum gentium. The word signifies as much as consentientes; that is, who consented to the deliberations of Jupiter's council. They were twelve in number, whose name Ennius has briefly expressed in these lines,

Fons, Febo, Minerva, Ceres, Diana, Venus, Mars,
Mercurius, Jove, Neptune, Pelusius, Apollo

CONSEQUENCE, in logic, the conclusion, or what results from reason or argument. See Conclusion. The consequence is that other proposition in which the extremes or premises of a syllogism are joined, or separated; and is gained from what was asserted in the premises. This word, in a more restrained sense, is used for the relation or connection between two propositions, wherever one is inferred from the other.

CONSEQUENT, something deduced or gathered from a former argumentation. But, in a more precise sense, it is used for the proposition which contains the conclusion, considered in itself, without any regard to the antecedent: in which sense the consequent may be true, though the consequent be false. See the preceding article.

CONSERVATOR, an officer ordained for the security and preservation of the privileges of some cities and communities, having a commission to judge of and determine the differences among them. In most Catholic universities there are two conservators; the conservator of royal privileges, or those granted by kings; and the conservator of apoloitical privileges, or those granted by the pope. The first takes cognizance of personal and mixed causes between the regents, students, &c. and the latter of spiritual matters between ecclesiastics.
Anciently there were appointed conservators of treaties of peace between princes; which conservators became judges of the infractions made on a treaty, and were charged with procuring satisfaction to be made. These were usually the feudatories of the several powers. In lieu of conservators princes now have recourse to other indifferents to guarantee their treaties.

Conservator of Scots Privileges, at Campvere, is an officer belonging to the royal boroughs of Scotland, who takes care of the mercantile affairs of Scotland, agreeable to the staple contract between them and the States-General.

Conservator of the Peace, in the ancient English customs, was a person who had an especial charge, by virtue of his office, to see the king's peace kept. Till the creation of justices of the peace by King Edward III. there were several persons who by common law were interested in keeping the same. Some having that charge as incidental to other offices; and others simply, or of itself, called consilod, or conservators of the peace. The chamberlain of Chester is still a conservator in that county; and petty constables are, by the common law, conservators, &c. in the first tenure, within their own jurisdiction: to do are also the coroner and the sheriff within their own county. The king is the principal conservator of the peace within all his dominions: the lord chancellor, lord treasurer, lord high steward, lord marshal, lord high constable, all the justices of the court of king's bench, by their office, and the master of the rolls, by prescription, are general conservators of the peace through the whole kingdom, and may commit breakers of the peace, and bind them in recognizances to keep it.

Conservator of the Truce, and Safe Conducts, was an officer appointed in every sea-port, under the king's letters patent. His charge was to inquire of all offences committed against the king's truce, and safe conducts upon the main sea, out of the franchises of the six ports, as the admirals were wont to do. There are four of these at Venice, others of the cinque-ports, as the admirals were wont to do, but the conservators, in Europe.

Conservatories, or musical schools established for the instruction of children in the profession of music. There are four of these at Venice, designed for the education of girls, and lice at Naples, for the education of boys. It has been suggested that the operation of castration was performed in the conservatories, but the practice is absolutely prohibited, and the young castrati are brought from Lucia in Puglia: but before the operation is performed, their voices are tried in a conservatory. The scholars of the Venetian conservatories have been chiefly celebrated for taste and neatness of execution; and those of Naples have had the reputation of being the first contra puni menti, or composers, in Europe.

Conservatory, a term sometimes used for a green-house or ice-house.

Conserves, in pharmacy, a form of medicine contrived to preserve the herbs, flowers, roots, or fruits of several simples, as near as possible to what they are when fresh gathered. See Pharmacut.

Consignment, in law, the depositing any sum of money, bills, papers, or commodities, in good hands; either by appointment of a court of justice, in order to be delivered to the persons to whom they are adjudged; or voluntarily, in order to their being remitted to the persons they belong to, or sent to the places they are designed for.

Consignment of Goods, in commerce, is the delivering or making them over to another: thus, goods are said to be consigned to a factor, when they are sent to him to be sold, &c.; or when a factor sends back goods to his principal, they are said to be consigned to him.

Consistence, in physics, that state of a body wherein its component particles are so connected or entangled among themselves, as not to separate or recede from each other. It differs from continuity in this, that it implies a regard to motion or rest, which continuity does not, it being sufficient to denominate a thing continuous that its parts are contiguous to each other.

Consistentes, in church-history, a kind of petitioners who were allowed to aitff at prayers, but who could not be admitted to receive the sacrament.

Consistory (consistorium), signifies as much as praetorium, a tribunal: it is commonly used for a council-house of ecclesiastical persons, or place of justice in the spiritual court; a felion or assembly of prelates. And every archbishop and bishop of every diocese hath a consistory court held before his chancellor or commissary in his cathedral church, or other convenient place of his diocese, for ecclesiastical causes. The bishop's chancellor is the judge of this court, supposed to be skilled in the civil and canon law; and in places of the diocese far remote from the bishop's consistory, the bishop appoints a commissary to judge in all causes within a certain district, and a regifter to enter his decrees, &c.

Consistory, at Rome, denotes the college of cardinals, or the pope's senate and council, before whom judicial causes are pleaded. Du Cange derives the word from consistorium; i.e. locus ubi consilium; used chiefly for a vestibule, gallery, or antechamber, where the courtiers wait for admission; and called a consistorial multitude.

The consistory is the first court, or tribunal of Rome: it never meets but when the pope pleases to convocate it: the pope presides in it in person, mounted on a magnificent throne, and habited in his pontifical dress: on the right are the cardinal-bishops and priests, and on the left the cardinal-deacons. The place where it is held, is a large hall in the apothecary palace, where princes and ambassadors of kings are received. The other prelates, prothonotaries, auditors of the rota and other officers, are seated on the steps of the throne: the courtiers sit on the ground; ambassadors on the right, and consistorial and fiscal advocates behind the cardinals.

Besides the public consistory, there is also a private one, held in a retired chamber, called the chamber of papacy: the pope's throne here being only raised two steps high. No body is here admitted but the cardinals whose opinions are collected, and called fiduciae. Here are first proposed and passed all bulls for bishoprics, abbeys, &c. Hence bishoprics and abbeys are said to be consistorial benefices; in regard, they must be proposed in the consistory, the names be paid.
Confiracy.  

Confiracy to the pope, and his bulls taken. Anciency they were executive; but by the concordat, which abolishes elections, they are appointed to be collated by the pope alone, on the nomination of the prince.

Consistory was also the name of a court under Conpante, where he sat in person, and heard causes: the members of this court were called comites.

Consistory is also used among the reformed, for a council or assembly of ministers and elders, to regulate their affairs, discipline, &c.

Consistory, or court; Christian in the English laws, is a council of ecclesiastical persons, or the place of justice in an ecclesiastical or spiritual court. Every abbot and bishop has a consistory-court, held before his chancellor or commissary, either in his cathedral, in some chapel, side, or portico, belonging thereto; or in some other convenient place of his diocese, for ecclesiastical causes. The spiritual court was anciently, in the time of the Saxons, joined with the county court; and the original of the consistory, as divided from those courts, is found in a law of the conqueror, quoted by Lord Coke. From this court there lies an appeal to the archbishop of each province respectively.

Consolation, one of the places in rhetoric wherein the orator endeavours to abate and moderate the grief or concern of another.

Console, in architecture, an ornament cut upon the key of an arch, which has a projecture, and on occasion serves to support little cornices, figures, bufts, and vases.

Consolidation, in law, the combining and uniting two benefices into one. The term is borrowed on occasion serves to support little cornices, figures, bufts, and vases.

Consolidation, in law, the combining and uniting two benefices into one. The term is borrowed from the French, Sir William Blackstone is rather inclined to deduce it, with Sir Henry Spelman and Dr. Cowel, from that language; wherein it is plainly derived from the Latin consistere, an officer well known in the empire; so called, because, like the great consolable of France, as well as the lord high constable of England, he was to regulate all matters of chivalry, tilts, tournaments, and feats of arms, which were performed on horseback.—The Lord High Constable of England is the seventh great officer of the crown; and he, with the earl marshal of England, were formerly judges of the court of chivalry, called in king Henry IV.'s time Curia Militaris, and now the court of honour. It is the fountain of the martial law, and anciently was held in the king's hall. The power of the lord high constable was formerly so great, and of which so improper a use was made, that so early as the 13th of king Richard II. a statute passed for regulating and abbreviating the same, together with the power of the earl marshal of England; and by this statute, no plea could be tried by them or their courts, that could be tried by the common law of the realm. The office of constable existed before the conquest. After the conquest, the office went with inheritance, and by the tenure of the manors of Harlesfield, Newman, and Whithurft, in Gloucestershire, by grand jerseant in the family of the Bohuns Earl of Hereford and Exeter, and afterwards in line of Safford as heirs-general to them; but in 1521, this great office became forfeited to the king in the person of Edward Stafford duke of Buckingham, who was that year attainted for high treason; and in consideration of its extensive power, dignity, and large authority, both in time of war and peace, it has never been granted to any person, otherwise than as vice, and that to attend at a coronation, or trial by combat. In France, the same office was also suppressed about a century after by a edict of Louis XIII; though it has been exercized, in the command of the Marshals, by the first officer in the army.

Lord high consolable of Scotland was an office of great antiquity and dignity. The first upon record is Hugo de Morville in the reign of David I. He had two grand prerogatives, viz. First, the keeping of the king's sword, which the king, at his promotion, when he sweares fealty, delivers to him naked. Hence the badge of the constable is a naked sword. —Second, The absolute and unlimited command of the king's armies while in the field, in the absence of the king; but this command does not extend to castles and garrisons. He was likewise judge of all crimes committed within two leagues of the king's house, which precinct was called the Chalmers of Peace. Though his jurisdiction came at last to be exercized only as to crimes during the time of parliament, which some extended likewise to
There are also constables denominated from particular places, as constable of the Tower, of Dover castle, of Windsor castle, of the castle of Caernarvon, and many other of the castles of Wales; whose office is the same with that of the castellan, or governors of castles.

**Constables of London.** The city of London is divided into 26 wards, and the wards into precincts, in each whereof is a constable. They are nominated by the inhabitants of each precinct on St Thomas's day, and confirmed, or otherwise, at the court of wardmote. After confirmation, they are sworn into their offices at a court of aldermen, on the next Monday after Twelfth day. Such as are chosen into the office, are obliged to place the king's arms, and the arms of the city, over their doors; and if they reside in alleys, at the ends of such alleys toward the streets, to signify that a constable lives there, and that they may be the more easily found when wanted.

**Constables to keep the Peace.** In Scotland, are the proper officers for executing their orders. They have powers to suppress tumults, and apprehend delinquents and those who can give no good account of themselves, and carry them to the next justice.

**Constance,** a strong town of Germany, in the circle of Suabia, with a bishop's see, whose bishop is a prince of the empire. It has a handsome bridge, and several fine structures, as well sacred as profane. It carries on a great trade, and is well fortified; and though it pretends to be an imperial town, the Austrians keep a garrison here. It is famous for a council held here in 1514, when there were three popes; but they were all deposed, and Martin V. was elected in their room. The council casted Jerom of Prague to be burnt, though the emperor Sigismund had given him a safe conduct; in pursuance of this maxim, "that no faith is to be kept with heretics." They likewise condemned the doctrine of Wickliff, and ordered his bones to be burned 40 years after he was dead. However, the inhabitants now are Protestants. It is seated on a lake of the same name. E. Long. 9. 12. M. Lat. 47. 35.

**Constantia,** a great lake of Germany, between Suabia and Switzerland. It is 30 miles in length, and 8 in breadth. It is crost by the river Rhine; and there are several towns on its banks.

**Constance,** in a general sense, denotes immutability, or invariableness.—In ethics, or when applied to the human mind, the term implies resolution or steadiness, particularly under sufferings and the trials of adversity.

It was the saying of a heathen philosopher, That there cannot be imagined upon earth a spectacle more worthy the regard of the Creator intent on his works, than a brave man superior to his sufferings. Nothing indeed can be more noble or honorable than to have courage enough to execute the commands of reason and confidence; to maintain the dignity of our nature, and the station assigned us; and to be proof against poverty, pain, and death itself, so far as not to do anything that is scandalous or sinful to avoid them. To be thus, is to be great above title and fortune. This argues the soul of an heavenly extraction, and is worthy the offspring of the Deity.

Of this virtue the following example, related in English
Sir William Askew of Kelfay, in Lincolnshire, had several daughters. His second, named Anna, had received a genteel education; which, with an agreeable figure and good understanding, rendered her a very proper person to be at the head of a family. Her father, regardless of his daughter's inclination and happiness, obliged her to marry a gentleman who had nothing to recommend him but his fortune, and who was a most bigoted Papist. No sooner was he convinced of his wife's regard for the doctrines of the reformation from popery, than, by the instigation of the priest, he violently drove her from his house, though she had born him two children, and her conduct was unexceptionable. Abandoned by her husband, she came up to London, in order to procure a divorce, and to make herself known to that part of the court who either professed or were favourers of protestantism; but as Henry VIII. with consent of parliament, had just enacted the law of the fix articles, commonly called the bloody statute, she was cruelly betrayed by her own husband; and, upon his information, taken into custody, and examined concerning her faith. The act abovementioned denounced death against all those who should deny the doctrine of transubstantiation; or that the bread and wine made use of in the sacrament was not converted after consecration into the real body and blood of Christ; or, maintain the necessity of receiving the sacrament in both kinds; or affirm, that it was lawful for priests to marry; that the vows of consecration were not necessary to salvation. Upon these articles she was examined by the inquisitor, a priest, the lord-mayor of London, and the bishop's chancellor; and to all their queries gave proper and pertinent answers; but not being such as they approved, she was sent back to prison, where she remained eleven days to ruminate alone on her alarming situation, and was denied the small consolation of a friendly visit. The king's council being at Greenwich, she was once more examined by chancellor Wriothesley, Gardiner bishop of Winchester, Dr Cox, and Dr Robinson; but not being able to convince her of her supposed errors, she was sent to the Tower. Mr Strype, from an authentic paper, gives us the following short account of her examination, which may not, perhaps, be unentertaining or useful to the reader: "Sir Martin Bowes (lord mayor) sitting with the council, as moft meet for his wisdom, and seeing her stand upon life and death, I pray you, quoth he, my lords, give me leave to talk to this woman? Leave was granted. Lord Mayor. Thou foolish woman, sayst thou that the priest cannot make the holy body of Christ? A. Askew. I say so, my lord: for I have read that God made man; but that man made God I never read; nor I suppose ever shall read it. Lord Mayor. No! Though foolish woman, after the words of consecration, is it not the Lord's body? A. Askew. No; it is but consecrated bread, or sacramental bread. Lord Mayor. What if a mouse eat it after consecration; what shall become of this mouse? what sayst thou, thou foolish woman? A. Askew. What shall become of her, say you, my lord? Lord Mayor. I say, that the mouse is damned.
The country priority, however, is owing to anything peculiar in the manner of preparing it, being extremely probable; for then, without doubt, a great deal more of it would be made. In fact, Dr. Sparrmann informs us, that the genuine wine can only be produced by certain particular soils. The districts that lie next to the yield merely the common Cape wine, notwithstanding that they have been planted with vine-shoots taken from Ciss, as well as with some brought from the banks of the Rhine, whence it is supposed that the true Constantia from originally comes; nay, even tho' all the vineyards about Constantia seem to have the same soil. We have plantations at the Cape, as well as in Europe, that good grapes sometimes produce a bad wine; while, on the other hand, bad grapes will yield a good sort of wine. Therefore, towards making wine of a certain quality, besides finer materials, there must be certain conditions and circumstances, which, by a diligent and rational investigation, might probably be explored to the greatest benefit of mankind. Such are apprized in what quantities Constantia wine is consumed in Europe, which perhaps think the above calculation of the produce too limited. This, however, Dr. Sparrmann assures us, is by no means the case; the overplus being the produce of avarice, which goes on by the desire of gain, will always hit upon some method of satisfying the demands of luxury and sensuality. The vintners of these, accustomed to be put off with empty sounds, do not seldom drink with the highest rethian an imaginary Constantia, with which, however, this liquor has nothing in common besides the mere name. It is therefore advisable, even at the Cape itself, to take care, that whilst one has a genuine sample given one to taste, one is not made to pay for a made-up red Constantia, which otherwise is in general sold for half the price. When a wine of this kind has been (as it usually is) mollerated by a voyage, and at the same time corrupted with the famous name of genuine Constantia, of which it has indeed in some measure the flavour, it easily sells for such in Europe.

CONSTANTINA, a strong considerable town of Africa, in the kingdom of Algiers, and capital of a territory of the same name. It is the largest and strongest place in all the eastern parts; and it is seated on the top of a great rock. There is no way to it but by the way of the rock itself, and the process of punishing criminals here is to throw them down the cliff. Here are a great many Roman antiquities, particularly a triumphal arch. E. Long. 7. 12. N. Lat. 36° 4'.

CONSTANTINA, a town of Spain, in Andalusia, and capital of a small territory of the same name, with a castle seated on a mountain. W. Long. 5° 35'. N. Lat. 37° 40'.

CONSTANTINE, a kingdom of Barbary of that name in Africa. It is bounded on the north by the Mediterranean, on the east by the kingdom of Tunis, on the south by Biltulgerid, and on the west by the river Safegmar, which separates it from the kingdom of Tunisania. The territory is the new Numidia of the ancients, and had its own king; but it is now a province to Algiers.

CONSTANTINE the Great, the first emperor of the Romans who embraced Christianity. His father, Constantius Clorus, rendered himself famous by his victorious expeditions to Germany and Britain: upon the abduction of Diocletian, he shared the Roman empire with Galerius Maximinus in 305; and was at that time at York, where he died in 306; having first caused his son Constantine the Great to be proclaimed emperor by his army, and by the English. Galerius at first refused to admit Constantine to his father's share in the imperial throne; but after having lost several battles he conquered in 308. Maximinus, who succeeded Galerius opposed him; but was defeated, and drowned himself in the Tyber. The Senate then declared Constantine chief of /fris Augustus, and Licinius his fellow associate in the empire, in 312. These princes published an edict, in their joint names, in favour of the Christians; but soon after Licinius, jealous of Constantine's renown, conceived an implacable hatred against him, and renewed the persecutions against the Christians. This brought on a rupture between the emperors; and a battle in which Constantine was victorious. A short peace ensued; but Licinius having shamefully violated the treaty, the war was renewed; when Constantine, totally defeating him, he fled to Nicomedia, where he was taken prisoner and slay'd in 323. Constantine, now become sole master of the western and eastern empires, immediately formed the plan of establishing Christianity as the religion of the state; for which purpose, he convoked several ecclesiastical councils: but finding he was likely to meet with great opposition from the Pagan interest at Rome, he conceived the design of founding a new city, to be the capital of his Christian empire; i.e. Constantinople. The glory Constantine had acquired by establishing the Christian religion, was tarnished by the part he took in the persecutions carried on by the Arians, towards the close of his reign, against their Christian brethren who differed from them; seduced by Eusebius, of Nicomedia, he banished several eminent prelates: soon after which he died in 337, the 66th year of his age, and 31st of his reign.

As to the character of Constantine, he was valiant, pious, laborious, and indefatigable; a great general, successful in war, and deferving his successes by his shining valour and by the brightness of his genius; a protector of arts, and an encourager of them by his beneficence. If we compare him with all his predecessors, we shall find that he ruined idolatry, by the same precaution and the same address that the other used to destroy liberty. Like Augustus, he laid the foundation of a new empire; but left skillful, and left police, he could not give it the same stability: he weakened the body of the state by adding to it, in some measure, a second head in the foundation of Constantinople; and transporting the centre of motion and strength too near the eastern extremity, he left without heat, and almost without life, the western parts, which soon became a prey to the barbarians. The Pagans were too much his enemies to do him justice. Eusebius says, that in the former part of his reign he was equal to the most accomplished princes, and in the latter to the meanness. The younger Victor, who makes him to have reigned more than 37 years, pretends, that in the first 10 years he was a hero; in the 12 succeeding, the
Constantine, a robber; and in the role of a spendthrift. It is easy to perceive, with respect to these two reproaches of Victor's, that the one relates to the riches which Constantine took from idolatry, and the other to those with which he loaded the church.

Constantine emperor of the East in 902, left the care of the empire to his wife Helena, who loaded the people with taxes, and sold all the offices in church and state to the highest bidders; while the emperor employed himself in reading, writing, and the fine arts, till he became as good an architect and painter as he was a bad prince; he wrote several biographical and geographical works, which would have done honour to his name, if he had not neglected his duty to compose them. He died in 960.

Constantine (Draceus), the son of Emmanuel Paleologus, was placed on the throne by Sultan Amurath in 1448. But Mahomet II. his successor, resolved to dethrone him, laid siege to Constantinople by sea and land, and took it by assault in 1453, after it had held out 58 days. The unfortunate emperor, being thronged into the breaches, threw himself into the children of the imperial house were massacred by the soldiers; and the women referred to gratify the lust of the conqueror; and thus terminated the dynasty of the Constantinians, 1,123 years after its establishment at Constantinople.

Constantine (Robert), a learned physician born at Caen, taught polite literature in that city and acquired great reputation by his skill in the Greek language, in history, and in medicine. He died in 1605, aged 103. He wrote a dictionary in Greek and Latin, and other works, which are esteemed.

Constantinople, the modern name of the city of Byzantium in Thrace. It was enlarged and beautified by the Roman emperor Constantine the Great, in the year 330. At the same time he transferred thither the seat of the empire; and this removal is generally thought to have been one of the principal causes of the sudden decline of the western empire after this period.

In the year 332, the Sarmatians implored Constantine's alliance against the Goths, who had made an irruption into their territories, and destroyed everything with fire and sword. The emperor readily granted their request, and gained a complete victory. Near 100,000 of the enemy perished either in the battle, or after it with hunger and cold. In consequence of this overthrow, the Goths were obliged to sue for peace; but the ungrateful Sarmatians no sooner found themselves delivered from their enemies, than they turned their arms against their benefactor, and ravaged the provinces of Macedonia and Thrace. The emperor, receiving intelligence of this treachery, returned with incredible expedition, cut great numbers of them in pieces, and obliged the rest to submit to what terms he was pleased to impose.

Constantine seems to have been a prince highly respected, even by far different nations. In 333, according to Eusebius, ambassadors arrived at Constantinople from the Blemyes, Indians, Ethiopians, and Persians, courting his friendship. They were received in a most obliging manner; and learning from the ambassadors of Sapor king of Persia, that there were great numbers of Christians in their master's dominions, Constantine wrote a letter in their behalf to the Persian monarch.

Next year, the Sarmatians being again attacked by the Goths, found themselves obliged to set at liberty and arm their slaves against them. By this means they indeed overcame the Goths; but the victorious slaves turning their arms against their masters, drove them out of the country. This misfortune obliged them, to the number of 300,000, to apply for relief to the Roman emperor, who incorporated with his legions such as were capable of service; and gave settlements to the rest in Thrace, Sceania, Macedonia, and into Italy. This was the last remarkable action of Constantine the Great. He died on May 25, 337, having divided the empire among his children and nephews, and divided in the following manner. Constantine, his eldest son, had Gaul, Spain, and Britain: Constans, the second, had Asia, Syria, and Egypt: and Constantius, the youngest, Illyricum, Italy, and Africa. To his nephew Dalmatius, he gave Thrace, Macedonia, and Armenia: and to king Annibalianus, his other nephew, Armenia Minor, Pontus, Cappadocia, and the city of Caesarea, which he desired might be the capital of his kingdom.

After the death of Constantine, the army and Allhiaea, the senate proclaimed his three sons emperors, without taking any notice of his two nephews, who were soon after murdered, with Julius Constans the late emperor's brother, and all their friends and adherents. Thus the family of Constantine was at once reduced to three sons, and two nephews.

In 340, Constantine having in vain solicited Constans to yield part of Italy to him, raised a considerable army; and under pretence of marching to the assistance of his brother Constans, who was then at war with the Persians, made himself master of several places in Italy. Hereupon Constans detached part of his army against him; and Constantine, being drawn into an ambuscade near Aquileia, was cut off with his whole forces. His body was thrown into the river Annea; but being killed. Afterwards discovered, was sent to Constantinople, and interred there near the tomb of his father.

By the defeat and death of his brother, Constans remained sole master of all the western part of the empire, in the quiet possession of which he continued till the year 350. This year, Magnentius, the son of one Magnus, a native of Germany, finding Constans deprived of the dominions of the emperor by the army on account of his insolence an indiscretion, resolved to murder him, and set up for himself. Having found means to gain over the chief officers of the army to his designs, he seized on the Imperial palace at Aunun, and distributed among the populace what sums he found there; which induced not only the city, but the neighbouring country, to espouse his cause. But Constans being informed of what had passed, and finding himself unable to resist the usurper, fled towards Spain. He was overtaken, however, by Gaio, whom Magnentius had sent after him with a chosen
At first the emperor would hearken to no terms; but afterwards, that he might not have to oppose two enemies at once, concluded a separate treaty with Venetian, by which he agreed to take him for his partner in the empire. But when Venetian attended the tribunal along with Constantius, the soldiers pulled him down from thence, crying out, That they would acknowledge no other emperor than Constantius alone. On this Venetian threw himself at the emperor's feet, and implored his mercy. Constantius received him with great kindness, and sent him to Prusia in Bithynia, where he allowed him a maintenance suitable to his quality.
