ENCYCLOPAEDIA;
OR, A
DICTIONARY
OF
ARTS, SCIENCES,
AND
MISCELLANEOUS LITERATURE;
Constructed on a Plan,
BY WHICH
THE DIFFERENT SCIENCES AND ARTS
Are digested into the Form of Distinct
TREATISES OR SYSTEMS,
COMPREHENDING
THE HISTORY, THEORY, and PRACTICE, of each,
According to the Latest Discoveries and Improvements;
AND FULL EXPLANATIONS GIVEN OF THE
VARIOUS DETACHED PARTS OF KNOWLEDGE,
WHETHER RELATING TO
NATURAL and ARTIFICIAL Objects, or to Matters ECCLESIASTICAL,
CIVIL, MILITARY, COMMERCIAL, &c.
Including ELUCIDATIONS of the most important Topics relative to RELIGION, MORALS, MANNERS,
and the ECONOMY of LIFE:
TOGETHER WITH
A DESCRIPTION of all the Countries, Cities, principal Mountains, Seas, Rivers, &c.
throughout the WORLD;
A General HISTORY, Ancient and Modern, of the different Empires, Kingdoms, and States;
AND
An Account of the Lives of the most Eminent Persons in every Nation,
from the earliest ages down to the present times.

Compiled from the writings of the best Authors, in several languages; the most approved Dictionaries, as well of general science as of its particular branches; the Transactions, Journals, and Memoirs, of various Learned Societies, the MS. Lectures of Eminent Professors on different sciences; and a variety of Original Materials, furnished by an Extensive Correspondence.

THE FIRST AMERICAN EDITION, IN EIGHTEEN VOLUMES, GREATLY IMPROVED.

ILLUSTRATED WITH FIVE HUNDRED AND FORTY-TWO COPPERPLATES.

V O L. VIII. G O B—H Y D

PHILADELPHIA:
PRINTED BY THOMAS DOBSON, AT THE STONE HOUSE, No 41, SOUTH SECOND STREET.
M.DCC.XCVIII.

GOBBO (PIETRO PAOLO CORTONESI, so called), a celebrated painter of fruit and landscapes, was born at Cortona in 1580, and learned the principles of design from his father; but was afterwards the disciple of Carleccia at Rome, and perfected himself in the most essential parts of his profession, by studying after nature, with judgment and accuracy. His merit soon recommended him to the notice and esteem of the most able judges at Rome; and as he excelled equally in painting fruit and landscape, he found a generous patron in cardinal Borghese, who employed him to adorn his palace. The fruit which he painted had so true and expressive an imitation of nature, that nothing could possibly be more exact; and by his thorough knowledge of the chiaro-fero, he gave an extraordinary roundness and relief to every object. But his greatest excellence consisted in his colouring; for in design he was not remarkably superior to others. He died in 1640.

GOBELIN (Giles), a famous French dyer, in the reign of Francis I. discovered a method of dying a beautiful scarlet, and his name has been given ever since to the finest French scarlets. His house, in the suburb of St Marcel at Paris, and the river he made use of, are still called the gobelins. An academy for drawing, and a manufactury of fine tapestries, were erected in this quarter in 1666; for which reason the tapestries are called the gobelins.

GOBIUS, in ichthyology, a genus of fishes belonging to the order of thoracici. They have two holes between the eyes, four rays in the membrane of the gills, and the belly-fins are united in an oval form. There are eight species, principally distinguished by the number of rays in their fins.

GOBEL, or GOBELLET, a kind of drinking cup, or bowl, ordinarily of a round figure, and without either foot or handle. The word is French, goblet; which Salmasius, and others, derive from the barbarous Latin cupa. Budes deduces it from the Greek κυρα, a sort of cup.

GOD, one of the many names of the Supreme Being. See Christianity, Metaphysics, Moral Philosophy, and Theology.

God is also used in speaking of the false deities of the heathens, many of which were only creatures to which divine honours and worship were superstitiously paid.

The Greeks and Latins, it is observable, did not mean by the name God, an all-perfect being, whereof eternity, infinity, omnipotence, &c. were essential attributes; with them, the word only implied an excellent and superior nature; and accordingly they gave the appellation gods to all beings of a rank or class higher and more perfect than that of men; and especially to those who were inferior agents in the divine administration, all subject to the one Supreme. Thus men themselves, according to their system, might become gods after death; inasmuch as their souls might attain to a degree of excellence superior to what they were capable of in life.

The first divines, father Bossa observes, were the poets; the two functions, though now separated, were originally combined; or, rather, were one and the same thing.

Now the great variety of attributes in God, that is, the number of relations, capacities, and circumstances, wherein they had occasion to consider him, put these poets, &c. under a necessity of making a partition, and of separating the divine attributes into several persons; because the weakness of the human mind could not conceive so much power and action in the simplicity of one single divine nature. Thus the omnipotence of God came to be represented under the person and appellation of Jupiter; the wisdom of God, under that of Minerva; the justice of God under that of Juno.

The first idols or false gods that are said to have been adored, were the stars, fire, moon, &c. on account of the light, heat, and other benefits, which we derive from them. Afterwards the earth came to be deified, for furnishing fruits necessary for the subsistence of men and animals; then fire and water became objects of divine worship, for their usefulness to human life. In process of time, and by degrees gods became multiplied to infinity; and there was scarce any thing but the weakness or caprice of some devotee or other elevated into the rank of deity; things useless or even destructive not excepted. See Mythology.

GODALMING, a town of England, in the county of Surry, on the river Wey, 35 miles from London. It is a corporation; by whose charter their chief magistrate is a warden chosen yearly, who has 8 brethren his assistants. The parish is divided into 9 tithings. Its river abounds with good fish; and drives a grist-mill, two paper-mills, and three corn-mills; over which river a new bridge was begun July 22d 1783. Here is a manufactury of mixed and blue kerseys, also a manufactury of stockings; and the place is also famous for liquorice, and store of peat that burns better than pitch-coal; but a woman of this town (Mary Tuffs) in 1726 endeavoured to render it infamous, by a pretend-
Godfathers of some of the inhabitants. In that college in 1647. As he was a fellow of the college of physicians in 1646, and appointed reader of the anatomical lecture in that college in 1647. As he took part against Charles I., accepted the wardenship of Merton-college, Oxford, from Oliver Cromwell when chancellor, and sat for representative of that university in Cromwell's parliament, he was removed from his wardenship in a manner disgraceful to him by Charles II. He was however then professor of physic at Gresham college, to which he retired, and continued to attend those meetings that gave birth to the Royal Society; upon the establishment of which, he was nominated one of the first members. Being fully persuaded that the preparation of medicines was not the physician's business, he constantly prepared his own; and in 1668 published a treatise recommending his example to general practice. He died of an apoplectic fit in 1674; and his memory was preserved by the drops that bore his name, otherwise called Gutta Percha, the secret of which he sold to Charles II., and which Dr. Lifter affuies was only the volatile spirit of raw silk rectified and sifted with oil of cinnamon or some other essential oil. But he claims more credit for the translation of the works of medicine than for prescribing them, he constantly prepared his own; and in 1668 published a treatise recommending his example to general practice. Lincoln, the visitor. The only entire part is small, formerly a private chapel. Not many years since a stone coffin, said to have been Rosamond’s, who perhaps was removed from the church to this place, was to be seen here. The building has been put to various uses, and at present serves occasionally for a stable.

GODWIN (Francis), succisively bishop of Landaff and Hereford, was born in 1567. He was eminent for his learning and abilities; being a good mathematician, an excellent philosopher, a pure Latinist, and an accurate historian. He understood the true theory of the moon’s motion a century before it was generally known. He first hinted those hints afterwards purified by bishop Wilkins, in his “Secret and swift messenger,” and published “A catalogue of the lives of English bishops.” He has nevertheless been accused as a great sinner, for omitting no opportunity of disposing of preferments in order to provide for his children. He died in 1648.

GODWIN (Thomas), a learned English writer born in 1517, was master of the free-school at Abington in Berkshire; where he educated a great many youths, who became eminent both in church and state. His works show him to have been a man of great learning: such as, Historie Romane antiquitates, Synopsis antiquitatum Hebraicarum, Moses & Aaron, Florilegium Floridum, &c. He died in 1642.

GODWIN, or Godwin Sands, famous sand-banks off the coast of Kent, lying between the N. and S. Foreland; and as they run parallel with the land; and as they run parallel with the land; they have been the desideratum of those Jews who were firm to their religion; and by the person of the same name in the Revelation, they suppose Antichrist to be meant; the great enemy of the church and faithful. Some have endeavoured to prove that Gog, spoken of in Ezekiel, and Cambyses king of Persia, were one and the same person; and that Gog and Magog in the Revelations denote all the enemies of the church, who should be protectors of it to the commutation of ages.

GOGGLES, in surgery, are instruments used for curing squinting, or that distortion of the eyes which occasions this disorder. They are short conical tubes, composed of ivory stained black, with a thin plate of the same ivory fixed in the tubes near their anterior extremities. Through the centre of each of these plates is a small circular hole, about the size of the pupil of the eye, for the transmission of the rays of light. These goggles must be continually worn in the daytime, till the muscles of the eye are brought to act regularly and uniformly, so as to direct the pupil straight forwards; and by these means the cure will be sooner or later effected.

GOMMAGOG-HILLS, are hills so called, three miles from Cambridge, remarkable for the intrenchments and other works call’d up there: whence some suppose it was a Roman camp; and others, that it was the work of the Danes.

GOGUET (Antony-Yves), a French writer, and author of a celebrated work, intituled, L’Origine des Lois, des Arts, des Sciences, &c de leur Prayres chez les anciens Peuples, 1759, 3 vols. 4to. His father was an advocate, and he was born at Paris in 1716. He was very unpromising as to abilities, and reckoned even dull in his early years; but his understanding developing itself, he applied to letters, and at length produced the above work. The reputation he gained by it was great; but he enjoyed it a very short time, dying the same year of the small-pox; which disorder, it seems, he always dreaded. It is remarkable, that Conrad Fuger, to whom he left his library and his MSS, was so deeply affected with the death of his friend, as to die himself three days after him. The above work has been translated into English, and published in 3 vols. 8vo.

GOLCONDA, a kingdom in Asia, in the peninsula on this side the Ganges. It is bounded on the north by that of Oria, on the west by that of Balagate, on the south by Billagar, and on the east by the gulf of Bengal. It abounds in corn, rice, and cattle; but that which renders it most remarkable, are the diamond-mines, they being the most considerable in the world: they are usually purchased of the black merchants, who buy parcels of ground to search for these precious stones in. They sometimes fail in meeting with any, and in others they find immense riches. They have also mines of salt, bauxite for sword-blades, and curious callicoes and Chelsea.

Vol. VIII. Part I.
GOLD, the most valuable of all the metals, is of a bright yellow colour when pure, but becomes more or less white in proportion as it is alloyed with other metals. It is the heaviest of all known bodies, platinum only excepted, its specific gravity being that of distilled water as 19.640 to 1000. It melts in a low white heat; requiring, according to Mr Wedgewood’s calculation, 5237 degrees of Fahrenheit’s, or 32 of his own, thermometer for its fusion; a heat greatly superior to that which melts silver or copper; the former requiring only 4717, and the latter 4587 of Fahrenheit. Other metallurgists, however, have differed, and affirmed that copper requires for its fusion a greater degree of heat than either gold or silver.

Gold is by far the most tough and ductile, as well as the most malleable of all metals. According to Cronstedt, one grain of it may be stretched out so as to cover 98 Swedish ells, equal to 63.66 English yards of silver wire; but Wallerius asserts, that a grain of gold may be stretched in such a manner as to cover 500 ells of wire. At any rate, the extensio is prodigious; for, according to the leaf of these calculations, the millionth part of a grain of gold may be made visible to the naked eye. Nor is its malleability inferior to its ductility. Boyle, quoted as Apligny in his Treatise of Colours, says, that one grain and an half of gold may be beaten into 50 leaves of one inch square, which, if intercalated by parallel lines drawn at right angles to each other, and distant only the 100th part of an inch from each other, will produce 25 millions of little squares, each very easily discernible by the naked eye. Mr Magellan tells us, that its surface may be extended by the hammer 15000 times. "I am informed," says he, "by an intelligent gold-beater in England, that the finest gold leaf is that made in new ships, and must have an alloy of three grains of copper to the ounce troy of pure gold, or else it would be too soft to pass over the irregularities of the skin. He affirms, that 80 books, or 2000 leaves of gold, each measuring 33 square inches, viz. each leaf containing 10.89 square inches, weigh less than 384 grains. Each book, therefore, or 25 leaves, =272.23 inches, weighs less than 4 grains; so that each grain of the metal will produce 56,718 square inches."

From further calculations it may be made to appear, that the thickness of these leaves is less than 1/15000 of an inch; and that 16 ounces of gold would be sufficient to gold a silver wire equal in length to the whole circumference of the globe.

Gold is more elastic than lead or tin, but less so than iron, or even copper. It grows hard and brittle by hammering, but resumes its ductility on being slowly heated. Gold leaf exhibits a fine green colour on being interposed between the eye and the beams of the sun or any other luminous body. When exposed for some time to a strong heat, it becomes ignited, and at half melts, assuming at the same time a fine bluish-green colour; and, when cold, crystallizes into quadrilateral pyramids. This bluish-green colour, according to Mr Magellan, as well as the former, when a thin film of the metal is interposed between the eye and the luminous body, is owing to transmitted light. "The green light (says he) is transmitted in both cases, since all reflected colours are produced by the transmutation of light, as the ingenious philosopher Mr Delavals has lately discovered and demonstrated in his very elaborate treatise on this subject, inferred in the second volume of the memoirs published in 1753 by the Philosophical Society of Manchester." Sir Isaac Newton, in his Optics (page 162, edition of 1730), accounts for that phenomenon, saying, that "gold foliated, and held between the eye and the light, looks of a greenish blue; and therefore (says he) many gold leaves let into its body the blue rays to be reflected to and fro within it, till they be stopped and reflected; while it reflects the yellow outwards, and therefore looks yellow." It is therefore, in the two above cases, that some of the blue rays are transmitted along with the yellow ones; and both together appear of a bluish-green. If gold be exposed to the joined rays of light, excepting only the yellow ones, which we suppose stopped after they were separated by a prism, it only looks white like silver; "which flows (says Sir Isaac Newton) that its yellownefs arises from the excess of intercepted rays tinging that whitenefs with their colour when they are let to pass. It is a pleasing observation to look with a deep magnifier on various pieces of gold, silver, and Dutch (copper) leaves between the eye and the sunshine. The particles of silver are seen in the form of oblong dark lumps, with some interlines, like net-work, between them: those of the copper-leaf are more numerous and more regularly distributed; but the particles of the gold-leaf appear like little green transparent and similar particles, uniting between themselves by nearly diaphanous joints, as if they were forced to flatten in their edges, rather than they would break their mutual cohesion with one another."

Gold is more generally found native than any other metal; though Bergman informs us, that he does not know an instance of its ever being found perfectly free of alloy. Kirwan says it is seldom found pure; being generally alloyed with silver, copper, or iron, and sometimes with all the three. According to Wallerius, native gold is found, 1. In solid masses, in Hungary, Transylvania, and Peru. 2. In grains in the Spanish West Indies. 3. In a vegetable form like the branches, or twigs of plants. 4. In a druse figure, as composed of groups or clusters of small particles united together, found in Hungary. 5. Composed of thin plates, or thin pellicles, covering other bodies, found in Siberia. 6. In a crystalline form in Hungary.

The same author informs us, that gold, in its regular state, is formed either into angular crystals composed of yellow octaedrons, or into yellow irregular masses, which flow a grain-like texture. Brunnich says, that the native gold found in leaves is always crystallized on the surface; and with a magnifier they may be seen of a triangular pyramidal form. He informs us also, that in Transylvania he procured a specimen of cubic native gold, but never saw it any where else.

Gold is also found in the form of thick solid pieces. It is in general more frequently imbedded in quartz, and mixed with it, than with any other stone; and the quartz in which the gold is found in the Hungarian
Gold is principally supplied with gold from Chili and Peru in South America. A small quantity is likewise imported from China and the coast of Africa. The principal gold mines of Europe are those of Hungary, and next to them the mines of Salzburg. The mines of Adelfors in Smaland are likewise worked to advantage; and the veins of metal appear to be diffused over a great tract of land. Some gold from four to seven grains in the mark is also said to be extracted from the silver of the mines of Ofterilvarberget in the province of Dalarno. Native gold has also been found in Lapland above Tornea, and in Westmanland. In Peru it is found mixed with a flouzy matter not well known, from which it is extracted by amalgamation. Mr. Pallas mentions three gold mines that are worked there, near the river Pyshma, in which 500 men are employed. The metal is found in a powdery form, and also thin plates or leaves. Sometimes kernels or lumps of a spongy texture, and very light, are met with which contain a good quantity of gold dust. This gold-dust or waft-gold is usually washed out of sands wherein it lies in the form of loose grains or lumps. It is distinguished by the variously coloured substances wherewith it is mixed. The metal is also found separate from any matrix in lumps or visible grains mixed with sands. Thus it is met with in many rivers of Europe as well as in the other quarters of the world. It is also very diffused through masses of sand, particularly such as is of a yellowish-red or violet-colour; and in this state it is so universally diffused through every kind of earth, that Mr. Bergman thinks it the most common of all the metals, iron alone excepted. If 100 pounds of sand contain 24 grains of gold, the separation is said to be worth attending to. In Africa 5 pounds of sand often yield 63 grains of gold, or even more; and the heaviest sand, which is often black or red, contains the most. In Hungary, however, only 10 or 12 grains of gold are contained in 10,000 pounds of sand, and even this trifling quantity it has been extracted, though with labour.

Gold is brought down with most of the large rivers; even those which do not take their rise in mountains where gold is found. In Transylvania the river of Avanyos affords sufficiency to upwards of 700 Gipley families, who collect the gold from it. In Brazil it is found in such abundance, that their torrents are often turned with great labour and expense into new beds, in order to gather the gold there deposited by the running waters. It is also found there mingled with the earth in various shapes and forms. It is likewise said to be sometimes found in veins running through beds of coals.

Gold is said to be mineralized, when it is mixed with some other substance in such a manner as not to be acted upon by aqua regia. In this manner gold is mineralized.

1. By Sulphure. Many have insisted, that as gold and sulphur are not found to have any chemical attraction for one another, it is impossible that marcasite can contain any of the metal, or indeed that it can be found in any ore containing sulphur: but since we know by experience, that gold can be melted out of these ores, even after they have been digested in aqua regia, and that gold likewise enters into their sulphurated regulars, there is the greatest reason to believe, that some third substance, probably a metal, has by its admixture enabled the sulphur to unite with the minute quantity of gold. Marcasites, however, contain, at any rate, only a small quantity of the precious metal; and none is to be expected from them in places where no gold is in the neighbourhood. "I am not perfectly clear (says Cronstedt) whether the gold is really dissolved and indurated, or, if I may so express myself, vitrified in the fchiris; provided by this mineral body, we mean a garnet substance. But I have seen a piece of what is called fchir, whose texture was exactly like the Schemnitz blende; and in this case it might perhaps hold the same contents."

2. With Sulphur by means of Iron. Gold pyrites, or marcasité gold ore. This is a close and compact substance of a bright yellow colour. Here the gold is said to be mineralized by sulphur by means of iron, because it cannot be extracted by aqua regia or by amalgamation. A kind of gold pyrites is found at Adelfors in the province of Smaland, which contains an ounce or less of gold in an hundred weight of the ore. The Transylvania gold pyrites, according to Brunnicl, in which no gold can be perceived by the naked eye, contain from 30 to 100 and 110 ounces and upwards in an hundred weight. Those where the gold appears in the pyrites like fired Spanish stuff, hold 520 ounces, but they are very scarce. The mountain of Fazzebaye, near Zalaitha, is remarkable for gold pyrites; and here they seem also to contain semi-metallic parts.

The following is M. Magellan's method of accounting for the union of gold with this kind of pyrites. "It is well known, that gold may be dissolved by liver of sulphur. The procès given for this purpose by M. Apliny, p. 136 of his Treatise on Colours, is as follows. Reduce to powder four pounds of vegetable alkali (citrine, tartar), and as many of sulphur, with one of leaves of gold. Melt this mixture in a crucible with its cover; pour the fused matter out on a marble stone; pound it again when cold, and put the whole in a mortar with hot water; which being filtrated is of a greenish yellow colour, containing the gold dissolved. Now, as we know that hepdr sulphuris has been found in several pyrites, and Mafigani says that he found it in those lagoons near Sienna in Italy; is it not very natural to conclude, that this noble metal may be really mineralized in the auriferous pyrites?"

3. Auriferous Cassiterite, in which the metal is mineralized by means of quicksilver, said to be found in Hungary. Mr. Sage speaks of a specimen of gold from Hungary, now in the French king's cabinet at Paris, which is crystallized into quadrangular prisms of a grey yellowish colour and a brittle consistence, which he supposes to be the result of a mercurial amalgam of native gold.

5. The Schemnitz Blende, in which the gold is mineralized by means of zinc and iron. Cronstedt informs us, that the ores of zinc at Schemnitz in Hungary contain a great deal of silver, and that this silver is very rich in gold. Professor Brunnicl enumerates the following varieties of this ore. 1. Where the metal...
Gold is mineralized by means of a cubic lead-ore, containing silver found in the mines of Michaeli and some places in Transylvania. 2. By a copper pyrites with silver. This kind is called gold in Hungary: it has a compact surface of a pale yellow colour; but must not for that reason be confounded with the auriferous pyrites. 3. The Creminitz-ores in which the metal is mineralized by means of red gilder-ore. 4. By means of the metal scattered very minutely in it. The vein is quartz, seen through microscopes, and often cannot be seen at all before it is separated by various processes. 5. By cubic lead-ore, iron, and some unknown volatile parts. This ore, as described by Scopoli, is black; the richest pieces are laminated almost like an iron-glimmer, with a degree of flexibility. The vein is quartz, which is sometimes loose, and the metal scattered very minutely in it. It is found in Transylvania. 6. Native gold, with black-lead (or molybdana), has been found near Rimezembut in Upper Hungary; but our author (Professor Brunnicl) has not had any opportunity of examining whether it is mineralized by it or not. In all the above species, the gold is either entirely native, but so minutely divided, and so loosely scattered, that it can only be seen through microscopes, and often cannot be seen at all before it is separated by various processes: or it may not be in the form of native gold, but the metal as it were in embryo; in which case fire is necessary to bring the constituent parts together, and to add those that are wanting; in that cafe likewise it is never without some degree of metallic properties of gold. Kunckel and Boyle made the experiment by expelling gold for several months to the fire of a glafs-hole. It appears, however, that, by the violent heat of the sun-beams collected in the focus of a burning-glafs, some alteration may be produced in it. Komnekel and Boyle made the experiment by expelling gold for several months to the fire of a glafs-hole. It appears, however, that, by the violent heat of the sun-beams collected in the focus of a burning-glafs, some alteration may be produced in it. Homberg observed that gold, when exposed to the lens of Tichirhausen, formed, was volatilized, and even vitrified: and Macquer found, that the metal, when exposed to the lens of Mr. Trudaine, exhaled a fume which gilded silver, and was therefore gold in a volatile state: the globule of melted gold was agitated with a rapid circular motion, and became covered with a dull and as it were calciform pellicle: and lastly, that a violet vitrification was formed on the middle of the globule. This vitrification gradually extended, and produced a kind of button, flatter, or of a larger curvature, than that of the globe, and which stuck upon it as the transparent cornea appears on the sclerotica of the eye. This glafs increased in size, while the gold itself continually diminished: the support always appeared tinged with a purple colour, seemingly produced by the absorption of part of the glafs. Time did not permit him to vitrify a quantity of gold entirely. He observes, that it is a necessary condition to the violet glafs should be reduced with combustible matters, in order to justify the affection that it is the calx of that perfect metal, which would evidently appear to be the cause if it became revived into gold. But however this may be, Mr. Fourcroy is of opinion that this ought to be confidered as a true vitrified calx of gold; and this with the greater probability, as in many operations with this metal the purple colour is constantly produced, and many preparations of gold are employed to give that colour to enamel and porcelain. "Gold (says he) is therefore calcinable like the other metals; and only requires, as likewise does silver, a stronger heat, and a longer time to unite with the base of air than other metallic substances." Mr. Kirwan, on the other hand, tells us, that "gold exposed to the utmost heat of Mr. Parker's lens for some hours, lost no sensible part of its weight; yet, when in contact with earthy matters, it communicated a blue or purplish tinge to them; so that he believes an exceeding small portion of it might be dephlogistificated."

This experiment with the lens of Mr. Parker does not invalidate that of Macquer: for either Trudaine's lens may be more powerful than Mr. Parker's; or the air in France being more clear than in England, the action of the sun must be stronger. We are assured, however, that by means of the electric fire gold may be infamistaneously calcinable and even vitrified, whence we must conclude, not only that gold is really calcinable, but that the electric fire is almost infinitely more powerful than any other; as by its means we may in a moment accomplish what either cannot be done otherwise at all, or very imperfectly, even by the fiercest fire we can raise. The flame of a lamp blown by dephlogistificated air is also found sufficient to volatilize gold.

Gold being thus indestructible by the common operations of fire, equally resists its slow action in the atmosphere. It is altogether exempted from rusting; and though its surface becomes tarnished by exposure to the air, it is merely in consequence of the deposition of foreign bodies upon it. Water preserves no change, says Mr. Fourcroy; though, according to the experiments of Lagaraye, it seems capable of dividing it nearly in the same manner as it does iron.

Gold combines with various metals; and is commonly alloyed in a certain proportion with copper, which gives it a red colour and greater firmness than it possesseth when very pure, at the same time that it is thus rendered more fusible. In this state it is used for money, plate, and toys of different kinds. It is sometimes also alloyed with silver, which deprives it of its colour, and renders it very pale: this alloy, however, is not made without some difficulty, on account of the very different specific gravities of the two metals, as Homberg observed, who saw them separate during their fusion. The alloy of gold with silver forms the green gold of the jewellers and gold-beaters.

As gold has been rendered, by the universal consent of mankind, the most valuable substance in the world, it is of great consequence to be able to discover its degree of purity, in order to prevent the adulterations which would naturally be practiced, and to pro...
Gold. produce an equality of value in the different pieces dispersed in commerce. The chemical methods by which this is accomplished, are related under the articles Chemistry, and Essaying of Metals. To ascertain with precision the quantity of imperishable metal it may contain, a given mass of gold is supposed to contain 24 parts called carats; each carat being supposed divided into 32 parts called thirty-seconds of a carat. If the gold after the operation has lost one grain in 24, it is gold of 23 carats; if it has lost a grain and a half, it is gold of 22 carats 16 thirty-seconds, and so on.

The weight used in the assay of gold is called the assay weight, and usually consists of 24 grains; it is divided into 24 carats, which are likewise subdivided into 32 parts. An assay weight is likewise used which weighs 12 grains; and is likewise divided into 24 carats, subdivided again into thirty-seconds.

The scarcity and great price of gold prevents its being made into vessels or utensils; but as its brilliancy and colour are agreeable, methods have been found of applying it to the surface of a great number of bodies, which it thus not only beautifies, but by its indestructibility preserves from the injuries of the atmosphere. The art of applying it in this manner is called gilding; and the immense ductility of gold already mentioned, renders it capable of being applied in this manner at much less expense than could be imagined. It is used besides in gilding, either in a state of solution by acids, or amalgamated with mercury, which are called watery gilding. It was formerly used in medicine, and great Virtues were ascribed to it; whence the great number of golden tinctures, elixirs, &c. of quacks; but all these are now defervedly exploded, and the best practitioners allow that gold, in whatsoever manner it be prepared, is either inactive or dangerous.

Gold in its metallic state cannot be combined with the vitriifiable earths, but its calces may; for which reason they are often used in enameled painting and in porcelain, where they produce a beautiful violet-colour. Glafs is tinged by the means of a beautiful red of which we have an account in Neri's art of glafs-making; though Dr Lewis says he never could succeed in making the colour diffuse itself equally throughout the substance of the glafs. See Colouring of Glass.

The preparation of gold called aurum fulminans is taken notice of under the article Chemistry, No 103, M. Magellan takes notice of its extraordinary fulminating property, and says that its fragrance is 64 times greater than that of an equal quantity of gun-powder. According to Bergman, the strength of the explosion is 176 times greater than that of gun-powder (20 grains of aurum fulminans being equivalent to half a pound of gun-powder). Bergman accounts for the amazing strength of this explosion, by supposing it owing to the quantity of air extricated at the time; but this, according to his own account, cannot be at all sufficient for such a purpose; and Magellan is of opinion that "this wonderful phenomenon seems not yet completely accounted for by any hypothesis yet known." See the articles Chemistry, and Explosion.

It is on account of the singular and excellent natural qualities of this metal (says our author), which are considerably heightened by its scarcity, that gold is so much valued among all the civilized nations of the world. Mr Pautcson, in his Meteorologik, p. 34, says, that one cubic foot (French measure) of gold is worth 2,153,000 livres tournoyes, or 89,708 guineas and seven shillings, supposing the Louis d'Or to be equal to the guineas; and that the respective value of the former cubic foot of gold is equal to 25,6 cubic feet of silver; each of this last metal being reckoned worth about 84,000 French livres, or 3503 guineas and eight shillings; so that if we suppose the monied species in France to be but two milliards of French livres, according to the estimation of Mr Neckar in his Treatise upon the Commerce of Corn, the whole amount should make but a solid cube of gold less than 10 feet on each side. So trifling is the physical object that excites the activity of 222,000 of the human species, the number that is paid to be that of the inhabitants of France.

We shall close this article with some observations by M. Magellan on the state in which gold is found in the bowels of the earth, and consequently of the origin of gold ores. "As to the natural existence of gold in the bowels of the earth (says he), there have been two opinions among mineralogists; some pretending that it is only found in its metallic or native form; and others, that it is sometimes found mineralized in an intimate union with other substances. M. Kirwan holds the former, and the celebrated Bergman the latter. But, says Mr Kirwan, though Mr Bergman inclines to the opinion of the mineralization, yet he is candid enough to own, that the gold, when extracted from this ore, is of a granular or angular form. It is therefore very doubtful, whether it was not rather mixed, than truly combined with the sulphur and iron: and its proportion being exceedingly small so that 100 pounds of the pyrites scarcely contain an ounce of gold, it is not a wonder that it should escape the action of aqua regia; more especially as the nitrous acid becomes so phlogisticated by acting on the pyrites, as not to be able to dephlogisticate the marine. Likewise mercury, by reason of the gold particles being enveloped in the fulphurous iron, can hardly 20 parts to it. 

"These arguments (says M. Magellan) against the true mineralization of gold, are fully answered by the facts already mentioned. Besides, it is well known, that gold can be combined and calcined, via fessa, by the liver of sulphur and femimetals. This being acknowledged on both sides of the question, why should we insist on denying this mineralization, when it is out of doubt, among mineralogists of rank, that volcanic fires have had a great share in the convulsions and revolutions of this globe, of which every one has the most convincing proofs almost everywhere. "The account given by Mr Hacquet of the gold mines at Nagy-ag in Transylvania, the ancient Dacia, which lies about 45° latitude, offers the most convincing proofs of this assertion. The country all round these mines bears an incontrovertible appearance of being a volcanic one; and among various other metals, there are at least 13 kinds of gold ores, most of them mineralized. These are, 1. Gold mineralized by sulphur, zinc, and arsenic, in a grey-yellowish volcanic ore, which is called cottuners, or cotton ore, on account of its lightness and texture. 2. By iron and arsenic, formed by strata; one containing black silver ore, then sphaltum, galena, quartz, and grey gold ore: it yields about half an ounce in the 100 pounds. 3. By sulphur, antimo-
Gold.

4. In the form of crooked threads mixed with quartz and gypseous spath; a poor mine. 5. Dendritiform, like the moco stone, or the agate from Aberdein in the Palatinate; but these black dendrites are in a reddish stone. 6. Amorphous, very compact, in small grains, with spath and quartz. A quintal of it yields two ounces of gold, and more of silver.

7. By sulphur, great part of zinc, and a little antimony and arsenic; not rich. 8. Of a black or dark-reddish colour, containing an affirmative pyrites; not rich. 9. Of a bluish colour, mineralized by sulphur, antimony, iron, and a little arsenic mixed with silver; very rich in gold.

10. Parly laminated with needles of a blackish yellow colour: this gives 66 ounces of gold per cwt of gold, according to Scopoli. 11. Polished with gypseous spath and yellow pyrites. 12. In irregular laminae, on a grayish argille. The gold looks like silver, is surrounded by spars of a pale rosy colour. 13. In crystallized laminae from two to four lines diameter, of an hexagonal form, and very much resembling molybdena. The vein was lost for some time, but lately found again on mining for letting out water from the main. This ore is very rare, and has given 372 ounces per cwt of a mixed metal; five of which were gold, and one silver.

Method of Recovering Gold from Gilt Works. The solvent power of gold, and the indissolubility of silver, in aqua regia, affords a principle on which gold may be separated from the surface of silver; and, on this foundation, different processes have been contrived, of which the two following appear to be the best. Some powdered sal ammoniac, moistened with aquafortis into the hexagonal form, and very much resembling molybdena. The vein was lost for some time, but lately found again on mining for letting out water from the main. This ore is very rare, and has given 372 ounces per cwt of a mixed metal; five of which were gold, and one silver.

The Editors of the Encyclopædia give a method of recovering the gold from wood that has been gilt on a water-size: this account is extracted from a memoir on the same subject, presented to the Academy of Sciences by M. de Montamy. The gilt wood is steeped for a quarter of an hour in a quantity of water sufficient to cover it, made very hot: the size being thus softened, the wood is taken out, and scrubbed, piece by piece, in a little warm water, with short stiff bristle brushes of different sizes, some small for penetrating into the carvings, and others large for the greater dispatch in flat pieces. The whole mixture of water, size, gold, &c. is to be boiled to dryness, the dry matter made red hot in a crucible to burn off the size, and the remainder ground with mercury, either in a mortar, or where the quantity is large, in a mill.

Cold-Wire. See Guinea.

Cold-Wire, a cylindrical ingot of silver, super fixtures gilt or covered with gold at the fire, and afterwards drawn successively through a great number of little round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See Wire-Drawing.

It may be observed that, before the wire be reduced to this excessive fineness, it is drawn through above 140 different holes; and that each time they draw it, it is rubbed after with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

Cold-Wire flattened, is the former wire flattened between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is, without spinning, in certain stuffs, laces, embroideries, &c. See Stuff, &c.

Cold-Thread, or Spun-gold, is flattened gold, wrapped or laid over a thread of silk, by twining it with wheel and iron-bobbins.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two is rendered quite flat, but without losing any thing of its gilding: and is rendered so exceedingly thin and flexible, that it is easily spun on silk thread, by means of a hand-wheel, and so wound on a spool or bobbin. See Wire-Drawing.
Gold-Leaves or Beaten Gold, is gold beaten with a hammer into exceeding thin leaves, so that it is composed that an ounce may be beaten into 1650 leaves, each three inches square, in which state it takes up more than 159,052 times its former surface. See Gold-Leaf.

It must be observed, however, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire drawers toOULD their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. See Gilding.

Gold-Bread. See Brocade.

Mosaic-Gold. is gold applied in panells on a proper ground, distributed into squares, lozenges, and other compartments; part of which is shadowed to raise or heighten the rest. See Mosaic.

Gold-Plate for Enamelling are generally made of ducat gold, whose fineness is from 235 to 237 carats; and the finest gold is the best for this purpose, unless where some parts of the gold are left bare and unplated, as in watch-cases, snuff-boxes, &c. for which purpose a mixture of alloy is necessary, and silver is preferred to copper, because the latter disposes the plates to tarnish and turn green. See Enamelling.

Shell-Gold is that used by the gilders and illuminers, and with which gold letters are written. It is made by grinding gold leaves, or gold-beaters fragments, with a little honey, and afterwards separating the honey from the powdered gold by means of water. When the honey is washed away, the gold may be put on paper or kept in shells; whence its name. When it is used, it is diluted with gum-water or soap-finds. The German gold-powder, prepared from the Dutch gold-leaf in the same manner, is generally used; and when it is well foured with varnish, answers the end in japanners gilding as well as the genuine.

Gold-Size for burnished gilding is prepared of one pound and an half of tobacco-pipe clay, half an ounce of red chalk, a quarter of an ounce of black lead, forty drops of sweet oil, and three drams of pure tallow; grind the clay, chalk, and black lead, separately, very fine in water; then mix them together, add the oil and tallow, and grind the mixture to a due confluence.

Gold-size of japanners may be made by pulverizing gum animi and asphaltum, of each one ounce; red-lead, a little charge of gold, and umbre, of each one ounce and a half, mixing them with 3 pounds of linseed-oil, and boiling them, observing to stir them till the whole be incorporated, and appears on growing cold of the confluence of tar; strain the mixture through a funnel, and keep it stopped up in a bottle for use. When it is used, it must be ground with as much varnish as will give it an opaque body, and diluted with oil of turpentine, so that it may be worked freely with the pencil. A simple preparation consists of one pound of linseed oil and four ounces of gum animi; powder the gum, and mix it gradually with the boiling oil; let it continue to boil till it becomes of the confluence of tar; strain it through a coarse cloth; keep and use it as the other.

Gold-Finch, in ornithology. See Fringilla.

These are seed-birds of very curious colours, and which, were they not so common, would probably be very much esteemed.

Vol. VIII.
GOL

[ 10 ]

GOLDEN, particularly of the philosopher's stone. Others have explained it by the profit of the wool-trade to Celts, or the gold which they commonly gathered there with fleeces in the rivers. See ARGONAUTS.

Order of the Golden Fleece, is a military order instituted by Philip the Good, duke of Burgundy, in 1390. It took its denomination from a representation of the golden fleece, borne by the knights on their collars, which consisted of flints and fleeces. The king of Spain is now grand master of the order, in quality of duke of Burgundy: the number of knights is fixed to thirty-one.

It is usually said to have been instituted on occasion of an immense profit which that prince made by wool; though others will have a chemical mystery couched under it, as under that famous one of the ancients, enough of metallurgy to be able to infinuate that the fabulous conquest particularly of the duke of Burgundy had in view both the golden fleece of Jason, and a[ured the young prince to leave materials of the ingot to the thinness they wanted: besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be foiled and forfeited to the king. The cities of York, Exeter, Bristol, &c. are places appointed for the assay wrought-plate of goldsmiths; also a duty is granted on silver-plate of sixpence an ounce, &c. Plate made by goldsmiths shall be of a particular fineness, on pain of forfeiting, and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broken and defaced; and the fees for assay are particularly limited.

GOLDSMITH (Oliver), a celebrated English writer, was born at Roscommon in Ireland in the year 1731. His father, who possessed a small estate in that county, had nine sons, of whom Oliver was the third. He was originally intended for the church; and with that view, after being well instructed in the classics, was, with his brother the Rev. Henry Goldsmith, placed in Trinity-college, Dublin, about the latter end of the year 1749. In this seminary of learning he continued a few years, when he took a bachelor's degree: but his brother not being able to obtain any preferment after he left the college, Oliver, by the advice of Dean Goldsmith of Cork, turned his thoughts to the study of physic; and, after attending some courses of anatomy in Dublin, proceeded to Edinburgh in the year 1751, where he studied the several branches of medicine under the different professors in that university. His beneficent disposition soon involved him in unexpected difficulties; and he was obliged precipitately to leave Scotland, in consequence of engaging himself to pay a considerable sum of money for a fellow-student.

A few days after, about the beginning of the year 1754, he arrived at Sunderland, near Newcastle, where he was arrested at the suit of a tailor in Edinburgh, to whom he had given security for his friend.
Goldsmith. By the good offices of Laughlin Maclane, Esq.; and Dr. Sleigh, who were then in the college, he was soon delivered out of the hands of the bailiff; and took his passage on board a Dutch ship to Rotterdam, where, after a short stay, he proceeded to Brussels; he then visited great part of Flanders; and after passing some time at Strinburg and Louvain, where he obtained a degree of bachelor of physic, he accompanied an English gentleman to Bern and Geneva.

It is undoubtedly fact, that this ingenious unfortunate man travelled on foot most part of his tour. He had left England with very little money; and being of a philosophical turn, and at that time possessing a body capable of sustaining every fatigue, and a heart not easily terrified at danger, he became an enthusiast to the design he had formed of seeing the manners of different countries. He had some knowledge of the French language and music, and he played tolerably well on the German flute; which, from an amusement, became at times the means of subsistence. His learning produced him a hospitable reception at most of the religious houses; and his music made him welcome to the peasants of Flanders and other parts of Germany. "Whenever I approached," he used to say, "a peasant's house towards night-fall, I played one of my motley tunes; and that procured me not only a lodging, but subsistence for the next day: but in truth (his confiant expression) I must own, whenever I attempted to entertain persons of a higher rank, they always checked my performance odious, and never made me any return for my endeavours to please them."

On Mr Goldsmith's arrival at Geneva, he was recommended as a proper person for a travelling tutor to a young man, who had been unexpectedly left a considerable sum of money by his uncle Mr S., formerly an eminent pawnbroker near Holborn. This youth, who had been articled to an attorney, on his engaging with his preceptor, made a sketch of his delightful poem called the Traveller, and his Vicar of Wakefield, was followed by the performance of his comedy of the Good-natured Man at Covent-Garden theatre, and placed him in the first rank of the poets of the present age.

Among many other persons of distinction who were desirous to know him, was the Duke of Northumberland; and the circumstances that attended his introduction to that nobleman is worthy of being related, in order to show a striking trait of his character. "I was invited," said the Duke (as he was then universally called) "by my friend Mr Piercy, to wait upon the duke, in consequence of the satisfaction he had received from the perusal of one of my productions. I dressed myself in the best manner I could; and, after paying some compliments I thought necessary on such an occasion, proceeded to Northumberland-house, and acquainted the servants that I had particular business with his Grace. They showed me into an antichamber; where, after waiting some time, a gentleman
Goldsmith, gentleman very gently dressed made his appearance.

Tying him for the duke, I delivered all the fine things I had composed in order to compliment him on the beauty he had done me: when, to my great astonishment, he told me I had mistaken him for his matter, who would see me immediately. At that instant the duke came into the apartment; and I was so confused on the occasion, that I wanted words barely sufficient to express the sense I entertained of the duke's politeness, and went away extremely chagrined at the blunder I had committed."

Another feature of his character we cannot help laying before the reader. Previous to the publication of his Deferted Village, the bookseller had given him a note for one hundred guineas for the copy, which the Doctor mentioned a few hours after to one of his friends: who observed, it was a very great sum for so short a performance. "In truth," replied Goldsmith, "I think so too; I have not been easy since I received it; therefore I will go back and return him his note;" which he absolutely did; and left it entirely to the bookseller to pay him according to the profits produced by the sale of the piece, which turned out very considerable.

During the last rehearsal of his comedy intitled She Stoops to Conquer, which Mr. Coleman had no opinion would succeed, on the Doctor's objecting to the repetition of one of Tony Lumpkin's speeches, being apprehensive it might injure the play, the manager with great keenness replied, "Psha! my dear Doctor, do not be fearful of quibbs, when we have been sitting almost these two hours upon a barrel of gunpowder." The piece, however, contrary to Mr. Goldsmith's expectation, was received with uncommon applause by the audience; and Goldsmith's pride was so hurt by the severity of the above observation, that it entirely put an end to his friendship for the gentleman that made it.

Notwithstanding the great success of his pieces, by some of which it is ascertained, upon good authority, he cleared 1800l. in one year, his circumstances were by no means in a prosperous situation; which was partly owing to the liberality of his disposition, and partly to an unfortunate habit he had contracted of gaming; the arts of which he knew very little of; and consequently became the prey of those who were unprincipled enough to take advantage of his simplicity.

Just before his death he had formed a design for executing an Universal Dictionary of Arts and Sciences, the prospectus of which he actually published. In this work several of his literary friends (particularly Sir Joshua Reynolds, Dr. Johnson, Mr. Beauclerck, and Mr. Garrick) had undertaken to furnish him with articles upon different subjects. He had entertained the most favourable expectations from the success of it. The undertaking, however, did not meet with that encouragement from the booksellers which he had longed for; it would undoubtedly receive; and he used to lament this circumstance almost to the last hour of his existence.

He had been for some years afflicted, at different times, with a violent strangury, which contributed not a little to embitter the latter part of his life; and which, united with the vexations which he suffered upon other occasions, brought on a kind of habitual debility. In this unhappy condition he was attacked by a nervous fever, which, being improperly treated, terminated in his dissolution on the 4th of April 1774.

As to his character, it is strongly illustrated by Mr. Pope's lines,

GOMBROON, by the natives called Bander Abassi, a city of Persia, situated in N. Lat. 27. 40. E. Long. 55. 30. The name of Gombroon, or Gomorong, Captain Hamilton tells us, it had from the Portuguese, because it was remarkable for the number of prawns and shrimps caught on its coasts, by them called come-rong. This city owes its wealth and grandeur to the demolition of Ormus, and the downfall of the Portuguese empire in the East Indies. It is now justly accounted one of the greatest marts in the East, was built by the great Shah Abas, and from him, as some think, obtained the name of Bander Abassi, which signifies the court of Abas. It stands on a bay about nine leagues to the northward of the east end of the island of Kilimnath, and three leagues from the famous Ormus. The English began to settle here about the year 1631, when, in consideration of their services against the Portuguese, Shah Abas granted them half the customs of that port. This was confirmed by a plenipotentiary, and duly regarded, till the coronation of Kishmili, when the revenue of the town had been sacked and ravaged by a European nation. The English have a country-house and gardens, to which they retire occasionally. Here they have whole groves of Seville orange-trees, which though not natural to the country, thrive very well, and are always verdant, bearing ripe and green-fruits, with blossoms, all at the same time. They have likewise tanks and ponds of fine fresh-water, with every thing else that can moderate the heat of the climate, and render life agreeable and elegant. About ten miles from Asfæn is a place called Minas, where are cold and hot natural baths, reckoned infallible in the cure of all scrophulous disorders, rheumatisms, and other diseases, by bathing.

Gombroon is extremely populous, on account of the commerce carried on by the Dutch and English factories, as well as the natives. The English factory is close by the sea, at some distance from the Dutch, which is a commodious and fine new building. A great part of the company's profits arises from freights. As the natives have not one good ship of their own, and are extremely ignorant of navigation, they freight their goods for Surat, and other Indian marts, in English and Dutch bottoms, at an exorbitant rate. The commodities of the Gombroon market are, fine wines of different kinds, raisins, almonds, kifh-milhes, prunelles, dates, pistachio-nuts, ginger, silk, carpets, leather, tutton, galbanum, ammoniac, asa-fatida, tragacanth, with other gums, and a variety of shop medicines. These are in a great measure the produce of Carmania, which they bring to Gombroon in caravans. The English company has once a small factory in the province of Carmania, chiefly for the sake of a fine wool produced there, and used by the hatters. The said company had once a project of carrying a breed of the Perian goats to St. Helena; but whether it was executed, or what success it met with, we cannot say. Although the company pay no customs, yet they usually make a present to the Shabander, to avoid the trouble he has it in his power to give them. All private traders with the company's paffes, enjoy the same privileges, on paying two per cent. to the company, one to the agent, and one to the broker. All private trade, either by European or country ships, has long been engraffed by the company's servants.

GOMERA, one of the Canary islands lying between Ferro and Teneriffe. It has one good town of the same name, with an excellent harbour, where the Spanish fleet often takes in refreshments. They have corn sufficient to supply the inhabitants, with one sugar-work, and great plenty of wine and fruits. It is subject to the Spaniards, who conquered it in 1445. W. Long. 17. 10. N. Lat. 28. 0.

GOMORRAH (anc. geog.), one of the cities of the plain or of the vale of Siddim in Judæa, destroyed 48-
GOMOZIA, in botany: A genus of the digynia order, belonging to the tetrandria class of plants. The corolla is campanulated, quadripartite above; there is no calyx; the berry bicolunar.

GOMPHOSIS, in anatomy, that kind of articulation by which the teeth are fixed in the jaw-bone. See Anatomy, n. 2.

GONDI, (John Francis Paul), Cardinal de Retz, was the son of Philip Emmanuel de Gondi, Count de Joigny, lieutenant-general, &c. and was born in 1613. From a doctor of the Sorbonne, he first became coadjutor to his uncle John Francis de Gondi, whom he succeeded in 1654 as archbishop of Paris; and was finally made a cardinal. This extraordinary person has drawn his own character in his memoirs with impartiality. He was a man, who from the greatest degree of debauchery, and till languishing under its consequences, made himself adored by the people as a preacher. At the age of 23, he was at the head of a conspiracy against the life of Cardinal Richelieu: he precipitated the parliament into cabals, and the people into sedition; he was (says M. Voltaire) the first bishop who carried on a civil war without the mask of religion. However, his intrigues and schemes turned out ill, that he was obliged to quit France; and he lived the life of a vagrant exile for five or six years, till the death of his great enemy. Cardinal Mazarin when he returned on certain stipulated conditions. After afflicting in the concave at Rome, which chose Clement IX. he retired from the world, and ended his life like a philosopher in 1679; which made Voltaire say, that in his youth he lived like Catiline, and like Atticus in his old age. He wrote his Memoirs in his retirement; the best edition of which is that of Amsterdam, 4 vols 12mo. 1719.

GONDOLA, a flat boat, very long and narrow, chiefly used at Venice to row on the canals. The word is Italian, gondola. Du Cange derives it from the vulgar Greek gondole, "a bark," or "little ship." Lancelot deduces it from gondus, a term in Athenaeus for a sort of vase.

The middle-sized gondolas are upwards of thirty feet long and four broad; they always terminate at each
Gondola each end in a very sharp point, which is raised perpendicularly to the full height of a man.

The address of the Venetian gondoliers, in passing along their narrow canals, is very remarkable: there are usually two to each gondola, and they row by pulling before them. The fore-man reaps his oar on the left side of the gondola: the hind man is placed on the stern, that he may see the head over the till or covering of the gondola, and reaps his oar, which is very long, on the right side of the gondola.

Gondola is also the name of a passage-boat of six or eight oars, used in other parts of the coast of Italy.

Gonorrhoea, an effluvium of white, greenish, or differently-coloured, matter from the urethra; most commonly owing to venereal infection. See Medicine and Surgery.

Gonzaga (Lucretia), was one of the most illustrious ladies of the 16th century; and much celebrated for her wit, her learning, and her delicate style. Hortensio Lando wrote a beautiful panegyric upon her, and dedicated to her his dialogue of moderating the passions. Her beautiful letters have been collected from the notes she wrote to her servants; several were made to her. All that came from her even of the notes she wrote to her servants; several of which are to be met with in the edition of her letters.

Good, in general, whatever is apt to encrease pleasure, to diminish pain in us; or, which amounts to the same, whatever is able to procure or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

Moral Good denotes the right conduct of the several senes and passions, or their just proportion and accommodation to their respective objects and relations. See Morals.

Good bearing, (bonus gestus,) signifies an exact carriage or behaviour of a subject towards the king and the people, whereunto some persons upon their misbehaviour are bound: and he that is bound to this, is said to be more strictly bound than to the peace; because where the peace is not broken, the surety de bonus gesto may be forfeited by the number of a man's company, or by their weapons.

Good behaviour, in law, an exact carriage and behaviour to the king and his people. A justice of the peace in Britain may, at the requisition of another, or where he sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any persons whatsoever, below the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's bench, where such nobleman may be bound to keep the peace. Infants and feem-coverts, who ought to find surety by their friends, may be bound over to their good behaviour; as also lunatics, that have sometimes lucid intervals, and all others who break the peace, or being suspected to do it by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. A person may be likewise bound to his good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whores-mongers, common whores, cheats, libellers, &c. He who demands surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

Good-Breeding. See Good-Manners.

Good-Friday, a fast of the Christian church, in memory of the sufferings and death of Jesus Christ. It is observed on the Friday in holy or passion week; and it is called, by way of eminence, good, because of the blest effects of our Saviour's sufferings, which were a propitiatory or expiating sacrifice for the sins of the world. The commemoration of our Saviour's sufferings has been kept from the very first ages of Christianity, and was always observed as a day of fasting and humiliation. Among the Saxons it was called Long Friday: but for what reason, except on account of the long fasting and offices then used, is uncertain. On Good-Friday the pope sits on a plain form; and, after service is ended, when the cardinals wait on him back to his chamber, they are obliged to keep a deep silence, as a testimony of their sorrow. In the night of Good-Friday the Greeks perform the obsequies of our Saviour round a great crucifix, laid on a bed of state, adorned with flowers; these the bishops distribute among the attendants when the office is ended. The Armenians, on this day, set open a holy sepulchre, in imitation of that of mount Calvary.

Good-Hope, or Cape of Good Hope, a promontory of Africa, where the Dutch have built a good town and fort. It is situated in the country of the Hottentots; for an account of whom, and of the country at large, with its first discovery, see the article Hottentots.

The Cape of Good-Hope has been generally esteemed the most southerly point of Africa, though it is not truly so. In Phillip's Voyage to Botany Bay, we are told, that the land which projects farthest to the south is a point to the east of it, called by the English Cape Agulhas; a name corrupted from the original Portuguese das Agulhas, which, as well as the French appellation des Agulhes, is descriptive of its form, and would rightly be translated Needle Cape.

On approaching the Cape, a very remarkable eminence may in clear weather be discovered at a considerable distance; and is called the Table-mountain from its appearance, as it terminates in a flat horizontal surface, from which the face of the rock descends almost perpendicularly. In the mild or summer season, which commences in September, and continues till March, the Table Land or Mountain, is sometimes suddenly capped with a white cloud, by some called the spreading of Table-cloth. When this cloud seems to roll down the steep face of the mountain, it is a sure indication of an approaching gale of wind from the south-east; which generally blows with great violence, and some-
...sometimes continues a day or more, but in common is of short duration. On the first appearance of this cloud, the ships in Table Bay begin to prepare for it, by striking yards and top-masts, and making every thing that can be an obstacle to the wind. When the wind strikes the Table Land, divided by a small valley, stands on the right hand side of Table Bay a round hill, called the Sugar Loaf; and by many the Lion's Head, as there is a continuance from it contiguous to the sea, called the Lion's Rump; and when you take a general view of the whole, it very much resembles that animal with his head erect. The Sugar Loaf or Lion's Head, and the Lion's Rump, have each a flag-raft on them, by which the approach of ships is made known to the governor, particularly their number, nation, and the quarter from which they came. To the eastward, separated by a small channel from the Table Land, stands Charles's Mount, well known by the appellation of the Devil's Tower, or Devil's Head; and so called from the violent gusts of wind supposed to issue from it when it partakes of the cap that covers the Table Land, though these gusts are nothing more than a degree of force the wind acquires in coming through the channel. When this phenomenon appears in the morning, which is by no means so frequent as in the evening, the sailors having a saying, as the Devil's Tower is almost contiguous to the Table Land, that the old gentleman is going to breakfast; if in the middle of the day, that he is going to dinner; and if in the evening, that the cloth is spread for supper. Table-mountain rises about 3567 feet above the level of the sea; the Devil's Tower, about 3368; and the Lion's Head, 2764. In the neighbourhood of the latter lies Cape Flats, a district consisting of two farms, wherein the famous wines of that name are produced.

The above described high lands form a kind of amphitheatre about the Table-valley, where the Cape settlements are situated. This is situated at the bottom of the middle height, or Table-mountain; and almost in the centre of the Table Bay, so called from that mountain.—This bay, it is observed in Philip's Voyage, "cannot properly be called a port, being by no means a station of security; it is exposed to all the violence of the winds which set into it from the sea; and is far from sufficiently secured from those which blow from the land. The gusts which descend from the summit of Table-mountain are sufficient to force ships from their anchors, and even violently to annoy persons on the shore, by destroying any tents or other temporary edifices which may be erected, and raising clouds of fine dust, which produce very troublesome effects. A gale of this kind, from the south-east, blew for three days successively when Captain Cook lay here in his first voyage; at which time, he informs us, the Resolution was the only ship in the harbour that had not dragged her anchors. The storms in the sea are still more formidable: so much so, that ships have frequently been driven by them from their anchorage, and wrecked at the head of the bay. But these accidents happen chiefly in the quarte month, or winter months, from May to August; during which time few ships venture to anchor here. The British fleet arriving late lay perfectly unmoored as long as it was necessary for it to remain in this situation.—Farie Bay, on the south-east side of the Cape, is more secure than Table Bay during the prevalence of the north-west winds, but liable for strong gales from the south-east. It is, however, less frequented, being 24 miles of very heavy land in front of Cape Town, whence almost all necessaries must be procured. The most sheltered part of False Bay is a recess on the west side, called Simon's Bay."
In a word, Cape Town is at this time fortified with strength, regularity, and judgment. The governor's house is delightfully situated, nearly in the centre of an extensive garden, the property of the Dutch East India company, usefully planted, and at the same time elegantly laid out. The governor's family make what use they please of the produce of the garden, which is various and abundant; but the original intention of the company in appropriating to their hospital which is generally pretty full when their convalescents reap the benefit of a change of air, and for its handsome, pleasant, and well-shaded walks, is much frequented by people. The governor's family make what use they please of the produce of the garden, which is various and abundant; but the new menagerie, in which the company have half a dozen wild animals and about the same number of curious birds.

There are two churches in the town; one large, plain, and unadorned, for the Calvinists, the prevailing sect; and a smaller one for the Lutherans. The hospital, which is large and extensive, is situated at the upper end of the town, close to the company's garden; where the convalescents reap the benefit of a wholesome pure air, perfumed with the exhalations of a great variety of rich fruit trees, aromatic shrubs, and odorous plants and flowers; and likewise have the use of every production of it.

Besides their hospital, the Dutch East India company have several other public buildings, which tend to improve the appearance of the town. The two principal of these are, the stables and a house for their horses. The former is a handsome range of buildings, capable of containing an incredible number of horses. Those have at the cape are small, spirited, and full of life. The latter is a building of considerable extent, where the slaves, both male and female, have separate apartments, in a very comfortable style, to reside in after the fatigue and toil of the day; and there are several officers placed over them, who have commodious apartments, and treat them humanely.

The inhabitants of the Cape, though in their persons large, stout, and athletic, have not all that phlegm about them which is characteristic of Dutchmen in general. The physical influence of climate may in some degree account for this; for it is well known that in all southern latitudes the temper and disposition of the people are more gay, and that they are more inclined to luxury and amusements of every kind, than the inhabitants of the northern hemisphere. The ladies are lively, good-natured, and familiar; and from a peculiar gay turn, they admit of liberties that would be unutterable in England, though perhaps they as seldom overstep the bounds of virtue as the women of other countries.

The heavy draft work about the Cape is mostly performed by oxen; which are here brought to an uncommon degree of usefulness and docility. It is not uncommon to see 14, 16, and sometimes 18, in one of their teams; when the roads are heavy, they sometimes, though rarely, yoke 20; all which the Hottentots, Malays, and Cape slaves, have in the most perfect subjection and obedience. One of these fellows places himself on the fore part of the waggons, or, when loaded, on the top of the load, and with a tremendous long whip, which from its size he is obliged to hold in both his hands, manages these creatures with inexplicable dexterity. When he finds expedition needful, he can make them keep whatever pace he chooses, either trot or gallop (a gait performed or kept up with difficulty by European oxen), and that with as much ease as if he was driving horses. They likewise manage horses with the same dexterity; and to see one of them driving three, four, five, and sometimes six pair, in hand, with one of these long whips, would make the most complete master of the whip in England cut a despotic figure. Carriages are not very numerous at the Cape, as the inhabitants in general travel in covered waggons, which better suit the roughness of the country. The governor and some few of the principal people keep coaches, which are a good deal in the English style, and always drawn by fine horses.

GOOD MANNERS. See MANNERS.

GOODINGS, in sea-language, are clamps of iron bolted on the stern-post of a ship, whereon to hang the rudder and keep it steady; for which purpose there is a hole in each of them, to receive a correspondent spindle bolted on the back of the rudder, which turns thereby as upon hinges.

GOOSE, in ornithology. See ANAS. The goose was held in great esteem amongst the Romans, for having faved the Capital from the invasion of the Gauls by cackling and clapping its wings. Geese were kept in the temple of Juno; and the cenfors, when they entered upon their office, provided meat for them. There was also an annual feast at Rome, at which they carried a silver image of a goose in flute; and hanged a dog, to punish that animal because he did not bark at the arrival of the Gauls.

Goose-Neck, in ornithology. See MERGUS. Goose-Berry, in botany. See RUBUS. Goose-Neck, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whip-staff or the wheel-rope comes, for steering the ship.

Goose-Wing, in the sea-language. When a ship fails before, or with a quarter-wind on a fresh gale, to make the more haste, they lanch out a boom and fall on the lee-side; and if so fitted, is called a goose-wing.

GORCUM, a town of the United Provinces, in South Holland, which carries on a considerable trade in cheese and butter. It is situated on the rivers Ligne and Maese, in E. Long. 4° 55'. N. Lat. 51° 49'.

GORDIANUS I. (a Roman general), was for his valor and virtues chosen emperor by the army in the reign of Maximinus, A. D. 237; but his son, whom he had associated with himself in the throne, being slain by Capellian, the governor of Mauritania for Maximinus, Gordianus killed himself the same year. See Rome.

GORDIANUS III. (grandson of the former), a renowned warrior, was styled The guardian of the Roman
GORDIAN-KNOT, in antiquity, a knot made in the leathers or harness of the chariot of Gordius king of Phrygia, so very intricate, that there was no appointing where it began or ended. The inhabitants had a tradition, that the oracle had declared, that he who untied this knot should be master of Asia. Alexander having undertaken it, was unable to accomplish it; when tearing left his not untiring it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

GORDIUS, the hair-worm, a genus of insects belonging to the family of vermis interlinea. There are several species. 1. The aquaticus, or water hair-worm, is 10 or 12 inches in length, and of about the thickness of a hoarse hair; its skin is smooth and somewhat glossy, without furrows; its colour pale yellowish white all over, except the head and tail, which are black and glossy. The body is rounded, and very slender in proportion to its length: the mouth is small, and placed horizontally; the jaws are both of the same length, and obtuse at their extremities. This species is common in fresh waters, more especially in clay, through which it passes as a fifth deep through the water, and the author of many springs. This is the worm that in Guinea is only a variation of the preceding one in colour, and more especially in clay, through which it attempts this. 2. The argillaceus, or clay hair-worm, or muscular hair-worm, is all over of a pale yellowish at the extremities. It chiefly inhabits the clay; and Linneus calls that its proper element, from its being generally dug out of it. 3. The medicinis, or muscular hair-worm, is all over of a pale yellowish colour. It is a native of both Indies; frequent in the morning dew, from whence it enters the naked feet of the slaves, and occasions a disagreeable smell in those countries, and to which children are very liable: it creates the most troublesome itchings, and too often excites a fever and inflammation. It particularly infects the muscles of the arms and legs, from whence it may be drawn out by means of a piece of silk or thread tied round the head; but the greatest caution is necessary in this simple operation, lest the animal, by being thrained too much, should break; for if any part remains under the skin, it quickly grows with reddened vigour, and becomes a cruel and sometimes fatal enemy, to the poor slaves in particular. Baths with infusions of bitter plants, and all verminous drugs, destroy it. 4. The marinus, or sea hair-worm, is siliiform, twisted spirally, and lying flat, about half an inch in length: of a whitish colour, smooth, and scarcely diminishing at the head. It is as great a tormenter of herrings, bleak, and various other fish, as the gordius medicinis is of man. The fish when infested with these animals sinks to the surface, and tumbling about as if in great agony.

GORDIAN, king of Phrygia, and father of Midas, was a poor husbandman, with two yokes of oxen, wherewith he ploughed his land and drew his wain. An eagle sitting a long while upon one of his oxen, he confessed the footthayers; a virgin bid him sacrifice to Jupiter in the capacity of king. He married the virgin, who brought forth Midas. The Persians instructed by the oracle to set the first person they met in a wain upon the throne, met Gordius, and made him king. Midas for this good fortune dedicated to Jupiter his father's cart. The knot of the yoke, they say, was so well twisted, that he who could unloose it was promised the empire of Asia; hence the proverb of the Gordion knot had its original. See GORDIAN KNOT.

GORDON (Alexander), an excellent draughtsman and a good Grecian, who resided many years in Italy, visited most parts of that country, and had also travelled into France, Germany, &c. was secretary to the Society for Encouragement of Learning; and afterwards to the Egyptian Club, composed of gentlemen who had visited Egypt (viz. lord Sandwich, Dr Shaw, Dr Poocke, &c.) He succeeded Dr Stukely as secretary to the Antiquarian Society, which office he resigned in 1741 to Mr Joseph Ames. He went to Carolina with governor Glen, where, besides a grant of land, he had several offices, such as registrar of the province, &c. and died a justiciary of the peace, leaving a handsome estate to his family. He published 1. Itinerarium Septentrionale, or a journey through most parts of the Counties of Scotland, in two parts, with 66 copperplates, 1726, folio. 2. Supplement to the Itinerarium, 1727, folio. 3. Histories of Pope Alexander VI. and his son Caesar Borgia. 4. A complete History of the ancient Amphitheatres, 1730, 8vo. afterwards enlarged in a second edition. 5. An Essay towards explaining the hieroglyphical figures on the coffin of the ancient Mummy belonging to Capt. William Letheullier, 1737, folio, with cuts. 6. Twenty-five Plates of all the Egyptian Mummies and other Egyptian Antiquities in England, 1739, folio.

GORDON (Thomas), noted for his translations and political writings, was born at Kirkudbright in North Britain. He came young to London; where he supported himself by teaching languages, until he procured employment under the earl of Oxford in queen Anne's time, but in what capacity is not now known. He first distinguished himself in the defence of Dr Hoadly in the Bangorian controversy; which recommended him to Mr Trenchard, in conjunction with whom he wrote the well-known Cato's Letters, upon a variety of important public subjects. These were followed by another periodical paper, under the title of the Independent Whig, which was continued some years after Mr Trenchard's death, by Gordon alone, against the hierarchy of the church; but with more acrimony than was shown in Cato's Letters. At length Sir Robert Walpole retained him to defend his administration, to which end he wrote several pamphlets. At the time of his death, July 28th 1750, he was first commissioner of the wine licences, an office which he had enjoyed many years. He was twice married. His second wife was the widow of his great friend Trenchard, by whom he had children. He published English translations of Sallust and Tacitus, with additional discourses to each author, which contain much good matter. Also, two collections of his tracts have been preserved: the first intitled, A Cordial for Low-spirits, in three volumes; and the second, The Pillars of Priestcraft and Orthodoxy shaken, in two volumes.

GORDEONIA

in botany: A genus of the polyantrum order, belonging to the monadelphous class of plants. The calyx is simple; the style five-cornered, with the stigma quinquenul; the capsule quinquenulocul; the seeds two-fold with a leafy wing. This is a tall and very straight tree, with a regular pyramidal head. Its leaves are shaped like those of the common bay, but serrated. It begins to blossom in May, and continues bearing its flowers the greatest part of the summer. The flowers are fixed to foot-flakes, four or five inches long; are monopetalous, divided into five segments, encompassing a tuft of flamina headed with yellow apices; which flowers, in November, are succeeded by a conic capsule having a divided calyx. The capsule, when ripe, opens, and divides into five sections, disclosing many small half-winged seeds. This tree retains its leaves all the year, and grows only in wet places, and usually in water. The wood is somewhat soft; yet Mr. Careby mentions his having seen some beautiful tables made of it. It grows in Carolina, but not in any of the more northerly states.

GORE, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arches, one drawn one from the finifer chief, and the other from the finifer base, both meeting in an acute angle in the middle of the ffs point. See HERALDRY.

GOREE, a small island of Africa, near Cape de Verd, subject to the French. It is a small spot not exceeding two miles in circumference, but its importance arises from its situation for trade so near Cape de Verd, and it has been therefore a bone of contention between European nations. It was first poledited by the Dutch, from whom, in 1663, it was taken by the English; but in 1665 it was retaken by the Dutch, and in 1677 retaken by the French, in whose possession it remained till the year 1759, when the British armies were every where triumphant; and it was reduced by commodore Keppel, but restored to the French at the treaty of peace in 1763. It was retaken by the English in the last war, but again restored at the peace of 1783.

GOREE, the capital town of an island of the same name in Holland, eight miles south of Briel.

GOREY, a borough, fair, and port town in the county of Wexford, province of Leinster; otherwise called Newborough. It stands about 18 miles north of Wexford town, and 45 from Dublin.

GOLT, a small island of the South Sea, 12 miles west of the coast of Peru, in America. It is of different high land, very woody, and some of the trees are very tall and large, and proper for mast. It is about 10 miles in circumference, and has several springs and rivulets of excellent water, but is subject to conflagrant rains.

GORGONIA, a small island of Italy, in the sea of Tuscany, and near that of Corfica, about eight miles in circumference; remarkable for the large quantity of anachovies taken near it. E. Long. 10. 0. N. Lat. 43. 23.

GORDONIA, a small island of the South Sea, 12 miles west of the coast of Peru, in America. It is of different high land, very woody, and some of the trees are very tall and large, and proper for mast. It is about 10 miles in circumference, and has several springs and rivulets of excellent water, but is subject to conflagrant rains.

GORGONIA, in natural history, a genus of zoophytes, which formerly were called ceratophytons, and are known in English by the names of sea-fans, sea-feathers, and sea-whips. Linnaeus and Dr. Pallis consider them as of a mixed nature in their growth, between animals and vegetables; but Mr. Ellis shows them to be true animals of the polyse kind, growing up in a branched form resembling a shrub, and in no part vegetable. They differ from the fresh water polype in many of their qualities, and particularly in producing from their own substance a hard and solid support, serving many of the purposes of the bone in other animals. This is formed by a concretion; juice thrown out from a peculiar set of longitudinal parallel tubes, running along the internal surface of the fishy part; in the coats of these tubes are a number of small orifices, through which the offensive liquor exudes, and concreting, forms the layers of that hard part of the annular circles, which form, judging from the conchology rather than the texture, harks erroneously denominated wood. The surface of the gorgonia is composed of a kind of scales, so well adapted to each other as to serve for defence from external injuries; and the flesh, or as some have called it, the bark or cortex, consists of proper muscles and tendons for extending the openings of their cells; for sending forth from these their polype fuckers in search of food; and for drawing them in suddenly, and contracting the sphencter muscles of these flabby cells, in order to secure these tender parts from danger; and also of proper secretory ducts, to furnish and depilate the offensive matter that forms the skin and branches as well as the base of the bone. Mr. Ellis affirms, that there are ovaries in these animals, and thinks it very probable that many of them are viviparous. See CORALLINES.

GORGONS, in antiquity and mythology. Authors are not agreed in the account they give of the Gorgons. The poets represent them as three sisters, whose names were Stheno, Euryale, and Medusa; the latter of whom was mortal, and, having been deformed by Neptune, was killed by Perseus; the two former were subject neither to age nor death. They are described with wings on their shoulders, with serpents round.
Goritia round their heads, their hands were of brass, and their teeth of a prodigious size, so that they were objects of terror to mankind. After the death of Medusa, her sisters, according to Virgil, were appointed to keep the gate of the palace of Pluto.

Diodorus Siculus will have the Gorgons and Amazons to have been two warlike nations of women, who inhabited that part of Libya which lay on the lake Tritonides. The extermination of these female nations was not effected till Hercules undertook and performed it.

Pausanius says, the Gorgous were the daughters of Phorbas; after whose death Medusa, his daughter, reigned over the people dwelling near the lake Tritonides. The queen was passionately fond of hunting and war, so that she laid the neighbouring countries quite waste. At last, Perseus having made war on them, and killed the queen herself, when he came to take a view of the field of battle, he found the queen’s corpse so extremely beautiful, that he ordered her head to be cut off, which he carried with him to show his countrymen the Greeks, which could not behold it without being struck with alarm and horror.

Others represent them as a kind of monstrous women, covered with hair, who lived in woods and forests. Others, again, make them animals resembling wildbeep, whole eyes had a poisonous and fatal influence.

Goritia, or Goritz, a strong town of Germany, in the circle of Aurelia, and duchy of Carniola, with a caftle; seated on the river Lisonzo, 20 miles north-east of Aquileia, and 70 north-east of Venice. E. Long. 12° 43'. N. Lat. 45° 12'.

Gorlæus (Abraham), an eminent antiquary, was born at Antwerp, and gained a reputation by collecting medals and other antiques. He was chiefly fond of the rings and seals of the ancients, of which he published a prodigious number in 1601, under this title, Dafyllithotecases: a Vrarios Sigillarum, quorum apud priscos tam Graecos quam Romanos usus fero, ere, argentae, et aure, Fromuptum. This was the first part of the work: the second was intitled, Variarum Gemmarum et antiquitatis in fingunmotifis fiulpturae. This work has undergone several editions, the bulk of which is that of Leyden, 1605: but it not only contains a vast number of cuts, but also a short explication of them by Gronovius. In 1608, he published a collection of medals, which, however, if we may believe the Scaligerus, it is not safe always to trust. Gorlæus died upon Delph for the place of his residence, and died there in 1609. His collections of antiques were sold by his heirs to the prince of Wales.

Gorlitz, a town of Germany, in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Neisse, in E. Long. 15° 15'. N. Lat. 51° 10'.

Goritzia, or Goritz, a strong town of Germany, in the circle of Aurelia, and duchy of Carniola, with a castle; seated on the river Lisonzo, 20 miles north-east of Aquileia, and 70 north-east of Venice. E. Long. 12° 43'. N. Lat. 45° 12'.

Gorstia, or Goritz, a strong town of Germany, in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Neisse, in E. Long. 15° 15'. N. Lat. 51° 10'.

Gorstia, or Goritz, a town of Germany, in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Neisse, in E. Long. 15° 15'. N. Lat. 51° 10'.

Gorstia, or Goritz, a strong town of Germany, in Upper Lusatia, subject to the elector of Saxony. It is a handsome strong place, and seated on the river Neisse, in E. Long. 15° 15'. N. Lat. 51° 10'.

Joseph procured for his father and brethren when they came to dwell in Egypt. It was the most fruitful part of the country; and its name seems to be derived from the Hebrew, gôl, which signifies "rain," because this province lying very near the Mediterranean, was exposed to rains, which were very rare in other cantons, and more especially in Upper Egypt. Calmet does not question but that Goshen, which Joshua (X. 41. X. 16. XV. 51.) makes part of the tribe of Judah, is the same as the land of Goshen, which was given to Jacob and his sons by Pharaoh king of Egypt: (Gen. xli. 28.) It is certain that this country lay between Palestine and the city of Tanais, and that the allotment of the Hebrews reached southward as far as the Nile. (Joh. xiii. 5.)

Goslar, a large and ancient town of Lower Saxony, and in the territory of Brunswick; it is a free imperial city, and it was here that gunpowder was first invented, by a monk as is generally supposed. It is a large place, but the buildings are in the ancient taste. In 1728, 280 houses, and St. Stephen's fine church, were reduced to ashes. It is seated on a mountain, near the river Goe, and near it are rich mines of iron. The inhabitants are famous for brewing excellent beer. E. Long. 9° 37'. N. Lat. 51° 53'.

Gospel, the history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.—The word is Saxon, and of the same import with the Latin term evangclium, which signifies glad tidings; or good news.

This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John; who from thence are called evangelists. The Christian church never acknowledged any more than these four gospels as canonical; nor withstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

Gosport, a town of Hampshire, 79 miles from London, in the parish of Alverstock. It has a ferry over the mouth of the harbour to Portsmouth, and is a large town and of great trade, especially in time of war. Travellers choose to lodge here, where every thing is cheaper and more commodious for them than at Portsmouth. The mouth of the harbour, which is not so broad here as the Thames at Westminster, is secured on this side by four forts, and a platform of above 20 cannon level with the water. Here is a noble hospital built for the cure of the sick and wounded soldiers in the service of the navy; besides a free school.

Gossamer is the name of a fine filmy substance, like cobweb, which is seen to float in the air, in clear days in autumn, and is more observable in flufhfields, and upon furze and other low bushes. This is probably formed by the flying spider, which in traversing the air for food, shoots out these threads from its anus, which are borne down by the dew, &c.

Gossypium, or Cotton: A genus of the polygonaorder, belonging to the monadelphia class of plants; and in the natural method ranking under the 37th order, Columaffera. The calyx is double, the exterior one trifid; the capsule quadrilocular; the seeds wrapped in cottonouble. There are four carpels, all of them natives of warm climates. 1. The herbaceous, or common herbaceous cotton, hath an herbaceous smooth stalk two feet high, branching upwards; five-
COTTON. 1. The American cotton, hath hairy stalks, branching laterally two or three feet high; palmated, three and five lobed, smooth leaves, and yellow flowers, succeeded by large oval pods furnished with seeds and cotton. 2. The Barbados, or Barbadoes yellow-flowered, succeeded by large pods, containing seeds and cotton. 3. The arboreum, or tree cotton, hath an upright, woolly perennial stalk, branching six or eight feet high; palmate, four or five lobed smooth leaves; and yellow flowers, succeeded by large pods filled with seeds and cotton.

The first three species are annual, but the fourth is perennial both in root and stalk. In warm countries these plants are cultivated in great quantities in the fields for the sake of the cotton they produce; but the first species is most generally cultivated. The pods are sometimes as large as middling-sized apples, closely filled with the cotton surrounding the seed. When these plants are raised in Britain, they must be continually kept in a warm house, where they will produce seeds and cotton. They are propagated by seeds.

The American islands produce cotton shrubs of various sizes, which rise and grow up without any culture; especially in low and marshy grounds. Their produce is of a pale red; some paler than others; but so short that it cannot be spun. None of this is brought to Europe, though it might be usefully employed in making of hats. The little that is picked up, serves to make mattresses and pillows.

The cotton shrubs that supplies our manufactures, requires a dry and sandy soil, and thrives best in grounds that have already been tilled. Not but that the plant appears more flourishing in rich lands than in those which are exhausted; but while it produces more wood, it bears less fruit.

A western exposure is fittest for it. The culture of it begins in March and April, and continues during the first spring-rains. Holes are made at seven or eight feet distance from each other, and a few seeds thrown in. When they are grown to the height of five or six inches, all the stems are pulled up, except two or three of the strongest. These are cropped twice before the end of August. This precaution is the more necessary, as the wood bears no fruit till after the second pruning; and, if the shrub was suffered to grow more than four feet high, the crop would not be the greater, nor the fruit so easily gathered. The same method is pursued for three years; for so long the shrub may continue, if it cannot conveniently be renewed oftener with the profit of an advantage that will compensate the trouble.

This useful plant will not thrive if great attention is not paid to pluck up the weeds that grow about it. Frequent rains will promote its growth; but they must not be incessant. Dry weather is particularly necessary in the months of March and April, which is the time of gathering the cotton, to prevent it from being defecund and spotted. When it is all gathered in, the seeds must be picked out from the wool with which they are naturally mixed. This is done by means of a cotton-mill; which is an engine composed of two rods of hard wood, about 18 feet long, 18 lines in circumference, and fluted two lines deep. They are confined at both ends, so as to leave no more distance between them than is necessary for the feed to slip through. At one end is a kind of little millstone, which, being put in motion with the foot, turns the rods in contrary directions. They separate the cotton, and throw out the feed contained in it.

GOTHA, a town of Germany, in the circle of Upper Saxony, and capital of the duchy of Saxe-Gotha, in E. Long. 10° 36'. N. Lat. 51°. Some fancy this town had its name from the Goths, and that they fortified it in their march to Italy; but it was only a village till furnished with walls by the bishop of Mentz in 964. It is situated in a fine plain on the river Leina, well built and strongly fortified. Here are two handsome churches and a very good hospital. Its chief trade is in dyers wood, of which they have three crops, but the third grows wild. The neighbouring country produces a vast deal of corn. The castle or ducal palace of Gotha was rebuilt in the 16th century by duke Ernest, furnished the Pious, who caufed both that and the town to be encompassed with ditches and ramparts; and gave it the name of Friedenstein, or the Castle of Peace, in opposition to its ancient name of Grinemberg, or the Castle of the Furies. It is situated on a neighbouring eminence, from whence there is a vast prospect of a fruitful plain. In one of the apartments there is a collection of valuable rarities, and a noble library.

The dukedom of Saxe-Gotha is about 30 miles long, and 12 broad. The reigning duke is Lewis Ernst, born in 1745, and married to the princess Maria Charlotte of Saxe-Meiningen, by whom he has issue. He is the head of the Ernestine line of Saxony, descended from the elector John Frederic the Magnanimous, who was deprived of the electorate by the emperor Charles V. in 1574; since which the youngest branch called the Albertine has enjoyed it. He has several other principalities besides that of Saxe-Gotha; and his revenues are computed at L. 200,000 a year, with which he maintains about 3000 regular troops. As he is the most powerful of all the Saxon princes of the Ernestine branch; so of all the courts of Saxony, next to that of Dresden, he has the most numerous and the most magnificent. His guards are well clothed, his liberities rich, and his tables served with more elegance than profusion. And yet by the prudent management of his public finances, his subjects are the least burdened with taxes of any state in Germany. The religion is Lutheran.

GOTTFRIED, or Gottenburg, or Gottenburg. See GOTTENBURG.

GOTHIC, in general, whatever has any relation to the Goths: thus we say, Gothic costumes, Gothic architecture, &c. See ARCHITECTURE.

GOTHLAND, the most southern province of Sweden, being a peninsula, encompassed on three sides by the Baltic Sea, or the channel at the entrance of Y.
At what time Woden reigned in this country, is quite uncertain; but all historians agree, that he went out in quest of new settlements with incredible numbers of people following him. He first entered Roxolania, comprehending the countries of Prussia, Livonia, and great part of Muscovy. From thence he went by sea into the north parts of Germany; and having reduced Saxony and Jutland, he at last settled in Sweden, where he reigned till his death, and became so famous that his name reached all countries, and he was by the northern nations worshipped as a god. He is supposed to have brought with him the Runic characters out of Asia, and to have taught the northern nations the art of poetry; whence he is styled the father of the Scaldi or Scaldrì, their poets, who described in verse the exploits of the great men of their nation, as the bards did among the Gauls and Britons.

The Romans distinguished the Goths into two classes; the Ostrogoths and Visigoths. These names they received before they left Scandinavia, the Visigoths being softened by the Latins from Welfergoths, or those who inhabited the western part of Scandinavia, as the Ostrogoths were those who inhabited the eastern part of that country. Their history affords nothing of moment till the time of their quarrelling with the Romans, which happened under the reign of the emperor Caracalla, son to Severus. After that time their history becomes so closely interwoven with that of the Romans, that for the most remarkable particulars of it we must refer to the article Rome. After the destruction of the Roman empire by the Heruli, the Ostrogoths, under their king Theodoric, became masters of the greatest part of Italy, having overcome and put to death Odoacer king of the Heruli in 494. They retained their dominion in this country till the year 553; when they were finally conquered by Narsetes, the emperor Justinian’s general. See (History of) Italy. The Visigoths settled in Spain in the time of the emperor Honorius, where they founded a kingdom which continued till the country was subdued by the Saracens; see the article Spain.

The Goths were famous for their hospitality and kindness to strangers, even before they embraced the Christian religion. Nay, it is said, that from their being eminently good they were called Goths, by the neighbouring nations; that name, according to Grotius and most other writers, being derived from the German word goten, which signifies “good.” They encouraged, says Dio, the study of philosophy above all other barbarous or foreign nations, and often chose kings from among their philosophers. Polygamy was not only allowed but countenanced among them; every one being valued or respected according to the number of his wives. By so many wives they had an incredible number of children, of whom they kept but one at home, sending out the rest in quest of new settlements; and hence those swarms of people which overran so many countries. With them adultery was a capital crime, and irreformibly punished with death. This severity, and likewise polygamy, prevailed among them when they were known to the Romans only by the name of Getes (their most ancient name); as appears from the poet Menander, who was himself one of that nation; and from Horace, who greatly commends the chastity of their women. Their laws fell little short of those of the

Goths.

It is divided into several parts, which are, East Gothland, West Gothland, Smaland, Halland, Blekinge, and Schonen. It was a long time in the possession of the kings of Denmark, but was ceded to Sweden in 1654. The principal towns of Gothland are Calmar, Landcrum, Christiansople, Daleburg, Gothenburg, Helmut, Lundem, Malmon, and Vexo.

GOTHS, a warlike nation, and above all others famous in the Roman history, came originally out of Scandinavia (the name by which the ancients distinguished the present countries of Sweden, Norway, Lapland, and Finnmark). According to the most probable accounts, they were the first inhabitants of those countries; and from thence sent colonies into the islands of the Baltic, the Cimmerian Chersonesus, and the adjacent places yet destitute of inhabitants. The time of their first settling in Scandinavia, and the time when they first peopled with their colonies the abovementioned islands and Chersonesus, are equally uncertain; tho’ the Gothic annals suppose the latter to have happened in the time of Serer the great grandfather of Abraham. This first migration of the Goths is said to have been conducted by their king Eric; in which all the ancient Gothic chronicles, as well as the Danish and Swedish ones, agree. Their second migration is supposed to have happened many ages after; when, the abovementioned countries being overstocked with people, the Bersig, at that time king of the Goths, went out with a fleet in quest of new settlements. He landed in the country of the Ulmerugians, now Pomerania, drove out the ancient inhabitants, and divided their lands among his followers. He fell next upon the Vandals, whose country bordered on that of the Ulmerugians, and overcame them; but instead of forcing them to abandon their country, he only made them share their possessions with the Goths.

The Goths who had settled in Pomerania and the adjacent parts of Germany being greatly increased in numbers, under Filimer, son of the Great, their fifth prince after leaving Scandinavia, and taking their route eastward, entered Scythia, advanced in the neighborhood they undertook a third migration in accordance taking their route eastward, entered Scythia, advanced in the neighborhood they undertook a third migration in...
GOTHEFRED, born at Geneva in 1580. As soon as he had finished his studies, he went to Paris; where he conformed to the Roman religion, and applied with indefatigable industry to the study of history, that of France particularly, wherein he became very eminent, as appears by his works. In 1632, the king made him one of his historiographers, with a stipend of 3000 livres; and, in 1636, he was sent to Cologne, to assist at the treaty of peace negotiating there, on the part of France, by the cardinal of Lyons. This treaty being removed to Munster, Gotthfried was sent thither, where he drew up Memoirs on the subject; and continued in that city, in the king’s service, to his death in 1649. His principal work is his "Account of the Ceremonial of the Kings of France."

GOTHEFRED (James), brother of the preceding, was born at Geneva in 1587. Applying himself to the study of the law, he obtained the professor’s chair there, was made counsellor of the city, and was several times employed in France, Germany, Piedmont, and Switzerland, to negotiate their affairs in the name of the republic. He died in 1652; and his chief work is his Codex Theodorianus, cum perpetuo commentariis, &c.

GOTHEFRED (Dennis), a son of Theodore above mentioned, was born at Paris in 1615. He studied history after his father’s example; became as eminent in that department of knowledge; and obtained the reversion of his father’s place of historiographer royal, from Louis XIII., when he was but 25 years of age. He published his father’s Ceremonial of France; finished his Mémoirs de Philippe de Commynes; and was preparing a History of Charles VIII., when he died in 1681. It was published by his eldest son, Dennis, in 1684.

GOTTENBURG, a rich and strong town of West Gothland, in Sweden, with a good harbour, at the mouth of the river Gothelba; which is the chief port for foreign trade of any in Sweden, as it lies without the Sound. It occupies the site of an ancient town, named Lodofe, which was built by Gustavus Vasa; and became with considerable privileges, from the grant of several additional privileges. — It is built in a very singular situation. At a small distance from the sea is a marshy plain, scarcely more than half a mile in breadth, watered by the rivers Gotha and Motala, and almost entirely inclosed with high ridges of rocks, so bare and rugged, that they scarcely produce a single blade of grass, and exhibit as barren an appearance as the summits of the loftiest Alps. Gottenburg stands partly upon the hills, and partly in the plain; and is divided from these different situations into the Upper and Lower Town. The latter is entirely level, intersected by several canals in the manner of the Dutch towns; and its houses are all constructed up on piles: the upper part hangs upon the declivities; and rows of buildings rise one above the other like the feats of an amphitheatre. The whole is regularly fortified; and its circumference is near three miles, exclusive of the suburbs, called Haga, which lie towards the harbour. The streets are all uniformly straight; a few of the houses are of brick; but the generality are constructed with wood painted red. The harbour is formed by two good inlets, and is about a quarter of a mile in breadth. Its entrance is defended by the fort of Elfsborg, which stands upon a small rocky island, and contains a garrison of 300 men. There has been lately established at Gottenburg a Royal Society of Sciences and Literature, upon the plan of that of Upsala. Mr. Coxe was informed by a merchant who had resided 22 years at Gottenburg, that, during that period, its population had increased considerably, and that it now contained about 30,000 inhabitants. This flourishing state is attributed to the extension of its commerce, particularly its East India Company, and the fisheries of the herring fishery. An English consul and several merchants of that nation reside at Gottenburg; and a chapel, with a regular chaplain, is appropriated to their use. E. Long. 11° 50', N. Lat. 57° 44'.

GOTTINGEN, a considerable town of Lower Saxony in Germany, and in the duchy of Brunswick; formerly free and imperial, but now subject to the elector of Hannover. Here his late Majesty George II., founded an university. It is seated on the river Leine, in E. Long. 10° 5', N. Lat. 51° 32'.

GOTTORP,
GOTTORP, a town of the duchy of Holstein, where the duke has a very fine palace.

GOUANIA, in botany: A genus of the monoea order, belonging to the polygama class of plants. The calyx of the hermaphrodite is quinquedent; there is no corolla; there are five anthers covered with an elasic calyptra or hood; the style trifid; the fruit, inferior to the receptacle of the flower, divided into three seeds. The male is like the hermaphrodite, but wanting stigma and germen.

GOUDA, or TUGOW, a considerable town of South Holland, in the United Provinces, remarkable for its stately church. It is seated on the river IJssel, in E. Long. 4. 37. N. Lat. 52. 2.

GOUDT (Henry), usually called Count Goudt, was born of a noble family at Utrecht, in 1750; and was a knight of the Palatinate. Being passionately fond of the arts, particularly painting and engraving, and desirous of engaging in them, he applied himself diligently to drawing, and made a great proficiency therein. He went to Rome, to examine the works of the great masters in that city. Here he contracted an intimacy with that excellent artist Adam Elsheimer; studied his manner of pencilling, designing, and colouring; and made his works models for his own imitation. He pre-engaged all the pictures that his friends and favourite could finish, and even paid liberally for them before-hand; by which means he found himself in possession of a most desirable treasure. Those pictures which Goudt himself painted were neatly and delicately touched, in colour and pencil resembling Elsheimer, though they were in no degree equal to the paintings of that admirable master. On his return to his native country, a young woman who was in love with him, and desirous of fixing his affections upon her gave him in his drink a love philter: which, however, terminated in a very melancholy manner, by depriving him totally of his senses; and in the dreadful state of idiotism he dragged on a miserable life to the age of 59, his death happening in 1639. It is remarkable, that though left to every other subject, when painting was spoken of he would discourse upon it in a very retentive manner.

Goudt practised engraving as well as painting, and made seven beautiful prints after the pictures of Elsheimer, which are well known to the curious, and are to be met with in most choice collections. He worked with the graver only, in a very neat style; and produced a most powerful effect, not by strengthening the strokes, according to the usual method, but by crossing them with additional strokes, equally neat, and that five or six times, one over another, in the deep shadows. Considering the precision with which he executed his engravings, the freedom of housing the graver which may be discovered in them, is very astonishing. The weeds and other parts of the fore-ground in that admirable print of the Ceres are very finely expressed. The heads of the figures are correctly drawn, and the other extremities are managed in a judicious manner. The seven prints done by him, from Elsheimer, mentioned above, are, 1. Ceres drinking from a pitcher. An old woman appears holding a candle at the door of the cottage, and a boy naked blazing by her is laughing and pointing at the goddess; for which contempt he was metamorphosed by her into a frog. The powerful and striking effect of this engraving cannot be properly described. This print is distinguished also by the name of the forestry. 2. The flight into Egypt: A nocturnal scene, in which the moon and stars are introduced with great success. 3. The angel with Tobit, who is drawing a filh by his side. The back-ground is a landscape; the weeds in the foreground, and the branches of the trees in front, as well as the foliage and weeds hanging from them, are beautifully expressed. 4. The angel with Tobit, crossing a stream of water: The back-ground, a landscape. 5. Baucis and Philemon entertaining Jupiter and Mercury. 6. A landscape, called the Aurora, representing the dawn of day. The effect is very beautiful. 7. The change of St John in prison, a very small upright oval print, which is by far the finest.

GOVERNMENT, in general, is the policy of a state, or an orderly power constituted for the public good.

Civil government was instituted for the preservation and advancement of men's civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some fort of civil authority: but as men are seldom unanimous in the means of attaining their ends, so their differences in opinion in relation to government has produced a variety of forms of it. To enumerate them would be to recapitulate the history of the whole earth. But, according to Montesquieu, and most other writers, they may in general be reduced to one of these three kinds. 1. The republican. 2. The monarchial. 3. The despotic. The first is that, where the people in a body, or only a part of the people, have the sovereign power; the second, where one alone governs, but by fixed and established laws; but in the despotic government, one person alone, without law and without rule, directs every thing by his own will and caprice. See the article Law, n° i. 3-10. On the subject of government at large, see Montesquieu's L'Espirit des Lois, l. 2. c. i.; Locke, ii. 129, &c. quarto edition, 1708; Sidney on Government; Sir Thomas Smith de republic. Angl. and Ackerhy on the Political Constitution. As to the Gothic government, its original and faults, &c. see Montesquieu's L'Espirit des Lois, l. i. c. 8. With respect to the feudal policy, how it limited government; see Feudal System.

Government is also a post or office, which gives a person the power or right to rule over a place, a city, or a province, either supreme or by deputation.

Government is likewise used for the city, country, or place to which the power of governing is extended.

GOUGE, an instrument used by divers artificers, being a sort of round hollow chisel; serving to cut holes, channels, grooves, &c. in wood, stone, &c.

GOULART (Simon), a famous minister of Geneva, was born at Senlis in 1543; and was one of the most indefatigable writers of his time. He made considerable additions to the Catalogue of witnesses of the truth, composed by Hlyricus; and acquired a great reputation by his works; the principal of which are, 1. A translation of Seneca. 2. A collection of memorable histories. 3. A translation of St Cyprian De

D(437)
GOURD, in botany. See *Cucurbita*.

GOURGES (Dominique de), an illustrious French patriot, a private gentleman of Gafcony. The Spaniards having inhumanly massacred a colony of Frenchmen who had settled in Florida, Gourges took a severe revenge on them, an account of which is given under the article *Floroda*. On his return, he was received with acclamations by his countrymen, but was forbidden to appear at court. Queen Elizabeth invited him to command an English fleet against the Spaniards in 1593; but he died at Tours in his way to England.

GOURNAY, a town of France, in the duchy of Normandy and territory of Bray, celebrated for its butter market. It is situated on the river Epte, in E. Long. 4° 33'. N. Lat. 49° 25'.

GOURNAY (Mary de Jars de), a lady celebrated for her learning, was the daughter of William de Jars, lord of Neuvil and Gournay. After the death of her father, she was protected by Montaigne and Cardinal Richelieu. To the daughter of the former she dedicated her *Nefoguy de Pindus*; and composed several other works, the most considerable of which is *Les Audis*. She died at Paris in 1685, aged 80. The critics are divided concerning the reputation of this lady; some say she is styled the *Siren* of France; others say her works should have been buried with her.

GOUT. See *Index* subjoined to *Medicine*.

Gower (John), one of the most ancient English poets, was contemporary with Chaucer, and his intimate friend. Of what family, or in what county he was born, is uncertain. He studied the law, and was sometime a member of the society of Lincoln’s-inn, where his acquaintance with Chaucer began. Some have asserted that he was a judge; but this is by no means certain. In the first year of Henry IV. he became blind; a misfortune which he laments in one of his Latin poems. He died in London in 1401, and was buried in St Mary Overie, which church he had rebuilt chiefly at his own expense, so that he must have lived in affluent circumstances. His tomb was magnificent, and curiously ornamented. It still remains, but hath been repaired in later times. From the collar of SS round the neck of his effigies, which lies upon the toftb, it is conjectured that he had been knighted. As to his character as a man, it is impossible, at this distance of time, to say any thing with certainty. With regard to his poetical talents, he was undoubtedly admired at the time when he wrote, though a modern reader may find it difficult to discover much harmony or genius in any of his compositions. He wrote:—

1. *Septem medicinatis*, in French, in ten books. There are two copies of this in the Bodleian library.

2. *Vox clasmatis*, in Latin verse, in seven books. Preserved also in the Bodleian library, and in that of All Souls. It is a chronicle of the insurrection of the commons in the reign of Richard II.

3. *Confessio amantis*; printed at Wellminster by Caxton in 1493. Lond. 1532, 1554. It is a sort of poetical system of morality, intermixed with a variety of moral tales.

4. *De roge Henrico IV.*. Printed in Chaucer’s works. There are likewise several historical tracts, in manuscript, written by our author, which are to be found in different libraries; also some short poems printed in Chaucer’s works.

GOWN, robe, a long upper garment, worn by lawyers, divines, and other graduates; who are hence called *men of the gown*, or gownmen.

The gown is an ample sort of garment, worn over the ordinary cloaths, hanging down to the feet. It is fashioned differently for ecclesiastics and for laymen. At Rome they gave the name *virile gown*, *toga virilis*, to a plain kind of gown which their youth assumed when arrived at puberty. This they particularly denominated *prætexta*. See *Toga*, *Prætexta*, &c.

“The remarkable dress of our British ancestors (Mr Whittaker observes) which continued very nearly the same to the commencement of the last century, is 30a. among the natives of Ireland, and has actually descended to the present among the mountaineers of Scotland, and is therefore rendered very familiar to our ideas, carried in it an astonishing appearance to the Romans. And it seems to have been equally the dress of the men and women among the nobles of Britain. But in a few years after the erection of the Roman-British towns in the north, and in the progress of refinement among them, this ancient habit began to be disapproved by the chiefs of the cities, and looked upon as the badge of ancient barbarism. And the growing prejudices were soon so greatly improved, that within 20 years only after the construction of the towns, the British fagum was actually resigned, and the Roman *toga* or gown assumed by many of them.

“The gown, however, never became universal in Britain: and it seems to have been adopted only by the barons of the cities and the officers of the crown; and has therefore been transmitted to us as the robe of reverence, the ensign of literature, and the mantle of magistracy. The woollen and plaided garments of the chiefs having naturally superseded the leathern veitures of their clients, the former were still wore by the generality of the Britons; and they were retained by the gentlemen of the country, and by the commonalty both in the country and the cities. That this was the case, appears evident from the correspondent conduct of the Gauls and Britons; who kept their *Virgata Sagula* to the last, and communicated them to the Franks and Saxons. The plaided drapery of the Britons still appeared general in the streets of Manchester; and must have formed a striking contrast to the gown of the chief, the dark mantle of Italy: and it and the ornamented buttons on the shoulder were preferred among us even to the present moment, in the parti-coloured cloathing and the taffelled shoulder-knots of our footmen.”

In some universities physicians wears a scarlet gown. In the Saracens, the doctors are always in gowns and caps. Beadles, &c. wear gowns of two or more colours.

Among the French officers, &c. they distinguishe those of the short gown or robe; which are such as have not been regularly examined. They have also barbers of the short gown, who are such as are obliged to prætexte in an inferior way to those of the long robe.

Gown is also taken in the general for civil magistrature, or the profession opposite to that of arms. In this sense it was that Cicero faid *vedant arma togae*.
GOVERN, a borough, fair, and post town, in the county of Kilkenny and province of Leinster, Ireland. N. Lat. 52°. 43'. W. Long. 7°. 0'. It is governed by a constable, recorder, and town clerk. Here are the ruins of an old church, also the handsome seat of the late Lord Clifden; and three miles beyond Gowran are the ruins of Ballinabola castle.

GOVERN (John Van), painter of landscapes, cattle, and sea-pieces, was born at Leyden in 1596; and was for some time instructed by Isaac Nicolai, who was regarded as a good painter; but afterwards he became the disciple of Eelco Vandersadle, the most celebrated landscape painter of his time. Van Goyen very soon took a general esteem; and his works are more universally spread throughout all Europe than the works of any other master, for he possessed an uncommon readiness of hand and freedom of pencil. It was his constant pleasure and practice to sketch the views of villages and towns situated on the banks of rivers or canals; of the sea-ports in the Low Countries; and sometimes of inland villages, where the scenes around them appeared to him pleasing or picturesque. Thence he afterwards used as subjects for his future landscapes; enriching them with cattle, boats, and figures in character, just as the liveliness of his imagination directed. He understood perspective extremely well, and added the principles of the chiaro-沈ro; which branches of knowledge enabled him to give his pictures a strong and agreeable effect. He died in 1656, aged 60. — His usual subjects were sea-pieces, or landscapes with views of rivers, enlivened with figures of peasants either ferrying over cattle, drawing their nets in still water, or going to or returning from market. Sometimes he represented the boats on the banks of rivers, with overhanging trees, and a beautiful reflection of their branches from the transparent surface of the waters. These were the subjects of his best time, which he generally marked with his name and the year; and the high finished pictures of Van Goyen will be ever eminable. But as he painted abundance of pictures, some are flight, some too yellow, and some negligently finished; though all of them have merit, being marked with a free, expeditious, and easy pencil, and a light touch. His pictures frequently have a greyish cast, which did not arise from any mismanagement of the tints, or any want of the skill in laying on the colours; but was occasioned by his using a colour called holiday blue, much approved of at that time, though now entirely disused, because the artists found it apt to fade into that greyish tint; and it hath also rendered pictures of this master exceedingly difficult to be cleaned without injuring the finer touches of the finishing. His best works are valued so highly in most parts of Europe, especially in the Low Countries, that they deservefully afford large prices, being ranked in Holland with the pictures of Teniers; and at this time are not easily procured, particularly if they are damaged, though his lighter performances are sufficiently common.

GRAAF (Regnier de), a celebrated physician, born at Schoonhaven, in Holland, in 1641. He studied physic at Prussia. He was educated in Leyden, where he acquired great honour by publishing a treatise De Siccis Phanocritici. He also published three pieces upon the organs of generation, both male and female; upon which subject he had a controversy with Swammerdam. He died young, in 1673; and his works, with his life prefixed, were published at Leyden in 1677, in 8vo.

GRABE (John Ernest), a very learned writer in the beginning of the 18th century, a native of Königsberg in Prussia. He was educated in the Lutheran religion; but the reading of the fathers led him into doubts. He presented to the electoral consistory at Sam­bia in Prussia a memorial containing his doubts. The elector gave orders to three eminent divines to answer them. Their answers shook him a little in his resolution of embracing the Roman Catholic religion; and one of them, Spener, advised him to go to England. He went; and king William gave him a pension, which was continued by queen Anne. He was ordained a priest of the church of England, and honoured with the degree of doctor of divinity by the university of Oxford; upon which occasion Dr George Smalridge pronounced two Latin orations which were afterwards printed. He wrote, 1. Spicilegium S. S. Patrum, ut et Hereticorum faciuli post Christum natum, 8vo. 2. An edition of the Septa­ugint, from the Alexandrian manuscript in St James's library. 3. Notes on Justin, &c.; and other works, which are esteemed by the learned.

GRACCHUS (Tiberius), elected tribune of the Roman people in the year 103 B.C. He carried forward the execution of the Agrarian law; by which all persons possessing above 300 acres of land were to be deprived of the surplus, for the benefit of the poor citizens, amongst whom an equal distribution of them was to be made. Having carried his plan into execution by violent measures, he fell a victim to his zeal, being assassinated by his own party, 133 B.C. Caius his brother pursuing the same steps, was killed by the consul Ominus, 121 B.C. See (history of Rome).

GRACE, among divines, is taken, 1. For the free love and favour of God, which is the spring and source of all the benefits we receive from him. 2. For the work of the Spirit renewing the soul after the image of God; and continually guiding and strengthening the believer to obey his will, to resist and mortify sin, and overcome it.

Grace is also used, in a peculiar sense, for a short prayer said before and after meat.

The proofs of the moral obligation of this ceremony, drawn from different passages of the New Testament, are so well known, that it is needless to insist on them here. Some others, drawn from the practice of different nations, and of very remote antiquity, may not be disagreeable to our readers.

1. Athenaeus tells us, in his Deipnosof. lib. ii. that in the famous regulation made by Amphictyon king of Athens with respect to the use of wine, both in sacrifices and at home, he required that the name of Jupiter the Sustainer should be decently and reverently pronounced. The same writer, in lib. iv. p. 149, quotes Hermeias, an author extant in his time, who informs us of a people in Egypt, inhabitants of the city of Naukratis, whose custom it was on certain occasions, after they had placed themselves in the usual posture of eating at the table, to rise, again and kneel; when the priest or presbyter to the solemnity began to chant a grace, according to a stated form among them; and when that was over, they joined in the meal in a solemn faciicial manner. Heliodorus has a passage in his Ethiopic to the same purpose, that is
was the custom of the Egyptian philosophers to pour libations and put up ejaculations before they sat down to meals. Porphyr., in his treatise De abstin., lib. iii. p. 408, gives a great character of the Samian gymnosophists in Egypt for the strictness of their lives: as one article in their favour, he observes, that at the sounding of a bell before their meals, which consisted only of rice, bread, fruits, and herbs, they went to prayers; which being ended, and not before, the bell was sounded again, and they sat down to eating. In general this was a religious usage or rite among the ancient Greeks; and derived from yet older ages, if Clement of Alexandria rightly informs us. He mentions, that these people, when they met together to refresh themselves with the juice of the grape, sung a piece of music, in imitation of the Hebrew Psalms, which they called a *gibhion*. Livy, lib. xxxix. speaks of it as a festal custom among the old Romans; that they offered sacrifice and prayer to the gods at their meals and complotations. But one of the fullest testimonies to our purpose is given by Quintilian, *Declam.* 301. *Ad finem manum fays, ducat quidam convenerit epumus, Deus in nomo;* "We approached the table (at supper time) armed with bread and with an offering to accompany." 

The *Joanit Tregant*, in his very elegant and instructive narrative of the Christian expedition of their missionaries into China, book i. p. 69, gives this account of the people there in the particular now under consideration. "Before they place themselves for partaking of an entertainment, the person who makes it sets a vessel, either of gold, or silver, or marble, or some such valuable material, in a charger full of wine, which he holds with both his hands, and then makes a low bow to the person of chief quality or character at the table. Then, from the hall or dining-room, he goes into the porch or entry, where he again makes a very low bow, and turning his face to the fourth, pours out this wine upon the ground as a thankful oblation to the Lord of heaven. After this, repeating his reverential obeisance, he returns into the hall," &c.

The Turks pray for a blessing on their meat; and many more instances might be produced of infidels who have constantly observed the like custom in some way or other.

2. The fact, therefore, with respect to the heathen world, being thus evident, we proceed to the sentiments and behaviour of the Jews in this particular. Their celebrated historian Josephus, giving a detail of the rites and customs of the Ephesians, who were confessedly the strictest and most pious professors of the Jewish religion, has this remarkable passage to the present purpose: "The priest," says he, "begs a blessing before they presume to take any nourishment; and it is looked upon as a great sin to take or taste before." Then follows the thanksgiving before meat: "And when the meal," proceeds he, "is over, the priest prays again; and the company with him bless and praise God as their protector, and the donor of their life and nourishment."

*Philo*, in his book *De vita Contemplativa*, gives an account of a body of men and women stricter than even the Ephesians themselves. He distinguishes them by no particular name, though his relation is very accurate and circumstantial; namely, that on certain special occasions, before "they took their meals, they placed themselves in a proper decent order; when, lifting up their hands and eyes to heaven, they prayed to God that he would be pleased to propitiate them in the use of these his good creatures."

From the Hebrew ritual it appears, that the Jews had their hymns and psalms of thanksgiving, not only after eating their pasover, but on a variety of other occasions, and after meals, and even between their several courses and dishes; as when the best of their wine was brought upon the table, or their aromatic confections, or the fruit of the garden, &c. On the day of the pasover was sung Psalm cxiv. "When Israel came out of Egypt," &c.

Aristides has a passage full on the present subject. "Moses," says he, "commands, that when the Jews are going to eat or drink, the company should immediately join in sacrifice or prayer." Where Rabbi Eleazar (upon that author) met with this sentence, has been controverted. But supposing it not to be found in *toras", it is sufficient for us to know that the Jews did most constantly profess this custom, upon the foundation of an ancient and general tradition and usage. That this practice the prophet Daniel gave thanks before meat, is evident from the Apocryphal book concerning Bel and the Dragon, where, ver. 38, 39, we find, that "Daniel said, Thou hast remembered me, O God! neither hast thou forsaken them who seek thee and love thee. So Daniel rote, and did eat." Of this text Prudentius takes notice in Cathemirin, *hymn* iv.

His *sumptus Daniell excidit Alum faciun, cibus fortis Amen reddidit, alleluia dixit.*

The much-beloved took the repast, And up to heaven his eyes he cast; By which refresh'd, he sang aloud, Amen and Alleluia to his God.

Where, by the way, it may be observed, that the poet is a little mistaken in making the prophet give thanks after meat; whereas, according to the text, he did it before.

**Grace**, or *gracefulness*, in the human character, an agreeable attribute, inseparable from motion as opposed to rest, and as comprehending speech, looks, gesture, and loco-motion.

As some motions are homely, the opposite to graceful; it is to be inquired, With what motions is this attribute connected? No man appears graceful in a walk; and therefore, laying aside the expressions of the contenience, the other motions may be genteel, may be elegant, but of themselves never are graceful. A motion adjusted in the most perfect manner to answer its end, is elegant; but still somewhat more is required to complete our idea of grace or gracefulness.

What this unknown more may be, is the nice point. One thing is clear from what is said, that this more must arise from the expressions of the contentenience; and from what expressions so naturally as from those which indicate mental qualities, such as sweetnefs, benevolence, elevation, dignity? This promises to be a fair analysis; because all objects mental qualities affect us the most; and the impression made by graceful appearance upon every spectator of taste, is too deep for any cause purely corporeal.

The next step is, to examine what are the mental qualities,
GRA

qualities, that, in conjunction with elegance of motion, produce a graceful appearance. Sweetness, cheerful-
ness, affability, are not separately sufficient, nor even in conjunction. Dignity alone, with elegant motion,
produce a graceful appearance, but still more graceful with the aid of other qualities, those especially that are
the most exalted. See DIGNITY.

But this is not all. The most exalted virtues may
be the lot of a person whose countenance has little ex-
pression; such a person cannot be graceful. Therefore
to produce this appearance, we must add another cir-
cumstance, viz. an expressive countenance, displaying
to every spectator of taste, with life and energy, every
thing that pales in the mind.

Collecting these circumstances together, grace may
be defined as "that agreeable appearance which aris-
e from elegance of motion and from a countenance ex-
pressive of dignity." Expressions of other mental
qualities are not essential to that appearance, but they
heighten it greatly.

Of all external objects, a graceful person is the most
agreeable.

Dancing affords great opportunity for displaying
grace, and haranguing still more. See Dancing,
Declamation, and Oratory.

But in vain will a person attempt to be graceful who
is deficient in amiable qualities. A man, it is true,
may form an idea of qualities he is deficient of, and,
by means of that idea, may endeavour to express these
qualities by looks and gestures: but such studied ex-
pression will be too faint and obscure to be graceful.

All of Grace, the appellation given to the act of
parliament 1765, c. 52, which allows prisoners for
civil debts to be set at liberty, upon making oath that
they have not wherewithal to support themselves in
prison, unless they are alimented by the creditors on
whose diligences they were imprisoned, within ten
days after intimation made for that purpose.

Days of Grace, three days immediately following
the term of payment of a bill, within which the cre-
ditor must protest if payment is not obtained, in or-
der to initiate him to recover again the drawer.

Grace is also a title of dignity given to dukes,
archbishops, and in Germany to barons and other in-
ferior princes.

Graces, Graces, Charities, in the heathen
theology, were fabulous deities, three in number, who
attended on Venus. Their names are, Aglia, Thalia, and
Euphrofyne; i.e. shining, flourishing, and gay; or, ac-
cording to some authors, Pafithea, Euphris, and Ap-
gale. They were supposed by some to be the daughters
of Jupiter and Evynome the daughter of Oceanus; and
by others, to be the daughters of Bacchus and Venus.

Some will have the Graces to have been four; and
make them the fames with the Horae, or Hours, for
other with the four seasons of the year. A marble in
the king of Prussia's cabinet represents the three Graces
in the usual manner, with a fourth seated and covered
with a large veil, with the words underneath, All So-
vers IIII. But this group we may understand to be
the three Graces, and Venus, who was their sifler, as
being daughter of Jupiter and Dione.

The Graces are always supposed to have hold of
each other's hands, and never parted. They were
painted naked, to show that the Graces borrow nothing
from art, and that they have no other beauties than
what are natural.

Yet in the first ages they were not represented nak-
ed, as appears from Paufianias, lib. vi. and lib. ix. who
describes their temples and statues. They were of
wood, all but their head, feet, and hands, which were
white marble. Their robe or gown was gilt; one of
them held in her hand a rofe, another a dyce, and the
third a spig of myrtle.

Graclilis, a musele of the leg, thus called from
its slender shape. See Anatomy, Table of the Muscles.

Gracula, the Gracle, in ornithology, a genus
belonging to the order Picae. The bill is convex,
cultivated, and bare at the point; the tongue is not clo-
ven, but is fleshy and sharpish; it has three toes before
and one behind. 1. The religiosa, lesser grackle, or
Indian curle, is about the size of a blackbird, the bill an
inch and a half long, and of an orange colour. The
general colour of the plumage is black, grolled with
violet, purple, and green, in different reflections of
light; on the quills is a bar of white: the feathers and
legs are orange yellow, and the claws a pale brown.
The species, which is found in several parts of the East
Indies, in the isle of Hanian, and almost every isle be-
Yond the Ganges, is remarkable for whistling, singing,
and talking well, much better than any of the parrot
genre, and in particular very dainty. Its food is of
the vegetable kind. Those kept in this climate are
observed to be very fond of cherries and grapes: if
cherries are offered to one, and it does not immedi-
ately get them, it cries and whines like a young
child, till it has obtained its desire. It is a very tame
and familiar bird. 2. The barita, or boat-tailed
grackle, is about the size of a cuckow. The bill is
sharp, black, and an inch and a half in length; the
general colour of the plumage is black, with a glos-
of purple, especially on the upper parts; the legs
and claws are black, the latter hooked. There is a
singularity in the folding up of the tail feathers, which,
instead of forming a plain surface at top, sink in
a hollow like a deep gutter. It always carries its tail
expanded when on the ground, folding it up in the
above singular manner only when perched or flying.
It inhabits Jamaica; and it feeds on maize, beetles,
and other insects, as well as on the fruit of the banana.
It is likewise common in North America, keeping
company with the flocks of the maize-thieves, and red
winged orioles. These breed in the swamps, and
migrate in September, after which none are seen. 3. The
quiquila, purple-jackdaw, or Barbadoes blackbird, is-
about the size of a blackbird; the whole bird is black,
but most beautifully and richly glossed with purple,
especially on head and neck. The female is wholly
of a brown colour, deepest on the wings and tail. This
species inhabits Carolina, Mexico, and other parts of
North America, also Jamaica. These birds for the
most part feed on maize, whence the name of maize
thieves has been given them; but this is not their
only food, for they are known also to feed on many other
things. In spring, soon after the maize feed is put into
the ground, they scratch it up again; and as soon as
the leaf comes out, they take it up with their bills, root
and all, but when it is ripe they do still more damage,
for at that time they come in troops of thousands, and are so bold, that if disturbed in one part of a field they only go to another. In New Jersey and Pennsylvania three peice per dozen was once given for the dead birds, and by means of this premium they were nearly extirpated in 1750; when the persecution of them was abated on account of the great increase of worms which had taken place in the meadows, and which in the preceding year had left to little hay in New England as to occasion an importation from other parts. The grakles were therefore again tolerated, as it was observed that they fed on these worms till the maize was ripe. These birds build in trees. They are said to pass the winter in swamps, which are quite overgrown with wood, from thence only appearing in mild weather; and after the maize is got in, are content to feed on other things, as the aquatic tame-grafo, and if prefied by hunger, buck-wheat and oats, &c. they are said also to destroy that pernicious infect the bruchus pli. Their note is pretty and agreeable; but their flesh is not good to eat. The erititellis, or Chinese starling, is a little bigger than a blackbird. The bill is yellow or orange; and the general colour of the plumage blackish, with a tinge of blue: the legs are of a dull yellow. These birds, which are said total and whifhe very well, are common in China, where they are very much esteemed, and the figures of them are seen frequently in Chinese paintings. Their food is rice, infects, worms, and fuch like. They are seldom brought to England alive, requiring the greatest care in the passage.—There are eight other species of Graculus.

GRACULUS, in ornithology. See Corvus.

GRADATION, in general, the ascending step by step, or in a regular and uniform manner.

GRADATION, in logic, a form of reasoning, otherwife called Sorites.

GRADATION, in painting, a gradual and insensible change of colour, by the diminution of the teints and shades.

GRADATION, in rhetoric, the same with Climax.

GRADISKA, a strong town of Hungary in Scavonia, on the frontier of Croatia, taken by the Turks in 1691. It is feated on the river Save, in E. Long. 17. 55. N. Lat. 45. 38.

GRADISKA, a strong town of Italy, in a small island of the same name on the frontiers of Friuli, in E. Long. 13. 37. N. Lat. 46. 6. It is subject to the houfe of Austria.

GRADO, a strong town of Italy, in a small island of the same name, on the coast of Friuli, in the territory of Venice. E. Long. 13. 35. N. Lat. 45. 52.

GRADUATE, a person who has taken a degree in the university. See Degree.

GRÆVIUS (John George), one of the most learned writers in the 15th century. In the 24th year of his age, the elector of Brandenburg made him professor at Dofibourg. In 1658, he was invited to Deventer to succed his former master Gronovius. In 1661, he was appointed professor of eloquence at Utrecht; and 14 years after he had the professorship of politics and history conferred on him. He fixed his thoughts here, and refused several advantageous offers. He had, however, the satisfaction to be fought after by divers princes, and to see several of them come from Germany to study under him. He died in 1703, aged 71. His Thesaurus antiquitatum et historiarum Italiae, &c. and other works, are well known.

GRAFTING, or Engrafting, in gardening, is the taking a shoot from one tree, and injuring it into another, in such a manner that both may unite closely and become one tree. By the ancient writers on husbandry and gardening, this operation is called incision, to distinguish it from inoculation or budding, which they call inferre caulis.

Grafting hath been practised from the most remote antiquity; but its origin and invention is differently related by naturalists. Theophrastus tells us, that a bird having swallowed a fruit whole, cast it forth into a leaf or cavity of a rotten tree; where mixing with some of the purified parts of the wood, and being washed with the rains, it budded, and produced within this tree another tree of a different kind. This led the husbandman to certain reflections, from which afterwards arose the art of engrafting.

Pliny sets the same thing in a different light: a countryman having a mind to make a palliade in his grounds, that it might endure the longer, he himself to fill up and strengthen the bottom of the palliade, by running or wasting it with the trunks of ivy. The effect of this was, that the flakes of the palliades taking root, became engrafted into the trunks, and produced large trees; which suggested to the husbandman the art of engrafting.

The use of grafting is to propagate any curious sorts of fruits so as to be certain of the kinds; which cannot be done by any other method: for as all the good fruits have been accidentally obtained from seeds, so the seeds of these, when sown, will many of them degenerate, and produce such fruit as is not worth the cultivating; but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be their flock or tree on which they are grafted.

The reason or philosophy of engrafting is something obscure; and had not accident given the first hint, all our knowledge of nature would never have led us to it. The effect is ordinarily attributed to the diversity of the pores or ducts of the graft from those of the flock, which change the figure of the particles of the juices in passing through them to the root of the tree.

Mr Bradley, on occasion of some observations of Agricola, suggests something new on this head. The flock grafted on, he thinks, is only to be considered as a fund of vegetable matter, which is to be filtered through the cyon, and digested, and brought to maturity, as the time of growth in the vessels of the cyon directs. A cyon, therefore, of one kind, grafted on a tree of another, may be rather said to take root in the tree it is grafted in, than to unite itself with it: for it is visible that the cyon preserves its natural purity and intent, though it be fed and nourished with a mere crab; which is, without doubt, occasioned by the difference of the vessels in the cyon from those of the flock: so that grafting may be justly compared to planting.

In prosecution of this view of that ingenious author, we add, that the natural juices of the earth, by their secretion
G R A T I N G.

Fermentation and comminution in passing through the roots, &c. before they arrive at the cyon, must do a great deal to half elaborated and so disposed for a more easy, plentiful, and perfect assimilation and nutrition; whence the cyon must necessarily grow and thrive better and faster than if it were put immediately in the ground, there to live on coarse diet and harder of digestion; and the fruit produced by this further preparation in the cyon, must be finer and further exalted than if fed immediately from the more imperfectly prepared and altered juices of the cyon.

Many have talked of changing of species, or producing mixed fruits, by engrafting one tree on another of the same class; but as the graft carries the juices from the cyon to the pulp of the fruit, there is little hope of succeeding in such an expectation by ever so many repeated grafts; but if, after changing the graft and tree, several successive times, you felt the seed of the fruit produced on the graft in a good mould, it is possible that a change may happen, and a new mixed plant may be produced. Thus the almond and peach may, by many changes in the graftings, and by intertentions of the stones of the peaches, and of the shells of the almonds, and by terbiations of the stem of the root here and there, alter their nature so much, that the coat or pulp of the almond may approach to the nature of the peach, and the peach may have its kernel enlarged into a kind of almond; and on the same principle, the curious gardener may produce many such mixed kinds of things.

Mr Du Hamel has observed, that, in grafting of trees, there is always found at the insertion of the graft, a change in the directions of fibres, and a fort of twinging or turning about of the vessels, which greatly imitates that in the formation of certain glands in animal bodies; and from thence he infers, that a new sort of veins being formed by this means, the fruit may very naturally be so far influenced by it, as to be meliorated on the new branch; but that no such sudden and edentential changes can be effected by those means, as too many of the writers on agriculture pretend. He observes, however, that this anatomical observation would not have been sufficient to convince him of the falsity of too many of these relations, had not experiment joined to confirm him in his opinion. He tried many grafts on different trees; and, for fear of error, repeated every experiment of consequence several times: but all served only to convince him of the truth of what he at first suspected. He grafted in the common way the peach upon the almond, the plum upon the apricot, the pear upon the apple, the quince, and the white thorn; one species of plum on other very different species, and upon the peach, the apricot and the almond. All these succeeded alike: the species of the fruit was never altered; and in those which would not come to fruit, the leaves, the wood, and the flowers, were all the same with those of the tree from whence the graft was taken.

Authors on agriculture have also mentioned a very different sort of grafting; namely, the setting grafts of one tree upon stocks of a different genus; such as the apricot the pear upon the oak, the elm, the maple, or the plum, &c. Mr Du Hamel tried a great number of these experiments carefully, and found every one of them unsuccessful; and the natural conclusion from this was, that there must be some natural alliance between the stocks and their grafts, otherwise the latter will either never grow at all or very soon perish.

Notwithstanding the facility with which grafts generally take on good stocks, there are many accidents and uncertainties attending them in their different periods. Some perish immediately; some, after appearing healthy for many months, and some even for years. Of these last some die without the stock suffering any thing; others perish together with the stocks. It is very certain, that the greater part of grafted trees do not live so long as they would have done in their natural state; yet this is no exceptionable rule: for there are some which evidently live the longer for this practice; nay, there are instances of grafts which, being placed on stocks naturally of short duration, live longer than when placed on those which are more robust and lasting. These irregularities have been but little considered hitherto, though they might be made productive of considerable advantages.—One great requisite for the succeeding of any graft is, that it be in its own nature capable of so close and intimate an union with the substance of the stock, that it becomes as it were a natural branch of it. If all trees resembled one another in their structure and juices, the size and elasticity of their vessels, &c. probably the grafts of all trees would succeed upon one another; but this is by no means the case.

Trees are well known to be composed of numerous arrangements of hollow fibres, and these are different and unequal in every species of tree. In order to the succeeding of any graft is, that there must be a conformity in its vessels and juices with those of the stock; and the more nearly they agree in this, probably the better they succeed; and the farther they differ, the worse. If there be, however, some difference in the solid parts of trees, there are evidently many more in the juices. The sap of some trees is white as milk, in others it is red, and in some as clear and limpid as water. In some, it is thin and very fluid; in others, thick and viscous. In the taste and smell of the juices there are also not less differences: some are sweet, some insipid, some bitter, some astringent, and some fetid: the quality of the sap thus makes a very great difference in the nature of trees; but its quantity, and derivation to the parts, is scarce less observable. Of this we have familiar instances in the willow and the box; one of which will produce longer shoots in one year than the other in twenty.

Another difference yet more striking, and indeed more essential in regard to the growth of grafts than all these, is the different season of the year at which trees shoot out their leaves, or ripen their flowers. The almond-tree is in flower before other trees in general have opened their earliest buds; and when other trees are in flower, this is full of leaves, and has its fruit set before the mulberry begins to push out its earliest buttons. When we consider all these differences in trees, we cannot but wonder how it is possible for a branch of one to live upon another; and it becomes a much more perplexing question how any graft can succeed, than how such numbers come to miscarry. A graft of one pear upon another shall be seen
Grafting.

Grafting, seen to succeed presently as if upon its own tree; and in a fortnight will gain six inches in length, and so of some others.—This must be owing to the great similarity between the flock and the graft in all respects; and a great contrariety or difference in structure of parts will make it as remarkable a difference on one hand, and an instance of this may be observed in the plum and the elm; which no art can ever make to succeed upon another, whether the plum be grafted on the elm, or the elm upon the plum flock. These are examples of the extremes of easy growth, and of absolute decay; but there are many conjunctions of trees which seem of a middle nature between the two, and neither immediately perish, nor totally succeed. Of these, such as were grafted in autumn usually remain green the whole winter without pulling; and those which are grafted in spring remain green a month or longer, but still without shooting. Some particular ones have also been known to make a few shoots the first, or even the second sap season after the operation; but all perish at the end of these times. Of this kind are the grafts of the pear-tree upon the elm, the maple, and the hornbeam, and the mulberry upon the elm and fig, with many others.

When we come to inquire into the cause of this, we find that these grafts, though unnatural, have yet had a communication with the flock by means of a few small vessels, which has been sufficient to keep them green, or even to make them shoot a little, during the great ascent of the sap: But the far greater number of the fibres have had all the while no communication, and are found putrified, dried up, or covered with a putrid juice. This has evidently happened by means of the disproportion in size between the vessels of the flock and of the graft, and the great difference between their natural juices, which are obstacles abundantly sufficient to prevent either an union of the fibres or the introduction of new sap.

The grafts of the almond on the plum, and of the plum on the almond, always grow very vigorously for the first year, and give all the appearances imaginable of succeeding entirely; yet they always perish in the second or third year. The almond graft upon the plum-flock always pushes out very vigorously at first; but the part of the flock immediately under the graft grows smaller and perishes, the graft absoiling too much of the juices, and the graft necessarily perishes with it. The decay of the whole generally happens early in the spring; and that plainly from the different season of the natural shooting of the two trees, the almond pushing very vigorously, and consequently draining the flock of its juices, at a time when, according to its nature, the juices are but in small quantity in it, and the sap does not begin to ascend. The grafts of the plum on the almond are, from the same cause, furnished with an abundance of sap which they have at that time no occasion for; and consequently they as certainly perish of repletion, as the other of invasion.

As the peach grafted on the plum succedeth excellently, and lives longer than it would have done in a natural state; the reason seems to be, that the peach is a tender tree, shoots with great vivacity, and produces more branches than the root is able to maintain. Thus the peach trees are usually full of dead wood; and often their large branches perish, and sometimes their whole trunk. On this occasion the plum, being a slow shooting tree, communicates its virtue to the graft; and the peach consequently sends out shoots which are more robust and strong, and there is no more in number than the root is able to supply with nourishment, and consequently the tree is the more lasting.

The grafts, or cions, with which the grafting is effected, are young shoots of last summer's growth, for they must not be more than one year, and such as grow on the outside branches, and robust but moderate shooters; such also as are firm and well ripened, should always be chosen from healthful trees: observing, that the middle part of each shoot is always the best graft, cut at the time of grafting to five or six inches in length, or so as to have four or five good eyes or buds; but should be preferred at full length till grafting time, and then prepared as hereafter directed.

They should be collected or cut from the trees in February, in mild weather, before their buds begin to swell, or advance much for shooting; in collecting them, choose such as have not made lateral or side shoots; cut them off at full length; and if they are not to be used as soon as they are collected, lay their lower ends in some dry earth in a warm border till grafting time, and if ever weather should happen, cover them with dry litter.

The proper tools and other materials used in grafting, are, 1. A strong knife for cutting off the ends of the flocks, previous to the insertion of the graft; also a small hand-saw for occasional use in cutting off the heads of large flocks. 2. A common grafting-knife, or strong sharp pen-knife, for cutting and shaping the grafts ready for insertion; also to slope and form the flocks for the reception of the grafts. 3. A flat grafting-chisel and small mallet for cleaving large flocks, in cleft-grafting, for the reception of the graft. 4. A quantity of new hays-firings for bandages, for tying the grafted parts close, to secure the grafts, and promote their speedy union with the flock. And, 5. A quantity of grafting clay, for laying closely round the grafts after their insertion and binding, to defend the parts from being dried by the sun and winds, or too much liquified by wet, or pinched by cold; for these parts ought to be closely surrounded with a coat of clay in such a manner as effectually to guard them from all weathers, which would prove injurious to young grafts, and destroy their cementing property, so as to prevent the junction: therefore, a kind of stiff loamy mortar must be prepared of strong fat loam, or, in default thereof, any sort of tough binding clay, either of which should be laid in an heap, adding thereto about a fourth of fresh horse-dung free from litter, and a portion of cut hay, mixing the whole well together, and adding a little water: then let the whole be well beaten with a stick upon a floor, or other hard substance; and as it becomes too dry, apply more water, at every beating turning it over, always continuing to beat it well at top till it becomes flat; which must be repeated more or less according to the nature of the clay, but should be several times done the first day; next morning repeat the beating, still moistening it with water; and by thus repeating the beating six or eight times every day for two or three days, or every other day at least, for a week, it will be in proper...
Grafting, per order for use; observing, it should be prepared a week or at least before it is used, but if a month, the better.

The season for performing the operation of grafting is February and March; though, when the work is performed in February, it is for the general part proves the most successful, more especially for cherries, plumbs, and pears; and March grafting is well adapted for apples.

There are different methods of grafting in practice, termed Whip-grafting—Cleft-grafting—Crown-grafting—Cheek-grafting—Side-grafting—Root-grafting—and Grafting by approach or Inarching; but Whip-grafting and Cleft-grafting are most commonly used, and Whip-grafting most of all, as being the most expeditious and successful of any.

Whip-grafting—This being the most successful method of grafting is the most commonly practised in all the nurseries; it is always performed upon small stocks, from about the size of a goose-quill to half an inch or a little more or less in diameter, but the nearer the stock and graft approach in size the better, and is called whip-grafting, because the grafts and stocks being nearly of a size, are laid on one side, so as to fit each other, and tied together in the manner of whips, or joints of angling rods, &c. and the method is as follows. Having the stocks or grafts, knife, bandages, and clay ready, then begin the work by cutting off the head of the stock at some clear smooth part thereof; this done, cut one side sloping upward, about an inch and half or near two inches in length, and make a notch or small slit near the upper part of the slope downward about half an inch long, to receive the tongue of the cyon; then prepare the cyon, cutting it to five or six inches in length, forming the lower end of it in a sloping manner, so as to fit the sloped part of the stock, as if cut from the same place, that the rinds of both may join evenly in every part; and make a slit so as to form a sort of tongue to fit the stock made in the slope of the stock; then place the graft, inserting the tongue of it into the slit of the stock, applying the parts as evenly and close as possible, and immediately tie the parts close together with a string of basts, bringing it in a neat manner several times round the stock and graft; then clay the whole over near an inch thick on every side, from about half an inch or more below the bottom of the graft; then take the whole over near an inch thick over the top of the stock, finishing the whole coat of clay in a kind of oval globular form, rather long, up and down, closing it effectually about the cyon, and every part, so as no fun, wind, nor wet may penetrate, to prevent which; is the whole intention of claying: observing to examine it now and then, to see if it any where cracks or falls off, and if it does it must be instantly repaired with fresh clay. This sort of grafting may also be performed, if necessary, upon the young shoots of any bearing tree, if intended to alter the sorts of fruits, or have more than one sort on the same tree. By the middle or latter end of May, the grafts will be well united with the stock, as will be evident by the showing of the graft; then the clay should be wholly taken away: but suffer the basts bandage to remain sometime long after the united parts seem to swell and be too much confined by the ligature, then take the tying wholly off. Their farther culture is directed under the respective articles, whether designed for dwarfs or standards, &c.

Cleft-grafting—This is focalled, because the stock being too large for whip-grafting is cleft or slit down the middle for the reception of the graft; and is performed upon stocks from about one to two inches diameter. First, with a strong knife cut off the head of the stock; or if the stock is very large, it may be headed with a saw; and cut one side sloping upwards about an inch and half to the top; then proceed with a strong knife or chisel, to cleave the stock at top, crofs-way the slope, fixing the knife or chisel towards the back of the slope, and with your mallet strike it, so as to cleave the stock about two inches, or long enough to admit the graft, keeping it open with the chisel; this done, prepare the cyon, cutting it to such length as to leave four or five eyes, the lower part of which being sloped on each side, wedge-fashion, an inch and half or two inches long, making one side to a thin edge, the other much thicker, leaving the rind thereon, which side must be placed outward in the stock; the cyon being thus formed, and the cleft in the stock being made and kept open with the chisel, place the graft therein at the back of the stock the thickest side outward, placing the whole cut part down like the cleft of the stock, making the rind of the stock and graft join exactly: then removing the grafting chisel, each side of the cleft will closely squeeze the graft, so as to hold it fast: it is then to be bound with a ligature of basts, and clayed over, as observed in whip-grafting, leaving three or four eyes of the cyons uncovered. If intended to graft any pretty large stocks or branches by this method, two or more grafts may be inserted in each; in this case the head must be cut off horizontally, making no slope on the side, but smooth the top, then cleave it quite across, and place a graft on each side, as the stock may be cleft in two places, and insert two grafts in each cleft; they are thus to be tied and clayed as in the other methods. This method of grafting may be performed upon the branches of bearing trees, when intended either to renew the wood or change the sort of fruit. Towards the latter end of May, or the beginning of June, the junction of the graft and stock in either method will be effectually formed, and the graft begin to shoot, when the clay may be taken off, and in a fortnight or three weeks after take off also the bandages.

Crown-Grafting—This kind of grafting is commonly practised upon such stocks as are too large to cleave, and is often performed upon the large branches of apple and pear trees, &c. that already bear fruit, when it is intended to change the sorts, or renew the tree with fresh-bearing wood. It is termed crown-grafting, because the stock or branch being headed down, several grafts are inserted at top all around both the wood and bark, so as to give it a crown-like appearance: observing, that this kind of grafting should not be performed until March or early in April; for then the sap being in motion, renders the bark and wood of the stock much easier to be separated for the admission of the graft. The manner of performing this sort of grafting is as follows: First, cut off the head of the stock or branch with a saw horizontally, and pare the top smooth, then having the grafts, cut one side of each flat, and somewhat sloping, an inch and
Grafting. a half, forming a sort of shoulder at top of the slope to rest upon the crown of the stock; and then raising the kind of the stock with a wedge, for to admit the cyon between that and the wood two inches down, place the grafts with the flat side next the wood, thrusting it down far enough for the shoulder to rest upon the top of the stock; and in this manner may be put three, four, five, or more grafts in one large stock or branch. When the grafts are all thus inserted, let the whole be tied tight and well clayed: observing to leave two or three eyes of each graft uncovered, but raising the clay an inch above the top of the stock, so as to throw the wet quickly off, without lodging about the grafted parts, which would ruin the whole work. Crown-grafting may also be performed, by making several clefts in the crown of the stock, and inferting the grafts round the top of the clefts. The grafts will be pretty well united with the stock, and exhibit a state of growth, by the end of May or beginning of June, and the clay may then be taken away. The trees grafted by this method will succeed extremely well; but, for the first two or three years, have this inconvenience attending them, of being liable to be blown out of the stock by violent winds; which must be remedied by tying long stocks to the body of the stock or branch, and each graft tied upon one of the stocks.

Check-grafting.—Cut the head of the stock off, horizontally, and pare the top smooth; then cut one side flioping an inch and half or two inches deep, and cut the lower part of the graft flioping the same length, making a sort of shoulder at top of the flioped part; it is then to be placed upon the flioped part of the stock, resting the shoulder upon the crown of it; bind it with bafe, and finifh with a covering of clay as in the other methods.

Side-grafting.—This is done by inferting grafts into the sides of the branches without heading them down; and may be practifed upon trees to fill up any vacancy, or for the purpose of variety, to have several sorts of apples, pears, plums, &c. upon the same tree. It is performed thus. Fix upon each parts of the branches where wood is wanted to furnish the head or any part of the tree; there fliop the trunk, little of the wood, and cut the trees along the grafts to fit them as near as poifible; then join them to the branch, and tie them with bafe and clay them over.

Root-grafting.—This is done by whip-grafting cyons upon pieces of the root of any tree of the fame genus, and planting the root where it is to remain; it will take root, draw nourishment, and feed the graft.

Grafting by approach, or Inarching.—This sort of grafting is, when the flocks designed to be grafted, and the tree from which you intend to take the graft, either grow too near, or can be placed fo near together, that the branch or graft maybe made approach the flock, without separating it from the tree, till after its union or the branch be bent to the flock; so that the branch or graft being bent to the flock, they together form a f ort of arch; whence it is called Grafting by Approach, or Inarching. Being a fure method, it is commonly practifed upon fuch trees as are with difficulty made to fucceed by any of the former ways of grafting. When intended to propagate any kind of tree or shrub by this method of grafting, if the tree, &c.
## GRA [35] GRA

**Grafting.**

*Grain.* as to have very beautiful pyramids of fruit upon them, which will exceed in beauty, flavour, and quantity, all that can be otherwise produced. This, he says, he had long experienced, and gives the following method of doing it. The trees are to be transplanted in autumn, and all their branches cut off. Early in the following summer the young shoots are to be pulled off, and the buds then to be ingrafted into them in an inverted direction. This, he says, adds not only to the beauty of the pyramids, but also makes the branches more fruitful. These are to be closely connected to the trunk, and to be fastened in with the common ligature: they are to be placed circularly round the tree, three buds in each circle, and these circles at six inches distance from one another. The old trees may be ingrafted in this manner, the success having been found very good in those of twenty years standing; but the most eligible trees are those which are young, vigorous, and full of juice, and are not above a finger or two thick. When these young trees are transplanted, they must be fenced round with pales to defend them from the violence of the wind; and there must be no dung put to them till they are thoroughly rooted, for fear of rotting them before the fibres strike. The buds ingrafted must be small, that the wounds made in the bark to receive them, not being very large, may heal the looser, and if the buds do not succeed, which will be perceived in a fortnight, there must be others put in their place. The wound made to receive these buds must be a straight cut, parallel to the horizon; and the piece of bark taken out must be downward, that the rain may not get in at the wound. In the autumn of the same year, this will be a green and flourishing pyramid; and the next summer it will flower, and ripen its fruit in autumn.

**Graham.**

*Graham.* which will at the rage and the insult of his enemies. We meet his usual Graemes of mind, and expressed a just exec.. The death of that prince; though he obtained a pardon by the queen’s intercession. He spent the remainder of his days in retirement, and published an elegant translation of “Boethius on the confusion of philosophy.” He died in 1695.

**Graham (George),** clock and watch maker, the most ingenious and accurate artist in his time, was born in 1675. After his apprenticeship, Mr Tompion received him into his family, purely on account of his merit; and treated him with a kind of parental affection as long as he lived. Before his universally acknowledged skill in his profession, he was a complete mechanic and astronomer; the great mural arch in the observatory at Greenwich was made for Dr Halley, under his immediate inspection, and divided by his own hand; and from this incomparable original, the best foreign instruments of the kind are copies made by English artists. The fector by which Dr Bradley first discovered two new motions in the fixed stars, was of his invention and fabric: and when the French academicians were sent to the north to ascertain the figure of the earth, Mr Graham was thought the fittest person in Europe to supply them with instruments; those who went to the south were not so well furnished. He was for many years a member of the Royal Society, to which he communicated several ingenious and important discoveries; and regarded the advancement of science more than the accumulation of wealth. He died in 1751.

**Graham’s Dyke.** See *Antonius’s Wall.*

**Grain.** corn of all sorts, as barley, oats, rye, &c. See Corn, Wheat, &c.

**Grain** is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight Troy. A grain-weight of gold-bullion is worth two-pence, and that of silver, but half a farthing sterling.

**Grain** also denotes the component particles of stones and metals, the veins of wood, &c. Hence crosgained, or against the grain, means contrary to the fibres, of wood, &c.

**Grain** (Baptist le), master of the requests in ordinary to Mary de Medicis queen of France’s household, wrote *The History of Henry the Great,* and of *Louis XIII.* from the beginning of his reign to the death of the marshal d’Ancre in 1617. This history is reckoned to be written with impartiality, and the spirit of a true patriot; and contains many things not to be found anywhere else. He vigorously afferts the edict that had been granted to the reformed.

**Grallae,** in ornithology, is an order of birds analogous to the *brata* in the clas of mammalia, in the Linnean system. See Zoology and Ornithology.

**Gramina,** grasses; one of the seven tribes or natural families, into which all vegetables are distributed by Linnaeus in his *Philosophia Botanica.* They are defined to be plants which have very simple leaves, a jointed stem, a hollow calyx termed *gluma,* and a single seed. This description includes the several sorts of corn as well as grasses. In Tournefort they constitute a part of the fifteenth class, termed *apetalae,* and in Linnaeus’s sexual method, they are mostly contained in the second order of the third clas, called *trian-dria digynia.*

---

*This page contains historical information about the Scottish politician and statesman George Graham (1578–1650), his contributions to science and the arts, and his role in the Civil War.*
This numerous and natural family of the grasses has engaged the attention and researches of several eminent botanists. The principal of these are, Ray, Monti, Micheli, and Linnæus.

M. Monti, in his Catalogus Stirpium Agri Bononiensis, printed at Bononia in 1719, divides the grasses from the disposition of their flowers, as, Theophrastus and Ray had divided them before him into three sections or orders. These are, 1. Grasses having flowers collected in a spike. 2. Grasses having their flowers collected in a panicule or loose spike. 3. Plants that in their habit and external appearance are allied to the grasses.

This class would have been natural if the author had not improperly introduced sweet-rue, juncus, and arrow-headed grass, into the third section. Monti enumerates about 360 species of the grasses, which he reduces under Tournefort's genera; to these he has added three new genera.

Scheuchzer, in his Ariflographia, published likewise in 1719, divides the grasses, as Monti, from the disposition of their flowers, into the five following sections: 1. Grasses with flowers in a spike, as phalaris, anthoxanthum, and frumentum. 2. Irregular grasses, as Schrennum, and cornzco. 3. Grasses with flowers growing in a simple panicule or loose spike, as reed and millet. 4. Grasses with flowers growing in a compound panicule, or diffused spike, as oats and poa. 5. Plants by their habit nearly allied to the grasses, as eypres-grasses, scirpus, Linagrotilus, rufen, and tichelichoria.

Scheuchzer has enumerated about four hundred species, which he describes with amazing exactness.

Micheli has divided the grasses into six sections, which contain in all 44 genera, and are arranged from the situation and number of the flowers.

Gramina, the name of the fourth order in Linnæus's Fragments of a Natural Method, consisting of the numerous and natural family of the grasses, viz. Poa, alopecurus or fox-tail grasses, anthoxanthum or vernal grases, aridina arundo or reed, avena or oats, boba, bata, briza, bromus, chin, cornzco, or horn of plenty grass, cymoturus, daethylis, eyma, fæfica or fæfica-grasses, hordine or barley, lagurus or hare's tail grases, lollum or danel, lygrium or hooded matweed, melicia, milleum or millet, nardus, oryza or rice, panicum or panic-grasses, palpalm, phalaris, or canary-grasses, pleum, poa, sacharum or sugar-cane, secale or rye, fita or winged spike-grasses, triticum or wheat, unio, or pea-side oats of Carolina, cox or Job's tears, olyra, pharus, triplicum, zea, Indian Turkey wheat or Indian corn, zizania, æglops or wild fæfica-grasses, and ropogon, aplus, cenchtus, holcus or Indian millet, ifchænum. See Botany, p. 458, col. 2. and Grasses.

Composition. 1. Grammar is the art of speaking or of writing any language with propriety; and the purpose of language is to communicate our thoughts.

2. Grammar, considered as an art, necessarily supposes the previous existence of language; and as its design is to teach any language to those who are ignorant of it, it must be adapted to the genius of that particular language of which it treats. A just method of grammar, therefore, without attempting any alterations in a language already introduced, furnishes certain observations called rules, to which the methods of speaking used in that language may be reduced; and this collection of rules is called the grammar of that particular language. For the greater difficulties with regard to these rules, grammarians have usually divided this subject into four distinct heads, viz. Orthography, or the art of combining letters into syllables, and syllables into words; Etymology, or the art of deducing one word from another, and the various modifications by which the sense of any word can be diversified consistently with its original meaning or its relation to the term whence it is derived; Syntax, or what relates to the construction or due disposition of the words of a language into sentences or phrases; and Prosody, or that which treats of the quantities and accents of syllables, and the art of making verses.

3. But grammar, considered as a science, views language only as it is significant of thought. Neglecting all particular and arbitrary modifications introduced for the sake of beauty or elegance, it examines the analogy and relation between words and ideas; distinguishes between those particulars which are essential to language and those which are only accidental; and thus furnishes a certain standard, by which different languages may be compared, and their several excellencies or defects pointed out. This is what is called Philo sophic or Universal Grammar.

4. The design of speech is to communicate to others the thoughts and perceptions of the mind of the speaker: but it is obvious, that between an internal idea and any external found there is no natural relation; that the word fire, for instance, might have denominated the substane which we call ice, and that the word ice might have signified fire. Some of the most acute feelings of man, as well as of every other animal, are indeed expressed by simple inarticulate sounds, which as they tend to the preservation of the individual or the continuance of the species, and invariably indicate either pain or pleasure, are universally understood: but these inarticulate and significant sounds are very few in number; and if they can with any propriety be said to constitute a natural and universal language, it is a language of which man as a mere sensitive being partakes in common with other animals.
5. Man is endowed not only with sensation, but also with the faculty of reasoning; and simple inarticulate sounds are insufficient for expressing all the various modifications of thought, for communicating to others a chain of argumentation, or even for distinguishing between the different sensations either of pain or of pleasure: a man scourched with fire or unexpectedly plunged among ice, might utter the cry naturally indicative of sudden and violent pain; the cry would be the same, or nearly the same, but the sensations of cold and heat are widely different. 

Articulation, by which those simple sounds are modified, and a particular meaning fixed to each modification, is therefore absolutely necessary to such a being as man, and forms the language which distinguishes him from all other animals, and enables him to communicate with facility all that diversity of ideas with which his mind is stored, to make known his particular wants, and to distinguish with accuracy all his various sensations. Those sounds thus modified are called words; and as words have confidedly no natural relation to the ideas and perceptions of which they are significant, the use of them must either have been the result of human sagacity, or have been forgotten to the first man by the Author of nature.

6. Whether language be of divine or human origin, is a question upon which, though it might perhaps be soon resolved, it is not necessary here to enter. Upon either supposition, the first language, compared with those which succeeded it, or even with itself as afterwards enlarged, must have been extremely rude and narrow. If it was of human contrivance, this will be readily granted; for what art was ever invented and brought to a height of perfection by dilator savages? If it was taught by God, which is at least more probable supposition, we cannot imagine that it would be more comprehensive than the ideas of those for whose immediate use it was intended: that the first men should have been taught to express pains or pleasures which they never felt, or uttered sounds that should be afterwards significant of ideas which at the time of utterance had not occurred to the mind of the speaker: man, taught the elements of language, would be able himself to improve and enlarge it as his future occasions should require.

7. As all language is composed of significant words variously combined, a knowledge of them is necessary previous to our acquiring an adequate idea of language as constituted into sentences and phrases. But as it is by words that we express the various ideas which occur to the mind, it is necessary to examine how ideas themselves are forgotten, before we can ascertain the various classes into which words may be distributed. It is the province of logic to trace our ideas from their origin, as well as to teach the art of reasoning; but it is necessary at present to observe, that our earliest ideas are all ideas of sensation, excited by the impressions that are made upon our organs of sense by the various objects with which we are surrounded. Let us therefore suppose a reasonable being, devoid of every possible prepossession, placed upon this globe, and it is obvious, that his attention would in the first place be directed to the various objects which he saw existing around him. Thence he would naturally endeavour to distinguish from one another; and if he were either learning or inventing a language, his first effort would be to give them names, by means of which the ideas of them might be recalled when the objects themselves should be absent. This is one copious source of words; and forms a natural class which must be common to every language, and which is distinguished by the name of nouns; and as these nouns are the names of the several substances which exist, they have likewise been called substantives.

8. It would likewise be early discovered, that every one of these substances was endowed with certain qualities or attributes, to express which another class of words would be requisite, since it is only by their qualities that substances themselves can attract our attention. Thus, to be weighty, is a quality of matter; to think, is an attribute of man. Therefore in every language words have been invented to express the known qualities or attributes of the several objects which exist. These may all be comprehended under the general denomination of attributives.

9. Nouns and attributives must comprehend all that is essential to language (a); for every thing which exists, or of which we can form an idea, must be either a substance or the attribute of some substance; and therefore those two classes which denominate substances and attributes, must comprehend all the words that are necessary to communicate to the hearer the ideas which are present to the mind of the speaker. If any other words occur, they can only have been invented for the sake of dispatch, or introduced for the purposes of ease and ornament, to avoid tedious circumlocutions or disagreeable tautologies. There are indeed grammarians of great name, who have considered essential to language an order of words, of which the use is to connect the nouns and attributives, and which are said to have no signification of themselves, but to become significant by relation. Hence all words which can possibly be invented are by these men divided into two general classes: those which are significant of themselves and those which are not. Words significant of themselves are either expressive of the names of substances, and therefore called substantives; or of

(a) This is the doctrine of many writers on the theory of language, for whose judgment we have the highest respect; yet it is not easy to conceive mankind so far advanced in the art of abstraction as to view attributes by themselves independent of particular substances, and to give one general name to each attribute wherever it may be found, without having at the same time words expressive of affirmation. We never talk of any attribute, a colour for instance, without affirming something concerning it; as, either that it is bright or faint, or that it is the colour of some substance. It will be seen afterwards, that to denote affirmation is the proper office of what is called the substantive verb; as, "Milk is white." That verb therefore appears to be as necessary to the communication of thought as any species of words whatever; and if we must range words under a few general classes we should be inclined to say, that 

nouns, attributives, and affirmative, comprehend all that is essential to language.
of attributes, and therefore called *ATTRIBUTIVES.*

Words which are not significant of themselves, must acquire a meaning either as defining or connecting others; and are therefore arranged under the two classes of *DEFINITIVES* and *CONNECTIVES.*

10. That in any language there can be words of themselves have no signification, is a supposition which a man free from prejudice will not readily admit, or that purpose should they have been invented? as they are significant of no ideas, they cannot facilitate the communication of thought, and must therefore be only an incumbrance to the language in which they are found. But in answer to this it has been said, that these words, though devoid of signification themselves, acquire a sort of meaning when joined with others, and that they are as necessary to the structure of a sentence as cement is to the structure of an edifice: for as stones cannot be arranged into a regular building without a cement to bind and connect them, so the original words significant of substances and attributes, cannot be made to express all the variety of our ideas without being defined and connected by those words which of themselves signify nothing. It is evident, therefore, that he who first suggested this supposition did not perceive that it tends to overthrow the doctrine which it is meant to illustrate: for surely the cement is as much the matter of the building as the stones themselves; it is equally solid and equally extended. By being united with the stones, it neither acquires nor loses any one of the qualities essential to matter; it neither communicates its own softness, nor acquires its hardness. By this mode of reasoning therefore it would appear, that the words called *definitives* and *connectives,* so far from having of themselves no signification, are equally essential to language and equally significant with those which are denominated *substantives* and *attributes;* and upon investigation it will be found that this is the truth. For whatever is meant by the definition or connection of the words which all men confide to be significant, that meaning must be the sense of the words of which the purpose is to define and connect; and as there can be no meaning where there are no ideas, every one of these *definitives* and *connectives* must be significant of some idea, although it may not be always easy or even possible to express that idea by another word.

11. These different modes of dividing the parts of speech we have just mentioned, because they have been largely treated of by grammarians of high fame. But it does not appear to us, that any man can feel himself much the wiser for having learned that all words are either *SUBSTANTIVES* or *ATTRIBUTIVES,* *DEFINITIVES* or *CONNECTIVES.* The division of words into those which are *significant of themselves,* and those which are *significant by relation,* is absolute nonsense, and has been productive of much error and much mystery in some of the most celebrated treatises on grammar. It is indeed probable, that any attempt to establish a different classification of the parts of speech from that which is commonly received, will be found of little utility either in practice or in speculation. As far as the former is concerned, the vulgar division seems sufficiently commodious; for every man who knows any thing, knows when he uses a *noun* and when a *verb.* With respect to the latter, not to mention that all the grammarians from *Aristotle* to

**CHAPTER I.**

**Of the Noun or Substantive.**

12. *Nouns* are all those words by which objects or substances are denominated, and which distinguish from one another, without marking either quantity, quality, action, or relation. The *substantive* or *noun* is the name of the thing spoken of, and in Greek and Latin is called *nomen,* for it is *wita* in the one, and *nomem* in the other; and if in English we had called it the *name,* rather than the *noun,* the appellation would perhaps have been more proper, as this last word being used only in grammar, is more liable to be misunderstood than the other, which is in *confront* and *familiar* use. That *noun* or the names of things must make a part of every language, and that they must have been the words first suggested to the human mind, will not be disputed. Men could not speak of themselves or of any thing else, without having names for themselves and the various objects with which they are surrounded. Now, as all the objects which exist must be either in the same state in which they were produced by nature, or changed from their original state by art, or abstrai-
Different kinds of nouns.

ed from substances by the powers of imagination, and conceived by the mind as having at least the capacity of being characterized by qualities; this naturally suggests a division of nouns into natural, as man vegetable, tree, &c. artificial, as house, ship, watch, &c. and abstract, as whiteness, motion, temperance, &c.

But the diversity of objects is so great, that had we attempted to frame a complete and perfect alphabet of all the names of substances there would be an impossibility for the most tenacious memory, during the course of the longest life, to retain even the names of the narrowest language. It has therefore been found expedient, when a number of things resemble each other in some important particulars, to arrange them all under one species; to which is given a name that belongs equally to the whole species, and to each individual comprehended under it. Thus the word man denotes a species of animals, and is equally applicable to every human being. The word horse denotes another species of animals, and is equally applicable to every individual of that species of quadrupeds; but it cannot be applied to the species of men, or to any individual comprehended under that species. We find, however, that there are some qualities in which several species resemble each other; and therefore we refer them to a higher order called a genus, to which we give a name that is equally applicable to every species and every individual comprehended under it. Thus, men and horses, and all living things on earth resemble each other in this respect, that they have life. We refer them therefore to the genus called animal; and this word belongs to every species of animals, and to each individual animal. The same classification is made both of artificial and abstract substances; of each of which there are genera, species, and individuals. Thus in natural substances, animal, vegetable, and mineral, denote genera; man, horse, tree, metal, are species; and Alexander, Bucephalus, oak, gold, are individuals. In artificial substances, edifice is genus; house, church, tower, are species; and the Vatican, St Paul's, and the Tower of London, are individuals. In abstract substances, motion and virtue are genera; flight and temperature are species; the flight of Madamet and temperance in wine are individuals. By arranging substances in this manner, and giving a name to each genus and species, the names necessary to any language are comparatively few and easily acquired; and when we meet with an object unknown to us, we have only to examine it with attention; and comparing it with other individuals, to refer it to the genus or species to which it most nearly resembles. By this contrivance we supply the want of a proper name for the individual, and so far as the resemblance is complete between it and the species to which it is referred, and of which we have given it the name, we may conversely and reason about it without danger of error: whereas had each individual in nature a distinct and proper name, words would be innumerable and incomprehensible; and to employ our labours in language, would be as idle as though of numberless written symbols which have been attributed to the Chinese.

Besides number, another characteristic, visible in substances, is that of sex. Every substance is either male or female; or both male and female; or neither one nor the other. So that with respect to sexes and their negation, all substances conceivable are comprehended under this fourfold consideration, which language would be very imperfect if it could not express. Now the existence of hermaphrodites being rare, if not doubtful, and language being framed to answer the ordinary occasions of life, no provision is made, in any of the tongues with which we are acquainted, for expressing, other than by the names made on purpose, or by a plurality, duplicity of sex. With regard to this great natural characteristic, grammarians have made only a threefold division of nouns: those which denote males are said to be of the masculine gender; those which denote females, of the feminine; and those which denote substances that admit not of sex, are said to be neuter or of neither gender. All animals have sex; and therefore the names of all animals should have gender. But the sex of all is not equally obvious, nor equally worthy of attention. In those species that are most common, or

unity and plurality; and this variation is called number. Thus in the English language, when we speak of a single place of habitation, we call it a house; but if of more, we call them houses. In the first of these cases the noun is said to be in the singular, in the last case it is in the plural, number. Greek nouns have also a dual number to express two individuals, as have likewise some Hebrew nouns; but this variation is evidently not essential to language; and it is perhaps doubtful whether it ought to be considered as an elegance or a deformity.

But although number be a natural accident of nouns, it can only be considered as essential to those which denote genera or species. Thus we may have occasion to speak of one animal or of many animals, of one man or of many men; and therefore the nouns animal and man must be capable of expressing plurality as well as unity. But this is not the case with respect to the proper names of individuals: for we can only say Xenophon, Aristotle, Plato, &c. in the singular; as, were any one of these names to assume a plural form, it would cease to be the proper name of an individual, and become the common name of a species. Of this, indeed, we have some examples in every language. When a proper name is considered as a general appellative under which many others are arranged, it is then no longer the name of an individual but of a species; and such admits of a plural; as, the Curtys, the Humours, the Pelhams, the Mantegues, &c. but Socrates can never become plural, so long as we know of no more than one man of that name. The reason of all this will be obvious, if we consider, that every genus may be found whole and entire in each of its species; for man, horse, and dog, are each of them an entire and complete animal; and every species may be found whole and entire in each of its individuals: for Socrates, Plato, and Xenophon, are each of them completely and entirely a man. Hence it is, that every genus, though one, is multiplied into many; and every species, though one, is also multiplied into many, by reference to those beings which are their subordinates: But as no individual has any such subordinates, it can never in strictness be considered as many; and so, as well in nature as in name, is truly an individual which cannot admit of number.

The origin of the singular and plural numbers.

Nouns general terms.

of which the male and the female are, by their size, form, colour, or other outward circumstances, eminently different. Hence, the male is sometimes called by one name, which is masculine; and the female by a different name, which is feminine. Thus in English we say, husband, wife; king, queen; father, mother, son, daughter, &c. In others of similar distinction, the name of the male is applied to the female only by prefixing a syllable or by altering the termination; as man, woman; lion, tigress; emperor, empress, &c. When the sex of any animal is not obvious, or not material to be known, the same name, in some languages, is applied, without variation, to all the species, and that name is said to be of the common gender. Thus in Latin bovis albus is a white ox, and bovis alba a white cow. Diminutive insects, though they are doublets male and female, seem to be considered in the English language as if they were really creeping things. No man, speaking of a worm, would say he creeps, but it creeps, upon the ground. But although the origin of genders is thus clear and obvious; yet the English is the only language, with which we are acquainted, that deviates not, except in this single instance of insects, from the order of nature. Greek and Latin, and many of the modern tongues, have nouns, some masculine, some feminine, which denote substances where sex never had existence. Nay, some languages are so particularly defective in this respect, as to call every object, inanimate as well as animate, under either the masculine or the feminine gender, as they have no neuter gender for those which are of neither sex. This is the case with Hebrew, French, Italian, and Spanish. But the English, strictly following the order of nature, puts every noun which denotes a male animal, and no other, in the masculine gender; every name of a female animal, in the feminine; and every animal whose sex is not obvious or known, as well as every inanimate object whatever, in the neuter gender. And this gives our language an advantage above many others in the poetical and rhetorical style: for when nouns naturally neuter are conveyed into masculine and feminine, the personification is more distinctly and more forcibly marked. (See Personification.) Some very learned and ingenious men have endeavoured, by what they call a more subtle kind of reasoning, to discern in things without sex a distant analogy to that natural distinction, and to account for the names of inanimate substances being, in Greek and Latin, masculine and feminine. But such speculations are wholly fanciful; and the principles upon which they proceed are overthrown by an appeal to facts. Many of the substances, that, in one language, have masculine names, have in other names that are feminine; which could not be the case were this matter regulated by reason or nature. Indeed for this, as well as many other anomalies in language, no other reason can be assigned than that of custom.

Quem penes arbitrium est, et jus, et norma, loquendi.

16. Origin of
catch.

18. It has been already observed that most nouns are the names of individuals, but of whole classes of objects termed genera and species. In clasifying a num-

ber of individuals under one species, we contemplate only those qualities which appear to be important, and in which the several individuals are found to agree about the mind from the consideration of all those which appear to be least essential, and which in one individual may be such as have nothing exactly similar in any other individual upon earth. Thus, in clasifying the individuals which are comprehended under the species denominated horse, we pay no regard to their colour or their size; because experience teaches us, that no particular colour or size is essential to that individual living creature, and that there are not perhaps upon earth two horses whose colour and size are exactly alike. But the qualities which in this process we take into view, are the general shape, the symmetry, and proportion of the parts; and in short every thing which appears evidently essential to the life of the individual and the propagation of the race. All these qualities are strikingly similar in all the individuals which we call horses, and as strikingly dissimilar from the corresponding qualities of every other individual animal. The colour of a horse is often the same with that of an ox; but the shape of the one animal, the symmetry and proportion of his parts, are totally different from those of the other; nor could any man be led to class the two individuals under the same species. It is by a similar process that we ascend from one species to another, and through all the species to the highest genus. In each species or genus in the ascending series fewer particular qualities are attended to than were considered as essential to the genus or species immediately below it; and our conceptions become more and more general as the particular qualities, which are the objects of them, become fewer in number. The use of a general term, therefore, can recall to the mind only the common qualities of the class, the genus or species which it represents. But we have frequent occasion to speak of individual objects. In doing this, we annex to the general term certain words significant of particular qualities, which discriminate the object of which we speak, from every other individual of the class to which it belongs, and of which the general term is the common name. For instance, in advertising a thief, we are obliged to mention his height, complexion, gait, and whatever may serve to distinguish him from all other men.

The process of the mind in rendering her conceptions particular, is indeed exactly the reverse of that by which the generalizes them. For as in the process of generalization, the abstraction from her ideas of any number of species certain qualities in which they differ from each other, and of the remaining qualities in which they agree, constitutes the first genus in the ascending series; so when she wishes to make her conceptions more particular, the annexes to her idea of any genus those qualities or circumstances which were before abstracted from it; and the genus, with this annexation, constitutes the first species in the descending series. In like manner, when she wishes to descend from any species to an individual, she has only to annex to the idea of the species those particular qualities which discriminate the individual intended from the other individuals of the same kind.
This particularizing operation of the mind points out the manner of applying the general terms of language for the purpose of expressing particular ideas. For as the mind, to limit a general idea, connects that idea with the idea of some particular instance, so in language, as we have already observed, in order to limit a general term, connects that term with the word denoting the particular circumstance. Thus, in order to particularize the idea of horse, the mind connects that general idea with the idea of some particular instance, so in language, as we have already observed, in order to limit a general term, connects that term with the word denoting the particular circumstance. Thus, in order to particularize the idea of horse, the mind connects that general idea with the idea of some particular instance, so in language, as we have already observed, in order to limit a general term, connects that term with the word denoting the particular circumstance. Thus, in order to particularize the idea of horse, the mind connects that general idea with the idea of some particular instance, so in language, as we have already observed, in order to limit a general term, connects that term with the word denoting the particular circumstance.

17. *Cafus*, therefore, though they are accidents of nouns not absolutely necessary, have been often considered as such; and they are certainly worthy of our examination, since there is perhaps no language in which some cases are not to be found, as indeed without them or their various powers no language could readily answer the purpose of life.

All the oblique cases of nouns (if we accept the vocative) are merely marks of annexation; but as the connections or relations subsisting among objects are very various, some cases denote one kind of relation, and some another. We shall endeavour to investigate the connection which each case denotes, beginning with the genitives. This is the most general of all the cases, and gives notice that some connection indeed subsists between two objects, but does not point out the particular kind of connection. That we must infer, not from the nature or termination of the genitive itself, but from our previous knowledge of the objects connected. That the genitive denotes merely relation in general, might be proved by adducing innumerable examples, in which the relations expressed by this case are different; but we shall content ourselves with one observation, from which the truth of our opinion will appear beyond dispute. If an expression be used in which are, connected by the genitive case, two words significant of objects between which a twofold relation may subsist, it will be found impossible, from the expression, to determine which of these two relations is the true one, which must be gathered wholly from the context. Thus, for example, from the phrase *inuria regis*, no man can know whether the injury mentioned be an injury suffered or an injury inflicted by the king; but if the genitive case notified any particular relation, no such ambiguity could exist. This case therefore gives notice, that two objects are, such or other, connected, but it marks not the particular sort of connection. Hence it may be translated by our particle of, which will be seen afterwards to be of a signification equally general.

The dative an accusative cases appear to have nearly the same meaning; each of them denoting apposition, or of the double relation of one object with another. Thus when any one says, *Parmenium Homero, Homen vel Virgilius occidit*, are conceived to be placed beside one another, in order to their being compared; and this sort of connection is denoted by the dative case. In like manner, when it is said *latus homero, breadth is conceived as joined to or connected in apposition with shoulders*; and the expression may be translated "broad at the shoulders."

This apposition of two objects may happen either without previous motion, or in consequence of it. In the foregoing instances no motion is presupposed; but if one say, *Hec aliquos subdicto oram*, the apposition is there in consequence of motion. In like manner, when it is said, *Profectus est Romam*, his apposition with home is conceived as the effect of his motion thither.

From this idea of the accusative, the reason is obvious why the object after the active verb is often put in that case; it is because the action is supposed to proceed from the agent to the patient. But the same thing happens with respect to the dative case, and for the same reason. Thus, *Antonius labit Cicero*, and *Antonius vocat Cicereon*, are expressions of the same import, and in each the action of hurting is conceived as proceeding from Antony to Cicero; which is finely illustrated by the passive form of such expressions, where the procedure abovementioned is expressly marked by the preposition ab; *Cicero nocet*, *Cicero labet* an *Antonio*. It is therefore not true, that "the accusative is that case, at least the only case, which to an efficient nominative and a verb of action subjoins either the effect or the passive subject; nor is the dative the only case which is formed to express relations tending to itself." The only thing essential to these two cases is to denote the apposition or conjunction of one object with another; and this they do nearly, if not altogether, in the same manner, although from the current of language they may not be indiscriminately subjoined to the same verb.

The Greek language has no ablative case; but in the Latin, where it is used, it denotes concomitancy, or that one thing accompanies another. From this concomitancy we sometimes draw an inference, and sometimes not. For example, when it is said, *Templum clamor petebat*, clamor is represented as concomitant with their going to the temple; and here no inference is drawn; but from the phrase *pales metus*, although nothing more is expressed than that palæns is a concomitant of the fear, yet we instantly infer that it is also the effect of it. In most instances where the ablative is used, an inference is drawn, of which the foundation is some natural connection observed to subsist between the object thus connected in language. When this inference is not meant to be drawn, the preposition is commonly added: as, *interfectus est cum gladiis*; "he was slain with a sword about him," *interfectus est gladio*; "he was slain with a sword as the instrument of his death."

The remaining cases, which have not been noticed, are the nominative and the vocative. These are in most minimative instances alike in termination, which makes it probable that they are of the general case.
that they were originally one and the same cafe. The foundation of this conjecture will appear from con-
 pondering the use to which each of these cafes is applied.
The nominative is employed to call up the idea of any
 object in the mind of the hearer. But when a man
 hears his own name mentioned, his attention is infant-
lily roused, and he is naturally led to listen to what is to
 be said. Hence, when a man meant particularly to
 solicit one's attention, he would naturally pronounce
 the person's name; and thus the nominative cafe would
 pass into a vocative, of which the use is always to solicit
 attention (b).

20. The Greek and Latin among the ancient, and
 the German among the modern languages, express dif-
 ferent connections or relations of one thing with anot-
 her by cafes. In English this is done for the most part
 by prepositions; but the English, being derived from
 the same origin as the German, that is, from the Teu-
tonic, has at least one variation of the substantive to
 answer the same purpose. For instance, the relation of
 possession, or belonging, is often expressed by a differ-
 ent ending of the substantive, which may be well called a
 cafe. This cafe answers nearly to the nominative cafe in
 Latin; but as that is not a denomination significant of
 the name of the cafe in any language, it may perhaps in
 English be more properly called the possessive cafe.
 Thus, God's grace, anciently Godis grace, is the grace
 belonging to or in the possession of God: and may be
 likewise expressed by means of the preposition: thus,
 the grace of God.

Although the word God is as evidently an inflexion
 of the noun God as the word Dei is an inflexion of De-
 not, there are grammarians who have denied that in
 English there is any true inflexion of the original noun,
 and who have said that the noun with the addition of
 that syllable, which we consider as the sign of a cafe,
 cafes to be a noun, and becomes a substantive; a word
 which with them is devoid of inflexion. Thus, in the
 expression Alexander's house, the word Alexander's
 stands not as a noun, but as an article or substantive,
 serving to ascertain and point out the individuality of
 the house. But this is a palpable mistake: the word Alex-
 ander's serves not to point out the individuality of the
 house, but to shew to whom the house belongs; and is
 therefore, beyond dispute, not an article but a noun in
 the possessive cafe. Again, when we say St Peter's at
 Rome and St Paul's at London, the words St Peter's
 and St Paul's are neither articles, nor, as has been ab-
 surdly imagined, the proper names of edifices, like the
 Rotundo or the Circum ambus; but they are in the pos-
 sessive cafe, the names of the two apostles to whom the
 churches were dedicated, and to whom they are suppos-
 ed to belong.

But that this, which we have called the possessive cafe,
is really not so, must be evident, it is said, because there
 are certain circumstances in which it cannot be sub-
 stituted for the noun with the preposition prefixed. This,
 though a man may say, I speak or Alexander, or Ca-
 sars, I think or Pompey; he cannot say, I speak
 Alexander's, I write Caesar's, or I think Pompey's. This
 is indeed true, but it is nothing to the purpose; for
 though I may say, Lequrro de Alexander, Scribo de
 Cæsare, Cogito de Pompeio; I cannot say, Lequrro Al-
 lexanderi, Scribo Casari, or Cogito Pompeii: and there-
 fore all that can be inferred from this argument is,
 that as the Latin nominative is not always of the same
 import with the preposition de, so the English possessive
 is not always of the same import with the preposition of.

Upon the whole, then, we may conclude, that English
 nouns admit of one inflexion; and that though cafes
 are not so essential to nouns as gender and number, no
 language can be wholly without them or their various
 powers.

CHAPTER II.

Of Articles or Definitives.

21. The intention of language is to communicate
 thought, or to express those ideas which are suggested
to us by our senses external and internal. The ideas
first suggested to us are those of pain and pleasure,
and of the objects with which we are surrounded; and
therefore the words first learned must be nouns, or the
names of objects natural, artificial, and abstract. Every
object about which the human mind can be convertant
is strictly and properly speaking particular; for all
things in nature differ from one another in numberless
respects, which, not to mention the idea of separate
existence, so circumstance and individuate them, that
no one thing can be said to be another. Now the use
of language being to express our ideas or conceptions
of these objects, it might naturally be expected that
every object should be distinguished by a proper name.

This would indeed be agreeable to the truth of things,
but we have already seen that it is altogether imprac-
ticable. Objects have therefore been classified into
genera and species; and names given, not to each individu-
al, but to each genus and species. By this contrivance of
language we are enabled to ascertain in some measure any
individual that may occur, and of which we know not the
proper name, only by referring it to the genus or species
to which it belongs, and calling it by the general or
specific name; but as there is frequent occasion to dis-
tinguish individuals of the same species from one an-
other, it became necessary to fall upon some expedient
to mark this distinction. In many languages general
and species terms are modified and restricted by three
orders of words; the article, the substantive, and
the oblique cases of nouns. The cafes of nouns we
have already considered: the substantive will employ our
fay and use attention afterwards: at present our observa-
tions are confined to the article; a word to very necessary,
title, that without it or some equivalent invention, men
could not employ nouns to any of the purposes of life, or
indeed communicate their thoughts at all. As the
benefit of articles is to enable us, upon occasion, to
employ general terms to denote particular objects, they
must be considered, in combination with the general terms,
as merely substitutes for proper names. They have, how-
ever, been commonly called definitives; because they
serve

(b) The chief objection to this conjecture, that the nominative and vocative were originally the same cafe, is
taken from the Latin tongue, in which the names of the second declension ending in us terminate their voca-
tive in e. But this is easily accounted for. The e in such words was often dropped, as appears from the scanning
of old Latin poetry; and when this was done, the u being short, would naturally in pronunciation pass into
e, like short vowel; and thus, in the vocative cafe, e would in time be written instead of u.
The nature of them may be explained as follows.

22. An object occurs with which, as an individual, we are totally unacquainted; it has a head and limbs, and appears to possess the power of self-motion and senation: we therefore refer it to the genus, and call it an animal.

But this is not enough. The object at which we are looking, and which we want to distinguish, is not a species or a genus, but an individual. Of what kind? known or unknown? Seen now for the first time, or seen before and now remembered? This is one of the instances in which we shall discover the use of the two articles a and the: for, in the case supposed, the article a respects our primary perception, and denotes an individual as unknown; whereas the respects our secondary perception, and denotes individuals as known. To explain this by an example: I see an object pass by which I never saw till now. What do I say? There goes a beggar with a long beard. The man departs, and returns a week after: What do I then say? There goes the beggar with the long beard. Here the article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual once vague is now recognized as something known; and that merely by the efficacy of this latter article, which tacitly intimates a kind of previous acquaintance, by referring a present perception to a like perception already past.

This is the explanation of the articles a and the as given by the learned Mr Harris, and thus far what he says on the subject is certainly just; but it is not true that the article the always intimates a previous acquaintance, or refers a present perception to a like perception already past. I am in a room crowded with company, of which the greater part is to me totally unknown. I feel it difficult to breathe from the grossness of the inclosed atmosphere; and looking towards the window, I see in it a person whom I never saw before. I gladly lend my compliments to the gentleman in the window, and request, that if it be not inconvenient, he will have the goodness to let into the room a little fresh air. Of this gentleman I have no previous acquaintance; my present perception of him is my primary perception, and yet it would have been extremely improper to lend my compliments, &c., to a gentleman in the window. Again, there would be no impropriety in saying—A man whom I saw yesterday exhibiting a show to the rabble, was this morning committed to jail with the crime of housebreaking. Notwithstanding the authority, therefore, of Mr Harris and his master Apollonius, we may venture to affirm, that it is not essential to the article a to respect a primary perception, or to the article the to indicate a previous established acquaintance. Such may indeed be the manner in which these words are most frequently used; but we see that there are instances in which they may be used differently. What then, it may be asked, is the import of each article, and in what respects do they differ?

23. We answer, that the articles a and the are both of them definite, and are by being prefixed to the names of genera and species to circumscribe the latitude of those names as to make them for the most part denote individuals. A noun or substantive, without any article to limit it, is, taken in its widest sense, the word man means all mankind:

"The proper study of mankind is man." where mankind and man may change places without making any alteration in the sense. But let either of the articles of which we are treating be prefixed to the word man, and that word is immediately reduced from the name of a whole genus to denote only a single individual; and instead of the noble truth which this line affirms, the poet will be made to say, that the proper study of mankind is not the common nature which is diffused through the whole human race, but the manner and caprice of one individual. Thus far therefore the two articles agree: but they differ in this, that though they both limit the specific name to some individual, the article a leaves the individual itself undefined; whereas the article the affects the individual itself, and can be prefixed to the specific name only when an individual is intended, of which something may be predicated that distinguishes it from the other individuals of the species. Thus, if I say—A man is fit for the definite tresses, my affirmation may appear strange and vague; but the sentence is complete, and wants nothing to make it intelligible; but if I say—the man is fit for tresses, I speak nonsense; for as the article the shows that I mean some particular man, it will be impossible to discover my meaning till I complete the sentence, and predicate something of the individual intended to distinguish him from other individuals.

"This man that both not as lightly, &c.

"Is fit for tresses"—A man, therefore, means some one or other of the human race indefinitely; the man means, definitely, that particular man who is spoken of; the former is called the indefinite, the latter the definite article.

The two articles differ likewise in this respect, that the difference the article a serves only to separate one individual from the general class to which it belongs, it cannot be applied to pluralis. It has indeed the same signification nearly with the numerical word one; and in French and Italian, the same word that denotes unity is also the article of which we now treat. But the difference in the article the being to define objects, by pointing them out as those of which something is affirmed or denied which is not affirmed or denied of the other objects of the same class, it is equally applicable to both numbers; for things may be predicated of one sex of men, as well as of a single man, which cannot be predicated of other men. The use and import of each article will appear from the following example: Man was made for society, and ought to extend his goodwill to all men; but a man will naturally entertain a more particular regard for the man with whom he has the most frequent intercourse, and enter into a still closer union with the man whose temper and disposition suit best with his own.

We have said, that the article a cannot be applied
to plurals, because it denotes unity: but to this rule there is apparently a remarkable exception in the use of the adjectives few and many (see note above). When we join the word great before it), which, though joined with plural substantives, yet admit of the singular article a; as, a few men, a great many men. The reason of this is manifest from the effect which the article has in these phrases: it means a small or a great number collectively, taken, to which it gives the idea of a whole, that is, of unity. Thus, likewise a hundred, a thousand, is one whole number, an aggregate of many collectively taken, and therefore still retains the article a, though joined as an adjective to a plural substantive; as, a hundred years. The exception therefore is only apparent; and we may affirm, that the article a universally denotes unity.

24. The indefinite article is much less useful than the other; and therefore the Greek and Hebrew languages have it not, though they both have a definite article. In languages of which the nom., adjectives, and verbs, have inflexion, no mistake can arise from the want of the indefinite article; because it can always be known by the terminations of the noun and the verb, and by the circumstances predicated of the noun, whether a whole species or one individual be intended. But this is not the case in English. In that language, the adjectives having no variation with respect to gender or number, and the tenses of the verbs being for the most part the same in both numbers, it might be often doubtful, had we not the indefinite article, whether the specific name was intended to express the whole species or only one individual. Thus, if we say in English, "Man was born jest from God," we must be understood to mean that the birth of every man is from God, because the specific term the indefinite article is not prefixed. Yet the words εν υις ἐκ τοῦ Θεοῦ convey no such meaning to any person acquainted with the Greek language; as the word ἄνθρωπος, without any article, is reftricted to an individual by its concord with the verb and the participle; and the sense of the passage is, a man was born (or existed) jest from God.

But though the Greeks have no article correspondent to the article a, yet nothing can be more nearly related to their ο' our the ο' his—THE KING; ΤΟ ΕΥΡΗΚΑ—THE GIFT. In one respect, indeed, the Greek and English articles differ. The former is varied according to the gender and the number of the noun with which it is associated, being—masculine, feminine, neuter, and οί, άι, έν, in the plural number; whereas the English article suffers no change, being invariably the before nouns of every gender and in both numbers. There are, however, some modern languages which, in imitation of the Greek, admit of a variation of their article which relates to gender; but this cannot be considered as essential to this species of words, and it may be questioned whether it be any improvement to the language. In tongues of which the nouns have no inflexion, it can only serve to perplex and confude, as it always presents a particular idea of fix where in many cases it is not necessary.

25. The articles already mentioned are allowed to be firstly and properly such by every grammarian; but there are some words, such as this, that, any, some, all, other, &c. which are generally said to be sometimes articles and sometimes pronouns, according to the different modes of using them. That words should change their nature in this manner, so as to belong to one part of speech, and sometimes to another, must to every unprejudiced person appear very extraordinary; and if it were a fact, language would be a thing so equivocal, that all inquiries into its nature upon principles of science and reason would be vain. But we cannot perceive any such fluctuation in any word whatever; though we know it to be a general charge brought against words of almost every denomination, of which we have already seen one instance in the perversible case of nouns, and shall now see another in those words which are commonly called pronounnal articles.

If it be true, as we acknowledge it to be, that the genuine pronoun always stands by itself, assuming the power of a noun, and supplying its place, then it is certain that the words this, that, any, some, &c. can never be pronouns. We are indeed told, that when we say this is virtue, give me that, the words this and that are pronouns; but that when we say, this habit is virtue, that man defrauded me, then are they articles or definitions. This, however, is evidently a mistake occurred by overlooking those abbreviations in construction which are frequent in every language, and which, on account of that very frequency, have perhaps escaped the attention of grammarians whose faculty has been successfully employed on matters less obvious. When we say this is virtue, it is evident that we communicate no intelligence till we add a substantive to the word this, and declare what is virtue. The word this can therefore in no instance assume the power of a noun, since the noun to which it relates, though for the sake of dispatch it may be omitted in writing or conversation, must always be supplied by the mind of the reader or hearer, to make the sentence intelligible, or this itself of any importance.

When we have viewed speech analyzed, we may then consider it as compounded. And here, in the first place, we may contemplate that synthesis, which by combining simple terms produces a truth; then by combining two truths produces a third; and thus others and others in continued demonstration, till we are led, as by a road, into the regions of science. Now this is that superior and most excellent synthesis which alone applies itself to our intellect or reason, and which to conduct according to rule constitutes the art of logic. After this we may turn to those inferior compositions which are productive of the pathetic, &c. Here, if any where, the word this may be thought to stand by itself, and to assume the power of a noun; but let any man complete the construction of each sentence, and he will perceive that this is no more than a definite article. Thus,—"we may contemplate that synthesis which by combining simple terms produces a truth; then by combining two truths produces a third truth; and thus other truths and other truths in continued demonstration, till we are lead, as by a road, into the regions of science. Now this combination of truths is that superior and most excellent synthesis which alone applies itself to our intellect or reason, and which to conduct according to rule constitutes the art of logic. After we have contemplated this art, we may turn," &c.
Articles in the Latin language.

28 Articles in the Latin language.

article, sometimes a pronoun, and sometimes a conjunction. In the following extract it appears in all these capacities: and yet, upon resolving the passage into parts and completing the construction, it will be found to be invariably a definite article.—"It is necessary to that perfection, of which our present state is capable, that the mind and body should both be kept in action; that neither the faculties of the one nor of the other be suffered to grow lax or torpid for want of use: but neither should health be purchased by voluntary submilion to ignorance, nor should knowledge be cultivated at the expense of health; for that must enable it either to give pleasure to its possessor, or assistance to others." If this long sentence be resolved into its constituent parts, and the words be supplied which complete the construction, we shall see the import of the word that to be precisely the same in each clause. "The mind and body should both be kept in action; that action is necessary to that perfection of which our present state is capable: neither the faculties of the one nor of the other should be suffered to grow lax or torpid for want of use; the degree of action proper to present that state; is necessary: but neither should health be purchased by voluntary submission to ignorance, nor should knowledge be cultivated at the expense of health; for that must enable it either to give pleasure to its possessor, or assistance to others." Again,

"He that's unskillful will not toss a ball!"

"A man unskillful (he is that) will not toss a ball." Here the word that, though substituted for what is called the relative pronoun (a), still prefers unchanging its definite import; and in every instance except where it may be used very improperly, it will be found to be neither more nor less than a definite article.

26. It appears then, that if the essence of an article be to define and ascertain, the words this and that, as well as any, some, all, &c. which are commonly called pronounal articles, are much more properly articles than any thing else, and as such should be considered in universal grammar. Thus when we say, this picture I approve, but that I dislike; what do we perform by the help of the words this and that, but bring down the common apppellative to denote two individuals; the one as the more near, the other as the more distant? So when we say, some men are virtuous, but all men are mortal; what is the natural effect of this all and some, but to define that universality and particularity which would remain indefinite were we to take them away? The fame is evident in such sentences as, some substances have sensation, others want it; choose any way of acting, and some men will find fault, &c.: for here some, other, and any, serve all of them to define different parts of a given whole; some, to denote any indeterminate part; any, to denote an indefinite mode of acting, no matter what; and other, to denote remaining part, when a part has been affirmed already.

27. We have said that the article is a part of speech so very necessary, that without it, or some equivalent invention (v), mankind could not communicate their thoughts; and that of words falling under this description, we knew no language which is wholly defective. We are aware that these positions may be controverted; and that the Latin may be inflected as a language which, without articles, is not only capable of communicating the ordinary thoughts of the speaker to the mind of the hearer; but which, in the hands of Cicero, Virgil and Lucretius, was made to serve all the purposes of the most profound philosopher, the most impassioned orator, and the sublimest poet. That the Latin has been made to serve all these purposes cannot be denied, although Lucretius and Cicero both complain, that on the subject of philosophy, where the use of articles is most conspicuous, it is a deficient language. But should we grant what cannot be demanded, that those two great men were acquainted with the powers of their native tongue, our positions would still remain unshaken; for we deny that the Latin is wholly without articles. It has indeed no word of precisely the same import with our the or the Greek k; but the place of the indefinite article A might be always supplied, if necessary, with the numerical word one. It may be so even in English; for we believe there is not a single instance where the words one man, one horse, one virtue, might not be substituted for the words a man, a horse, a virtue, &c. without the slightest degree altering the sense of the passage where such words occur. This substitution, however, can be but very seldom if ever necessary in the Latin tongue, of which the precision is much greater than that of the English would be without articles; because the oblique cases of the Latin nouns, and the inflexion of its verbs, will almost always enable the reader to determine whether an apppellative represents a whole species or a single individual. The want of the definite article the seems to be a greater defect; yet there are few instances in which its place might not be supplied by this or by that without obscuring the sense; and the Latin tongue is by no means deficient of articles corresponding to these two. Let us substitute the words one and that for a and the in some of the foregoing examples, and we shall find, though the sound may be unctuous, the sense will remain. Thus,

"That man who hath not music in himself, &c.

"Is fit for treasons,"—

conveys to the mind of the reader the very same sentiment which the poet expresses by the words "The man that hath not music," &c. Again, "Man was made for society, and ought to extend his good-will to all men; but one man will naturally entertain a more particular regard for those men with whom he has the most frequent intercourse, and enter into a still closer union with that man whole temper and disposition fair best with his own." Now the words his and ille being exactly the same import with the words this and that; it follows, that wherever the place of the article the may in English be supplied by this or by that, it may in Latin be supplied by hic or by ille. This is
is the case with respect to NATHAN'S reproof of DAVID, where the definite article is indeed most emphatical. The original words might have been translated into English, "THOU ART THAT MAN," as well as "THOU ART THE MAN!" and in Latin they may with the utmost propriety be rendered, "Tu es ille homo." Indeed the words HIC and ILLE, and we might instance many more, though they are commonly called pronouns, are in truth nothing but definite articles: HIC is evidently so; and ILLE is most probably derived from the Hebrew word aleph, in the plural aleph, which may be translated indifferently, either THE or THAT. But what proves beyond dispute that these two words are not pronouns but articles, is, that in no single instance will they be found to stand by themselves and assume the power of nouns. For the sake of dispatch, or to avoid disfigurable repetitions, the noun may indeed be often omitted; but it is always supplied by the reader or hearer, when HIC and ILLE appear in their proper place, and are seen to be invariably definite articles. We shall give an example of the use of each word, and diflince the subject.

In the first oration against Catiline, Cicero begins with addressing himself in a very impassioned style to the traitor, who was present in the senate-houfe. He then exclaims pathetically against the manners of the age, and proceeds in these words: Senatus haec intelligat, consul videt; hic tamen visit. Vivi fum non eftiani in fenatum venit; fit publici confiliarii particeps. In this passage HIC cannot be a pronoun; for from the beginning of the oration there occurs not a single noun of which it can possibly supply the place. When the orator uttered it, he was probably pointing with his finger at Catiline, and every one of his audience would supply the noun in his own mind, as we do when we translate it, "Yet this traitor lives!" When Virgil says,

\[
\text{ille ego, qui quondam iretral modi/latus avella} \\
\text{Carman,}
\]

it is obvious that he means, I AM THAT MAN OF THAT POET, who sung, &c.; and though we may translate the words "I AM WHO HEUSTED HIS SONG," &c. yet when we converse the passage, we are under the necessity of supplying either WHATSOEVER, which shows that HIC is nothing more than a definite article signifying THAT or THE. It appears then, that the Latin tongue is not wholly destitute of articles, as few cases can occur where the Greek i and our THE may not be supplied by the words HIC and ILLE; which have in our opinion been very improperly termed pronouns. If there be any such cases, we can only confess that the Latin language is defective; whereas, had it so articles, it is not easy to conceive how it could answer, to a cultivated people, the ordinary purposes of speech.

28. The articles THIS and THAT, unlike A and THE, are varied according as the noun, with which they are associated, is in the singular or in the plural number. Thus we say—this and that man in the singular, and these and those men in the plural. The Latin articles HIS and ILLE, for such we will call them, are varied like the Greek i, not only with the number, but also with the gender of their nouns. In languages, where the structure of a sentence may be so changed from the order of nature, as it commonly is in Greek and Latin, and where the reader is guided, not by the position, but by the termination of the words, to which are in con-
cord and those which are not, these variations of the article have their use; but in English they are of no importance. Were it not that the custom of the language—the form of the language, as Horace calls it—has determined otherwise, there would be no more impro- priety in saying THIS or THAT man, than in saying SOME men or the men.

29. As articles are by their nature definitives, it follows of course, that they cannot be united with such words as are in their own nature as definite as they may become: nor with such words as, being indefinable, cannot properly be made otherwise, but only with those words, which, though indefinable, are yet capable through the article of becoming definite. Hence the reason why it is absurd to say, THE, OR THE THOU; because nothing, as will be seen afterwards, can make these pronouns more definite than they are of themselves; and the same may be said of proper names. Neither can we say, THE BOTH, because the word BOTH is in its own nature perfectly defined. Thus, if it be said—"I have read both poets,"—this plainly indicates a definite pair, of whom some mention has been made already. On the contrary, if it be said, "I have read two poets," this may mean any pair out of all that ever existed. And hence this numeral being in this sense indefinite (as indeed are all others as well as itself), is forced to assume the article whenever it would become definite. Hence also it is, that as two, when taken alone, has reference to some primary and indefinite notion, while the article THE has reference to some definite and indefinite, it is bad language to say, TWO THE MEN, as this would be blending of incompatibles, that is, it would be representing two men as defined and indefinite at the same time. On the contrary, to say BOTH THE MEN is good language; because the substantive cannot possibly be left at by being defined, to coalesce with a numeral adjective which is defined as well as itself. So likewise it is correct to say, THE TWO MEN, THESE TWO MEN, OF THOSE TWO MEN; because here the article being placed at the beginning, extends its power, as well through the numeral adjective as the substantive, and tends equally to define them both.

30. As some of the above words admit of no article, because they are by nature as definite as may be; so there are others which admit it not, because they are not to be defined at all. Of this sort are all INTERROGATIVES. If we question about substances, we cannot say, THE WHO IS THIS, but WHO IS THIS! And the same in other qualities and such qualities: for we say, without an article WHAT SORT OF, HOW MANY, HOW GREAT? Therefrom is, the article THE respects beings of which we can predicate something; but interrogatives respect beings about which we are ignorant, and of which we can therefore predicate nothing; for as to what we know, interrogation is superfluous. In a word, the natural articles of the words they

31. We have said that proper names admit not of the article, being, in their own nature, definite. This is true, whilst each name is confined to one individual; but as different persons often go by the same name, it is necessary to distinguish them from one another, to prevent...
Chap. II.

preventing the ambiguity which this identity of name would otherwise occasion. For this purpose we are obliged to recur to 

adjuncts or epithets. For example, there were two Grecian chiefs who bore the name of Ajax; and it was not without reason that Aristophanes used epithets when his intention was to dis-

tinguish the one from the other: "If both Ajaxes cannot be spared (said he), at least let mighty Telamoni-

an Ajax come." But as epithets are diffused through various subjects, in as much as the same adjective may be referred to many substantives, it has been said to be necessary, in order to render both parts of speech equally definite, that the adjective itself assume an article before it, which may indicate a reference to some single person only. It is thus we say—Trypho the Grammarian; Apollodorus the Cyrenian, &c. This is the doctrine of Mr Harris; from which, though we have the highest respect for the learning of the author, we feel ourselves obliged to differ. In the example given, the article THE is certainly not associated with the words Grammarian and Cyrenian, in the same manner in which it is associated with the word man in the sentence—"The man that hath not music in himself," &c. When we say Apollodorus the Cyrenian, may we, without folly or impertinence, be asked—the Cyrenian, what (e) ? And the moment this question is answer-
ed, it will be seen that the article does not an adjective but a substantive. If the answer be the Cyrenian philosopher, the article THE is associated with the word philosopher, and the phrase Apollodorus the Cyrenian, is an abbreviation of Apollodorus the philosopher of Cyrene. In like manner, Trypho the gram- 

marian, is Trypho the grammarian writer, or Trypho the writer of grammar. Such abbreviations are very common. We familiarly say THE SPEAKER, and are understood to mean a high officier in the congress of parliament; yet as a speaker is a name common to many men, we may, without impropriety, be asked, what speaker we mean? and if so, we must reply, the speaker of the house of representatives. But that which is eminent is supposed to be generally known; and therefore, in common language, the speaker is deemed a sufficient designation of him who presides over the house of representatives. Hence, by an easy transition, the definite article, from denoting reference, comes to denote eminence also; that is to say, from implying an ordinary pre-acquaintance, to presume a kind of gen-

eral and universal notoriety. Thus the king is any king; but the king is that person who is acknowledged for a sovereign by any nation, as, the king of Great Britain. In Greek too, as in English, the article is often a mark of eminence; for the poet meant Homer, and the stagirite meant Aristotele; but not that there were many poets besides Homer, and many stagirites besides Aristotele, but none equally illustrious.

31. The great utility of this species of words.

32. Before we dismiss the article, we shall pro-
duce one example to shew the utility of this species of words; which, although they may seem to be of small importance, yet, when properly applied, serve to make a few general terms sufficient for expressing, with accuracy, all the various subjects about which mankind can have occasion to converse. Let man be the general term, which I have occasion to employ for the purpose of denoting some particular. Let it be required to express this particular as unknown; I say a man—known, I say the man—definite; a certain man—an indefinite; all men—animals; present, and near; this man—present, and at some distance; that man—like to some other; such a man—different from some other; another man—An indefinite multitude; many men—A definite multitude; a thousand men—The ones of a multitude, taken throughout; every man—The same ones taken with distinction; each man—taken in order; first man, second man, &c.—The whole multitude of particulars taken collectively; all men—The negation of that multitude; no man—A number of particulars present and near; these men—At some distance, or opposed to others; those men—A number of individuals separated from another number; other men—A small indefinite number; few men—A proportionally greater number; more men—A smaller number; fewer men—And so on we might go almost to infinitude. But not to dwell longer upon this subject, we shall only remark, "that minute changes in principles lead to mighty changes in effects; so that principles are well intimated to regard, however trivial they may appear."

CHAPTER III.

Of Pronouns, or Substantives of the second order.

33. To men who are neither intoxicated with their own abilities, nor ambitious of the honour of building new systems, little pleasure can accrue from differing upon points of science from writers of great and deferred reputation. In such circumstances a man of modesty, although he will not upon the authority of a celebrated name adopt an opinion of which he perceives not the truth, must always advance his own notions with some degree of diffidence, as being conscious that the truth which he cannot perceive, may be visible to a keener and more perspicacious eye. In these circumstances we feel ourselves with regard to some of the most celebrated writers on grammar, from whom, concerning one or two points, comparatively indeed of but little importance, we have already been compelled reluctantly to differ. In treating of pronouns we are likely to deviate full farther from the beaten track; but that we may not be accused of acting the part of dogmatists in literature, and of claiming from others that implicit confidence which we refuse to give, we shall state with fairness the commonly received opinions, point out in what respects we think them erroneous, affirm our reasons for calling them in question, and leave our readers to judge for themselves. The most celebrated writer in English who has treated of pronouns, and whom, since the publication of his Hermes, most other writers have implicitly followed, is Mr Harris, who, after a short introduction proceeds thus: "All conversation passes between individuals who will often happen to be that infant unacquainted with each other. What then is to be done? How shall the speaker address the other, when he knows not his name? or how explain himself by his own name, or which the other is wholly ignorant? Nouns, as they have
have been described, cannot answer this purpose. The
first expedient upon this occasion seems to have been
pointing, or indication by the finger or hand; some
traces of which are still to be observed, as a part of that action
which naturally attends our speaking. But the au-
torities of language were not content with this; they
invented a race of words to supply this pointing; which
words, as they always stood for substantives or names
were characterized by the name of pronouns. These
also they distinguished into three several forts, calling
them pronouns of the first, the second, and the third
person, with a view to certain distinctions, which may
be explained as follows.

"Suppose the parties conversing to be wholly unac-
quainted, neither name nor countenance on either side
known, and the subject of the conversation to be the
speaker himself. Here to supply the place of pointing,
by a word of equal power, the inventors of language
furnished the speaker with the pronoun I; I write, I
say,” &c.: and as the speaker is always principal
with respect to his own discourse, this they called,
for that reason, the pronoun of the first per-
son.

"Again, suppose the subject of the conversation to
be the party addressed. Here, for similar reasons, they
invented the pronoun thou; thou writest, thou
talkest, &c.: and as the party addressed is next in dig-
nity to the speaker, or at least comes next with refer-
tence to the discourse, this pronoun they therefore called
the pronoun of the second person.

"Lastly, suppose the subject of conversation neither
the speaker nor the party addressed, but some third ob-
ject different from both. Here they provided another
pronoun, he, she, or it; which, in distinction to the
two former, was called the pronoun of the third person:
And thus it was that pronouns came to be distinguished
by their respective persons.

36. The description of the different persons here
given is taken, we are told, from Priscian, who took it
from Apollonius. But whatever be the deference
due to these ancient masters, their learned pupil, though
guided by them, seems not to have hit upon the true
and distinguishing characteristic of the personal pronouns.
He supposes, that when the names of two persons
conversing together are known to each other, they
may, by the use of these names, express all that the
personal pronouns express: but this is certainly not true.
To us, at least, there appears to be a very ma-
terial difference between saying, “George did this,”
and “I did this,” nor do we think that the power of
the pronoun would be completely supplied by the name,
even with the additional aid of indication by the hand.
So when one man says to another, with whom he is
conversing, “James did so and so,” it is surely not
equivalent to his saying, “you did so and so.” If
such were the case, one might peremptorily ask, when
both persons are known to each other, Why do they use
the personal pronouns? Mr Harris tells us, that
“when the subject of conversation is the speaker him-
self, he uses I; and when it is the party addressed, he
uses thou.” But in fact the nature of the personal pro-
nouns has no fort of connection with the subject of con-
versation, whether that conversation relate to the speaker,
the party addressed, or a Greek book. In this instance,
“I say that the three angles of every triangle are equal
to two right angles,” the speaker is surely not the sub-
ject of the discourse: nor is the party addressed, but the
truth of his assertion, the subject of discourse in the follow-
ing sentence—“If you say that Homer took’s: Diversions
of Ixly is the most matterly treatise on grammar, so
far as it goes, that you have ever seen.” Mr Harris
uses the phrase becoming the subject of conversation,
in no other sense than that when the speaker has occasion to
mention himself, he uses I; when the party addressed,
thou; and when some other person or thing, he, she, or
it: but we know that he may use other words, by no
means equivalent to the true first of these pronouns, which
will sufficiently mark himself, and the party addressed;
and that he may use indifferently, and without the
smallest injury to the senfe, either the third pronoun,
or the word for which it is merely a substitute.
A man who bears various characters, may design himself
by any one of them. Thus Mr Pitt may speak of himself
as first lord of the treasury, chancellor of the exche-
quer, or member for the university of Cambridge; and in
each case he would be what Mr Harris calls the subject of
conversation: yet every one feels that none of these de-
signations is equivalent to I. What then is the force
of the personal pronouns?

37. It appears to be simply this: The first denotes
the real
speaker, as characterized by the present circum-
cstance of being addressed, in contradistinction to every other character.

In this account of the personal pronouns be true, and we flatten ourselves
that its truth will be obvious to everybody, there is but one
way of expressing by other words the force of the pro-
nouns of the first and second person. Thus,” The
person who now speaks to you did so and so,” is equiva-
lent to “I did so and so;” and “The person to whom I
now address myself did so and so,” is equivalent to
“you did so and so.”

Hence we see why it is improper to say the one or the
other; for each of these pronouns has of itself the force
of a noun with the definite article prefixed, and denotes
a person of whom something is predicated, which distinguis-
hes him from all other persons. I is the person who now
speaks, thou is the person who is now addressed by the
speaker. Hence too we see the reason why the pronoun
I is said to be of the first, and the pronoun thou of the
second person. These pronouns can have place only
in conversation, or when a man, in the character of a
public speaker, addresses himself to an audience; but it
is obvious that there must be a speaker before there can
be a hearer; and therefore, that the pronouns may fol-
low the order of nature, I, which denotes the person of
the speaker, must take place of thou, which denotes
the person of the hearer. Now the speaker and the
hearer being the only persons engaged in conversation or declamation, I is
with great propriety called the pronoun of the first, and thou the pronoun of the
second person. We have said, that, with respect to pro-
nouns, the third person, as it is called, is merely a nega-
tion of the other two. This is evident from the slightest
attention; that is, that there is no distinction of the first,second,
or third
pronouns of the third person. He, she, or it, denotes not
the person either of the speaker or of the hearer; and,
and, as we have just observed, no other person can have a share in conversation or declamation. An absent person or an absent thing may be the subject of conversation, but not of the person addressed; he, she, and it, however, as they stand by themselves, and assume the power of nouns, are very properly denominated pronouns; but they are not personal pronouns in any other sense than as the negation of sex is the neuter gender.

38. We have already seen that nouns admit of number; pronouns, which are their substitutes, likewise admit of number. There may be many speakers at once of the same sentiment, as well as one, who including himself, speaks the sentiment of many: speech may likewise be addressed to many at a time, as well as to one; and the subject of the discourse may likewise be many. The pronoun, therefore, of every one of the persons must admit of number to express the singularity or plurality. Hence the pronoun of the first person has the plural we; that of the second person thou has the plural ye or you; and that of the third person he, she, or it, has the plural they, which is equally applied to all the three genders.

The Greeks and Romans, when addressing one person, used the pronoun in the singular number thou; whereas, in the polite and even in the familiar style, we, and many other modern nations, use the plural you. Although in this case we apply you to a single person, yet the verb must agree with it in the plural number; it must necessarily be, you have, you hast. You was—the second person plural of the pronoun placed in agreement with the first or third person singular of the verb, an error, though common, fecile, which ought to be carefully avoided. In very solemn style, as when we address the Supreme Being, we use thou—perhaps to indicate that he is God alone, and that there is none like unto him; and we sometimes use the same form of the pronoun in contemptuous or very familiar language, to intimate that the person to whom we speak is the meanest of human beings, or the despised and most familiar of our friends. A king, exercising his authority on a solemn occasion, adjoins theplural of the first person, we strictly command and charge; meaning, that he acts by the advice of counsellors, or rather as the representative of a whole people. But in all cases in which the use of the pronoun deviates from the nature of things, the verb in common deviates with it; for, as will be seen afterwards, these two words universally agree in number and person.

39. But though all these pronouns have number, nearly in Greek, Latin, or any modern language, do those of the first and second persons carry the distinctions of sex. The reason is obvious (n), namely, that sex and Vol. VIII.

(1) The reason assigned by Mr Harris and his followers, is, that the speaker and hearer being generally present to each other, it would have been superfluous to have marked a distinction by art, which from nature and even dress was commonly apparent on both sides. This is perhaps the best reason which their description of the personal pronouns admits, but it is not satisfactory; for the speaker and hearer may meet in the dark, when different dressels cannot be distinguished.

(2) If we mistake not, Dr Johnson has somewhere affected to ridicule Bishop Lowth for considering the word mine as the possessive case of the pronoun of the first person. According to the Doctor, mine is the same word with the pronominal adjective my; and was anciently used before a vowel, as my was before a consonant. This is not said with the great Lexicographer's usual precision. That mine was anciently used before a vowel is certain; but it does not therefore follow, that it is the same word with my. If it were, we might on every occasion

In this respect the pronoun of the third person differs from the first and second.
That the word **me** is the same pronoun in the case which the Latin grammarians call the *acutissimum*, is evident from the import of that word in the sentence **He and me**, where the admiratio is supposed to proceed from (k) the person spoken of to the person who speaks. It appears therefore, that though English nouns have only two cases, the nominative and *possessive*, the pronouns of that language have three, as **I, mine, me**; **Thou, thine, thee**; **He, his, him**, &c.

That these are cases, can be questioned by no man who admits that **mei, mihi, me**, are cases of the Latin pronouns *ego*. Both pronouns, the Latin and the English, are irregularly inflected: and perhaps those words which are called the oblique cases of each may have originally been derived from nominatives different from *ego* and *I*; but these nominatives are now lost, and *mei* and *mihi* have, beyond all dispute, the effect of the genitives of the Latin and English pronouns of the first person. These variations, however, cannot be looked upon as an essential part of language, but only as a particular refinement invented to prevent the disagreeable repetition of the pronoun, which must frequently have happened without such a contrivance. This seems to have been the only reason why pronouns have been endowed with a greater variety of cases than nouns. *Nomi* are in themselves greatly diversified. Every genus and every species of objects has a distinct name, and therefore the sameness of sound does not so often occur among them as it would among the pronouns without cases, where the same, **I, thou he, she, or it**, answers for every object which occurs in nature: but by this diversity in the form of the words, the *onomatopoeia*, which would otherwise disgust, is in a great measure avoided. It is probably, for the same reason, that the plural of each of these pronouns is fo very different from the singular. Thus from **I, mine, me**, in the singular, is formed, in the plural, **we, us, our**; from **thou, thine, and thee, ye, or you, yours, you**; and from **he, she, it, his, hers, its, him, her, it, in the singular, they, their, them, in the plural**. In all of which there is not the least resemblance between the singular and the plural of any one word: and except in **he, his, him; it, its, their, theirs**; **they, their, them; there is not any similarity between the different cases of the same word in the fame number.**

From the account here given of the personal pronouns, it appears that the first or second will, either of them, coalesce with the third, but not with each other. For example, if it is good sense, as well as good grammar, to say in any language, **I am he—thou art he—we were they—you were they; but we cannot say—am I thou—not thou art I—now we are you, &c. The reason is, there is no ambiguity in the speaker to be the subject also of the discourse, as when it is said—**I am he; or for the person addressed, as when we say, thou art he. But for the same person in the same circumstances, to be at once the speaker and party addressed, is impossible; for which reason the coalescence of the pronouns of the first and second persons is likewise impossible.**

*That book is mine,** is good English; but **“that book is my,** would be a grofs solecism: the reason is, that **mine** is a genuine pronoun, and stands by itself with the power of a noun; but my, being an adjective, cannot stand by itself.

(a) See Chap. I. 19. on the Cafes of Nouns.
but there is another pronoun which has a character peculiar to itself; and which, as it is never employed but to connect sentences, and must therefore have always a reference to something preceding, is called the 

substantive or relative pronoun. This pronoun is in

Greek, ὁ, τοις, τί; in Latin, QUIS, QUOD; and in Eng-

lish, who, which, that.

44. In order to determine with precision the nature and import of the relative pronoun, it will be necessary to ascertain the powers which it contains, or the parts of speech into which it is capable of being resolved.

Now, it is obvious, that there is not a single noun, or prepositional pronoun, which the relative is not capable of representing: for we say, 1, who saw him yesterday, cannot be mistaken; you, who did not see him, may have been misinformed; they, who neither saw nor heard, can know nothing of the matter; the things, which he exhibited, were wonderful. From these examples it is apparent, in the first place, that the relative contains in itself the force of any other pronoun; but it contains something more.

45. If from any sentence in which there is a relat-

ive, that relative be taken away, and the prepositional pronoun, which it represents, be substituted in its stead, the sentence will lose its bond of union, and stand quite loose and unconnected. Thus, if instead of saying the man is wise who speaks little, we should say the man is wise he speaks little, the sentence would be resolved into two; and what is affirmed of the man's wisdom, would have no connection with the circumstance of his speaking little. Hence it is evident, in the second place, that the relative contains the force of a connective as well as of the prepositional pronoun. What kind of connection it denotes, is next to be ascer-

tained.

46. It may be laid down as a general principle, that, by means of the relative pronoun, a clause of a sentence, in which there is a verb, is converted into the nature of an adjective, and made to denote some attribute of a subject, or some property or circumstance belonging to the antecedent noun. Thus, when it is said, homo qui prudentia predicit efi, the relative clause— 

qui prudentia prædicit efi, expresses nothing more than the quality of prudence in concrete with the sub-

ject homo, which might have been equally well ex-

pressed by the adjective prædicas. In like manner, when we say, vir qui pauca loquitur, the relative clause 

expresses the property of speaking little as belonging to the man, and as being that quality which consti-

tutes, or from which we infer, his wisdom; but if there were such a word as paucolloquent, that quality might very properly be expressed by it, and the phrase vir 

qui pauca loquitur would express the same affection with vir qui pauca loquitur.

Now if a relative clause expresses that which might be expressed by an adjective, the presumption is, that it may be resolved into the same constituent parts. But every adjective contains the powers of an abstract substantive, together with an expression of connection; and may be resolved into the substantive of that substantive, or into the nominative with the particle of pre-

fixed, which, in English, corresponds to the termina-

tion of the substantive in the ancient languages. That 

the member of a sentence, in which there is a relative, may, in every instance, be analyzed in the same manner, will be apparent from the following examples. 

Vir qui sapiens, qui sapiens, and qui sapientissimum; "a man who is wise, a wife man, and a man of wisdom" are certainly phrases of the same import. Again, homo, qui ingratatus est animus, malus est amicus, may be translated into Greek, ὁμοί ὁ δεσπότης ὁ δέσποτης, and into Latin, "the man of ingratitude is a bad friend." 

47. Then it appears, that the relative pronoun contains in itself the force of the prepositional pronoun, together with that connection implied in English by the preposition of, and in the ancient languages by the genitive case. When one says, vir qui pauca loquitor, the relative clause qui pauca loquitor expresses that attribute of the man from which his wisdom is inferred: it is conceived by the mind, as script of its propotional form, and standing in the place of a substantive noun governed in the genitive case by vir. The whole sentence might be thus translated, "the man of little speaking is wise," or did the use of the English language admit of it, "the man of he speaks little is wise." In like manner, when it is said, "Man who is born of a woman is of few days and full of trouble," the relative clause is equivalent to an abstract noun in the genitive case, and the whole might be express-

ed in the following manner, "man of he is born of a woman is of few days and full of trouble." 

We are sensible, that these expressions into which, in the instances adduced, we have resolved the relative clauses, will appear extremely uncouth and offensive; but we mean not to recommend them as common modes of phrascology. Against their being employed, as such, present use loudly remonstrates (1). They are intro-

duced only with a view to throw the true import of the 

relative

(1) It is worthy of observation, however, that, repugnant as such expressions are to the present idiom of the English language, there is nothing in the nature of the thing that could render the use of them improper. All prepositions, as will be seen afterwards, are expressive of relations subtilifying between those objects of which they connect the signs in discourse. Those objects may be denoted, either by single words, and then the preposition will govern a noun; or by relations, and then it will govern a nominative and a verb. Thus, when it is said, "I came after his departure," the preposition after expresses the relation between two events—my coming and his departure, and governs a substantive noun: but if it be said, "I came after he departed," the preposition in this case (as shall be shown afterwards, is absurd to call it, in the one instance, a preposition, and in the other a conjunctin) expresses the same relation as before, but governs a nominative and a verb. This last expression is exactly similar to those employed above. When one says, for example, "the man of he speaks little is wise,"—however uncouth the expression may appear from its not being supported by the authority of custom, the preposition of is used precisely in the same manner, and serves the very same purpose, as when it is said, "the man of little speaking is wise." In both cases it denotes the relation between the two objects.
GRAMMAR.

Chap. III.

The learned and ingenious Mr Harris has, in his Treatise on Universal Grammar, given an analysis of the relative pronoun very different from that which has been given us. The result of his inquiry is, that the relative is equivalent to another pronoun, together with an expression of connection of that kind which is denoted by the particle and. This analysis he exemplifies, and endeavours to confirm by the following sentence: "Light is a body which moves with great celerity." Now, says he, instead of which substitute the words and it, and in their united powers you see the force and character of the pronoun here treated. But let any one attentively consider these two expressions, "Light is a body which moves with great celerity," and "Light is a body and it moves with great celerity," and he will find that they are not precisely equivalent. For to speak in the language of logic, there is in the first but one proposition, of which the subject is light, and the predicate a complex term expressed by the words—body which moves with great celerity. In the second there are two propositions, or two predications concerning light:—first, that it is a body; and secondly, that it moves with great celerity. The relative clause, in the first case, expresses a property of the antecedent body, which with that property is predicated of the subject light; in the second case, this property is removed from the predicate of which it was an essential part, and is improperly converted into a new predication of the subject. The sentence may be resolved upon our principles, and its precise import preferred; as—"Light is a body of it moves with great celerity," the clause—"it moves with great celerity," is conceived by the mind as having the force of an abstract substantive; and is connected with the antecedent body by the proposition of answering to the termination of the genitive case. This abstract substantive thus connected expresses a quality of the body light. But by this example Mr Harris's doctrine is not exhibited in all its absurdity: let us try it by another.

Suppose the following assertion to be true: "Charles XII. was the only monarch who conquered kingdoms to bestow them on his friends." Here it is evident there is but one proposition, of which the predicate is expressed by the words—"only monarch who conquered kingdoms to bestow them on his friends," so that the relative clause is a necessary part of the predicate, and has, like an abstract noun in the genitive case, the effect of modifying the general term monarch. Resolve this sentence on Mr Harris's principles, and you have two propositions, of which the first is a notorious falsehood:—"Charles XII. was the only monarch, and he conquered kingdoms to bestow them on his friends." But instead of and substance of—saying, "Charles XII. was the only monarch of he conquered kingdoms to bestow them on his friends," and you preserve the true import of the expression (m).

49. Are there no cases, then, in which the relative may be resolved into the connective and with a prepositive pronoun? Undoubtedly there are, and we shall now endeavour to ascertain them.

Adjectives in language have two different effects. In some cases Mr Harris's analysis of the relative pronoun may be admitted.

In some cases Mr Harris's analysis of the substantive to which they belong, according to the nature of the attribute which they express. If the attribute expressed by the adjective be competent to all the species of which the substantive is the specific name, it is plain that the adjective does not modify or limit the substantive, for this obvious reason, that nothing can modify which is not discriminative. Thus, when objects—man and little speaking; only in the one it is prefixed to a noun, in the other to an adverb. The noun is here represented by he? "The man of his speaking little is wife!" Who is meant by the pronoun he? We answer, the man who is declared to be wife. The objection proceeds from inattention to the radical signification of the word of, which a late ingenious writer has shown to be the fragment of a Gothis or Anglo-Saxon word, signifying confluence or offspring. If this be admitted, and, after the proofs which he has given, we think it cannot be denied, the uncouth phrase, "The man of his speaking little is wife," may be thus resolved, "The man, a confluence (of his mind) he speaks little, is wife;" or, in other words, "The man, in confluence of his speaking little, is wife." The same acute writer, Mr Horne Tooke, has shown that of said for, though of different radical meanings, may often be substituted the one for the other without injury to the sense. Let this substitution be made in the present instance, and the propriety of the phrase will be apparent: "The man is wife, for he speaks little." It must be remembered, however, that such a substitution cannot be made in every instance, because for signifies cause, and of signifies confluence.

(m) Mr Harris was probably led into his opinion, from considering the Latin qui or quis as compounded of que and it (see Horne Tooke, p. 81, 82, edit. 3d.) But the notion of Perizonius is perhaps better founded, who in his notes ad Suë. Miuev. confiders it as immediately taken from the Greek qui, which in the Doric made s, and in the Latin quis. For it seems highly probable, as some ingenious writers have endeavoured to show, that the Latin is a dialect of the Greek. Of this at least we are certain, that many words in the former are immediately adopted from the latter.
When Horace says, "Prata canis albicant prunus," the adjective canis denotes a quality common to all barking dogs; and therefore cannot modify the substantive, because it adds nothing to the conception of which that substantive is the name. But when the attribute expressed by the adjective is competent to some individuals only of the species of which the substantive is the name, the adjective has then the effect of modifying or limiting the substantive. Thus, when one says vir bonus, he makes use of an adjective which modifies the substantive vir, because it expresses a quality or attribute which does not belong to all men.

The clause of a sentence, in which there is a relative, as it is in every other respect, so is it in this, equivalent to an adjective; it either modifies, or does not modify, the antecedent, according as the attribute which it expresses is or is not characteristic of the species to which the antecedent belongs. Thus, when it is said, "Man, who is born of a woman, is of few days and full of trouble," the relative clause— qui est filius hominis, expresses an attribute common to all men, and therefore cannot modify. In like manner, when we say—"Socrates, who taught moral philosophy, was virtuous,"—the clause, qui haec delectante philosophiam, does not modify. In both these instances the relative clause might be omitted; and it might be said with equal truth, "Man is of few days and full of trouble,"—and "Socrates was virtuous."

But if it be said, "An wise man who punishes the subject, modifies the antecedent qui est sapit," for it is not affirmed of every man, that he is wise, but only of such men as speak little. So—"Charles XII. was the only monarch who conquered kingdoms to bellow them on his friends," and, "the man that endureth to the end shall be saved;" with which more examples that will occur to every reader.

Now it will be found, that it is only when the relative clause expresses such a property or circumstance of the antecedent as does not limit its signification, that the relative pronoun can be resolved into a prepositive pronoun with the conjunction and, and that in these cases the relative clause itself is of very little importance. Thus in the assertion,—"Charles XII. was the only monarch who conquered kingdoms to bellow them on his friends,"—where the relative clause is reftitutum, the who cannot be resolved into and be consistently with truth or common sense. But in the expression, "Man, who is born of a woman, is of few days and full of trouble," the relative who may be so resolved, at least without violating truth;—"Man is of few days and full of trouble, and he is born of a woman." The only difference between the sentence with the relative who, and the same sentence thus resolved, is—that, in the former case, it contains but one predicate; in the latter two, and these but loosely connected.

50. Thus then it appears that the general analysis of the relative pronouns is into the particle of, and a prepositive pronoun; but that there are also occasions on which it may be resolved into a prepositive pronoun and the particle and, without materially altering the sense. Now what is the reason of this distinction?

If the relative clause be equivalent to an adjective, or to an abstrait substantive in the genitive case, it is easy to see that the relative itself may, in every instance be, resolved into another pronoun and the particle of; but it will not perhaps be quite so evident how it should in any instance be resolved by and. This last analysis has its foundation in the nature of the particles of and and; or, to speak more properly, in the nature of the attribute which the relative clause expresses. Both the particles of and and are used to link or join conceptions together; but with this difference, that of has the effect of making the conceptions it connects figure in the mind as one object; whereas the conceptions connected by and are still conceived separately as before. To explain ourselves by an example: suppose we take two words, man and virtue, which denote two distinct ideas or conceptions, and join them together by the particle of, saying man of virtue; the mind no longer views them separately as significant of two conceptions, but of one. Take the same words, and join them together by the particle and, saying man and virtue; the conceptions denoted by man and virtue are still viewed separately as two; notice is only given that they are collaterally connected.

This being the case, it follows, that when the relative modifies the antecedent, or, in other words, when the relative clause and the antecedent denote but one conception, the relative must be resolved by of; in order to preserve this unity of conception. But when the relative does not modify the antecedent; that is, when its clause does not express any necessary part of a complex conception; then the conceptions or ideas denoted by the relative clause and the antecedent may be viewed separately as two; and therefore the relative may be resolved into the corresponding prepositive pronoun and the particle and.

To illustrate this reasoning in a light somewhat different. As every relative clause, which expresses an attribute that is not applicable to a whole genus or species, must necessarily modify some general term, that is, restrict its signification; and as that general term must belong either to the subject or to the predicate of a proposition; it is evident, that every such relative clause is a necessary part of that subject or predicate in which its antecedent stands. If therefore a relative clause, which modifies, be taken away either from the subject or the predicate of a proposition; or if that connection, in consequence of which it modifies, be dissolved (which is always done when the relative is resolved by and); the proposition itself will not hold true. The reason is, that the subject or the predicate becomes then too general: for, in the one case, something is predicated of a whole genus or species, which can be predicated only of some individuals of that genus or species: and in the other, a general predication is made where only a particular one can be applied. Thus, if it be said, "All men who transgress the laws are deserving of punishment," the subject of the proposition is expressed by the words, "all men who transgress the laws." Take the clause of the relative "who transgress the laws"—away, and say, "All men are deserving of punishment." and you have a proposition which is not true, because that is affirmed of the whole species; which can be affirmed only of some individuals. Retaining now the clause of the relative, but resolving it by and, you have the same proposition as before; and together with it, in this instance, another which is equally false:—"All men and they transgress..."
grows the laws, are deserving of punishment," that is, "all men are deserving of punishment, and all men transgress the laws."

But when the attribute expressed by the clause of the relative is characteristic of the genus or species of the antecedent, and consequently applicable to every individual which that genus or species comprehends, the relative clause may be entirely omitted without affecting the truth of the proposition, which is already as general as it can be. As in this case the import of the relative clause is not restitutive of the signification of the antecedent, it is of little consequence whether the attribute be represented by the connective part of the relative, as of, the antecedent, or be affirmed to belong to the antecedent in a separate assertion. Thus it matters not much, whether we say, "Man, who is subject to death, ought not to be too much elated;" that is, according to our analysis,—"Man of he is subject to death, ought not to be too much elated;" or, forming the relative clause into a separate assertion, and connecting the two by the particle and, we say, "Man, and he is subject to death, ought not to be too much elated." In the one sentence, indeed, the reason is implied why man should not be too much elated, viz. his being subject to death. In the other no reason is assigned for this; we only affirm that man is subject to death, and likewise that he should not be too much elated: but as both affirmations are equally true and evident, it is of little consequence, in such a case as this, whether the reason upon which either is founded be implied or not.

From the whole of this tedious investigation, we flatter ourselves that the following conclusions are deduced and sufficiently established: 1st. That the relative pronoun contains in itself the united powers of a connective and another pronoun. 2dly. That is the connective of which, together with another pronoun, it contains the powers, as in every possible instance it may be resolved into these constituent parts, and the import of the sentence in which it has place remain unaltered.

3dly. That the relative clause of a sentence has the import of an adjectival substantive, in the ancient languages, in the genitive case; in English, with the particle of prefixed. 4thly, That the relative pronoun is of necessary use only where there is a deficiency of adjectives or substantives to denote some complex attribute, by which we want to limit a general term or expression; but that where such adjectives or substantives exist in language, we may use the relative or not at pleasure. And, 5thly. That though, in cases where the relative clause does not limit a general term, the relative pronoun may, without violating truth, be analyzed by and; yet such analysis is never proper, as it gives two predicates to the same subject, which, in the original proposition, had but one predicate.

If the clause of the relative be equivalent to an adjective, as in every instance it seems to be, it will naturally occur, that, in the ancient languages, the relative should agree with its antecedent in gender, number, and case. They do agree for the most part in gender and number: in case they cannot often, because the very intention of introducing a relative into lan-

---

**(5)** "Who is by some authors made the possessive case of which, and applied to things as well as persons I think, improperly." Leathur.
In English, from the cool and phlegmatic arrangement of the language, occasioned by the want of inflexions and conjugations, the place of every part of a sentence is almost uniformly determined, and very little variety is allowed in the collocation of the words. The imperative is almost always placed in apposition with its subject, and the nominative with its verb. In consequence of this uniformity in the collocation of the words, the mind acquires a habit of connecting in idea any kind of word with the place in which it is used to stand; and is naturally led to consider every word that stands in such a place as belonging to such a clause. Hence it is, we imagine, that the definite that pales into the nature of the relative pronoun; as in those instances in which it occupies the place of the relative, it was natural to consider it as having the same import. Yet the word that has undoubtedly in itself no more the force of the relative pronoun than the or this, or any other definite whatever. In such expressions as the foregoing, it is not improbable that originally the clause of the definite that, which we now call the relative clause, was thrown in as a kind of modifying circumstance in the following manner: "The book (I read that) is elegant;" where the speaker, finding the word book too general for his purpose, throws in a clause to qualify and restrict it, or to confine his affirmation to that particular book which he is then reading. We can easily suppose, that through time the definite that in such an expression might be transposed or removed from its own place to that of the relative that so that the expression would run thus, "The book that I read is elegant;" which would be considered as precisely equivalent to "The book which I read is elegant." This opinion is not a little confirmed by a similar use in the article in Greek, which, though undoubtedly a definite like the English the, is often used instead of the relative pronoun. Numerous examples may be found in Homer and Herodotus, especially in the latter, who seldom refers what is properly called the relative. We shall produce one instance from each.

**55 Interrogative pronouns**

We have said that the interrogative pronouns, as they are called, who, which, what, are intimately connected with relatives; we now affirm, that the word of these words are nothing but relatives, and that the last contains in itself the united powers of a relative and definite. With respect to cases, number, and gender, the words who and which, when employed as interrogatives, differ not from the same words when employed as relatives; and we hold it as a maxim, without which science could not be applied to the subject of language, that the same word has always the same radical import in whatever different situations it may be placed. To understand this, it is necessary to observe, that all men have a natural propensity to communicate their thoughts in the fewest words possible; hence it follows, that words are often omitted which are necessary to complete the construction of the sentence; and this no where happens more frequently than in the use of who and which. In sentences where these words are confessedly relatives, we often find them without an antecedent; as, "Who means my purse, means truth." Shakespeare, "Which who would learn, as soon may tell the facts." Dryden. "Qui Baculum non odis, amatis sarminas, Meric, Virg. That is, "He who steals my purse, &c." "Which he would learn as soon, &c." and "ille qui Baculum non odis," &c. Such abbreviations occasion no obscurity, because from previous circumstances the hearer knows the mind of the speaker and the periphrasis to whom he refers. But it is not with respect to the relative and antecedent only that such abbreviations have place: in sentences of a different form, whole clauses are sometimes omitted, while the meaning of the speaker is made sufficiently plain. Thus when king Richard III. having lost his horse in battle, exclaims, "A horse! a horse! my kingdom for a horse!" there is no complete thought expressed; but the circumstances in which the king then was, enabled those about him to understand, that he wanted a horse. Accordingly Catesby answers him, "Withdraw, my lord, I'll help you to a horse." In like manner when a person asks a question, his expression is frequently incomplete; but the tone of his voice, or some other circumstance, enables us to ascertain his meaning, and to supply, if we please, the words that are omitted. Thus when it is said, An thief? nothing more is expressed than, If you did it (the Latin au being nothing else but the Greek α begged of the circumstances enable the person who hears it to know that the meaning is, Say if you did it." Let us apply these observations to the words who and which. If these words be relatives, and if our analysis of the relative be just, it is obvious, that no complete meaning can be contained in the clause, "Who is your principal friend?" for that clause contains nothing more than the circumstance of being your principal friend. We shall find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun. The custom, however, of language, and the tone of voice with which the relative clause is uttered, intimates, for he will find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun. The custom, however, of language, and the tone of voice with which the relative clause is uttered, intimates, for he will find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun. The custom, however, of language, and the tone of voice with which the relative clause is uttered, intimates, for he will find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun. The custom, however, of language, and the tone of voice with which the relative clause is uttered, intimates, for he will find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun. The custom, however, of language, and the tone of voice with which the relative clause is uttered, intimates, for he will find it impossible to affix to it any meaning and without supplying an antecedent clause, by which that which is called an interrogative will be immediately converted into the relative pronoun.
cencing these particulars; and that there may be
more, he describes the unknown person as having
dyed garments from Bozrah; but left even that descrip-
tion not be sufficiently accurate, he throws in the
definative clause, this is that person, pointing at
him, we may suppose, with his finger.—Which, used
as an interrogative, indicates a wish of knowing a par-
cular person or thing out of more than one mention-
ed, as, "Which of the two did it?" that is, "Tell me
the one of the two which did it?" for in old English
which as a relative is often used, where in modern
English we should say who; and that mode of speech
is full retained when the antecedent is omitted, and
the relative clause employed to indicate such a with
as that before us. What includes in itself the signification
of a definitive and a relative pronoun; as, "from
what has gone before, what follows may easily be
guessed?" where the word what is equivalent to that
which. When therefore we say, "What rude fellow
is that?" our meaning is, "Describe that person who
is that rude fellow." Upon the whole, then, it is
evident, that the words called interrogatives are merely
relative pronouns; and that the interrogative sentences
are relative clauses uttered in such circumstances as to
enable the hearer to supply the antecedents necessary
to complete the meaning.

56. To conclude: We have seen that substantives
are either primary or secondary; or, in other words,
NOUNS denote substances, and those either natural, artificial, or abstract. They
over denote things either general, or special, or particular;
and a general or specific name is made to denote an
individual by means of words called articles or de-
finitives. PRONOUNS are the substitutes of nouns,
and are either prepositive or substutive. The prepo-
sitive is distinguished into three orders, called the
first, the second, and the third person. The sub-
jective, otherwise called the relative, includes the
powers of all those three, having superadded as its
own the peculiar force of a connective.

Chapter IV.

57. The words which we have hitherto considered
are commonly called substantives primary or secondary,
and definite; because nouns are significant of substances;
pronouns are the substitutes of nouns; and the ad-
ticles serve to ascertain the extent of the noun; and to
determine whether on any occasion it be significant of
a whole class of substances, or only of one individual. But
substances are of importance to mankind only on ac-
count of their various qualities or attributes; for their
internal texture is a thing of which we are profoundly
ignorant, and with which we have no manner of con-
cern. Thus, experience teaches us, that certain vege-
tables are good to the taste, and wholesome food;
while others are unpleasant and poisonous. The for-
mer kinds are valuable only for their qualities or attri-
butes; and they are the qualities or attributes of the lat-
ter; that make them wretched or hurtful. A horse is
strong, and swift, and docile; and may be trained to
carry a man on a journey, or to drag a plough. It is
for his strength, swiftness, and docility, that he is the
most valuable of all quadrupeds. One man is brave,
another learned, and another eloquent; and by pos-
fessing these different qualities or attributes, each is fitted
for a different station in society. It is plain therefore,
that in contemplating substances, our attention must be
principally bestowed upon their qualities, and that the clas-
of words which serve to denote these qualities must be an
esential part of language. Such words are in genera-
called attributes; and are of three sorts, Verbs, Par-
ticiples, and Adjectives.

58. Of all the constituent parts of speech none
has given the grammarians greater trouble than the
verb. The vast variety of circumstances which it
blends together in one word, throws very considerable
difficulties in the way of him who attempts to analyze
it and ascertain its nature; at the same time, that by
its eminent use in language, it is entitled to all the
attention which can be bestowed upon it. To the dis-
cussion of the verb, Mr Harris, whose notions of this
as of the other parts of speech have been generally
adopted by the subsequent writers on grammar, has
dedicated a large proportion of his book, in which he
has thrown out many excellent observations, mixed, as
it appears to us, with several errors. We have already
observed, that no man is ignorant, when he uses what is
called a verb and when a noun. Every school boy knows
that the words is, lovetb, walketh, standeth,
in English; and est, amat, amatur, amatus, stat,
in Latin, are verbs: he knows likewise that they are
different kinds; some of them are said to be
active, some passive, and some neuter. But it should
seem, that the first object of our investigation ought to
be the characteristic of the verb, or that which all these
words have in common, and which constitutes verbs,
distinguishing them from every other species of
words. Now it is obvious to the slightest attention, that
every verb, whether active, passive, or neuter, may
rather be resolved into the substantive verb is, and another of the verb
attributive: for lovetb is of the same import with love;
walketh, with is walking; and amat, with amans est. But
loving, walking, and amans, are not verbs: whence it follows, that the characteristic of the
verb, that constitutes it what it is, and cannot be expressed by other words, must be that which is
signified by the word is; and to us that appears to be
neither more nor less than assertion.

Assertion therefore, or predication, is certainly
the very essence of the verb, as being that part of
its office, and that part only, which cannot be discharg-
ed by other kinds of words. Every other circumstance
which the verb includes, such as attribute, mode, time,
&c. it may be possible to express by adjectives, participles,
and adverbs; but without a verb it is impossible to predi-
cate, to affirm or deny, any one thing of any other thing.
The office of the verb, then, when stripped of all acciden-
tal circumstances, seems to be merely this, "To join
the subject and predicate of a proposition;" its powers
are analogous to those of the sign + in Algebra, which does not affect the separate value of
the quantities between which it is placed, but only in-
dicates their union or coalescence. To explain by an ex-
ample: When we say, Cicero eloquent, Cicero wise, these
are imperfect sentences, though they denote a substant
and an attribute. The reason is, that they want an
assertion, to show that such an attribute appertains to
such a substant. But when we insert the word was,
we join the substance and attribute together; we give notice that the wisdom and eloquence are applied to Cicero, and we do nothing more; we neither increase the wisdom nor diminish it; we neither make it real nor imaginary; for it was supposed in all its extent when the words Cicero and wise flood independent of each other. We may indeed use the verb in a form which implies not an assertion only, but likewise an attribute; as when we say George writeth, or George walketh: But as whitewash or any other particular colour is not of the essence of a horse, an animal which is found of all colours; so in the phrases quoted, the attribute, though implied, is not of the essence of the verb; for it may be equally well expressed by other words: George is writing, and George is walking, are phrases of the very same import with George writeth, and George walketh.

59. In revolving every verb, whether active, passive, or neuter, into the substantive-verb and another attributive, we have the honour to agree with all the grammarians; but to the word is itself the learned author of Hermes has given a meaning which, as a verb, it does not admit. He observes, that before any thing can be the subject of a proposition, it must exist: that all existence is either absolute or qualified, mutable or immutable: that the word is can by itself express absolute existence, but never the qualified, without subjoining the particular form; and that it signifies both mutable and immutable existence, having in these cases different meanings; altho' the sentences which he gives as examples are evidently constructed in the same manner and consist of the same parts of speech. His examples are: of absolute existence, B is; of qualified, B is an animal; of mutable, This orange is ripe; of immutable, The diameter of the square is incomparably with its side. But if predicament be the essence of verb, all this is nothing to the purpose, and part of it is not true. It is not true that the verb is ever varies its figuration; for it hath as verb no connection with existence of any kind. All such circumstantials are superadded to its verbal nature; or, to speak more accurately, we affix such names or terms from previous knowledge of the objects concerning which the predicament is made. When we say ‘this orange is ripe,’ we do indeed mean, as Mr Harris observes, that it is so now at this present in opposition to past and future time: but it is not the verb is, but the definitive THIS, which fixes the time of maturity, as well as the place of the orange; for had we said, oranges are ripe, we might have been properly asked, When and where are they ripe! although the same verb is used in both sentences. Even in the sentence ‘it is,’ absolute existence (the most simple of all) is inferred not expressly by the verb; and the inference is made from this obvious principle, ‘that when one utters a mark of predicament, we naturally conclude that he means to predicate something of the subject.’ If he adds no specific predicament, as B is round, we apply to B the most general that we can; and what other species is so general as existence?

That the idea of existence, considered as mutable or immutable, is not contained in the verb is itself, but is derived from our knowledge of the objects concerning which the predicament is made, appears manifestly from this: That if a person be supposed ignorant of the meaning of the words God and man, whilst he knows that of is; the uttering of the two propositions, God is happy, and this man is happy, will give him no notice of existence considered as mutable or immutable, temporary or eternal (o). His conclusion with respect to these modes of existence, if any such conclusion be drawn at all, must be derived entirely from his previous knowledge of the nature of God and the nature of man.

Some of our readers may possibly think this notion of verb too abstract and metaphorical; yet what other circumstance than mere predicament is essential to that species of words? We say ‘existent,’ not what is expressed by each individual verb, but what it is which is equally expressed by all verbs, and which distinguishes them from the other parts of speech. And if it be true, that every thing which the verb implies, predicament alone excepted, may be expressed by other parts of speech, and that no other part of speech can predicate; then we think ourselves warranted to affirm, that simple predicament is the essential character of verbs, that every word which predicates is a verb, and that nothing is so which does not predicate.

It must not, however, be conceived, that a doctrine very different from this has been lately maintained by Dr Gregory (p), an objector to the general theory. An objector has given no direct example of a word whose meaning is measured without affirmation, and a feeling or sentiment which is not uttered has nothing to do with language: but he has given a sentence in which there are three verbs, that in his opinion denote no affirmation, but a very plain supposition. If a supposition can be expressed without affirmation, we shall very readily allow that a wish or command may be so expressed likewise. The Doctor’s supposition is thus expressed: ‘Had any punishment ever overtaken you for your broken vows; were but one of your teeth growing black, or even were but one of your nails growing less solid, I should believe you. It is almost superfluous to observe, that to every verb not in the infinitive mode there must be a nominative, and to every active verb an object, whatever be the arrangement of the sentence in which such verbs are found. These

(o) The truth of this observation may be proved by experiment, by uttering to a man of good common sense these two propositions, taking care to express the words God and man in a language which he does not understand. Thus, Deus est happy, and hic homus is happy, uttered to a man totally unacquainted with the Latin tongue, will convey no notice of existence considered as mutable or immutable, &c.

are truths known to every schoolboy; the reasons of them shall be given afterwards. It is likewise undeniable, that in the sentence before us, the nominative to had is any punishment; to the first were, one of your teeth; and to the second, one of your nails. But the sentence arranged in grammatical order, with the several nominatives before their sense of the sentent is completed, express no affirmation; that it is only upon granting the truth of the affirmation which they denote, that the speaker says “I should believe you.” “Any punishment had ever overtaken you; if but one of your teeth were growing black, or even if but one of your nails were growing less beautiful, I should believe you.” Now it has lately been proved, by such evidence as leaves no room for doubt, that had, though called a conjunction, is in fact a verb in the imperative mode, of the same import with give; so that we may substitute the one for the other without in the smallest degree altering the sense. The sentence will then run thus: “Give any punishment had ever overtaken you; give but one of your teeth were growing black, &c. I should believe you.” It is therefore so far from being true, that had and were, when the sentence is completed, express no affirmation; that it is only upon granting the truth of the affirmation which they denote, that the speaker says “I should believe you.” “Any punishment had ever overtaken you,” is plainly an affirmation; if, give that affirmation, admit its truth, “I should believe you.” But it cannot be supposed that had and were change their significations by a mere change of place, or that by being removed from the middle to the beginning of a clause, they lose their original import, and come to denote something entirely different. Were this the case, every attempt to ascertain and fix the general principles of grammar would be as ridiculous as an attempt to express many circumstances by the course of time. For what purpose then, were it the case, to demand the truth of the affirmation, is evident; for when the word requiring the affirmation to be granted is supplied, the verb must be restored to its place in the middle of the clause. Such abbreviations, and such contrivances to mark them, are frequent in all languages, as will be seen more clearly when we come to treat of modes. Upon

the whole, notwithstanding the deference which we willingly pay to this very masterly writer, we are compelled reluctantly to differ from him, and still to think that simple predication is the very essence of the verb.

Should we be required to exemplify our theory by The theory of language, and to produce instances of this simplified process in practice, we might answer, that the not being able to produce such inferences would be no good argument against the truth of our principles. It is the nature of language to express many circumstances by the same word, all of which however are not essential to distinguish the species to which that word belongs from the other species of words; and it is the nature of man to infer from discourse many things which are not actually expressed. Perhaps, however, something nearly approaching to an exemplification of our idea of a simple verb will be found in the following proposition: “The three angles of every plane triangle are equal to two right angles.” What other office the verbs here perform is simply to join the subject and predicate, it is difficult to perceive. It does not give notice of time; or such notice, if given, is an imperfection; for the truth of the proposition is independent on time. Neither ought it to imply existence; for the proposition would be true, were there neither a triangle nor a right angle in nature.

This idea of verb, when it is well considered, we hope will be found just; but should any of our readers suspect it of novelty, and on that account be disposed to condemn it, we have only to request that he will refine his faculty till he has examined the writings of others, and nicely observed the several postures of his own mind in discourse; for meditation may perhaps show him that our theory is not false, and inquiry will satisfy him that it is not novel (q).

60. But although it is certain that asseveration, and asseveration only, is essential to the verb, yet the greater part of those species of words which grammarians call verbs are used to denote an attribute as well as an asseveration; or, in the language of logic, they express both the subject and the predicate of a proposition: thus, he is living, he is written, he is walking, are phrases equivalent in all respects to he is living, he is written, he is walking, denote some effect or action which grammarians call affresco. But although it is certain that asseveration only, is essential to the verb, this is not the case. But although it is certain that asseveration only, is essential to the verb, or, in the language of logic, they express both the subject and the predicate of a proposition: thus, he is living, he is written, he is walking, are phrases equivalent in all respects to he is living, he is written, he is walking, denote some effect or action which grammarians call asseveration.

(q) “Besides words, which are names of ideas in the mind, there are a great many others that are made use of, to signify the connexion that the mind gives to ideas or propositions one with another. The mind in communicating to the sight, organs, does not merely signifies of the ideas it has then before it, but also to show or intimate some particular action of its own at that time relating to those ideas. This it does in several ways; as is and is not are the general marks of the mind ascribing or denying.” Locke on Human Understanding.

“Verbum est pars orationis variabilitas, aliquid de re aliqua dici se affirmari significans. Vulgaris verbi definitio est, quod fit pars orationis, que agere, pati, aut esse significet. Sed nostra accuration, magisque ex ipso verbi cujusvis natura petita videtur. Ceutrum aut affirmari laxiorem hic fensi accipimus, pro eo quod praeclari Dialectici appellant, quo non modo affirmationes strictius sibi ducit, sed negationes etiam interrogationesque inclunatur.” Ruddimanii Grammaticae Institutiones; see also Dr Beattie’s Theory of Language.
black, and at some future time will be of a different colour. As, therefore, all motions and their privation, imply time; and as a proposition may be true one time, which is not true at another; all verbs, as well those which denote both an attribute and an affection, as those which denote an affection only, come to denote time also: Hence the origin and use of tenses, which are so many different forms asfigned to each verb, to show, without altering its principal signification, the various times in which the affection expressed by it may be true. Whether these various forms of the verb be essential to language, it is vain to dispute. They have place in every language with which we are acquainted; and as the use of the verb is to affirm one thing of another, it is absolutely necessary that the time, when such or such an affirmation is true, be marked by tenses, or some other contrivance. Concerning tenses, therefore, we shall throw together some observations equally applicable to every language, after prefixing a general remark or two which seem necessary in order to proceed with precision.

Time, although its existence consists in succession without implying at the same time that there is certainty or necessity in succession continued and unbroken, may yet be considered by the mind as divided into an infinite number of parts. There is, however, one grand division which necessarily occurs, and to which the different tenses of verbs are in all languages adapted. Computing from some portion conceived to be present, all times is either past or to come.

Again, from the very nature of time, it must be obvious, that all its parts are relative; i.e. that no portion of it can be ascertained by any thing inherent in itself, but only by referring it to some other portion, with respect to which it is past, present, or to come. In this respect time is perfectly analogous to space: for as the space in which any object exists, cannot be descried but by relating it to some other space, so neither can the time of any attribute or action be determined but by relating it to some other time. When, therefore, we would mark the time of any action or event, we must previously fix upon some point to which we may refer it. If this point be known, the time referred to it will be known also; but if the former be not known, neither will the latter.

Lastly, in contemplating an action, we may have occasion to consider it as going on, or as finished. This distinction is likewise denoted by the different tenses of verbs. In treating therefore of the tenses, there are two things to which attention ought principally to be turned:—the relation which the several tenses have to one another in respect of time; and the notice which they give of an action’s being completed or not completed.

62. Having premised these remarks, we proceed now to the tenses themselves; of which Mr Harris has enumerated no fewer than twelve. Of this enumeration we can by no means approve; for, without entering into a minute examination of it, nothing can be more obvious, than that his inceptive present—I am going to write—is a future tense; and his complective present—I have written—a past tense. But, as was before observed of the classification of words, we cannot help being of opinion, that, to take the tense as they are commonly received, and endeavour to ascertain their nature and their differences, is a much more useful exercise, as well as more proper for a work of this kind, than to raise, as might easily be done, new and hypothetical theories on the subjedt.

It has been already observed, that all the tenses must necessarily mark relative time. In one sense, this is extremely obvious. The present tense is used in contradistinction to both the past and future, and marks an attribute or action as existing in neither. The past and the future are in like manner used in contradistinction to the present; and mark an attribute or action which exists not now, but which in the one case has existed formerly, in the other will exist at some time coming. But besides this relation of contradistinction subsisting among the tenses, there is another of co-existence, as we may call it, to which it is of great consequence to attend—especially in examining the nature of the present.

63. The present tense refers not only to something which is past or future, but also to something with which the attribute or action of the verb is contemporary. This reference is necessarily implied in its very name; for we cannot say of any thing that it is present, without implying at the same time that there is something else with which it is present. Hence it appears with how little reason Mr Harris and others have given us an aorist of the present, as marking present time indefinitely in contradistinction to other presents, which have been called inceptive, extended, and complective presents. For from what has been said it follows, that the present tense is necessarily and from its very nature perfectly indefinite, and can of itself give notice of no precise or determinate portion or point of time whatever. A thing may have been present fifty years ago, may be present now, or at any future period. This tense implies the relation of co-existence between two or more things; but, without some auxiliary circumstance, it cannot in any language mark the particular portion of time in which those things exist. The indefinite nature of this tense is indeed most clearly seen in that use of it in which Mr Harris has styled it the aorist of the present; that is, in cases where it is employed to denote the repetition of an action which the agent is accustomed frequently to perform, or to express propositions of which the truth is ascertained by general experience; as in the following examples:

Hypocrite,—the only evil that walks
Invisible, except to God, he is known
Ad Iustitiam prospet qui sit judicin, &c.

In these instances it is plain there is no particular time pointed out: the propositions are true, or apprehended as true, at all times. Although the actions, therefore, of walking and hastening are expressed as present, it is impossible from the expressions to determine any precise point of time when they are present.

But if the present tense be thus indefinite, how, it may be asked, are we to ascertain the particular time which is intended? We answer, it is to be ascertained, either by relating the action of the verb as existing in some time already known, or by inference. If, for example, we say,—“Millions of spiritual creatures walk the earth unseen,”—the proposition is general, and the time of walking undetermined. But if we add,—“both when we wake and when we sleep”—the time is by this addition ascertained and specified; for if the time when men wake and sleep be known, the time when these spirits walk the earth is also known. When no specifying clause is given by which to determine the time of the present tense, it is very commonly determined by inference.
Thus, if one use such an expression as—"He sleeps while I am speaking to him,"—the time of his sleeping is ascertained by the subjunctive clause of the sentence; but if it be said simply—"He sleeps"—without alluding any data from which it may be concluded that he is sleeping, the time is altogether indefinite. Such inferences as this are common in language. The mind is desire to obtain complete information on every subject; and therefore frequently supplies to itself what is not expressed in the speech of others.

Both these ways of ascertaining the precise time of the present tense, are excellently illustrated by the use of the word "present" as applied to space. Take a familiar example:—"His brother and he were present when I read the letter." It is at first sight evident that this expression is perfectly indefinite. But if it be said—"His brother and he were present at your house when I read the letter,"—the place of action is inferred, by being referred to a portion of space which is known. If no such reference be made, the person who hears the speech uttered must either remain ignorant of the place intended, or he must ascertain it to himself by inference; and he will probably infer it to be that in which the speaker is at the time of uttering the indefinite sentence. This leads us to observe, that such inferences are not often made without sufficient foundation. Various circumstances may assist the reader or hearer in making them, and prevent all danger of mistake. He may have the evidence of sense, or of something preceding in the discourse, and a number of other particulars, to justify and warrant his conclusion. Thus, if when fitting by a large fire, one pronounce the words—"I am too warm;" to whom he addresses his speech are authorized to conclude, that he is too warm at the time of speaking, unless he expressly prevent the drawing of that conclusion by adding some such clause as—"when I wear a great coat."

It is strictly demonstrable, and hath by Mr. Harris been in fact demonstrated, that there is no such thing as present time. Yet do we not only conceive time as present and existing, but frequently as extending to a very great degree. We speak not only of the present instant, or the present day, but also of the present year, and even of the present century. This manner of conceiving time is indeed loose and unphilosophical; but it is sufficient for the ordinary purposes of language. To express time as it really is, we ought to say, the passing day, the passing year, and the passing century; but in common discourse we denominate any portion of time present, in which the present now or instant is included, although it is obvious that part of that portion is past, and the remainder is future. From the very nature of time thus conceived to be present, the tense now under consideration must represent the action of the verb as commenced, and not finished; for as time is continued succession, and accompanies every action; when any action is not commenced, it exists not in any time, though it may exist hereafter in time which now passeth, and when it is finished, it exists no longer in time present, but in time past. Hence the absurdity of introducing into a theory of the tenses an inceptive present and a complete present; for these terms imply each a direct contradiction.

64. After having said so much of the present tense, we shall have but little to say of the praeter-imperfect. It states an action in respect of time, as past, and in respect of progress, as unfinished. Legebam—"I was reading at some past time, but my reading was then interrupted." I had not finished the sentence when I read it, which is this tense. We must here observe, however, as we did with respect to the present tense, that although the praeter-imperfect represents the action as past, it does not inform us in what precise portion of past time the unfinished action was going on: this circumstance must either be given in separate words, or be inferred by the hearer. If one say simply—Legebam, the person to whom he addresses his speech will conclude, that the time of his reading was past with respect to the present time of his speaking. But if he say—Legebam antequam senseris, he expressly states the action of reading as past with respect to the time in which his hearer came to the place where they both are at the time of speaking. The time of the praeter-imperfect is always past with respect to the present instant when the imperfect is used, and of this the tense itself gives notice; but it may also be past with respect to some other time, and of this it conveys no information.

If we join two praeter-imperfects together, the expression will state the co-existence of two progressive actions, both of which were going on at a time past in respect of some determined time given or supposed. Cum tu feribebas ego legebam; "When you were writing I was reading." Hence the praeter-imperfect has by some grammarians been called the relative present; a name which, however, is by no means exclusively applicable to this tense. When the praeter-imperfect is by the conjunction and joined in the same sentence with a perfect-pass, the two tenses express two actions, both prior to the time of speaking; but the one as having continued after the other was finished. Thus, Eneas speaking of the destruction of Troy, says, that after having escaped with his father and followers, he returned to the city in quest of his wife, and went directly to his own house; but there, continues he, "in reo Danai, et eodem omnetenebam;"—"the Greeks had refiled in," that action was over and completed before his arrival; but the act of "poffessing the whole house," tenetbam was not over, but stil continuing.

65. But it is necessary that the verb denote actions which were completed or perfect, as past, as well as present or imperfect. For this purpose, Greek and English verbs have an aorist, a praeter-pass, and a plusquam-pass. Of these the Latin has only the two last. The praeter-perfect in that language possesses a twofold character: it performs the office of the Greek and English aorist, as well as of the praeter-perfect properly so called; that is, it denotes a finished action at some indefinite past time, as well as at some time of which both past and definite.

In attempting to analyse the signification of complex terms, by which we here mean words that include in their signification a variety of particulars, it is of great advantage to have these particulars separately expressed by different words in another language. The English has resolved the tense which in the Greek and Latin languages are denominated the aorist and the praeter-perfect, by means of what are commonly called auxiliary verbs, expressing the former by the verb did, the latter by the verb have. In examining therefore
The principal distinction in practice between the aorist and präter-perfect (for the difference seems little) The præter-perfect in their real import consists in the time by which the performance of the action admits of being particularly specified. The präter-perfect is always joined with a portion of time which includes the præsent new or perfect action, for otherwise it would not signify, as it always does, the present perfect or the finishing of an action. But the aorist, which signifies no such perfection, is as constantly joined with a portion of past time which excludes the præsent new or perfect. Thus we say, “I have written a letter this day, this week,” &c.; but “I wrote a letter yesterday, last week,” &c.; and interchange these expressions of time in Greek and English wherein the aorist and präter-perfect have different forms, would be improper. In Latin, indeed, where they have but one form, the impropriety does not appear.

67. Having considered the tenses which imply present and past time, it now remains that we examine the import of those which are expressive of time future.

In Latin and English there are two tenses for this purpose, of which the first represents an action in point of time as not yet existing, but as about to exist at some period in the future, and it does not signify the completion of the action into view. The other affords the futurity of an action together with its completion. Vorbeam, “I shall be writing,” denotes future time and incomplete action; for it does not say whether I am to write for a long or for a short time, or whether I shall finish what I promise to begin. This part of the verb, therefore, to which the Greek ἔγειρεν corresponds, is imperfect future, and likewise an aorist. The futurity of any action, it should seem, may always be computed from the time of speaking; for every action must be in future with respect to the time at which its futurity is declared: but the time of its futurity may be more precisely specified by fixing upon some other future time to which to refer it: “I shall be writing after he shall have departed.” Shall or will refers to future time indefinitely; and write or writing refers to an action which is indeed to begin and so far to proceed, but of which nothing is said concerning the completion.

On the other hand, scripsisse, “I shall have written,” is a perfect future denoting complete action: for shall denotes future time; written, perfect action; and have present perfection. So that the meaning of the whole affirmation is,
The Theory of Grammar.

72 Of the tenses of the subjunctive mode.

68. These are all the tenses, essentially different from each other, which have place in the indicative mode of any language with which we are acquainted (x); but as there are tenses in the mode called subjunctive, which bear the same names with those already examined, and which have yet a different import, it will be necessary to consider them before we dismiss the subject of tenses.

Of modes in general something must be said hereafter; at present we shall only observe, that the mode with which we are now concerned, is not very properly distinguished by the same affixed to it by the Latin grammarians. They call it the subjunctive, because it is often subjunctive, and forms the secondary clause of a sentence: but the mode called indicative frequently appears in the same circumstances. The differences between these two modes appear to us to consist in this, that the indicative affords something directly concerning the action; the subjunctive, something concerning the power or liberty of the agent to perform it: for that the latter affords as well as the former, admits not of dispute.

69. The present tense of the subjunctive mode, in the learned languages, answers to the English auxiliaries may and can. Let us consider these a little. — May is evidently a verb of the present or denoting liberty. When I assert that I may write, I give notice that "I am under no compulsion to abstain from writing," that there is no impediment from without by which I am restrained from writing. Can is also a verb of the present tense, expressive of internal power or skill. "I can write," is equivalent to — "There is nothing in myself which incapacitates me for performing the operation of writing." This verb seems originally to have denoted knowledge or skill, and to have been afterwards extended to signify power or ability of any kind. There is little doubt of its being the same with the old English verb to can, which signifies to know. The difference between the import of these two verbs may and can will be best perceived in a familiar example. Suppose we say to one of our transcribers, "You may write a treatise on grammar," to which he returns for answer, "I cannot!" our assertion evidently supposes him at liberty to write the treatise; his answer implies, that he is unable or unskilled to do it. We may conclude, then, that the present tense of this mode contains a declaration of present liberty, ability, or skill; and its other tenses will be found to have reference to the same capacities.

The observation is here to be repeated which was enlarged upon under the present of the indicative. The liberty or ability signified by this tense is always represented as present; but the time of this presence is indefinite. If no particular time be specified, we generally refer it to the time of speaking; but another point may be given from which we are to compute. "When he shall have finished, you may then proceed as you propose." Here the liberty of proceeding is stated as present, not at the time of speaking, but at the time of his finishing, which is future to the time of speaking. But though the liberty, ability, or skill, denoted by this tense, be represented as present, the action itself is stated as contingent, for it is not necessary that a man should perform an action because he has the capacity to perform it.

From this idea of the present of the conjunctive some of its most peculiar uses seem capable of being explained. — And, in the first place, it appears to have a near affinity with the future of the indicative; insomuch that in many instances they may be used promiscuously. Without materially altering the effect of the expression, we may say, "Dico me fac tum esse que imperet," or "que imperabis." The reason of this, perhaps, may be, that with respect to us, our actions and contingency are in most cases nearly the same, both being involved in equal obscurity; and therefore it is often of little consequence which mode of expression we employ.

Secondly, The present of the conjunctive is used to denote

(x) On this point we subscribe to the opinion of the elegant and ingenious Dr Beattie. — "It will perhaps occur (says he), that there are two Greek tenses, of which I have given no account; namely, the second aorist, and the second future. The truth is, that I consider them as unnecessary. Their place, for any thing I know to the contrary, might at all times be supplied by the first aorist and the first future. Some grammarians are of opinion, that the first aorist signifies time past in general, and the second, indefinite time past; and that the first future denotes a nearer, and the second a more remote futurity. But this, I apprehend, is mere conjecture, unsupported by proof: and therefore I incline rather to the tenets of those who teach, that the second future and the second aorist have no meaning different from the first future and the first aorist; and that they are the present and imperfect of some absolute theme of the verb, and, when the other theme came into use, happened to be retained for the sake of variety perhaps, or by accident, with a pretense and future signification. Be this as it will, as these tenses are peculiar to the Greek, and have nothing corresponding to them in other tongues, we need not formulate to overlook them as superfluous." — The Theory of Language, Part II. Chap. 11.

To these judicious observations we have nothing to add, but that they acquire no small degree of confirmation from this circumstance, that there are many Greek verbs which have no second future, and which are yet employed to denote every possible modification of future time. Of the pauly-pauly-futurum of the Greeks we have
The right of which a person is possessed. "I may or I can, tell this book." This application, which Dr Friesley considers as the primary signification of the tense, is easily deduced, or rather follows immediately, from the foregoing account of its import. For if one be under no restraint, either external or internal, to prevent him from performing an action, he has surely a right to perform it.

Thirdly, The present of the subjunctive is often used to signify command or request; as when one says, "You may give my compliments to such a person." This use of the tense under consideration seems to have arisen from a desire to soften the harshness of a command, by avoiding the appearance of claiming superiority. When a man utters the above sentence, he certainly utters no command, but only affirms that the person to whom he speaks has liberty or power to do him a favour. This assertion, however, may contain no new information; and therefore the person addressed, reflecting upon the intention of the speaker in making it, infers that it indicates a wish to desire that his compliments should be made to such a person.

70. Of the subjunctive as well as of the indicative, the præter-perfect is evidently the past tense of the present.

As the latter affords liberty, or ability, to perform some action, as existing at present, the former affords the same liberty or ability to have existed in time past; but the specific portion of time past, in which these capacities existed, must be specified by other words, or it will remain unknown. Thus in the following sentence, "Dixi me facturum esse quæ imperaret," the time of imperaret is referred to that of dixi: the person having the right to command, is supposed to have had it at the time when the other said that he would obey. This tense, as well as the present, states the action as going on and incomplete; and also as future with respect to the liberty or ability to perform it. It is rendered into English by the verbs could or might; of which the first is the past time of can, the second of may.

From the near affinity which the present of the subjunctive has to the future of the indicative, the tense now under consideration appears, in many instances, as the past time of the latter as well as the former. Thus Dixi me facturum esse quæ imperaret, may be rendered "I said that I would do whatever he might, or whatever he should command."

71. Of the præter-perfect, it is sufficient to observe, that as the present states the agent as at liberty to be performing an unfinished action; so this tense states him as at liberty to perform an action considered as finished. "I may be writing a letter when you come," i.e. "I am at liberty to be writing a letter when you come," or "I may have written a letter when you come," i.e. "I am at liberty to be in possession of the finished act of writing a letter when you come." It is a common mode of expression to say, "I may have done such or such a thing in my time," when he who speaks can have little doubt whether he has done the thing or not. In that case, the words may have done, cannot be considered as the præter-perfect of the

GRAMMAR.

The future of the verb do; for it is nonsense to talk of liberty, with respect to the performance of an action, which, at the time of speaking, is supposed to be past and completed. What then is the import of the phrase? We are persuaded that it is elliptical, and that the word say or affirm is understood: "I may (say that I) have done such or such a thing in my time," for liberty or contingency can relate to actions only as they are conceived to be past or future.

72. Of all the tenses, the most complex is the plu­

The plural of the subjunctive name or person, in every tongue of modes, with which we are acquainted, verbs are subject to another variation, which grammarians have agreed to call Moods. Of modes, as of tenses, it has been wisely urged whether or not they be essential to language. The truth seems to be, that the only part of the verb absolutely necessary for the purpose of communicating thought is the indicative mode; for all the others, as has been well observed by Dr Gregory, are referable, by means of additional verbs and a word denoting the action of the primary verb, into circumstantial expressions which

take no notice, because it is found only in the passive voice; to which if it were necessary, it is obvious that it would be necessary in all voices, as a man may be about to do as well as to suffer immediately.
which fully convey their meaning (s). But such expressions continually repeated would make language very prolix and wholly inanimated; for which reason, the import of each of the commonly received modes is a subject worthy of the philologist's investigation. About the number of modes, whether necessary or only expedient, as well as about the import of each, the writers on grammar have differed in opinion. Mr Harris, one of the most celebrated of those writers, has enumerated four modes of the verb, besides the infinitive; viz. The indicative of declarative, to assert what we think certain; the potential or subjunctive, for the purpose of whatever we think contingent; the interrogative, when we are doubtful, to procure us information; and the requisite, to achieve us in the gratification of our volitions. The requisite, too, according to him, appears under two distinct species; either as it is imperative in inferior, or preceptive to superiors.

For establishing such a variety of modes as this, no fort of foundation whatever appears. The same reasoning which induced the author to give an interrogative and requisite mode, might have made him give us a hortative, a desiderative, a volitive, and innumerable other modes, with which no language is acquainted. But besides perplexing his reader with useless distinctions, we cannot help thinking that Mr Harris has fallen into some mistakes with regard to the import of those modes which are universally acknowledged. According to him, assertion is the characteristic of the indicative, and that which distinguishes it from the subjunctive or potential; but this is certainly not true, for without an assertion, the verb cannot be used in any mode. Of this the learned author, indeed, seems to have been aware, when he observed of the subjunctive mode, that it is employed "when we do not assert," and that "it implies but a dubious and conjectural assertion." The truth is, that the assertion implied in this mode, tho' it is not concerning the same thing, is equally positive and absolute with that conveyed by the indicative. An example quoted by himself should have set him right as to this matter:

sed capit sui feliciter, nisi caperet.
Plus daps, &c.

Who does not feel that the assertion contained in habere, is as absolute and positive as any assertion whatever?

75. Perhaps we may be asked to define what we mean by a mode. We know not that we can define it to universal satisfaction. Thus much, however, seems to be obvious, that those variations which are called modes do not simply different modifications of the action of the verb. Amo, Amem, Amo, do not signify modes of loving; for modes of loving are, loving much, loving little, loving long, &c.—Shall we then get over the difficulty by saying, with Mr Harris, that "modes exhibit some way or other the soul and its affections?" This is certainly true; but it is nothing to the purpose; for it does not distinguish the meaning of mode from the object of language in general, all languages being intended to exhibit the soul and its affections.

Grammatical modes of verbs have been defined by Mode de Dr Gregory to be "concise modes of expressing some of those combinations of thoughts which occur most frequently, and are most important and striking." This is a just observation; but perhaps he would have given a more complete definition had he said, that grammatical modes of verbs are concise modes of expressing some of those combinations of thoughts which occur most frequently and of which assertion is an essential part (t). This indeed seems to be the real account of the matter, especially if our notions of the nature of verb be well founded.

(s) The imperative, for instance, may be resolved into a verb of commanding in the first person of the present of the indicative, and a word denoting the action of the primary verb, commonly called the infinitive mode of that verb. Thus, I nunc et versas tecum meditare canoros, and "Jubeo te nunc ire et tecum meditari," &c. are sentences of the very same import. The subjunctive may be resolved in the same manner by means of a verb denoting power or capacity; for credam, and possidium credere, may be often used indifferently. The indicative mode, however, is not thus convertible with another verb of affirming in the first person of the present of the indicative and a word denoting the action of the primary verb; for Titius scribit, "Titius writes," is not of the same import with dicito Titium scriberis, quod Titius scribat, "I say that Titius writes." The first of these sentences, as has been already shown, contains but one affirmation; the second obviously contains two. Titius writes is equivalent to Titius is writing; I say that Titius writes, is equivalent to I am saying that Titius is writing. The reason why the imperative and subjunctive are resolvable into expressions into which the indicative cannot be resolved, will be seen when the import of each of those modes is ascertained.

(t) Every verb, except the simple verb am, art, is, &c. expresses without modes a combination of thoughts, viz. affirmation and an attribute. The affirmation, however, alone is essential to the verb, for the attribute may be expressed by other words. It is indeed extremely probable, that in the earliest ages of the world, the affirmation and attribute were always expressed by different words; and that afterwards, for the sake of conciseness, one word, compounded perhaps of these two, was made to express both the affirmation and the attribute; hence arose the various classes of verbs, active, passive, and neuter. Of a process of this kind there are evident signs in the Greek and some other tongues. But the improvers of language did not stop here. The same love of conciseness induced them to modify the compound verb itself, that it might express various combinations of thoughts still more complex; but in all these combinations assertion was of necessity included; for if the word had ceased to assert, it would have ceased to be a verb of any kind.

Soon after this short note was written, and the whole article finished for the press, we accidentally met with Pickouen's Dissertation on the English Verb. Of that work it belongs not to us to give a character. Such of our readers as shall peruse it, will see that on many points we differ widely in opinion from the author; but we have no painful apprehension of any comparison which may be made. It gives us pleasure, however, to find,
founded,—that its essence consists in affirmation. And in this opinion we are to be more confirmed, from a conviction that no man ever employs language on any occasion but for the purpose of affirming something. The speaker may affirm something directly of the action itself; something of the agent's power or capacity to perform it; or something of his own desire that it should be performed, &c.—but still he must affirm.

If this be so, then are all the modes equally indicative. Some may be indicative of perceptions, and others of opinions; but still they all contain indications. On this idea the three foregoing modes of amo will be thus distinguished. When a man indicates his present feeling of the passion of love, he uses the first; when he indicates his present capacity of feeling it, he uses the second; and when he indicates his present desire that the person to whom he is speaking would entertain that passion, he uses the third.

76. As to what Mr Harris calls the interrogative mode, he himself observes that it has a near affinity to the indicative. It has in fact not only a near affinity to it, but, as far as language is concerned, there is not between the one and the other the slightest difference. For in written language, take away the mark of interrogation and, in spoken language, the peculiar tone of voice, and the interrogative and indicative mode appear precisely the same. That such should be the case is extremely natural.

To illustrate this, let us for once speak in the

VOL. VIII.

that his notions respecting the origin of such verbs as express at once affirmation and an attribute, are the same with those which had occurred to ourselves.

' The copula is (says Mr Pickhour) to have been coeval with language itself. But we have not the same evidence to convince us, that that must necessarily have been the case with any other finite verb; for the copula is, containing only an affirmation, is much more simple than a verb which unites in one word both an attribute and an affirmation. Since therefore people, in their first attempts to express their ideas by words, would scarcely think of any thing more than what was absolutely necessary, it is probable they would be some time before they anticipated any other word containing in itself an affirmation or affirmation; for they would not very early think of contriving words so complex in their nature as to include in them both the name of an action and an affirmation.

' I conjecture, that the first mode of expressing actions or passions, would be by participles or verbal nouns, i.e. words signifying the names of the actions or passions they wanted to describe; and these words, connected with their subjects by the copula is, might in those rude beginnings of language sufficiently supply the place of verbs; e.g. from observing the operations of nature, such words as rain or raining, thunder or thundering, would soon be invented; and by adding the copula is, they would say thundering or thunder is; or is not, raining or rain is; which by the rarity of pronunciation, might in time form the verbs rains, thunders, &c. The observation of their own actions, or the actions of the animals around them, would soon increase their flock of ideas, and put them upon contriving suitable expressions for them. Hence might arise such words as these: sleep or sleeping, stand or standing, run or running, bite or biting, hurt or hurting; and by joining these to substantives by means of the copula is, they might form such sentences as these,—lion is sleeping, or perhaps lion sleep is, stand is, &c. which would soon be contracted into lion sleeps, stands, runs, bites, hurts, &c. Thus our little insulated family might become possessed of verbs including an attribute and an affirmation in one word.'

This account of the origin of actions, passions, and neuter verbs, is certainly ingenious; and, in our opinion, is not more ingenious than just when applied to the Greek and other ancient languages, though it is not applicable to the English; but it seems to be quite irreconcilable with the definition of verb, which the author has adopted from Bishop Lowth; and indeed with every other definition except that which makes the essence of a verb to consist in simple affirmation.

(v) Of a question put in the form of an affirmation we have a remarkable instance in the Gospel of St Matthew. When Christ stood before Pilate, the governor asked him, saying, φανέρω τάς ὁμολογίας σας. That this sentence was pronounced with a view to obtain some answer, is evident from the context; yet it is as plainly an affirmation, though uttered in a feoffing tone, as the fierce confession of Nathaniel, ἐξενέγαζεν τῇ ὄνομα τυπώθηκεν. Had not the question been put in this form, which affirms Christ to be the king of the Jews, the reply could not have been ἐξενέγαζεν τῇ ὄνομα τυπώθηκεν, for without an affirmation the governor would have said nothing. See Dr Campbell's Translation of the Gospels, where the form used in the original is with great propriety retained in the version.
Of the optative mode.

tence may either be an abbreviation for die am sejifi, 'tell me if you did it;' or an may perhaps be, as if certainly is, the imperative mode of some obsolete verb equivalent to give; and in that case, au sejifi will be a complete interrogative sentence signifying, 'you did it, give that.'—But of the interrogative mode of Mr Harris we have said enough; perhaps, our readers will think, too much, since it is a useless distinction not found in any language. It will, however, be proper to say something of this imperative mode, as far as it is the same with the optative mode of the Greek grammarians. And,

77. Nothing, we think, can be clearer, than that the Greek optative signifies no distinct mode of the verb, whatever meaning be annexed to the word mode. The different tenses of the optative are evidently nothing but the past tenses of the corresponding tenses of the subjunctive. Pref. sub. τιμω, I might strike. Pref. opt. τιμήσει, I might strike, &c. This is proved to be indubitably the case by the uniform practice of the Greek writers. Examples might be found without number were one to read in search of them. The following sentence will illustrate our meaning: 'εικαστατι οδοι πα τους Αργάους, 'the Athenians came that they might assist the Argives.' Here the leading verb εικασατι being of the present tense, the dependent verb βοηθησι is the present subjunctive. But change the former to the past tense, and the latter must also be changed. ήεκασατι Οδοι πα τους Αργαους, 'the Athenians came that they might assist the Argives.' Here it is plain that βοηθησι, the present of the optative, is the past tense of βοηθης, the present of the subjunctive; and the same in other instances.

It is almost unnecessary to add, that when this mode is employed to denote a wish, the wish is not expressed by the verb, but is understood. Such abbreviated expressions to denote a wish are common in all languages. Thus, in Greek,

Ταυ ει τις ήταν, ελλωγετε της εκτρικινδρικι τοις τιμω, &c.

Signifies, 'The gods might give you (or, as we say in English, changing the position of the verb, might the gods give you) to destroy.' &c. So in Latin, Ut omnes di desineret perdant, 'That all the gods and goddesses may curse you!' Again, in English, 'O that my head were waters!' &c. In all these, and such like sentences, the words equivalent to I wish, I pray, are understood. In Greek a wish is sometimes introduced by the particle μω or μι, με; as in Homer,

'βιθ' ει τοις ει τις της αδικίας, εμενμενειν ήπερατρον.

'If it had been your fate not to be born, or to die unmarried!' The suppletion is, 'It would have been happy for your country;' or some such thing. In like manner, a poor person not uncommonly inreates a favor by saying, 'Sir, if you would be so good!' Here he speaks; but the completion of his sentence is, 'It would make me happy.' In all these cases a wish is not formally expressed by the speaker, but inferred by the hearer. They are therefore instances of that tendency which mankind universally discover to abbreviate their language, especially in cases where the passions or feelings are interested.

78. The interrogative and optative modes being set aside as superfluous, it would appear from our investigation, that the real distinct modes of the verb, which are found in the most copious and varied language, are only three; the indicative, the subjunctive, and the imperative: and that these are all that can be considered as necessary; the first to indicate the speaker's feeling or doing, the second to indicate his capacity of feeling or acting, and the third to indicate his desire that the person to whom he speaks should feel or act.

Here again we have the misfortune to find ourselves differ in opinion with Dr Gregory; who seems to think that a greater number of modes, if not absolutely necessary, would, however be highly useful. His words are: 'All languages, I believe, are defective in respect of that variety and accuracy of combination and of distinction, which we know with inable certainty take place in thought. Nor do I know of any particular in which language is more deficient than in the expressing of those energies or modifications of thought; some of which always are, and all of which might be expressed by the grammatical modes of verbs. Of this there cannot be a clearer proof than the well-known fact, that we are obliged to express by the same mood very different modifications or energies of thought. As, for instance, in the case of the grammatical mood called the imperative, by which we express occasionally prayer to God, command to a slave, request to a superior, advice to an equal or to any one, order as from an officer to his subaltern, supplication to one whom we cannot refuse.'—If these be, as the author calls them, specific differences of thought, he will not freely object to their being all ranked under one genius, which may be called desire (x). That the internal feelings which prompt us to pray to God, to command a slave, to request a superior, to advise an equal, to give an order to an inferior, and to supplicate one whom we cannot refuse, are all different in degree, cannot be denied. Each of them, however, is desire; and the predication, by which the desire is made known to the person whom we address, is the same in all, when we utter a prayer as when we utter a command, when we request as when we supplicate. But predication alone is that which constitutes the verb; for desire by itself, however modified, can be expressed only by an abstract noun; and the mere energy of desire, when not applied to a particular energizer, can be expressed only by a participle, or by what is commonly, though improperly called the infinitive mode. Now it is certainly conceivable, that a few shades of meaning, or a few (y) degrees of one general energy, might be marked by

(x) 'Desire;—with, with eagerness to obtain or enjoy.'—Johnson.

The uneasiness a man finds in himself upon the absence of any thing, whose present enjoyment carries the idea of delight with it, is that we call desire. Good and evil, present and absent, work upon the mind; but that which immediately determines the will, from time to time, to every voluntary action, is the uneasiness of desire, fixed upon some absent good.'—Locke.

This, whether it be found philosophy or not, is surely sufficient authority for using the word desire to denote the genus of which prayer, command, advice, supplication, &c. may be considered as so many distinct species. (y) Dr Gregory seems to think, that not barely a few, but a vast number, of these energies might be so marked.
by corresponding variations of such verbs as combine energy with predication; and there could be no great impropriety in calling those variations modes of modes; but that such a multiplication of modes would be an improvement in language, is by no means evident. The verb, with the modes and tenses which it has in all languages, is already a very complex part of speech; which few are able, and still fewer inclined, to analyze: and it would surely be of no advantage to make it more complex by the introduction of new modes, especially when those degrees of energy which could be marked by them are with equal occasion introduced. The indicative, subjunctive, and imperative, are therefore all the modes of the verb which to us appear to be in any degree necessary or expedient; and they are in fact all the modes that are really found in any language with which we are acquainted.

For the infinitive, as has been already observed, the infinitive on every account to be improperly styled a tense no mode. To that name it has no title which we can perceive, except that its termination sometimes (for ever the verb this is not true universally) differs in the learned languages from the terminations of the other parts of the verb. Nay, if infinitive be, as it has been proved to be, the very essence of a verb, it will follow, that the infinitive is no part of the verb at all; for it expresses no affirmation. It forms no complete sentence by itself, nor even when joined to a noun, unless it be aided by some real part of a verb either expressed or understood. Scribo, scribis, scribit, scripserit, scripsisse, scripsit; I am writing, I was writing, I have written, I shall write, I shall have written, do each of them contain an affirmation, and constitute a complete sentence: but scribere "to write" scripsisse "to have written," affirm nothing, and are not more applicable to any one person than to another. In a word, the infinitive is nothing more than a detached noun (2), designating the simple energy of the verb, in conjunction with

"Affirming (says he), denying, refusing, foretelling, asking, unlawfully, wishing, hoping, expecting, believing, knowing, doubting, supposing, stipulating, being able, commanding, praying, requesting, supplicating, loving, hating, fearing, despairing, being accosted, wondering, admiring, wavering, swearing, advising, refusing, exhorting, dissuading, encouraging, promising, threatening, &c. all admit very readily of being combined with the general import of a verb." He adds, that "if every one of them had been expressed in all languages by variations as striking as those of τοῦτος, τούτουμεν, and τοῦτοι, they must have been acknowledged as distinct moods of the verb."

If all these words denote different energies of thought, which, however, may be doubted, and if all these different energies, with many others for which, as the author judiciously observes, it is not easy to find names, could, like capacity and desire, be combined with the general action or energy of the verb; and if those combinations could be marked by corresponding variations of that verb; we should indeed acknowledge such variations to be distinct modes, or modes of modes, of the verb. But we doubt much if all this be possible. We are certain that it would be no improvement: for it seems to be evident, either that, in some of the modes, the radical letters of the original verb must be changed, and then it would cease to be the same verb; or that many of the modes must be expressed by words of very unmanageable length; not to mention that the additional complication introduced by so many minute distinctions into a part of speech already exceedingly complex, would render the import of the verb absolutely unintelligible to nine-tenths of those who are justly styled the learned.

(2) In our idea of the infinitive, we have the honor to agree with the learned and excellent Ruddiman; whose words are, "Non inepti hic modus un verbo quislibet verbis nomine est appellatum. Erit enim (si non veres ac temper, quod nonnulli volent, nonum substantivum) significatio erat ei maximem affinis; et quse vicis suffinet pro omnibus eaus. Et quum manifestum esse est additur neutrius generis; ut, Cic. Att. xiii. 29. Cum vivere ipsum turpe sit nobis.—Per. v. 53. Vide easnum, quae est.—Cic. Fin. i. 1. Tum hoc dislijet philosophus.—Petron. c. 52. Meum intelligere noluit, nec se vende. Item, ab urbe ad urbe: ut, Ovid Met. ii. 483. Poffe loqui eripitur, i. e. postes loquendi.—Plaut. Bacch. i. 2. 50. Hic veris perditis, i. e. verecundiam.—Cic. Tufc. v. 38. Lucrum de dolore boni et erudito, cui vivere est cogitare, i. e. ejus vita est cogitare. [Grammaticae Latinae Institutiones: Pars secunda, lib. i. cap. 2, where the reader will find examples of the infinitive used by the best Roman writers as a substantive noun in every case.]

This opinion of Rudder and his ancient grammarians has been lately controverted with much ingenuity by Dr. Gregory; who seems to think, that in the infinitive alone we should look for the essence of the verb delivered of every accidental circumstance, time only excepted. If this be indeed the case, almost every thing which we have said of the verb and its moods, is erroneous and false; and whatsoever its principles of grammar, from the Encyclopedia, will fill his head with a farrago of absurdities. The writer of the article, however, has been at much pains to acquire correct notions of the subject: he has studied the writings of others; he has
with time; and is not a mode, so far as we can conceive, of anything. Thus, Secundus nihil est, is the same with Scientia tua nihili est; and, "Death is certain," with "Ye die is certain."

79. Before we divide the subject of modes, it may not be improper to take notice of the connection which Mr. Harris, after Apollonius, has found between commanding and futurity. "Intreating and commanding (he says) have a necessary respect to the future only. For what have they to do with the present and the past, the nature of which are immutable and necessary?" This is surely confounding commands with the execution of commands. But the learned writer proceeds to inform us, that "it is from the connection of futurity with commands, that the future of the indicative is sometimes used for the imperative mode." The connection, of which he speaks, appears to us entirely imaginary; for futurity has nothing to do with commands, though it may with the execution of them. The present time is the time of commanding, the future of obeying. But supposing the connection real, it would not account for the future tenses being used imperfectly. For although it is future, it would not follow that the relation is convertible, or that employing the future should imply a command. The principle upon which such expressions as, Thou shalt not kill, come to have the force of a command, seems to be this. When a person, especially one possessed of authority, affirms that an action, depending on the will of a free agent, and therefore in its own nature contingent, shall or shall not actually take place; what are we to conclude from such an affirmation? Why surely it is natural to conclude, that it is in his will, his command, that his affirmation be verified. The English word shall, if we be well informed, denoted originally obligation; a sentence in which its past tense should be still has consulted several persons of undoubted learning, who have devoted a great part of their time to grammatical investigations; and he is extremely unwilling to suppose, that all his inquiries respecting the most important part of speech have ended in error. He trusts, therefore, that he shall not be deemed a pedant caviller, though he examine with some severity the principal observations and arguments upon which the Doctor has built his theory. Upon that examination he enters with diffidence: for the learned Professor's knowledge of the various powers of the mind appears, even in this essay, to be such as eminently qualifies him for ascertaining the precise import of every species of words employed for the purpose of communicating thought; and with such a man the present writer would be much happier to agree than to differ in opinion.

The Doctor concludes (Transact. of the Royal Society, Edinburgh, Vol. II. lit. clas. p. 195), that the infinitive is most improperly called a mode: and on that account he thinks we ought to turn our thoughts exclusively to it, "when we endeavour to investigate the general import of the verb with a view to ascertain the accident which it denotes; and be led, step by step, to form a distinct notion of what is common in the accidents of all verbs, and what is peculiar in the accidents of the several classes of them, and thereby be enabled to give good definitions, specifying the essence of the verb." It may be true, that the infinitive exclusively we should turn our attention, when we wish to ascertain the accident denoted by a particular verb or class of verbs; i.e. the kind of action, passion, or state of being, of which, superadded to affirmation, that verb or class of verbs is expressive: but in accidents of this kind, it may be doubted if there be any thing that with propriety can be said to be common to all verbs. There seems indeed to be nothing common to all verbs, but that which is essential to them, and by which they are distinguished from every other part of speech; but every kind of action, passion, and state of being, may be completely expressed by participles and abstract nouns; and therefore in such accidents we cannot find the essence of the verb, because such accidents distinguish it not from other parts of speech. Were a man called upon to specify the essence of verbs or modes, he would not say, that it consists in the meaning of the words, or in the using of these verbs according to the rules of syntax. In every kind of verse where words are used they have indeed a meaning, and in all good verses they are grammatically constructed; but this is likewise the case in prose, and therefore it cannot be the essence of verbs. The essence of verbs must consist in something which is not to be found in prose, viz. a certain harmonic succession of sounds and number of syllables; and the essence of the verb must likewise consist in something which is not to be found in any other part of speech; and that, we are persuaded, is nothing but affirmation. But if affirmation be the very essence of the verb, it would surely be improper, when we endeavour to ascertain the general import of that part of speech, to turn our thoughts exclusively to a word which implies no affirmation; for what does not affirm, cannot in strictness of truth be either a verb or a mode of a verb.

In the same page it is said, that "the indefinite denotes that kind of thought or combination of thoughts, which is common to all the other modes." In what sense this is true, we are unable to conceive: it denotes indeed the same accident, but certainly not the same thought or combination of thoughts. In the examples quoted, Non est vivere sed valere vita, &c. the infinitives have evidently the effect of abstract noun, and not of verbs; for though vivere and valere express the same states of being with vivo and valeo, they by no means express the same combination of thoughts. Vivo and valeo affirm that I am living, and that I am well; and he who utters these words must think that life and health in the abstract, but of life and health as belonging to himself. Vivere and valere, on the other hand, affirm nothing; and he who utters them thinks only of the states of living and of being in health, without applying them to any particular person.

The exquisitely learned author of The Origin and Progress of Language, having said that the infinitive is used either as a noun, or that it serves to connect the verb with another verb or a noun, and so is useful in syntax, the Doctor combats this opinion, and infers the infinitive to be truly a verb; because "the thought expressed by
Of verbs, as they are active, passive, or neuter.

86

By means of it, may be expressed in synonymous and convertible phrasés, in different languages, by means of other parts or moods of the verb. "Of these synonymous and convertible phrasés he gives several examples, of which the first is taken from Hamlet's soliloquy. "To be or not to be, that is the question," he thinks equivalent in meaning to, "The question is, whether we shall be or shall not be?" But we are persuaded he is mistaken. "Whether we shall be or shall not be," is a question asking, whether we shall exist at some future and indefinite time? But the subject of Hamlet's debate with himself was not, Whether, if his conscious existence should be interrupted, it would be afterwards at some future and indefinite time restored? but whether it was to continue uninterrupted by his exit from this world? This, we think, must be self-evident to every reader of the Soliloquies. Likewise, it is evident to us, that the word "question" in this sentence does not signify interrogatory, but subject of debate or affair to be examined; and that the word that serves for no other purpose than to complete the verbe, and give additional emphasis, perhaps, to an inquiry so important. "To be or not to be, that is the question," is therefore equivalent in all respects to "The continuance or non-continuance of my existence, is the matter to be examined;" and the indefinite is here indisputably used as an abstract noun in the nominative case. Should it be said, that the Doctor may have taken the sentence by itself, unconnected with the subject of Hamlet's soliloquy; we beg leave to reply that the opposition is impossible; for, independent of the circumstances with which they are connected, the words "To be or not to be" have no perfect meaning. Were it not for the subject of the soliloquy, from which every reader supplies what is wanting to complete the sentence, it might be asked, "To be or not to be"—"What? A coward, a murderer, a king, or a dead man! Questions all equally reasonable, and which in that case could not be answered.

With the same view, to prove the infinitive to be truly a verb, the Doctor proceeds to remark upon the following phrasés, Dico, credo, puto, Titius expriser, valere, jacere, eccidisse, procubuisse, projectus, quod Titus exprisit, quod jacet, quod eccidisset, &c. He adds, that "the infinitives, as thus used, acquire no other further meaning, in addition to the radical import of the verb with tenœ, like the proper moods; but the subjunctives after quod lose their peculiar meaning as moods, and signify no more than bare infinitives." In the sense in which this observation is made by the author; the very reverse of it seems to be the truth. The infinitives, as thus used, acquire, at least in the mind of the reader, something like the power of affirmation, which they certainly have not when standing by themselves whereas, the subjunctives neither lose nor acquire any meaning by being placed after quod. Dico, credo, puto, Titius expriser, valere, jacere, &c. when translated literally, signify, I say, believe, think, Titius to exist, to be well, to lie along; a mode of speaking which, though now not elegant, was common with the best writers in the days of Shakespeare, and is frequently to be found in the writings of Warburton at the present day. Dico, credo, puto, quod Titus exprisit, quod jacat, &c. signifies literally, I say, believe, think, that Titius may exist, may lie along, &c. Remove the verbs in the indicative mood from the former set of phrasés, and it will be found that the infinitives had acquired a meaning, when conjoined with them, which they have not, when left by themselves; for Titius expriser, jacere; "Titius to exist, to lie along," have no complete meaning, because they affirm nothing. On the other hand, when the indicative verbs are removed, together with the wonder-working quod, from the latter set of phrasés, the meaning of the subjunctives remains in all respects as it was before the removal; for Titius exprisit, jacat, &c. signify, Titius may exist, may lie along, as well when they stand by themselves as when they make the final clauses of a compound sentence. Every one knows, that quod, though often called a conjunction, is always in fact the relative pronoun. Dico, credo, puto, quod Titus exprisat, must therefore be confounded thus: Titus exprisat (part. pr.) quod dico, credo, &c. "Titius may exist in that thing, that proposition, which I say, believe, think." In the former set of phrasés, the infinitives are used as abstract nouns in the accusative case, denoting, in conjunction with Titius, one complex conception, the existence, &c. of Titius: Dico, credo, puto; "I say, believe, think;" and the object of my speech, belief, thought, is, Titius expriser, "the existence of Titius."
All verbs have a necessary reference to a noun in the nominative case.

Active verbs transitive or intransitive.

87

Active verbs denote action, and consequently of verbs denoting action, there are obviously two kinds. There is an action which passes from the agent to some subject, upon which he is employed; and there is an action which respects no object beyond the agent himself. Thus lego and ambulo are verbs which equally denote action: but the action of lego refers to some external object as well as to the agent; for when a man is reading, he must be reading something, a book, a newspaper, or a letter, &c. whereas, the action of ambulo is confined wholly to the agent; for when a man is walking, he is employed upon nothing beyond himself,—his action produces no effect upon any thing external. These two species of verbs have been denominated transitive and intransitive; a designation extremely proper, as the distinction which gave rise to it is philosophically just. Verbs of both species are active; but the action of these only which are called transitive, refers to an external object: and therefore, in these languages of which the nouns have cases, it is only after verbs which are transitive as well as active, that the noun denoting the subject of the action is in the accusative or objective case. Verbs which are intransitive, active, though they be really active, are in the structure of sentences considered as neuter, and govern no case.

And so much for that most important of all words the verb. We proceed now to the consideration of participles, adjectives, and adverbs; which, as they have a near relation to one another, we shall treat of in the same chapter.

CHAPTER V.

Of Participles, Adjectives, and Adverbs.

SECTION I. Of Participles.

81. The nature of verbs being understood, that of Participles is not of difficult comprehension. Every denote an verb, except that which is called the subjunctive verb is expreffive of an attribute of time, and of an affection. Now, if we take away the affection, and thus destroy the verb, there will remain the attribute and the time; and these combined make the essence of that species of words called

In confirmation of the same idea, that the infinitive is truly a verb, the author quotes from Horace a passage, which, had we thought quotations necessary, we should have urged in support of our own opinion:

Nec quicquam tibi profest
Aerias tentasse domos, animoque rotandum
Percurrisse polium, moriturus.

To our apprehension, nothing can be clearer than that tentasse and percurreste are here used as nouns; for if they be not, where shall we find a nominative to the verb profest? It was certainly what is signified by tentasse aerias domos, animoque rotandum percurrese polium, that is said to have been of no advantage to Archias at his death. This, indeed, if there could be any doubt about it, would be made evident by the two prose versions, which the professor supposes to be beautiful lines. The first of which is as follows: Nec quicquam tibi profest quod aerias domos tentaveris, et animo percurreste polium: which must be thus confirmed: Tentaveris aerias domos, et percurreste animo polium (sub id) quad nec quicquam tibi profest. This version, however, is not perfectly accurate; for it contains two propositions, while Horace's lines contain but one. The second, which, though it may be a crabb'd inelegant sentence, expresses the poet's sense with more precision, is in these words: Nec quicquam tibi profest moriturus tua tentatio domum aerius et cursus tus circa polium. Having observed, with truth, that this sentence has the same meaning with the lines of Horace, Dr Gregory asks, "Why are not tentatio and cursus reckoned as verbs as well as tentasse and percurreste?" Let those answer this question who believe that any of these words are truly verbs; for they are surely as he adds, all very near akin; indeed so near, that the mind, when contemplating the import of each, cannot perceive the difference. Mean while, we beg leave in our turn to ask, Why are not tentatio and percurreste reckoned abstract nouns as well as tentatio and cursus? To this question it is not easy to conceive what answer can be returned upon the Doctor's principles. In his theory there is nothing satisfactory; and what has not been done by himself, we expect not from his followers. On the other hand, our principles furnish a very obvious reason for excluding tentatio and cursus from the class of verbs; it is, because these words express no predication. Tentasse and percurreste indeed denote predication no more than tentatio and cursus; and therefore upon the same principle we exclude them likewise from a class to which, if words are to be arranged according to their import, they certainly do not belong.

Should the reader be inclined to think that we have dwelt too long on this point, we beg him to reflect, that if our ideas of the essence of the verb and of the nature of the infinitive be erroneous, every thing which we have laid of modes and Tenes is erroneous likewise. We were therefore willing to try the solidity of those principles which hold the essence of the verb to consist in energy: and we rejected Dr Gregory's theory for the subject of examination, not from any disrespect to the author, whom the writer of this article never knew; but because we believe his abilities to be such, that

Si Pergamu dextra
Defendi passum, etiam has defensa sua sunt.
PARTICIPEs. Thus take, away the affection from the verb writing, and their remains the participle written; which, without the affection, denotes the same attribute and the same time. After the same manner, by withdrawing the affection, we discover written in written; written about to write in written shall be written. This is Mr. Harris's doctrine respecting participles; which, in our opinion, is equally elegant, picturesque, and just. It has, however, been controverted by an author, whose rank in the republic of letters is such, that we should be wanting in respect to him, and in duty to our readers, were we to pass his writing yesterday, and I shall be writing to-morrow. This is acknowledged by Dr. Beattie, that this, which we have taken, is the most convenient light in which the participle can be considered in universal grammar: and yet he affirms that present participles do not always express present time, nor preterite participles past time; may, that participles have oftentimes no connection with time at all. He thus exemplifies his affection, in Greek, in Latin, and in English.

When Cebeus says, άρσν δ τον τάφυ του Σαύρων, the participle of the present, walking, is by means of the verb were applied to time past; and therefore of itself cannot be understood to signify any sort of time. Again, after observing, that in English we have but two simple participles, such as writing and written, of which the former is generally considered as the present and the latter as the past, the Doctor adds, But the writing joined, when a verb of different tenses, may denote either past or future action; for we may say not only, I am writing, but also, I was writing yesterday, and I shall be writing to-morrow; whence he infers that no time whatever is denoted by the present participle. But surely this is a hasty inference, drawn from the doctrine of absolute time and a definite present, which we have already flown to be groundwork and contradictory. When we speak simply of an action as present, we must mean that it is present with respect to something besides itself, or we speak a jargon which is unintelligible, but we do not ascertain the time of its presence. From the very nature of time, an action may be present now, it may have been present formerly, or it may be present at some future period; but the precise time of its presence cannot be ascertained even by the present of the indicative of the verb itself; yet who ever supposed that the present of the indicative denotes no time? The participle of the present represents the action of the verb as going on; but an action cannot be going on without being present in time with something. When, therefore, Cebeus says, "We were walking in the temple of Saturn," he represents the action of the verb walk as present with something; but by using the verb expressive of his affection in a past tense he gives us to understand that the action was not present with anything at the period of his speaking, but at some portion of time prior to that period: what that portion of time was, must be collected from the subsequent parts of his discourse. The same is to be said of the phrases I was writing yesterday, and I shall be writing to-morrow. They indicate, that the action of the verb was present with me yesterday, and will again be present with me to-morrow. The action and the time of action, are denoted by the participle; that action is affirmed to belong to me by means of the verb; and the time at which it belonged to me is pointed out by the tenses of that verb was, was, and shall be. All this is so plain, that it could not have escaped Dr. Beattie's penetration, had he not hastily adopted the absurd and contradictory notion of a definite present.

Of the truth of his affection respecting past participles he gives a Greek and a Latin example. The former is taken from St. Mark: εἰ ἀμαωσαν τοῦθεν; and the latter is that which is commonly called the perfect future of the passive verb aman, amatus fuerat. In the first instance, he says that the participles, though belonging to the sorith of the past time, must be rendered either by the indefinite present, "he who believest;" or by the future, he who will believe; and the reason which he gives for this rendering of the word is, that the believing here spoken of is considered as posterior in time to the enunciation of the promise." This is indeed true, but it is not to the purpose; for with the enunciation of the promise, the time of the participle has no manner of concern. The time of present depends entirely upon the time of the subject, with respect to which it must undoubtedly be past. Our Lord is not here alluring him who shall believe, at the day of final retribution, shall be saved, but that he who shall on that day be found to have believed in time past, shall be saved: and if the participle had not been expressive of a past perfect action and a past time, the whole sentence would have conveyed a meaning not friendly to the interests of the gospel. In like manner, the time of amatus is referred, not to the time of speaking, but to the time of such, with respect to which, he fees not that it is past? The two words, taken together, contain a declaration, that he who utters them shall, he sometime remembereth that of speaking, have been loved, shall have been loved denotes two times, both future with respect to the time of speaking; but when the time, denoted by shall have, comes to be present, that of the participle loved must be past, for it is declared that the action of it shall then be complete and finished.

We conclude, then, that it is essential to a participle to express both an attribute and time; and that such words as denote time, though they may be in the form of participles, as done is learned, elegent is eloquent, &c. belong to another part of speech, which we now proceed to consider.

SECT. II. OF ADJECTIVES.

82. The nature of verbs and participles being understood, that of adjectives becomes easy. A verb implies a quality, quantity, or relation, as doth, is learned, is eloquent, &c. are all denoted by adjectives.

83. To understand the import and the use of this they have species of words, it must be observed that every adjective the import of abstract adjectives necessarily involves an expression of relation equivalent to that. Thus, a good man is a man of good will; where we fee the attribute denoted by the adjective fully expressed by an adjectival noun. But it is evident.
the back of the horse. In the use of this word, it is well known that the idea first in order, as being the principal subject of the proposition, is commonly the man on the back of the horse; but it is not so always, for the mind may consider the horse as the principal object. Thus when Virgil says,

Insulare solo, et Graecus gloriosus superbus

the energies attributed to the object signified by equestem, make it evident that the horse and not the man is meant; for it is not the property of a man, insulare solo, et graecus gloriosus superbus.

The same observation holds true where the complex object is denoted by two or more words; an adjective, for instance, and a substantive. Thus in the phrase summus mons tertius subida condit, the words summus mons represent a complex conception, of which the constituent ideas are those of height and mountain, connected together by the substantive form of summus. Either of these ideas may be the subject of the proposition; and the expression will accordingly admit of two different significations. If mons be made the subject of the proposition, the meaning will be, ‘the highest mountain rises itself among the clouds.’ If the substantive included in the radical part of summus be made the subject of the proposition, the expression will signify, ‘the summit, or highest part of the mountain, rises itself among the clouds.’ The latter is the true import of the sentence.

From these observations and examples, we shall be enabled to understand the two uses of the adjective. Two uses: It is either employed, as has been already observed, of the adjectival to restrict or modify a general term; or the adjectival substantive. The substantive contained in the adjective is modified by the noun, with which, in the concrete or substantive form, that adjective substantive is joined. The first may be called the direct, the second the inverse, acceptance of adjectives.

The inverse acceptance of adjectives and participles (for both are used in the same manner) has not, except in a very few instances, been noticed by any grammarian; yet the principle involved is no less evident in any language. In order to explain it, we shall produce a few examples; which on any other principle it is impossible to understand.

Livy, speaking of the abolition of the regal authority at Rome, says Regnatum est post ab urbe condita, ad libertatem annos ducentos quadraginta quattuor, ‘Monarchy lifted at Rome, not from the city built (which would convey no meaning), but from the building of the city, to its deliverance,’ &c. Both the participles condita and libertatem are here used inversely; that is, the substantive substantive contained in condita and libertatem is modified or restricted by the substantive urbe and urbem, with which they unite. Again, Ovid, speaking of the contest between Ajax and Achilles for the arms of Achilles, has these lines:

Nam illis etiam seseque Nestora sinit.

Quam repetit, dextrae dejecta Nestora cinerem

Nullum ut iuvate.

Here also the adjective or participle desertum is taken inversely, and the general notion of desertion contained in it is modified or rendered particular by being joined with the substantive Nestora. The meaning of the passage reads, etc., in the substantive Nestora: and the substantive or participles desertum is ‘modified’ or restricted by the substantive Nestora.
The impo

It were easy to produce many more examples of
adjetives taken inverisly; but these may suffice to illus-
strate the general principle, and to show, that without
attending to it, it is impossible to understand the an-
cient authors. We shall adduce one instance of it from
Shakespear, to evince that it is not

from

itself only to an adjetive or participle, or a verb significant of an attribute; it does not attach itself to the pure verb,
to be a very just appellation, as denoting a part of speech, the natural appendage of such verbs. So great is this dependence in grammatical syntax, that an adverb can no more subsist without its verb, i.e. without some word signifying of an attribute, than a verb or adjective can subsist without its subject. It is the same here as in certain natural subjects. Every colour, for its existence, as much requires a superlative, as theSuperlative for its existence requires a solid body. At the mention of the attributes we reckon quantity and quality; thus we say a white garment, a high mountain, etc. Now some of these quantities and qualities are capable of intensity or remission; or, in other words, one attribute may have them in a greater or lesser degree than another. Thus we say, a garment exceedingly white, a mountain tolerably or moderately high. Hence, then, one copious source of secondary attributes or Adverbs, to denote these two, that is, intensity and remission; such as greatly, tolerably, fairly, extremely, indifferently, etc.

But where there are different intensions of the same attribute, they may be compared together: Thus, if the garment A be exceedingly white, and the garment B more nearly white, we may say, the garment A is more white than the garment B. This paper is white, and so is white; but snow is more white than this paper. In these instances, the adverb more not only denotes intensity, but relative intensity; nay, we speak not here, as we customarily do, of other degree than another. Thus we say, Sophocles was wife, Socrates was more wife than he, but Solomon was the most wife of men. Even verbs, properly speaking, which denote an attribute as well as an action, must admit both of simple and of comparative intensions; but the simple verb is to be admitted of neither the one nor the other. Thus, in the following example, he loves more than X; but the X, if not the Y, is the object of the verb, admits neither of intensity nor remission, but is the same in all possible propositions.

91. From this circumstance of quantities and qualities being capable of intensity and remission, arise the comparison of adjectives, and its different degrees, which cannot well be more than the two species above-mentioned; one to denote simple, and one to denote superlative. We were indeed to introduce more degrees than these, we ought perhaps to introduce infinite, which is absurd. For why stop at a limited number, when, in all subjects susceptible of intention, the intermediate extents are in a manner infinite? Between the first simple white and the superlative white is there an infinite degrees of more white; and the same may be said of more great, more strong, more minute, etc. The doctrine of grammarians about three such degrees of comparison, which they call the positive, the comparative, and the superlative, must be absurd; both because in their positive there is no comparison at all, and because their superlative is comparative as much as their comparative itself. Examples to evince this may be met with everywhere: Socrates was the most wise of all the Athenians; Homer was the sublame of all poets, etc. In this sentence Socrates is evidently compared with the Athenians, and Homer with all other poets. Again, if it be said that Socrates was more wise than any other Athenian, but that Solomon was the most wise of men, is not a comparison of Solomon with mankind in general, as plainly implied in the last clause of the sentence, as a comparison of Socrates with the other Athenians in the first?

But if both imply comparison, it may be asked, In what consists the difference between the comparative and superlative? Does the superlative always express a greater excess than the comparative? No: for through Socrates was the most wise of the Athenians, and is Solomon affirmed to have been more wise than he; so that here a higher superiority is denoted by the comparative more than by the superlative most. Is this then the difference between these two degrees, that the superlative implies a comparison of one with many, while the comparative implies only a comparison of one with one? No: this is not always the case. Either the Pilgrim says, that he is a better wife or more wife than all his mistresses;" where, though the comparative is used, there is a comparison of one with many. The real difference between these two degrees of comparison may be explained thus:

When we use the superlative, it is in consequence of having compared individuals with the species to which they belong, or one or more species with the genus under which they are comprehended. Thus, Socrates was the most wise of the Athenians, and the Athenians were the most enlightened of ancient nations. In the first clause of this sentence, Socrates, although compared with the Athenians, is at the same time considered as one of them; and in the last, the Athenians, although compared with ancient nations, are yet considered as one of those nations. Hence it is that in English the superlative is followed by the preposition of, and in Greek and Latin by the genitive case of the plural number; to show, that the object which has the pre-eminence is considered as belonging to that class of things with which it is compared.

But when we use the comparative degree, the objects compared are set in direct opposition; and the one is considered not as a part of the other, or as comprehended under it, but as something altogether distinct and belonging to a different class. Thus, were one to say, Cicero was more eloquent than the Romans, he would speak absurdly; because every body knows, that of the classes of men expressed by the word Romans Cicero was one, and such a sentence would affirm that orator to have been more eloquent than himself. But when it is said that Cicero was more eloquent than all the other Romans, or than any other Roman, the language is proper, and the affirmation true: for though the persus spoken of were all of the same class or city, yet Cicero is here set in contradistinction to the rest of his countrymen, and is not considered as one of the persons with whom he is compared. It is for this reason that in English the comparative degree is followed by a noun governed by the word of contradistinction then, and in Latin by a noun in the ablative case governed by the preposition pro (a) either expressed or understood. We have already observed, that the ablative case denotes concomitancy, and therefore when
an adjective in the comparative degree is prefixed to a noun, that noun is put in the ablative case, to denote that two things are compared together in company; but by means of the preposition, expressed or understood, that which is denoted by the comparative adjective is seen to be preferred for that which is denoted by the noun.

205 Or by inflection.

We have hitherto considered comparatives as expressed by the words more and most; but the authors, or improvers of language, have contrived a method to retrench the use of these adverbs, by expressing their force by an inflection of the adjective. Thus instead of more fair, they say fairer; instead of most fair, fairest; and the same method of comparison takes place in both the Greek and Latin Languages; with this difference, however, between the genius of these languages and ours, that we are at liberty to form the comparison either in the one method or in the other; whereas in those languages the comparison is seldom if ever formed by the assistance of the adverb, but always by the inflection of the adjective. Hence this inflection is by the Greek and Latin grammarians considered as a necessary accident of the adjective; but it has reached no farther than to adjectives, and participle forms having the nature of adjectives. The attributes expressed by verbs are as susceptible of comparison as those expressed by adjectives; but they are always compared by means of adverbs. The verb being too much diversified already to admit of more variation without perplexity.

206 Comparatives sometimes lose their relative nature.

As there are some qualities which admit of comparison, so there are others which admit of none; such, for example, are those which denote that quality of bodies arising from their figures; as one square table, a quadrangular court, a conical piece of metal, &c. The reason is, that a million of things participating the same figure, participate it equally, if they do it at all. To say, therefore, that while A and B are both quadrangular, A is more or less quadrangular than B, is absurd. The same holds true in all attributes denoting definite quantities of whatever nature: for as there can be no comparison without intention or remission, and as there can be no intention or remission in things always definite, therefore these attributes can admit of no comparison. By the same method of reasoning, we discover the cause why no sublatives are susceptible of these degrees of comparison.

A mountain cannot be said more to be or to exist than a mole-hill; but the more or less must be fought for in their quantities. In like manner, when we refer many individuals to one species, the lion A cannot be called more a lion than the lion B (c); but if more any thing, he is more fierce, more fruitful, or exceeding in some such attribute. So again, in referring many species to one genus, a crocodile is not more an animal than a lizard; nor a tiger more than a cat; but, if any thing, the crocodile and tiger are more bulky, more strong, &c., than

K 2

compared as of the same class; and when we use the comparative, as of different classes; yet is not this distinction always attended to by the best writers in any language. In Latin and Greek the comparative is sometimes used, where in English we should use the superlative; as dextra est forter manus; and in the Gospel is said, that "a grain of mustard-seed is the smallest of all seeds, but when grown up it is the greatest of garden herbs." Even in English, the custom of the language permits us not to say "he is the taller of the two," but must the taller of the two; but we cannot say "he is the taller of the three." For these and other deviations from the general rule no reason is to be found in the nature of things; they are errors made proper by use.

(c) In English, the termination -est is peculiar to the superlative of comparison, to which the definite article is prefixed. Thus we may say, "Homer was the sublimest of poets;" but we cannot say, "Homer was a sublimest poet." Again, we may say, "Homer was a very sublime poet;" but nor, "Homer was the very sublimest poet."
The animals with which they are compared; the excess, as before, being derived from their attributes.

95. Of the adverbs or secondary attributive already mentioned, those denoting intention and resolution may be called adverbs of quantity continuous, as greatly, vailly, tolerably, &c. once, twice, threc, &c. (e) are adverbs of quantity discrete; more and most, less and least, to which may be added equally, proportionally, &c. are adverbs of relation. There are others of quality, as when we say, honestly industrious, modestly brave; they fought bravely, he painted finely.

And here it may be worth while to observe, how the same thing, participating the same essence, assumes different grammatical forms from its different relations. For example, suppose it should be asked, How differ honest, honestly, and honesty? The answer is, They are in essence the same; but they differ in as much as honest is the attributive of a noun, honestly, of a verb, or adjective; and honestly being divided of these, its attributive relations assumes the power of a noun or substantival to, as to stand by itself.

96. The adverbs hitherto mentioned are common to verbs of every species; but there are some which are confined to verbs properly so called, that is, to such verbs as denote motions or energies with their privations. All motion and rest imply time and place as a kind of necessary coincidence. Hence, when we would express the place or time of either, we have recourse to adverbs formed for this purpose, as of place, as when we say he stood there; he went hence, he came thither, of time, as when we say, he stood there; he went thence, he travelled hence, to thence. To these may be added the adverbs which denote the intentions and resolutions peculiar to motion, such as speedily, hastily, swiftly, slowly, &c. as also adverbs of place made out of prepositions, such as upward and downward from up and down. It may, however, be doubted whether some of these words, as well as many others, which do not so properly modify attributes, as mark some remote circumstance attending an attribute or our way of conceiving it, are truly adverbs, though so called by the grammarians. The simple affirmative and negative eves and no are called adverbs, though they surely do not signify that which we hold to be the very essence of the verb, a modification of attributes. Is he learned? No, or Is he brave? Yes, and that he is, or he was, or he is, or he was, or the like.

Adverbs are indeed applied to many purpofes; and their general nature may be better understood by reading a list of them, and attending to their etymology, than by any general description or definition. Many of them seem to have been introduced into language in order to express by one word the meaning of two or three; and are mere abbreviations of nouns, verbs, and adjectives. Thus, the import of the phrase, in what place, is expressed by the single word where; to what place, by whither; from this place, by hence; in a direction ascending, by upwards; at the present time, by now; at what time, by when; at that time, by then; many times, by often; not many times, by seldom, &c.

97. Mr Horne Tooke has, with great industry and accuracy, traced many of the English adverbs from their origin in the ancient Saxon and other northern tongues, and shown them to be either corruptions of other words or abbreviations of phrases and sentences. He observes, that "all adverbs ending in ly, the most prolific branch of the family, are sufficiently understood: the termination being only the word like corrupted; and the corruption to much the more easily and certainly discovered, as the termination remains more pure and distinguishable in the other English languages, in which it is written tick, lyk, lig, liges." He might have added, that in Scotland the word like is, at this day, frequently used instead of the English termination ly; as for a goodly figure, the common people say a good like figure. Upon this principle the greater part of adverbs are resolved into those parts of speech which we have already considered, as honestly into honest-like, vailly into self-like, &c. In that we say of a man he is honestly industrious, we affirm that he is honest-like industrious, or that his industry has the appearance of being honest. Adverbs of a different termination the same acute writer resolves thus: A HAST into the past participle A GAZED, the French exclaimed,—the devil was in arms. All the whole army stood agazed on him. Shakespeare, into the past participle A GONE or COWE. Andek he drives from ASUNDER, separated; the past participle of the Anglo Saxon verb ADJUIN: a word which, in all its varieties, is to be found, he says, in all the northern tongues; and is originally from fand, i.e. fund. To wit, from WITT, to know; as widiject and felicit, in Latin, are abbreviations of widere-late and sine lice. Needs, he resolves into need is, used parenthetically as, "I must needs do such a thing," "I must (need is) do such a thing," i.e. "I must do it, there is need of it." Axon, which our old authors use for immediately, instantly, means, he says, in one; i.e. in one instant, moment, twixt. And, "And right above without more abode," "Axon in all the haste I can, the Dutch, senc is one and senc-en alone; and all-senc-like, only, anciently alone. Alive is on live, or twixt. Thus, "Christ ever on live." Chaucer, AUGHT OF OUGHT: A WHIT or O WHIT; or being formerly written for the article a, or for the numeral one; and whit or whits, in Saxon, signifying a small thing, a point or jot. Awhile, which is usually clasped with adverbs, is evidently a noun with the indefinite article prefixed; a while, i.e. a time. Whilst, anciently and more properly whiles, is plainly the Saxon whilsts, time that. Aloft was formerly written ON-LOFT; as, "And ye, my mother, my fovereine plaiseance." Over al thing, set Christ on loft. Chaucer, Now, says Mr Horne Tooke, left, in the Anglo Saxon, is.
GR A M M A R.

is in the air or the clouds, as in Lyfle Cummende, coming is the clouds, (St Luke.) In the Danish, Luft is air; and Luft is air; and at a strange is Luft is, ‘sto blow up into the air, or aloft.

So in the Dutch, de loof hebben, to fail before the wind; loofen, to ply to windward; loof, the weather gate, &c. From the same root are our other words: Left, lefty, to left, lee, toward, left, &c. It would be needless, as the ingenious author observes, to notice such adverbs as aloft, adays, ahoire, altays, aught, alyed, aback, ahead, afoot, alee, aloud, alyde, afoot, aroound, alynd, &c. These are at first view seen for what they are. Nor shall we follow him through the analysis which he has given of many other adverbs, of the origin is not so obvious as of these. Of the truth of his principles we are satisfied; and have not a doubt, but that upon these principles a man conversant with our earliest writers, and thoroughly skilled in the present languages, may trace every English (s) adverb to its source, and shew that it is no part of speech separate from those which we have already considered. The adverbs, however, of affirmation and negative, are of too much importance to be thus passed over; and as we have never seen an account of them at all satisfactory, except that which has been given by Horne Tooke, we shall transcribe the substance of what he says concerning Aye, Yea, Yes, and No. To us these words have always appeared improperly clasped with adverbs upon every definition which has been given of that part of speech. Accordingly, our author says, that Aye or Yea is the imperative of a verb of northern extraction; and means, have, possess, enjoy. And Yes is a contraction of Ayes, have, possess, enjoy, that. Thus, when it is asked, whether a man be present, if the answer be by the word Ayes, have, possess, or Yes, it is equivalent to have that, enjoy that, belief or that proposition. (See what was said of the nature of interrogative, Chap. IV. n° 76.

The northern verb of which yes is the imperative, is in Danish Ejer, to possess, have, enjoy. Eja, aye or yea; Eje, possession; Ejer, possessor. In Swedish it is Ega, to possess; of which the imperative is Ja, aye; Yea: Egare, possessor. In German, Ja signifies aye or yea; Eigen, possessor; owner; Eigen, own. In Dutch, Eigen is aye, yea.

Greenwood derives not and it's abbreviate no from the Latin Minnow, from the Hebrew; and Junius, from the Greek. Our author very properly observes, that the inhabitants of the North could not wait for a word expressive of different till the establishment of those nations and languages; and adds, that we need not be inquisitive nor doubtful concerning the origin and signification of not and so; since we find that, in the

Danish, nodig, in the Swedish, nodig, and in the Dutch, nood, node, and no, mean averse, unwilling.

So that when it is asked whether a man be, if the answer be no, it is a declaration that he who makes it is averse from, or unwilling to admit that proposition.

98. Most writers on grammar have mentioned a species of adverbs, which they call adverbs of interrogation; such as where, whence, whether, how, &c. But the truth is, that there is no part of speech, which, of itself, denotes interrogation. A question is never asked otherwise than by abbreviation, by a single word, whether that word be a noun, a pronoun, a verb, or an adjective. The word where is equivalent to—in what place; whence to—from what place; and how to—in what manner, &c. In these phrases, in what place, in what manner, the only word that can be supposed to have the force of an interrogative, is what, which is resolvable into that which: But we have already explained, in the chapter of Pronouns, the principles upon which the relative is made to denote interrogation, and the same reasoning will account for the adverbs where, whence, whether, how, &c. being employed as interrogatives. Why we say, where were you yesterday? whence have you come? whether are you going? how do you perform your journey? We merely use to many abbreviations for the following sentence; tell us, or describe to us, the place where (or in which) you were yesterday; the place whence (or from which) you have come; the place to which you are going; the manner in which you perform your journey. And in much for adverbs. We now proceed to those parts of speech which are usually called prepositions and conjunctions, and of which the use is to connect two or more simple sentences into one compound sentence.

CHAPTER VI.

Of Prepositions, Conjunctions, and Interjections.

99. It has been observed, that a man while awake objects, is conscious of a continued train of perceptions and of ideas passing in his mind, which depends little upon his own will; that he cannot to the train add a new idea; and that he can but very seldom break its connection. To the slightest reflection these truths must be apparent. Our first ideas are those which we derive from external objects making impressions on the senses; but all the external objects which fall under our observation are linked together in such a manner as indicates them to be parts of one great and regular system.
When we take a view of the things by which we are surrounded, and which are the archetypes of our ideas, their inherent qualities are not more remarkable than the various relations by which they are connected. Cause and effect, contiguity in time or in place, high and low, prior and posterior, resemblance and contrast, with a thousand other relations, connect things together without end. There is not a single thing which appears solitary and altogether devoid of connection. The only difference is, that some are intimately and some slightly connected, some nearly and some at a distance. That the relations by which external objects are thus linked together must have great influence in directing the train of human thought, so that not one perception or idea can appear to the mind wholly unconnected with all other perceptions or ideas, will be admitted by every man who believes that his senses and intellect represent things as they are.

This being the case, it is necessary, if the purpose of language be to communicate thought, that the speaker be furnished with words, not only to express the ideas of substances and attributes which he may have in his mind, but also to indicate the order in which he views them, and thus point out the various relations by which they are connected. In many instances all this may be done by the parts of speech which we have already considered. The closest connection which we can conceive is that which subsists between a substance and its qualities; and in every language with which we are acquainted, that connection is indicated by the immediate coalescence of the adjective with the substantive; as we say, a good man, a learned man; vir bonus, vir doctus. Again, there is a connection equally intimate, though not so permanent, between an agent and his action; for the action is really an attribute of the agent; and therefore we say, the boy reads, the man writes; the noun coalescing with the verb so naturally, that no other word is requisite to unite them. Moreover, an action and that which is called upon being contiguous in nature, and mutually affecting each other, the words which denote them should in language be mutually attractive, and capable of coalescing without external aid; as, he reads a book, he builds a house, he breaks a joint. Further: because an attribute and its modifications are inseparably united, an adjective or a verb is naturally coalesced with the substantive which illustrates or modifies its signification; and therefore, when we say, he walks slowly, he is prudently brave, it is plain that no other word is necessary to promote the coalescence of the attributes walking and bravery with their modifications of slowly and prudently.

The agreement between the terms of any proposition which constitutes truth is absolutely perfect; but as either of the terms may agree with many other things besides its correlate, some word is requisite in every proposition to connect the particular predicate with the particular subject; and that is the office of the simple verb to be; as the three angles of every rectilinear triangle are equal to two right angles.

Thus we see, that many of the relations subsisting between our ideas may be clearly expressed by means of nouns, adjectives, verbs, and adverbs; and in those languages of which the nouns have cases, there is perhaps no relation of more importance which might not be thus pointed out, without being under the necessity of employing the aid of any additional part of speech.

In English, however, the case is otherwise; for were we to say, "He rode Edinburgh, went the parliament-house, walked his council the court met," we should speak unintelligibly; as in these expressions there is either a total want of connection, or such a connection as produces falsehood and non-sense. In order to give meaning to the passage, the several gaps must be filled up by words significant of the various relations by which the different ideas are connected in the mind; as, "he rode to Edinburgh, went to the parliament-house, and walked with his council till the court met." Of these connecting words, to and with are called prepositions, and and till are usually called conjunctions. Although these prepositions and conjunctions are not absolutely necessary in Greek and Latin as they are in English; yet as there is no language wholly without them, nor any language in which it is not of importance to understand their force, they well deserve a place in universal grammar.

The use of conjunctions and prepositions in language is to connect either sentences or other words; but the theory of these connectives themselves has certainly never been understood, unless Mr. HARRIOT has at least hit upon the truth. Mr. HARRIOT writes about thum and about them, quoting passages from Greek and Latin authors, and produces at last no information. His definitions of both, as parts of speech with signification, are highly absurd; and even the principal distinction which he makes between them seems not to be well founded. Prepositions and conjunctions denote the relations subsisting between the ideas expressed by those words or sentences which they serve to connect; and as relations are contemplated by the mind as well as positive ideas themselves, the words which denote those relations cannot be insignificant. The essential difference between the conjunction and preposition, according to the same author, consists in this, that the former connects sentences, and the latter words: but the fact is often otherwise. An obvious example occurs where the conjunction and connects not sentences but words. "A man of wisdom and virtue is a perfect character." Here it is not meant to be alluded, "that the man of wisdom is a perfect character, and that of virtue is a perfect character:" both these affections would be false. This sentence therefore (and many such will occur) is not resolvable into two: whence it follows, that the conjunction and does not always connect sentences; and the same is frequently the case with other conjunctions.

Horne Tooke's idea of prepositions and conjunctions is, that they do not form distinct classes of words, but are merely abbreviations of nouns and verbs: and with respect to the English language, he has been remarkably successful in proving his position. But though such be undeniably the case in English, it would be rash to conclude a priori that it is so in all other tongues. To establish this general conclusion would require a long and tedious deduction in each particular language: and how much learning, leisure, industry, and acuteness, such an undertaking would require, even in one tongue, it is not easy to determine. In the languages with which we are best acquainted, many conjunctions, and most prepositions have the appearance at least of original words: and though this most acute grammarian, from his knowledge of the northern tongues, has been able to trace the most important of those in English to very
very planfible sources, the fame thing would be difficult in other languages of which the sources are obscure, and abolutely impossible in those of which they are wholly unknown. It is, however, a ftrong pre-emption in favour of his opinion, that grammarians have never been able to assign any general charafteristic of those species of words; which, did they confifte in different parts of speech, one would think could not have fo long remained undiscovered. It is a farther presumption in his favour, that many words in Greek and Latin, as well as in English, which have been called conjuctions, are obviously refolvable upon his principles, and indeed discover their meaning and origin upon mere inspection. We shall therefore content ourselves with recalling the common doctrine respecting these parts of speech as far as it is intelligible; subjoining at the bottom of the page the analysis given by Horne Tooke of the forms important English conjuctions and prepositions; and respecting our readers, who would understand the subjeft, to attend more to the relations between their various ideas, than to the frivolous diftinctions which, in compliance with custom, we are compelled to lay before them. We shall treat first of the conjuction.

Sect. I. Of Conjuctions.

116. A conjuction is a part of speech, of which, as its name implies, the function is to connect either two or more words in a sentence, or to make of two simple sentences one compound sentence. It is ufually faid, that conjuctions never connect words, but sentences only; and that this is the circumftance which diftinguishes them from prepositions. We have already given one example which proves this difference to be ill-founded; we shall now give from Horne Tooke one or two more, which will place its abfurdivty in a still clearer light: Two and two are four; John and Jane are a handsome couple; A and B and C form a triangle. Are two four? Is John a couple and Jane a couple? Does one straight line form a triangle? From the subjoined note it appears, that and (g) may connect any two things which can be connected, as it signifies addition.

Conjuctions connecting sentences, fometimes connect their meaning, and fometimes not. For example, let us take these two sentences, Rome was enflaved, Cæfar was ambitious, and connect them together by the conjuction because; Rome was enflaved because Cæfar was ambitious. Here the meanings, as well as the conjuctions, appear to be connected by that natural relation which fubfists between an effect and its caufe; for the enflaving of Rome was the effect of Cæfar's ambition. That particular relation therefore is that which is denoted by the conjuction because (h), which would be improperly used to connect two sentences between which the relation of an effect to its caufe exists not. If it be faid, manners must be reformed, or liberty will be lost; here the conjuction or, though it joins the sentences, yet as to their meaning is a perfect conjuction. Between the reftate words of manner and the loss of liberty there is certainly a natural relation; but it is not the relation of conftancy or fimilitude, or of caufe and effed, but of contrariety. The relation of contrariety therefore is the fignification of the word or (i). And thus it appears, that though all conjuctions may combine sentences, yet, with refeft to the fefte, some are conjunctive and others are disjunctive.

117. Thofe conjuctions which conjoin both sentences and their meaning are either copulative or continuative. The principal copulative in English is and, which have already been confidered. The continuatives are much more numerous; if, and, because, therefore, wherefore, hence, &c. The difference between them is this: The copulative does no more than barely couple words or sentences, and is therefore applicable to all subjects of which the natures are not incompatible (k). The relation which it denotes is that of juxtaposition or of one thing added to another. Continuatives, on the contrary, by a more intimate connecftion, consolidate sentences into one conftant whole; and are therefore applicable only to subjedts which have an effedtual relation to each other, fuch as that of an effedt to its caufe, or of a caufe to its effedt. For example, it is no way improper to lay, Lyfippus was a fatafly, and Prifian a grammarian; the fun fhines, and the fky is clear; becaufe these are things that may coexif, and yet imply no abfurdivty. But it would be aburd to fay, Lyfippus was a fatafly becaufe Prifian was a grammarian; though not to fay, the fun fhines becaufe the fky is clear. With refeft to the firft, the reason is, that the word becaufe denotes the relation which we have already consider'd. The continuative of Prifian in grammar could not possibly be the caufe of Lyfippus's skill in fagacity; the coincidence between the skill of the one and that of the other, in arts fo very different, was merely accidental. With refeft to the fhining of the fun and the cleaneft of the fky, the cafe is widely different; for the cleaneft of the fky is the cause of the fun's fhining, at leaft fo as to be seen by us.

As to the continuatives, they are either fuppositive, such as if, or positive, such as becaufe, therefore, and, &c. Take examples of each: You will live happily if you live honestly; you have happily because you live honestly; you live happily, therefore you live happily. The difference between these continuatives is this: The fuppositives denote connexions, but do not affect actual exifence.
The reason of all this will be apparent from the analysis given by Horne Tooke of those words which we have called suppositive conjunctions. If and an may be used mutually and indifferently to supply each other's place; for they are both verbs, and of the same import. It is merely the imperative of the Gothic and Anglo-Saxon verb GIVAN, to give; and in those languages, as well as in the English formerly, this suppositive conjunction was pronounced and written as the common imperative give. Thus, "My largest," "Hath lotted her to be your brother's mistreffe, Gif she can be reclaimed: gif not, his prey." Sad Shepherd, Act II. Scene i.f.

Gawain Douglas almost always uses gif for if, as the common people in some counties of Scotland do even at this day; and it is obvious, that our if has always the signification of the English imperative give, and no other. So that the resolution of the construction in the sentence, If you use honestly you will live happily, is simply this, Give you live honestly (taking you live honestly as an abstract noun) you will live happily. Your living happily is declared to depend upon your living honestly as the condition; but give that, and your happiness is positively asserted. In like manner may such sentences be resolved as, "I wonder he can move! that he's not fixed! If that his feelings be the same with mine." Thus, "His feelings be the same with mine, give that, I wonder he can move," &c. And here we cannot forbear giving our assent to the truth of Mr. Tooke's observation, that when the datum upon which any conclusion depends is a sentence, the article that, if not expressed, may always be inferred. We do not, however, think the inference at all times absolutely necessary to complete the syntax; for active verbs govern whole sentences and clauses of sentences as well as substantive nouns. Instances of this occur so frequently in the Latin classics, that they have escaped no man's notice, who has ever read Horace or Virgil with attention. We agree likewise with our most ingenious author, that where the datum is not a sentence, but some noun governed by the verb if or give, the article that can never be inferred. For example, if we be asked, how the weather will dispose of us to-morrow? we cannot say: "If that fair, it will send us abroad; if that foul, it will keep us at home;" but "if fair, it will send us abroad," &c. The reason is obvious: the verb in this case directly governs the noun; and the resolved construction is, "Give fair weather, it will send us abroad; give foul weather, it will keep us at home."

An, the other suppositive conjunction mentioned, is nothing else than the imperative of the Anglo-Saxon verb ANAN, which likewise means to give or to grant. As, "An you had an eye behind you, you might see more detection at your heels than fortunes before you;" that is, "Grant you had an eye behind you, you might see," &c. This account of the two conditional conjunctions in English is so rational and satisfactory, that we are strongly inclined to believe that all those words which are so called, are in all languages to be accounted for in the same manner. Not indeed that they must all mean precisely to give or grant, but some word equivalent; such as, be it, suppose, allow, permit, &c.; which meaning is to be sought for in the particular etymology of each respective language.

Of the causal conjunctions mentioned in the text, because has been already considered; and some account must now be given of the two words since and as. The former of these, according to Mr. H. Tooke, is a very corrupt abbreviation, confounding together different words and different combinations of words. To us it appears to be compounded of sean, seeing; and es, that or it; or of sin, seen, and es. Sean and sin are the present and past participles of the Anglo-Saxon verb seen, to see. In modern English since is used four ways: twas a preposition affecting words, and two as a conjunction affecting sentences. When used as a preposition, it has always the signification of the past participle seen joined to thence (i. e. seen and thereforward), or else the signification of the past participle seen only. When used as a conjunction, it has sometimes the signification of the present participle seeing, or seeing that; and sometimes the signification of the past participle seen, or seen that. We shall give examples of all these significations. If, As a preposition signifying seen and thereforward: "A more amiable sovereign than George III. has not swayed the English sceptre since the conquest." That is, "The conquest seen (or at the completion of the fight of the conquest), and thereforward, a more amiable sovereign than George III. has not swayed the English sceptre since the conquest." Since, taken in this sense, seems rather to be a corruption of sith or sithen, than a compound of sean and es. adly, As a preposition signifying seen simply: "Did George III. reign before or since that example?" 4thly, As a conjunction, since means seeing that: as, "If I should labour for any other satisfaction but that of my own mind, it would be an effect of phrenzy in me, not of hope; since (or seeing that) it is not truth but opinion that can travel through the world without a passport. 4thly, It means seen that, or that seen: as, "Since death in the end takes from all whatsoever fortune or force takes from any one, it were a foolish madness in the shipwreck of worldly things, when all links but the sorrow, to fave that: i. e. "Death in the end takes from all whatsoever fortune or force takes from any one; that seen, it were a foolish madness," &c. As; the other causal conjunction mentioned in the text, is an article meaning always it, or that, or which. Take the following example: "She glides away under the foamy seas As swift as darts or feather'd arrows fly."
Chap. VI.

Therefore (a) the sun is in eclipse. We therefore use causals in the same inferences where, the effect being conspicuous, we seek for its cause, and collectives, in demonstration and science, properly so called, where the cause being first known, by its help we discern effects.

As to causal conjunctions, we may further observe, that there is no one of the four species of causes which they are not capable of denoting. For example, the material cause; the trumpet sounds because it is made of metal. The formal cause; the trumpet sounds because it is long and hollow. The efficient cause; the trumpet sounds because an artist blew it. The final cause; the trumpet sounds because it may raise our courage. It is worth observing, that the three first causes are expressed by the strongest affirmation; because if the fact actually be, there must be also. But this is not the case with respect to the last, which is only affirmed as a thing that may happen. The reason is obvious: for whatever may be the end which set the artist first to work, that end may still be beyond his power to obtain; as, like all other contingents, it may either happen or not. Hence also it is connected by a particular conjunction, that (o), absolutely confined to this cause.

103. We come now to the DISJUNCTIVE CONJUNCTIONS: a species of words which bear this contradictory name, because while they CONJOIN the sentences, they DISJOIN the sense; or, to speak a language more intelligible, they denote relations of diversity or opposition.

That there should be such words, whether called conjunctions or not, is extremely natural. For as there is a principle of union diffused through all things, by which this whole is kept together and protected from dissipation; so is there in like manner a principle of diversity diffused through all, the source of distinction, of number, and of order. Now it is to express in some degree the modifications of this diversity, that these words called DISJUNCTIVE CONJUNCTIONS are employed.

Of these disjunctions, some are simple and some ad

Verseative: Simple; as when we say, without or ad

Verseative. as when we say, it is not day

or it is night: Adverseative: as when we say, it is not

day nor it is night. The difference between these is, that the simple express nothing more than a relation of diver

sity; the adverseative express a relation not barely of diversity, but also of opposition. Add to this that the adverseatives are definite, the simple indefinite. Thus when we say, the number three is not an even number, but (p) an odd; we not only disjoin two opposite attributes, but we definitely affirm the one to belong to

the

110

Disjunctive

conjunctions.

Vol. VIII.

That is, "She glides away (with) that swiftness (with) which darts or feathered arrows fly." In German, where as still retains its original signification and use, it is written so. So is another conjunction of the same import with as, being evidently the Gothic article sa or so, which signifies it or that.

(n) As Mr Harris has called therefore, whereas, &c. collective conjunctions, we have retained the denomination, though perhaps a more proper might be found. It is indeed of little consequence by what name even words of be called, provided the import of the words themselves be understood. Whereas and therefore evidently denote the relation of a cause to its effect. They are compounds of the Oxford words BUKER and then with for or voor; and signify, for which, for those or that. It is worthy of remark, that in some parts of Scotland the common people even at this day use this for these.

(o) We have already considered the word that, and seen that it is never a conjunction, but uniformly a definite article. "The trumpet sounds (for) that it may raise our courage," taking the clause it may raise our courage as an abstract noun in concord with that and governed by for. Or the sentence may be resolved thus: "The trumpet may raise our courage (for) that purpose it sounds."

(p) Mr Horne Tooke has favoured us with some ingenious remarks on the two different derivations of the word but; when used in the two acceptations that are usually annexed to it, viz. that which it bears in the beginning of a sentence, and that which it has in the middle. He has given it as his opinion, that this word, when employed in the former way, is corruptly put for butto, the imperative of the Oxford verb botan, to boot, to superadd, to supply, &c. and that when used in the latter, it is a contraction of be-utan, the imperative of beon-utan, to be out. Our ancient writers made the proper distinction between the orthography of the one word and that of the other. Gawin Douglas in particular, although he frequently confounds the two words, and uses them improperly, does yet abound with many inferences of their proper use; and so contrasted, as to awaken, fays our author, the most inattentive reader. Of the many examples quoted by him, we shall content ourselves with the two following:

"But thy works shall endure in laude and glorie,
"But spot or fault condigne eterne memorie." Pres. face.

"But gif the fates, but pleid,
"At my pleasure suffer it me life to leid." Book 4.

If this derivation of the word but from botan, to superadd, be just, the sentence in the text, "the number three is not an even number but an odd," will be equivalent to, "the number three is not an even number, superadd (it is) an odd number;" and if so, the opposition is not marked (at least directly) by the word but, but by the adjectives even and odd, which denote attributes in their own nature opposite. It is only when but has this sense that it answers to fed in Latin, or to main in French. In the second line of the quotation from Gawin Douglas's Preface, the word but is evidently a contraction of be-utan, and has a sense very different from that of bot in the preceding line. The meaning of the couplet is, "Superadd (to something laid or supped to be said before) thy work shall endure in laude and glorie, be out (i.e. without) spot or fault, &c. And in the following passage from Diug's Preface, the word but, although written in the same manner, is used in both its meanings: "You must anfwer, that she was brought very near the fire, and as good as thrown in or else, that she was provoked to it by a divine inspifation. But that another divine inspifation moved the beholders to believe that she did therein a noble act, this act of her's might have been calumniated." That is,
GRAMMAR.

Chap. VI.

As to adverbial conjunctions, it has been already said, after Mr Harris, that they imply opposition; but the truth seems to be, that they only unite in the same sentence words or phrases of opposite meanings. Now it is obvious, that opposite attributes cannot belong to the same subject: as when we say, Nerus was beautiful, we cannot superadd to this sentence, that he was ugly; we cannot say, he was beautiful but ugly. When there is opposition, it must be either of the same attribute in different subjects; as when we say, "Brutus was a patriot, but Caesar was not." Or of different attributes in the same subject; as when we say, Coriogus was a sophist, but not a philosopher." Or of different attributes in different subjects; as when we say, "Plato was a philosopher, but Hippasus was a sophist." The conjunctions used for all these purposes have been called absolute adverbatives, we think improperly, as the term is often used by the illiterate Scotch for what is, in modern English, properly to be called a conjunction. Mr Locke, speaking of the word but, says, that "it sometimes intimates a stop of the mind, in the course it was going, before it came to the end of it;" to which Mr Tooke replies with truth, that but itself is the forerunner of any word in the language from intimating a stop. On the contrary, it always intimates something to follow; information, that when any man in discourse finishes his words with but, instead of supposing him to have stopped, we always ask, but what?

Besides the adverbitives already mentioned, there are two other species, of which the most important are unless and although. For example, "Troy will be taken, unless the palladium be preferred; Troy will be taken, although Hector defend it." The nature of these adverbatives may be thus explained. As every event is naturally allied to its cause, so by parity of reason it is opposed to its preventive; and as every cause is either adequate or inadequate (inadequate when it endears without being effectual) so in like manner is every preventive. Now adequate preventives are expressed by such adverbatives as unless: "Troy will be taken, unless the palladium be preferred;" that is, this alone is sufficient to prevent it. The inadequate are expressed by such adverbatives as although: "Troy will be taken although Hector defend it." This, therefore, may be called adverbial adequate and inadequate.

Such is the doctrine of Mr Harris; which, although we can discover in it no determinate meaning, we have ventured with others to retain, in respect to our readers, who may be more perceptive than ourselves. The author was a man of great learning; and the subject, as he has treated it, appears to be intricate. But whatever fenfe or nonfence there may be in what he says of causes and preventives, adequate and inadequate, we have no hesitation to affirm that he has totally mistaken the import of the words unless and although. From these being called both preventives, the one adequate and the other inadequate, an unwary reader might be led to infer, that they denote the same idea or the same relation; and that the whole difference between them is, that the expression of the one is more forcible than that of the other. Nothing, however, can be further than this from the truth. The meaning of unless is directly opposite to that of although. Unless (r) and though

is, "You must answer, that she was brought very near the fire, &c. "Superadd (to that answer) be out (or unless or without); for, as will be seen by and by, all those words are of the same import) that another divine inspiration moved," &c. To these remarks and examples it may be worth while to add, that even now but is often used by the illiterate Scotch for without; as nothing is more common than to hear a clown say "He came from home but his breakfast." Having mentioned without as a word of the same import with but when distinguished from bot, it may not be improper to consider that word here; for though in modern English it is entirely confined to the office of a preposition, it was formerly used differently either as a preposition or a conjunction. Without then is nothing but the imperative wythan-utan, from the Anglo-Saxon and Gothic verb worthan withan; which in the Anglo-Saxon language is incorporated with the verb bæon, of. According to this derivation, which is Horne Tooke's, the word without, whether called conjunction or preposition, is the same be without; and such will be its import, should it after all be nothing more than a compound of wæth, which signifies to join and sometimes to be, and ute, on.

(q) Either is nothing more than the distributive pronoun, which every body understands; and or we have already explained.

(x) So low down as in the reign of queen Elizabeth (says Horne Tooke) this conjunction was sometimes written onles or onelle; but more anciently it was written onlies and sometimes onless. Thus, in the trial of Sir John Oldcastle in 1413, "It was not possible for them to make whole Christish eote without some, onlies certain great men were brought out of the way." So, in "The image of governance," by Sir T. Eliott, 1414, "Men do fere to approach to their sovereign Lord, onles they be called. So again, in "A necessary doctrine and erudition for any Christian man, set forth by the kinge's majestie of England," 1543, "Onles ye believe, ye shall not understand." "No man shall be crowned, onles he lawfully fight," "The soul waxeth feble, onlesse the fame be cheerrified." "It cannot be begynne, onlesse by the grace of God." Now, onles is the imperative of the Anglo-Saxon verb onlesan, to difmis, or remoue. Les, the imperative of lessan (which has the same meaning as onlesan), is likewise used sometimes by old writers instead of unless. Inflances might be given in abundance from G. Douglas and Ben. Johnson; but perhaps it may be of more importance to remark, that it is this same imperative les, which, placed at the end of nouns and coalescing with them, has given to our language such adjectives as hopeless, restless, deathless, motionless, &c. i. e. dismis hope, rest, death, motion, &c.

Mr Tooke observes, that all the languages which have a conjunction corresponding to less or unless, as well
Chap. VI.  

GRAMMAR.

are both verbs in the imperative mood; the former signifying take away or dismiss; the latter, allow, permit, grant, yield, affect. This being the case, "Troy will be taken unless the palladium be preferred," is a sentence equivalent to "Remove the palladium be preferred" (taking the palladium be preferred as an abstract noun, the preservation of the palladium) Troy will be taken." Again, "Troy will be taken, although Hector defend him," is the same as "Troy will be taken allow Hector (to) defend it." The idea, therefore, expressed by unless is that of the removal of one thing to make way for another; the idea expressed by although (s) is that of allowing one thing to co-exist with another, with which it is apparently incompatible.

104. Before we take leave of this subject, we might treat, as others have treated, of adverbial conjunctions, and conjunctions (of) various other denominations. But of multiplying subdivisions there is no end; and systems, in which they abound, convey for the most part no information. The nature of conjunctions can be thoroughly understood only by tracing each to its root, and allowing it to its parent or cognate tongue; and when

well as the manner in which the place of these words is supplied in the languages which have not a conjunction correspondent to them, strongly justify his derivation which we have adopted. The Greek nisi, the Latin nisi, the Italian se non, the Spanish si non, the French si non, all mean be it not. And in the same manner do we sometimes supply its place in English by but, without, be it not, but, &c. It may be proper just to add, that, according to the same author, the conjunction lest is a contraction of leas, the past participle of lees; and that lest, with the article that, either expressed or understood, means no more than hoc dimississe or quos dimississe.

(s) Although is compounded of al or all, and tho' though, than, or, as the vulgar more purely pronounce it, thaf, thaf, and thof. Now that or thof is evidently the imperative thaf of thaf of the verb thafian or thafigan, to allow, permit, grant, yield, affect; and thafian becomes thaf, though, though (and thech, as G. Douglas and other Scotch authors write it) by a transition of the same sort, and at least as early as that by which hafive becomes have. It is no small confirmation of this etymology, that in the languages which they often used all be, albeit it, all had, all were, all give, instead of although; and that as the Latin si (if) means be it, and nisi and sine (unless and without) mean be not, so nisi (although) means and be it.

(t) In a work of this kind, which professes to treat of universal grammar, it would be impertinent to waste our own and our readers time on a minute analysis of each conjunction which may occur in any one particular language. We shall therefore pursue the subject no farther; but shall subjoin Mr Horne Tooke's table of the English conjunctions, referring those who are desirous of fuller satisfaction to his ingenious work intitled The Diversions of Purley.

That is the article or pronoun that. As is es, a German article, meaning it, that, or which. And so is sa or so, a Gothic article of the same import as.
ordinary intercourse of life can be answered by the faculty of speech. It is a farther presumption in his favour, that in the rudest languages there are few if any conjunctions; and that even in others which are the most highly polished, such as Greek and Latin as well as English, many of those words which have been called conjunctions are obviously resolvable into other parts of speech. Thus **a** **n** **o** **l** **r** **t** **a** **l** translated, *but* is evidently the nearer gender of either the *nonunitius* or *acquisitive plural* of *alte* another; and when used as a conjunction, it intimates that you are going to *add something to what you have already said*. *Ceterum* has the same meaning, and is nothing but *mas venio*. *Mars* (but in French) is the Latin *majus*; *ut*, *at*, *en*, *que*, is the relative pronoun. Of *quoque*, *quis*, *praetera*, *antequam*, *quamquam*, *quamvis*, *quantumvis*, *quamlibet*, *occiput*; etc. The use, too, is obvious to require being mentioned. Where such revolutions as these can be made, or when the conjunctions of any particular tongue can be traced to their origin in any other, there needs be no dispute about their true import: but when the case is otherwise, and the conjunction either appears to be of any word, or is derived from a source to which it cannot be traced, we would advise such of our readers as wish to speak or write correctly, to difmiss from their minds all considerations of *copulative*, *continuative*, *causal* and *disjunctive* conjunctions, with the rest of that jargon which we have already mentioned; and to inquire diligently in what manner and for what purpose the conjunction in question is used by the best writers, both ancient and modern, of the particular language which they are studying. This will indeed be found a work of labour: but it appears to us to be the only means of discovering the precise relations which such conjunctions were intended to express, and, by consequence, of knowing what words or sentences they are fitted to connect, so as to produce a style at once accurate and perspicuous.

The import of conjunctions in any language to be learned from the best authors ancient and modern.

Prepositions unite two words that refuse to coalesce of themselves.

-- S E C T. II. O F P R E P O S I T I O N S. --

105. By Mr Harris and his followers, a **preposition** is defined to be a part of speech devoid itself of signification, but so formed as to unite two words that are significant, and that refuse to coalesce or unite of themselves. We have already expressed our opinion of that theory which holds certain words to be devoid of signification; but its absurdity, in the present instance, is more than ever glaring. Concerning the number of prepositions, it is well known that hitherto authors have never agreed. The ancient Greek grammarians admitted only 18; the ancient Latin grammarians above 50; though the moderns Sandius, Schopius, Perizonius, Vossius, and Ruddenman, have endeavoured to lessen the number without fixing it. Bishop Wilkins thinks that 36 are sufficient; and Girard says, that the French language has done the business effectually with 32. But if prepositions be words devoid of signification, why should there be disputes respecting their number? or why in any language should there be more than one preposition, since a single unmeaning mark of connection would certainly answer the purpose as well as a hundred? The *cypher*, which has no value of itself, and only serves (if we may use the language of grammarians) to connect and distinguish, and to change the value of figures, is not several and various, but uniformly one and the same. That "the preposition is so formed, as to unite two words which refuse to coalesce or unite of themselves," is indeed true; and this union it effects, *not* by having no signification of its own, but by signifying the relation by which the thing expressed by the united words are connected in nature. Prepositions are to be accounted for in much the same manner as the *causes of nouns*. The necessity of *this species* of words, or of some equivalent invention, follows from the impossibility of having in language a distinct complex term for each distinct collection of ideas which we may have occasion to put together in discourse. The addition or subtraction of any one idea, to or from a collection of ideas, makes it a different collection; and if, after either of these operations, it were to be expressed by the same word as before, nothing could ensue but misrepresentation and falsehood. Now, to use in language a different and distinct complex term for each different and distinct collection of ideas, is equally impossible, as to use a distinct particular term for each particular and individual idea. To supply, therefore, the place of the complex terms which are wanting in a language, are the *causes of nouns* and *prepositions* employed; by the aid of which, complex and general terms are prevented from being infinite or too numerous, and are used only for those collections of ideas which we have most frequent occasion to mention in discourse. By means of prepositions this end is obtained in the most simple manner. For, having occasion to mention a collection of ideas for which there is no single complex term in the language, we either take that complex term which includes the greatest number, though not all the ideas we would communicate; or else we take that complex term which includes all, and the fewest ideas more than those we would communicate; and then, by the help of the preposition, we either make up the deficiency in the one case, or retrench the superfluity in the other.

For instance, having occasion to mention a house of a particular description, and knowing that the term *house* is too general for our purpose, and that the building we have in view has no appropriate name, we say, perhaps, a *house with a party-wall*, or a *house without a roof*. In the first instance, the complex term *house* is deficient, and the preposition directs to add what is wanting. In the second instance, the complex term is redundant as it denotes a *complete house*; the preposition, therefore, directs to take away what is superfluous.

Now, considering prepositions in this the most simple light, as serving only to limit or modify general terms, it is absolutely necessary that they should have meanings of their own; for otherwise, how could we, in the inferences before us, make known by them our intention, whether of adding to or retrenching from, the same general term *house*. If, to a disciple of Mr Harris, we should say, *a house join*; he would reply, *join what*? But he would not contend that *join* is an indeclinable word which has no meaning of its own, because he knows that it is the imperative of a verb, of which the other parts are still in use; and its own meaning is clear, though the fen tence it not completed. If, instead of *join*, we should say, *a house with*; he would still ask the same question, *with what*? But if we were to discourse with him concerning the word *with*, he would probably tell us, that *with* is a preposition, an indeclinable word, which is itself devoid of signification, but so formed as to unite two words that are significant. And yet it would be evident by his question, that he felt it had a meaning of its own, which
Chap. VI.  

G R A M M A R.

is in really the same as join (v). Indeed, so far has always been plainly perceived, that with and without are directly opposite and contradictory; and it would puzzle the most acute philosopher to discover opposition and contradiction in two words where neither of them had any signification. Wilkins, therefore has well exprest their meaning, where he says, that with is a preposition "relating to the notion of focial, or circumstance of society assumed; and that without is a preposition relating to the same notion of focial, or circumstance of society denied." 106. But to denote the relation of adding and taking away, are not the only purposes for which prepositions are employed. They all indeed serve to modify some general term or general affirmation, but not precisely in the same way as with and without. It has been already observed, that words significant of those things which coincide in nature, coalesce with one another in syntax, without being beholden to any auxiliary tie. For instance, we use exactly the same expression with its substantive, a word with its substantive; a noun expressing an object acted upon, with a verb denoting action; and an adverb with its verb. Take the following example: THE SPLENDID SUN GENIALLY WARMETH THE FERTILE EARTH. But suppose we were desirous to modify some substantive, or general adjective, without having recourse to prepositions; but we can employ only such prepositions as point out the relation which the air and the beam have to the sun warming the earth. In English, we should say, the splendid sun warmeth the earth. The sentence, as before, remains entire and one; the substantives or adjectives required are both introduced; and not a word which was there before is detruded from its proper place. The import of with we have already discovered; it directs to unite the beam to the sun, as jointly with him performing the operation. But the air has no other connection with this operation but that the air, or passage between the sun and the earth, and therefore the preposition through (x) must denote that relation which subsists between an object in motion, and the medium in which it moves; nor could a preposition of a different import have been employed, without altering the meaning of the whole sentence (v). 107. Mr Harris is of opinion that with, if not all, pre-

(v) This account of prepositions is taken from Horace Tooke; who adds, that the only difference between the two words with and join, is, that the other parts of the Gothic and Anglo-Saxon verb withan, to join, (of which with is the imperative), have ceased to be employed in the language. As with means join, so the corresponding French preposition avez means, and have that, or, have that also. But though with, as the imperative of withan, means join, it has sometimes a very different signification. Mr Tyack in his Glossary has truly observed, that with and by are often synonymous. They certainly are so; but then with seems to be an abbreviation of the imperative of wythan to be; AS WITHOUT IS OF WYTHAN-UTAN TO BE CUIT. This being the case, our two instances in the text will stand thus: a house join a; a party wall; a house be-out a roof. Nor let any one be surprized that we make no difference between the conjunction with out and the preposition without. The word is the same, whether it be employed to unite words or sentences. Prepositions were originally, and for a long time, cladded with conjunctions; and when first separated from them, they were only distinguished by the name of prepositional conjunctions. They are generally used to unite words, but not always; for we may say independently, I came after his departure; or, I came after we departed. By the greater part of grammarians, indeed, after, when employed as in the first sentence, is cladded with the conjunctions. The word, however, is the same in both sentences; its meaning is the same, and its effect precisely the same. The only difference in point of denotation is, that in the first example it is prefixed to a noun, his departure; in the second, it is prefixed to a nominative and a verb be departed. But even the nominative and the verb, thus applied, express no more than a specifying circumstance annexed to the other preposition, I came; and whenever they are rightly apprehended by the mind, they are strips of their prepositional form, and considered abstrusely under a new phaen, his departure. Thus then, the two sentences are synonymous in every respect, excepting the apparent grammatical nature of the words his departure, and be departed; and even these are reduced to one grammatic form in the mind, whenever the import of the prepositions is rightly apprehended. Without, and many other prepositions, especially in the learned languages, are used exactly the same in the two instances which we have given. Horace Tooke, quotes Lord Mansfield for saying, "It cannot be read without the Attorney General contents to it." This, in modern English, is not the common phraseology; but it offends not against any principle of grammar. The nominative and the verb are here, as in the former instance, considered as an abstract noun; "It cannot be read without the content of the Attorney General."  

(x) THOROUGH, THOROUGH, THOROW, THROUGH, or THRO', is no other, says Horace Tooke, than the Gothic substantive dauro, or the Teutonic substantive thurh, and, like them, means door, gate, passage. So that the sentence in the text, resolved upon his principles, stands thus: "The splendid sun—join his beams genially warmeth—passage the air, (or, the air being the passage or medium)—the fertile earth." And in the same manner may we translate the preposition through in every instance where through is used in English, or its equivalent preposition in any language; as from the Latin and Italian word porta, (in Spanish puerta and in French porte), have come the Latin and Italian preposition per, the French par and the Spanish por.  

(y) If, for instance, we were to substitute with or instead of through, we should in the one case alter the

138

Prepositions originally denoted the various relations of body.

prepositions were originally formed to denote the relations of place. For this opinion we see not sufficient evidence. If indeed we could suppose the inventors of earliest improvements of language to have at all concerned themselves with relations as abstracted from the objects related, we must believe that those which first attracted their attention were the relations subsuming among themselves, and the various bodies with which they are surronded. We must likewise agree with our author, that place is the grand relation which bodies or natural substances maintain at all times to one another; but we do not therefore think that it would abstract place from body; an attempt which, according to some of the most profound philosophers (2), is not only difficult, but absolutely impracticable. But whatever be in this, the relations of cause and effect, of duration and motion, are in themselves as obvious, and as likely to arrest the attention and obtain names, as those of place. Among men totally illiterate, they are evidently more so; for pain and pleasure would suggest the idea of cause and effect as matters of importance. Here is, however, not only the strongest evidence that the inventors of any language had the least idea of abstract relations. They double expressed complex conceptions by nouns and verbs, significant at once of the particular ideas and of the various relations by which they viewed those ideas as combined together in a complex conception. Afterwards, when men's minds became enlarged, and when, from the fluctuation inexpressible from a living language, objects or ideas received new names, the old words, whether nouns or verbs, which were originally employed to express a particular complex conceptions of which certain particular relations made a part, might be retained for the purpose of denoting those and all similar relations; and thus verbs and nouns would degenerate into particles bearing the names of prepositions and conjunctions. For instance, one Anglo-Saxon being desirous to communicate to another his own conception of a house with a party-wall, and having (we shall suppose) no such word in his tongue as a proposition, would naturally utter the word house, defining his friend, at the same time, to add to that well known sound another sound (uttering it) significant of the particular circumstance wanting to complete his complex conception: — a house with (i.e. join) a party wall. The word with, as the imperative of a verb, denotes of course three ideas combined together, viz. a command or wish, an affirmation, and the idea of junctio. But when the word with was diversified from the English language, the imperative with was still retained; but losing its verbal and modal nature, it was thenceforth employed to denote only one of the three ideas for which it originally stood, viz. the idea of junctio. And thus it is, that verbs, and also nouns and adjectives, in passing from one language to another, may become propositions and conjunctions. Thus too it is, that some of those prepositions come to denote the contiguous, and some the detached relation of body. The contiguous, as when we say, Cains walked with a staff; i.e. Cains, join a staff, walked; the statue stood upon a pedestal; i.e. the statue stood (the place of its standing) the higher part of a pedestal; the river ran over a bank; i.e. the river ran (the place of its running) the higher part of a bank. The detached relation, as when we say, He is going to (c) staff, i.e. He is going to the END

meaning, and in the other speak non-ence. "The sun warmeth with the air the fertile earth," is an affirmation that the sun warmeth both the air and the earth; whereas the original entitement affirmed nothing more than that he warmeth the earth. "The sun warmeth of the air the fertile earth," is nonence, as it makes the earth a part, or a consequence, of the air. So necessary is it that prepositions have a meaning, and that the meaning of each be attended to.

(2) The Bishops Berkeley and Law, with the very learned and ingenious Principal Campbell of Aberdeen. See The Principles of Human Knowledge, Law's Notes on King's Origin of Evil, and The Philosophy of Rhetoric.

(a) As the Italian subjunctive case, a house, race, family, nation, &c. in passing to the French, becomes the preposition en, to which there is not, as we know, a preposition of precisely the same import in any language. Senza o senza in Italian becomes sans in French, and means absence. Nor is it necessary that verbs and nouns should always pass from one language to another, in order to be converted into prepositions: The Greek preposition χαρον is evidently the corrupted imperative of χαριν to favor, to disjoin, to separate. The Latin sine is sit ne, be not. The German sonder is the imperative of Sonderen, which has the same meaning as χαριν.

(b) Up, upon, over, above above, have all, says Horne Tooke, one common origin and signification. In the Anglo-Saxon, ufa, upera, uhemest, are the adjectives altus, altior, altissimus. Ufa or upan, up; comparative upera, operes or oper, over or upper; superlative uhemest, upmost or uppermost. Beupan, beufan, on-beufan, bove, above. If this be a just account of the origin of these words, the sentences in the text, where upon, over, and above, occur, will run thus: The statue stood on high a pedestal; "the river ran over a bank;" the sun is risen on the high hills." And here we may observe, that the mere relation between standing, running, &c. and places, is rather inferred from the verb itself, than expressed by a separate word: and the reason is obvious. For if a statue stand, every one knows that it must stand some thing as well as at some time. There is therefore no necessity, whatever elegance there may be in it, for employing any word to denote that relation, which is commonly believed to be signified by on; but it is necessary to infer, between the verb and pedestal, a word significant of place, that pedestal may not be mistaken, by an ignorant person, for a portion of time, or any thing else connected with the standing of the statue.

(c) That to is significant of detached relation, is the language of Mr Harris, which, though it may be allowed in a loose and vulgar sense, is certainly not philosophically just. The preposition to (in Dutch written tuk and to) is the Gothic subjunctive: tau of tautu, signifying all, effect, result, or consummation; which Gothic substantive itself is no other than the past participle tuad or tuadus of the verb taugan age...
Chap. VI.  

GRAMMAR.

END (of his journey) Italy; the sun is risen above the hills, i.e. the sun is risen (the place) THE TOP OF THE hills; these figs came FROM Turkey, i.e. these figs came BEGINNING (their journey at) Turkey.

Besides the detached relation of body, Mr Harris is of opinion that the preposition from denotes two other relations not observed than those of motion and respect. Thus if we say, "That lamp hangs from the ceiling, the preposition from assumes a character of quiescence."

But if we say, "That lamp is falling from the ceiling," the preposition in such cases assumes a character of motion."

But this is evidently a mistake: the detached relation in the former instance of the figs, as well as the motion and respect in the present instances, are expected not by the preposition, but by the verbs cause, fall, hang. The word from has as clear, as specific, and at all times as uniform and unequivocal a meaning, as any word in the language, from means merely beginning, and nothing...
thing else. It is simply the Anglo-Saxon and Gothic
noun from, beginning, origin, source, fountain, author
(The). Now if this meaning be applied to Mr Harris's
instances, from will speak clearly for itself, without
the assistance of the two following verbs, which are sup-
poised by him to vary its character.

"These figs came from Turkey."

"That lamp falls from the ceiling."

"That lamp hangs from the ceiling."

*came* is a complex term for one species of motion;
*falls* is a complex term for another species of motion;
and *hangs* is a complex (e) term for a species of attach-
ment. Have we occasion to communicate or mention the
commencement or beginning of these motions, and of this
attachment, and also the place where they
commence or begin? To have complex terms for each
occasion of this sort is absolutely impossible; and there-
fore nothing can be more natural or more simple than to
add the signs of these ideas, viz. the word *beginning*
(which will remain always the same) and the name of the
place (which will perpetually vary). Thus,

"These figs came—beginning Turkey."

"That lamp falls—beginning ceiling."

"That lamp hangs—beginning ceiling."

That is,

"Turkey the place of beginning to come."

"Cycling the place of beginning to fall."

"Cycling the place of beginning to hang."

It has been said that no less a man than bishop Wilkins,
that from letters primarily to place, and secondarily to
time. But the truth is, that from relates to every
thing to which beginning relates, and to nothing else.

"From morn till night the eternal larum rang.

That is, "The larum rang beginning morning (or
morning being the time of its beginning) tillnight."

As from always denotes beginning, so to and till
always denote the end. There is, however, this
difference between them, that to denotes the end of any
thing; till the end only of time. We may lay indif-
cernently—"From morn to night," or "From morn
till night, the eternal larum rang;" but we cannot say—
"These figs came from Turkey till England."

That *till* can, with propriety, be opposed to *from* only
when we are talking of time, is evident; for it is a
word compounded of *to* and *while*, i.e. time. And
as the coalescence of these two words *to*—*while*, took
place in the language long before the present super-
fluous of the article the, the phrase—"From morn
till night"—is neither more nor less than—*From
morn to time night*. When we say, "From morn to
night," the word *time* is omitted as unnecessary.

Besides, Mr Harris mentions over as significant,
sometimes of motion, and sometimes of rest; and quotes,
as instances, the following two passages from Milton.

---To support macOS ships

Over the burning marks.

Here, says he, over denotes motion. Again,

*He with looks of cordial love

Hung over her答案

Here over denotes rest. But the truth is, that over

denotes neither motion nor rest in either of the pas-
sages. In the first quotation, indeed, *motion is implied* but it

is implied in the word *steps*; and not in *over*, which
denotes only that the place of the steps was the top of
the burning marks. In the second quotation, *rest* is

implied, and that too a particular *species of rest*; but

it is implied or rather expressed by the verb *hung*, and

over denotes the place of that species of rest.

But though the original use of prepositions

was to denote the relation of body, they could not be

confined to this office only. They by degrees extend-

ed themselves to subjects *incorporate*; and came to be *by
degressions* noted relations, as well intellectual as local. Thus, becaue extended to

in place he, who is above, has commonly the advantage subjects in

over him who's below, therefore we transfer over and un-
corporal.

*Der* (f) to dominion and obedience. Of a king, we say, be

ruled over his people; of a soldier, be served under his gen-

eral. So too we say, without thought: without attention;

thinking over a subject; under anxiety; from fear; through

jealousy, &c. All which instances, with many others

of like kind, show, that the first word of men, like

their first ideas, had an immediate reference to sensible

objects; and that in all days, when they began to
discern with their intellect, they took these words in which

they

If a man should utter a sentence, and to the end of it subjoin the very general word *do*, the person to whom he
spoke, would naturally ask, *do what*? and this question would, of course, produce an *additional sentence or clause*
of a sentence. Besides, it is to be observed, *thence*, from the Latin preposition is derived, as well
as the Gothic verb, which is the source of the English particles, means not only *to do*, but also *to adduce or bring*;
so that when we say, "he is going to Italy," we do nothing more than *affirm* that "he is going,"
and deliberate the person to whom we speak, to "add Italy to the journey."

From this derivation of the preposition *to*, it will be seen at once upon what principle it is employed to
mark the infinitive mode. In the learned languages that mode is generally known by its termination; but
in English it would be impossible, without the aid of *to* or of some other word significant of action, to distinguish
the verb *love* from the noun *love* or *infant*. (p)

This derivation is Mr Horne Tooke's; and he supports it by the following sentence: 

Ner estate 

*On fruman worthe, he worhte weperman and wifemen*; which is Anglo-Saxon of St Matt.

"Annon legitistis, quod qui eos creavit, creavit eos marem et feminam."

"(a) There are complex terms because they are verbs. *Each* denotes an *affirmation and time*; and combined
with these, *came* and *falls* denote motion, and *hangs* denotes rest.

*Under* and *beneath*, though by the sound they seem to have little connection, are yet in fact almost
the same word, and many very well supply each other's place. *Under* is nothing but *on*, *beneath* is
composed of the imperative *be* and the noun *near*. *Neth* uncompounded having fallen away from
our language, would perhaps be unintelligible, had not the noun *nether* and *nethermost* still continued in
common use. *Neth*; Anglo-Saxon, *nethan*, *nethe*; Dutch, *neder*; Danish, *ned*; German, *niede*;
and Swedish, *nedre* and *nder*; is undoubtedly as much a substantive, and has the same meaning, as the word

*Nad* in common language it denotes the bottom.
they found already made, and transferred them by metaphor to intellectual conceptions.

Among the relations which may be considered rather as intellectual than corporeal, are those of cause and consequence; and for the denoting of these we have two prepositions, which sometimes appear in direct opposition to one another, and at other times may exchange places without injury to the sense.

"Well! 'tis e'en so! I have got the London diffuse they call love. I am sick of my husband, and for my gallant." — Wycherley's Country Wife.

Here of and for cemented almost in opposition; at least their effects in the sentence appear to be very different; for, by the help of these two prepositions alone, and without the affiance of any other words, the expresses the two contrary affection of loathing and desire. The truth, however, is, that the author, if he had pleased him, might have used of where he has employed for, and for where he has put of. This is evident from the following quotation:

"Marian. Come, Amie, you'll go with us.
Amie. I am not well.
Lionel. She's sick of the young shepherd that be- kilt her." — Sad Shepherd.

In the same manner we may, with equal propriety, say — "We are sick of hunger," or — "We are sick for hunger." And in both cases we shall have expressed precisely the same thing, with only this difference, that, in the former sentence, we declare sickness to be the consequence; in the latter, we declare hunger to be a cause. But to return to the poor country wife; that poor lady seems to have had a complication of distempers; she had, at least, two disorders — a sickness or loathing, and a sickness of love. She was sick for difficult, and sick for love. She was sick of difficult her husband; sick of love her gallant.

Sick for difficult her husband;
Sick for love her gallant.

In the first sentence, as thus stated, sickness is declared to be the consequence of difficult, of which her husband is declared to be the cause. In the second, sickness is declared to be the consequence of love, of which her gallant is declared to be the cause. In the third sentence, disgust is declared to be the cause of her sickness, and the consequence of offspring of her husband. In the fourth, love is declared to be the cause of her sickness, and the consequence of offspring of her gallant.

Thus, then, it appears, that though the two first of these sentences, taken entire, convey the very same meaning with the two last, yet the import of the preposition for is as different from that of of, as cause is from consequence (c). When two words or sentences are linked together by the former of these prepositions, the object expressed by the last word or sentence is declared to be the cause of that which is expressed by the pre- ceding; when two words or sentences are linked toge- ther by the latter preposition, the object expressed by the first word or sentence is declared to be the consequence of or to proceed from, the object expressed by the second. It is therefore a matter of perfect indifference to the sense, whether we say sickness of hunger, or sickness for hunger. The man who speaks little is, wife, or the man is wife, for he speaks little. By means of the preposition of, we declare sickness to be the consequence proceeding from hunger, and sickness to be the consequence we infer from the man's speaking little; by means of for, we declare hunger to be the cause of sickness, and the circumstance of speaking little to be the cause from which we infer the man's wisdom. In the one sentence, or is to be considered as a noun in apposition to sickness, in the other, as a noun in apposition to the man is wife taken abstractly as a noun. In the one sentence, for is to be considered as a noun in apposition to hunger; in the other, as the same noun in apposition to he speaks little, taken abstractly as noun.

In the foregoing use of prepositions, we have seen how they are applied by way of just a position; that is to say, where they are prefixed to a word with a pound, becoming a part of it. But they are also used by with the same word, in the way of composition; that is, they are prefixed to other words to become real parts of them. Thus in Greek we have ἐν ὑποτέλειαν; in Latin, intelligibilis, and in English understand. So also, to foretell, to overthrow, to undervalue, to outrage, &c. and in Greek and Latin other infinities innumerable. In this case the prepositions commonly transfix something of their own meaning into the word with which they are compounded. For example, if we suppose some given space, and a transfix signify out of that space; per, through it; in, within; something sub, under it. Hence e and ex in composition augment, Enormis is something not simply big, but big in excess, something got out of the rule, and beyond the measure. Disc, "to speak," edico, "to speak out," which editionis "an edit," something to effectually spoken as all are supposed to hear and all to obey. — On the contrary, in and sub diminish and lessen. Injustus iniquus, "unjust, inequitable," something that lies within justice and equity, that reaches not so far, that falls short of them. Sumiger, "blackish;" supribucundus, "reddish;" tending to black, and tending to red; but yet under the standard, and below perfection.

Before we dismiss this part of our subject, we shall make the same general remark on prepositions that we formerly made on conjunctuous; viz. that the precise mode of import of each can with certainty be known only by tracing it to its source in some word of known and determinate meaning, either in the language where the preposition itself has place, or in some parent or cognate tongue. And it may be laid down as an infallible rule, that where different languages use the same or a similar particle, that language ought to be considered as its legitimate parent, in which the true meaning of the word can be found, and where its use is common and familiar as that of any other verbs and sub-

(a) Junius derives for from the Greek προ; Skinner, from the Latin pro; but I believe, says Horne Tooke, that it is no other than the Gothic substantive vairina, "caufa." He imagines also that of (in the Gothic and Anglo-Saxon ap) is a fragment of the Gothic and Anglo-Saxon words afara and afora, parent, father, &c. In a word, he considers for and of as nouns or substantives; the former always meaning cause, the latter always meaning consequence, offspring, successor, follower, &c. If this account of these words be just, and we have no doubt of it, the prepositions for and of are in syntax to be considered as nouns in apposition with other nouns, or with sentences taken abstracly as nouns.
When prepositions can be traced to such sources as these, no room can be left for disputes concerning their meaning. In carrying on this etymological pursuit, we find advantages in the nature of prepositions which conjunctions do not afford us. With and without, from and to, with many other words belonging to this class, have meanings directly opposite and contradictory to each other. If, then, by the total or partial extinction of an original language, the root of any one preposition be lost, whilft that of its opposite remains, the philosopher ought to be satisﬁed with reasoning from contrariety; as nothing is more evident, than that the meaning of a word is known when we know with precision the meaning of its opposite. When we meet, however, with a luckless preposition of which no root is left to be dug up, and which has itself no direct opposite in the language, nothing remains but that we inquire for what purpose it is used by the best writers both ancient and modern; and if we can ﬁx upon one meaning which will apply, however awkwardly, to all the places where it occurs, or to the greater part of them, the probability is, that we have discovered the true and original (n) meaning of the preposition; and by keeping that meaning constantly in view, we shall ourselves be enabled to use the word with pertinacity and precision.

Sect. III. Of Interjections.

Besides the above parts of speech, there is another acknowledged in all the languages of Europe, called the interjection; a word which cannot be comprehended under any of the foregoing classes. The genuine interjections are very few in number, and of very little importance, as they are thrown into a sentence without altering its form either in syntax or in signiﬁcation. In the words of Horne Tooke, the bruitish uncultivated interjection has nothing to do with speech, and is only the miserable refuge of the speechless. The dominion of speech, according to the same author, is erected on the downfall of interjections. Without the artful contrivances of language, mankind would have nothing but interjections with which to communicate orally any of their feelings. "The neighing of a horse, the lowing of a cow, the barking of a dog, the purring of a cat, sneezing, coughing, groaning, shrieking, and every other involuntary convulsion with oral sound, have almost as good a title to be called parts of speech as interjections. In the intercourse of language interjections are employed only when the suddenness or vehemence of some affection or passion returns men to their natural state, and makes them for a moment forget the use of speech; or when, from some circumstance, the throats of time will not permit them to exercise it." The genuine interjection, which is always expressive of some very strong sensation, such as an when we feel pain, does not owe its characteristical expression to the arbitrary form of articulation, but derives its whole force from the tone of voice and modulation of countenance and gesture. Of conﬁdence, these tones and gestures express the same meaning, without any relation to the articulation which they may assume; and are therefore universally understood by all mankind. Voluntary interjections are used in books only for embellishment, and to mark forcibly a strong emotion. But where speech can be employed, they are totally useless; and are always insufﬁcient for the purpose of communicating thought. Dr Beattie ranks strange prodigies, amazing, wonderful, O dear, dear me, &c. when used alone, and without apparent grammatical syntax, among the interjections; but he might with as much propriety have considered hardly, truly, really, and even many Latin words, as interjections; for these too are often used alone to supply the place of whole sentences. The truth is, that all men, when suddenly and violently agitated, have a strong tendency to shorten their discourse by employing a single word to express a sentiment. In such cases, the word employed, whether noun, adjective, or verb, would be the principal word of the sentence, if that sentence were completed; and the agitation of the speaker is such, and the cause of it so obvious, that the hearer is in no danger of mistaking the sense, and can himself supply the words that are wanting. Thus if a perfon, after listening to a romantic narrative, were to exclaim, strange! would any man of common sense suppose, that the word strange, because uttered alone, had lost the power of an adjective and became an interjection? No, surely: Every one fees, that the exclamation is equivalent to, That is strange, or That is strange! Real interjections are never employed to convey truth of any kind. They are not to be found amongst laws, in books of civil institutions, in history, or in any treatise of useful arts or sciences; but in rhetoric and poetry, in novels, plays, and romances, where in English, so far from giving pathos to the style, they have generally an effect that is disgusting or ridiculous.

Having now analyzed every part of speech which can be necessary for the communication of thought, or which is acknowledged in any language with which we are acquainted; we shall dismiss the article of Grammar, after annexing a Table, which may present at one view the several classes and subdivisions of words. Of the different modes of dividing the parts of speech, as well as of the little importance of systematic classiﬁcations, we have already declared our decided opinion; but for the sake of those who may think differently from us, we shall in the annexed Table adopt Mr Harri’s classiﬁcation as far as it is intelligible; after informing our readers that Mr Horne Tooke admits only three parts of speech, the article, the noun, and the verb, and considers all other words as corruptions or abbreviations of the two last of these.

(II) For instance, let us suppose that Horne Tooke’s derivation of for, from the Gothic substantive faira, is fanciful and ill-founded, yet there can be little doubt but cause is its true and original meaning, when it is found, that of sixteen examples brought by Greenwood, and forty-six by Johnson, of different signiﬁcations of the word for, there is not one where the noun cause may not be substituted instead of the preposition for; sometimes indeed awkwardly enough, but always without injury to the sense. Even where for seems to be loco alterius, which Lowth afferts to be its primary sense, it will be found to be cause, and nothing else: Thus, He made considerable progress in the study of the law before he quitted that profession for this of poetry; i.e. before he quitted that profession, this of poetry being the cause of his quitting it.
A Grammatical Table

A Systematic View of Words as they are commonly arranged into distinct Classes, with their Subdivisions.
GRAMRIAN, one that is skilled in or teaches grammar.

Anciently the name grammarians was a title of honour, literature, and erudition, being given to persons accounted learned in any art or faculty whatever. But it is otherwise now, being frequently used as a term of reproach, to signify a dry pedling person, employed about words and phrases, but attentive to the true beauties of expression and delicacy of sentiment. The ancient grammarians, called also philologers, must not be confounded with the grammaitists, whole sole business was to teach children the first elements of language: Varro, Cicero, Meffala, and even Julius Caesar, thought it no dishonour to be ranked as grammarians, who had many privileges granted to them by the Roman emperors.

GRAMONT, a town of France, in the Limois, remarkable for its abbey, which is the chief of the order. E. Long. 133. N. Lat. 45. 56.

GRAMPYLAND-SHILL; a chain of high mountains in Scotland, which run from east to west almost the whole breadth of the kingdom. See (Settiff) Alpes and Scotland.—They take their name from only a single hill, the Most Grampyland of Tacitus, where Galgacus waited the approach of Agricola, and where the battle was fought so fatal to the brave nation, as is related in the Battle of the Caledonians.

GRAMPYLAND, a town of Cornwall in England, seated on the river Trelaw, over which there is here a bridge. W. Long. 5. 25. N. Lat. 50. 20. The inhabitants have a considerable manufacture of gloves; and the town sends two members to parliament. Some think that this town is the Voluba of the ancients because it stands on the same river; and that on the building of the bridge, the name was changed into Grandpoint. It was made a borough in the reign of Edward III. by whose charter it was endowed with large privileges, particularly freedom from toll through all Cornwall, a market on Saturday, and three fairs in the year; which the burghers hold of the duchy of Cornwall in free farm, at the rent of about 12 guineas. Its privileges were confirmed by King Henry VIII. but it did not send members to parliament till the reign of Edward VI. It is a corporation with a mayor, 8 magistrates, a recorder, and town-clerk. The mayor is chosen annually the Tuesday before Michaelmas, and the members by the majority of the magistrates and freemen, who are fuch of the inhabitants as pay foot and lot. There is a chapel of ease in the town to the parish-church, which is at Creed, about a quarter of a mile off.

GRAMUS, in ichthyology; a species of dolphin. See Delphinus,

GRANA, a province of Spain, which for a long time was a kingdom distinct from the rest of that country. See the article Spain.—It made a part of the ancient Baetica; and was inhabited by the Baetici, the Britani, &c. and at present it is sometimes called Upper Andalusia. It is bounded to the south and east by the Mediterranean, to the west and north by Lower Andalusia, and to the north-east by Murcia. Its extent from west to east is two hundred and ten miles; but its greatest breadth exceeds not eighty. The air here is temperate and healthy; and though there are many mountains in the province, and some of them very high, yet they are almost even where covered with vines and fruit-trees, together with laurel, myrtle, sweet-basil, thyme, lavender, marjoram, and other aromatic herbs, which give an exquisite taffle to the flesh of their sheep and cattle. A great deal of silk and sugar, flax and hemp, honey and wax is also produced here; besides dates and acorns, superior to the finest nuts; good stone for building; several sorts of gems; sumach, used in dressing goat skins; and galls, of which a dye is made for leather. The valleys, with which the mountains are interferted, are extremely beautiful and fertile. The inhabitants of some of the highest mountains are said to be descendants of the Moors; and, though they are become Roman-catholics, retain, in a great meafure, their ancient customs, manners, and language. The principal rivers in the province are the Genil, or Xeni, and Guadalantin, besides which there are many lesser streams. Abundance of salt is made in this province; which, though neither so populous nor so well-cultivated as when subject to the Moors, yet is as much so as any in Spain. It was the seat of the kingdom possessed by the Moors, and was not reduced and annexed to the crown of Castile until 1492.

GRANADA, the capital of the above province, is situated at the foot of the Sierra Nevada, or the Snowy Mountain, in a whole plain, full of air and fruitful country, an hundred and eighty miles south of Madrid, in W. Long. 2. 30. N. Lat. 36. 56. It stands upon two hills separated by the Darro. The Genil runs under the walls, and these two rivers are formed from the melting of the snow with which the mountain is constantly covered. The Darro is said to carry it small particles of gold; and its name, derived from dat aurum, may be alleged as a proof of this: the Genil, in like manner, rolls with its stream little pieces of silver. When Charles V. came to Granada, in 1526, with the empress Isabella, the city presented him with a crown made of gold gathered from the Darro. The city is large and magnificent, containing a great number of very handsome public and private buildings. Its walls, which are adorned with many towers at equal distances, are said to be ten miles in compass. Here are two castles; one built by the Moors, and the other by Charles V. and Philip II. They both command a very fine prospect; and the first is so large, that it looks like a city by itself; and, it is said, has room enough to accommodate forty thousand people, exclusive of the royal palace, and the convent of St Francis. Here is also a court of inquisition; a royal tribunal; and an university, founded in 1551; with the see of an archbishop, who has a revenue of forty thousand ducats per annum. A great many noblemen, clergy, and wealthy citizens, reside in this city, of which the silk trade and manufacture is very great, and the arsenal is said to be the best furnished of any in Spain. The inhabitants, who are partly descendants of the Moors, are largely supplied with water. There are several fine squares, particularly that called the Bivaramba or Placa Mayor, where the bull-fights are held; and without the city is a large plain, full of towns and villages, called La Vega de Granada.

The Moors are said to regret nothing but Granada, amongst all the lofts they have sustained in Spain; they mention it in all their evening prayers, and supplicate
Granada. heaven to restore it to their possession. The last Moors
ish ambassador who came into Spain obtained permission
of the king to see Granada; he fled tears on enter-
ing the Alhambra, and could not refrain from ex-
claiming, that the folly of his ancestors had deprived
them and their posterity of that delightful country.
Granada had formerly twenty gates: the first, that
of Elvira, which still remains; the second, that of Bi-
balmazar, or of conference, because, with the Moors, it
was a kind of place of resort where they convened on
affairs; the third, Vivarambla, called from its leading
to a grand square which still bears the fame name;
the fourth, Bib Racha, or of provisions; the fifth,
Bita-
tabin, or the gate of the hermits, which led to dif-
different solitude, the abodes of dervises; the sixth, Bib-
mite, or Biblacha, the first gate; the seventh,
the mill gate; the eighth, that of the sun, because it open-
ed to the east; the ninth, the gate of the Alhambra,
called by the Moors Bib Luxar; the tenth, Bib Adam,
or the gate of the bones of Adam; the twelfth, Bib
Ciedra, the gate of the nobles; the Moors kept this
gate shut for a long time, because it had been predic-
ted that the Moors who should one day take the city,
would enter by that gate; the thirteenth, that of
Fuxalauza, or of the hill of almond trees; the four-
teenth, the lion gate, in Arabic, Bib Elecici; the fif-
teenth, the coast gate, called by the Moors Alacabar;
the sixteenth, Bib Almomut, or the gate of the Banners,
at present the magdalen gate; the seventeenth, that of
the Darro; the eighteenth, that of the Mofayca; the
nineteenth, that called the gate of Ecco Homo; the
twentieth, that by the side of the Alhambra.
The Moors have left more monuments in Granada
than in any other city in Spain. From the great num-
ber of inscriptions in and about the city, and the line
decorations of the Alhambra and the Generalif, it might
be supposed these people intended to Make Granada
the great depository of their religion, manners, cus-
toms, and magnificence. There is not a wall which
do not bear some marks of their power; but, not-
withstanding this abundance of monuments, the reign
of the Moors in Spain is still buried in confusion and
obscurety. The ignorance of the Spaniards, their
superstition, and the hatred they bore the Moors, have
much contributed to this darknefs; they have either
destroyed, or suffered to be effaced by time, every
thing which bore the mark of mahometanism, instead
of preserving the monuments of antiquity, which at
the same time were theo of their own glory; and it
may be said, that chance alone, and the solidity of
their construction, much more than curiosity or a love
of the arts, has preserved those which still exist, al-
though daily going to ruin.

An account of the Alhambra has been already
given under its name in the order of the alphabet. From
the hall of Comares there mentioned, there is a modern
little fair-cafe; the old one, which corresponded to the
beauty of the edifice, having been destroyed. At the
top of the fair-cafe is a gallery, a part of which is in-
cluded with an iron railing; this kind of cage is called
the prison of the queen. It was here the wife of the
last king of Granada was imprisoned. The Genoals
and Legris, two families of distinction, bore false wit-
news against her virtue, and occasioned the destruction
of the greatest part of the Abencerrages, another
powerful and numerous family of Granada of whom
they were jealous. The history of this event is given
as follows.

In the year 1491, Abdali, furnamed the Little, still
reigned in Granada; but this city was upon the brink
of ruin, for the principal families were divided against
each other. The Moors had carried their arms against
Jaen, and had been bravely repelled. Abdali was con-
fiding himself in one of his pleasure houses for the de-
fense of his enterprise, when the Zegrifs, who long
had been the secret enemies of the Abencerrages,
took the opportunity of this defeat to represent them
to the king as rebellious subjects, who employed their
immense riches to gain the favour of the people and
declare their sovereigns. They accused Albin Ham-
et the moft rich and powerful among them, of ha-
vying an adulterous commerce with the queen, and pro-
duced witneffe who affirmed they had on a certain fe-
fival fheat, at Generalif, under a bowe of rofe trees,
Albin Hamet in the arms of that princess. The fury
of Abdali may easily be imagined; he swore the de-
struction of the Abencerrages. But the Zegrifs, too
prudent to let his anger break forth, advised him to
dilute, and not to suffer it to be known to that
numerous and powerful family that he was informed
of their perfidy. It will be better, said they, to entice
them into the fiare, and, before they can unite and
put themselves into a state of defence, revenge upon
their heads the insult offered to the crown. This ad-
vice was followed: Abdali went to the Alhambra,
having ordered thirty of his guards to arm themselves,
and the executioner to attend. The Abencerrages
were fent for one by one, and beheaded as soon as they
entered the hall of the lions, where there is still a large
vafe of alabaster, which was quickly filled with blood
and the heads of expiring bodies. Thirty-five heads
had already been struck off, and all the Abencerrages
would have died in the fame manner, had not a page,
who had followed his master, and remained unperce-
vied in the hurry of the execution, taken an oppor-
tunity of withdrawing and giving information to the reft
of the unhappy family of what had passed. Those
immediately assembled their friends in arms, crying out
through the city of Granada, "Treason! treason! Let
the king die! he unjustly puts to death the Aben-
cerrages!" The people, with whom they were favour-
vites, did not hesitate in affifting them: fourteen thou-
sand men were soon found in arms, and immediately
proceeded towards the Alhambra, shaming all the
way. Let the king die! Abdali, surprized his secret
should have been fo soon discovered, and feverely re-
penting of having followed the pernicious counsels he
had received, ordered the caffe gates to be shut; but
they were presently set on fire. Muley Hacen, who had
been forced to abdicate the throne in favour of his son,
having heard the tumult of the people, had one gate
opened, and prefented himself to appeafe the rage of
the citizens; but he no sooner appeared, than he was lift-
ed up by the multitude nearest the gate, who cried out
"Behold our king, we will have no other, long live
Muley Hacen!" and leaving him surrounded by a
strong guard, the Abencerrages, and other nobles, en-
tered the caffe, accompanied by upwards of an hun-
dred soldiers. But they found the queen only, with
her women, and in the utmost conffernation at the
sudden
The Granada, in the art of war, a hollow ball or shell of iron or other metal, about 24 inches in diameter, which being filled with fine powder, is set on fire by means of a small fuse driven into the fuse-hole, made of well-seasoned beech-wood, and thrown by the granadiers into those places where the men stand thick, particularly into the trenches and other lodgements made by the enemy. As soon as the composition within the fuse gets to the powder in the grenade, it bursts into many pieces, greatly to the damage of all who happen to be in its way. Granadoes were invented about the year 1594. The author of the Military Dictionary has the following remark on the use of granades. "Grenades have unaccountably sunk into disuse; but I am persuaded there is nothing more proper than to have grenades to throw among the enemy who have jumped into the ditch. During the siege of Cassel under the Count de La Lippe, in the campaign of 1744, a young engineer
undertook to carry one of the outworks with a much smaller detachment than one which had been repulsed, and succeeded with ease from the use of grenades; which is a proof that they should not be neglected, either in the attack or defence of posts."—The word Granado takes its rise from hence, that the shell is filled with grains of powder, as a pomegranate is with kernels.

GRANARD, a borough, market, fair, and post town in the county of Longford, province of Leinster; it gives title of earl to the family of Forbes; situated 52 miles from Dublin, and about 16 north east of Longford. N. Lat. 53° 44'. W. Long. 7° 30'. Here is a remarkable hill or mount, called the Most of Granard, thought to be artificial, and a fire of a Danish castle or fort; which commands from its summit a most extensive prospect into six or seven adjoining counties. In this town have lately been given annual prizes to the best performers on the Irish harp. Granard has a barracks for a company of foot; and returns two members to parliament; patronage in the families of Macarmey and Greville. Fairs held 3d May and 1st October. This place takes its name from Granard, or "the height of the firm," and was formerly the residence of the chiefs of north Teffia. It is sometimes written Grenard.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerible time.

Sir Henry Wotton advises to make it look towards the north, because that quarter is the coldest and most temperate. Mr. Worlidge observes, that the best granaries are built of brick, with quarters of timber wrought in the inside, to which the boards may be nailed, with which the inside of the granary must be lined 6d close to the bricks, that there may not be any room left for vermin to shelter themselves. There may be many stories one above another, which should be near the one to the other; because the shallower the corn lies, it is the better, and more easily turned.

The two great cations to be observed in the erecting of granaries are, to make them sufficiently strong, and to expose them to the most drying winds. The ordering of the corn in many parts of England, particularly in Kent, is thus: To separate it from dust and other impurities after it is threshed, they toss it with shovels from one end to the other of a long and large room; the lighter substances fall down in the middle of the room, and the corn only is carried from side to side, or end to end, of it. After this they ferrein the corn, and then bringing it into the granaries, it is spread about half a foot thick, and turned from time to time about twice in a week; once a week they also repeat the fereening it. This sort of management they continue about two months, and after that they lay it a foot thick for two months more; and in this time they turn it once a week, or twice if the season be damp, and now and then ferrein it again. After about five or six months they raise it to two feet thickness in the heaps, and then they turn it once or twice in a month, and ferrein it now and then. After a year, they lay it two and a half or three feet deep, and turn it once in three weeks or a month, and ferrein it proportionably. When it has lain two years or more, they turn it once in two months, and ferrein it once a quarter; and how long ever it is kept, the oftener the turn-

The public granaries at Dantzick are seven, eight, or nine stories high, having a funnel in the midst of every floor to let down the corn from one to another. They are built with securely, that though every way surrounded with water the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. The Russians preserve their corn in subterranean granaries of the figure of a sugar-loaf, wide below and narrow at top; the sides are well plastered, and the top covered with stones. They are very careful to have the corn well dried before it is laid into these stores, and often dry it by means of ovens; the summer dry weather being too short to effect it sufficiently.—Dantzick is the grand florshoene or repository of all the fruitful kingdom of Poland. The wheat, barley, and rye, of a great part of the country, are there laid up in parcels of 20, 30, or 60 lafts in a chamber, according to the size of the room; and this they keep turning every day or two, to keep it sweet and fit for shipping. A thunder storm has sometimes been of very terrible consequence to these stores. All the corn of the growth of former years having been found so much altered by one night's thunder, that though over night it was dry, fit for shipping or keeping, and proper for uses of any fort, yet in the morning it was found clammy and sticking. In this case there is no remedy but the turning of all such corn three or four times a day for two months or longer; in which time it will sometimes come to itself, though sometimes not. This effeet of thunder and lightning is only observed to take place in such corn as is not a year old, or has not sweated thoroughly in the straw before it was threshed out. The latter inconvenience is easily prevented by a timely care; but as to the former, all that can be done is carefully to examine all stores of the last year's corn after every thunder storm, that if any of this have been affected, it may be cured in time; for a neglect of turning will certainly utterly destroy it.

According to Vitruvius's rules, a granary should always be at the top of a house, and have its openings only to the north or east, that the corn may not be exposed to the damp winds from the south and west, which are very deftructive to it; whereas the contrary ones are very necessary and wholesome to it, serving...
Grain. to cool and dry it from all external humidity, from whatever cause. There must also be openings in the roof to be left open in dry weather, partly to let in fresh air, and partly to let out the warm effluvia which are often emitted by the corn. The covering of the roofs should always be of tiles, because in the worst seasons, when the other openings cannot be safe, there will always be a considerable inlet for fresh air, and a way out for the vapours by their joinings, which are never close. If there happen to be any windows to the south, great care must be taken to shut them up in moist weather, and in the time of the hot southern winds. There must never be a cellar, or any other damp place under a granary, nor should it ever be built over stables; for in either of these cases the corn will certainly suffer by the vapours and be made damp in one, and ill-tasted in the other.

M. Du Hamel and Dr Hales recommend various contrivances for ventilating or blowing fresh air through corn laid up in granaries or ships, in order to preserve it sweet and dry, and to prevent its being devoured by weevils or other insects. This may be done by nailing wooden bars or laths on the floor of the granary about an inch distant from each other, when they are covered with hair-cloth only; or at the distance of two or three inches, when coarse wire-work, or basket-work of oak is laid under the hair-cloth, or when an iron plate full of holes is laid upon them. These laths may be laid across other laths, nailed at the distance of 15 inches, and two or more deep, that there may be a free passage for the air under them. The under laths must come about six inches short of the wall of the granary at one end of them; on which end a board is to be let edgewise, and sloping against the wall: by this disposition a large air-pipe is formed. With having an open communication with all the interfices between and under the bars, will admit the passage of air below forcibly through a hole at the extremity of it, into all the corn in the granary, that will consequently carry off the moist exhalations of the corn. The ventilators for supplying fresh air may be fixed against the wall, on the inside or outside of the granary, or under the floor, or in the ceiling; but wherever they are fixed, the handle of the lever that works them must be out of the granary, otherwise the person who works them would be in danger of suffocation by the free admission of air below forcibly through a hole at the extremity of it, into all the corn in the granary, that will consequently carry off the moist exhalations of the corn.

The ventilators for ventilating corn in large bins in granaries, and may be easily moved from one bin to another. If the granary or corn ship be very long, the main air-pipe may pass lengthwise along the middle of it, and convey air, on both sides, under the corn. In large granaries, large double ventilators, laid on each other, may be fixed at the middle and near the top of the granary, that they may be worked by a wind-mill fixed on the roof of the granary in lying, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the several floors to the bottom of the granary, with branching trunks to each floor, by means of which the air may be made to pass into a large trunk along the adjoining cross walls: from these trunks several leffer trunks, about four inches wide, are to branch off, at the distance of three or four feet from each other, which are to reach through the whole length of the granary, and their farther ends are to be closed: teams of two or three of an inch are to be left open at the four joinings of the boards, where they are nailed together, that the air may pass through them into the corn. In some of these leffer trunks there may be sliding shutters, in order to stop the passage of the air through those trunks which are not covered with corn; or to ventilate one part of the granary more briskly than others, as there may be occasion. There must also be wooden shutters, hung on hinges at their upper part, so as to shut close of themselves: these must be fixed to the openings in the walls of the granary on their outside; by these means they will readily open to give a free passage for the ventilating air, which ascends through the corn, to pass off, but will instantly shut when the ventilation ceases, and thereby prevent any dampness of the external air from entering: to prevent this, the ventilation should be made only in the middle of dry days, unless the corn, when first put in, is cold and damp.

In leffer granaries, where the ventilators must be worked by hand, if these granaries stand on fiddles, so as to have their lowest floor at some distance from the ground, the ventilators may be fixed under the lowest floor, between the fiddles, so as to be worked by men standing on the ground, without or within the granary. A very commodious and cheap ventilator may be made for small granaries, by making a ventilator of the door of the granary; which may be easily done by making a circular screen, of the size of a quarter of a circle, behind the door: but in order to this, the door must be open, not inwards but outwardly of the granary, so that as it falls back, it may be worked to and fro in the screen; which must be exactly adapted to it in all parts of the circular face of the screen as well as at the top and bottom. But there must be a slot at about eight or ten inches distance from the wall, to prevent the door's falling back farther; that there may be room for a valve in the screen to supply it with air; which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there must be another valve over the hole in the wall, to prevent the return of the air.

To destroy weevils and other insects with which granaries are apt to be infested.—The preservation of grain from the ravages of insects may be best effected by timely and frequent fumming, and ventilation; as little or no inconvenience will follow corn or malt lodged dry, but what evidently results from a neglect of these precautions. For, whether the obvious damage arise from the weevil, the moth, or the beetle, that damage has ceased at the time the vermin make their appearance under either of these species, they being, when in this last state of existence, only propagators of their respective kinds of vermiculi; which, while they continue in that form, do the mischief.

In this last, or infest state, they eat little, their principal business being to deposit their ova (eggs), which issuing instinct prompts them to do where large collections of grain furnish food for their successors while in a vermicular state. It is therefore the business of industry to prevent future generations of these ravagers, by destroying the eggs previous to their hatching; and this
This bell accomplished by frequent screening, and exposure to draughts of wind or freth air. By frequently \[\ldots\] the cohesion of their ova is broken, and the nidus of those minute worms is destroyed, which on hatching collect together, and spin or weave numerous webs of a cobweb-like substance for their security. To these webs they attach, by an infinity of small threads, many grains of corn together, first for their protection, and then for their food. When their habitations are broken and separated by the screen, they fall through its small interstices, and may be easily removed from the granary with the dust. Those that escape an early screening will be destroyed by subsequent ones, while the grain is but little injured; and the corn will acquire thereby a superior purity. But by inattention to this, and sometimes by receiving grain already infected into the granary, these vermin, particularly the weevil, will, in a short time spread themselves in that state every where upon its surface, and darken even the walls by their number. Under such circumstances a hen or hens, with new hatched chickens, if turned on the heap, will traverse, without feeding (or very sparingly so) on the corn, wherever they spread; and are seemingly inoffensive in the pursuit of these pests. When the number is reduced within reach, a hen will fly up against the walls, and burst them down with her wings, while her chickens seize them with the greatest avidity. This being repeated as often as they want food, the whole species will in a day or two be destroyed. Of the phalana (moth), and the small beetle, they seem equally voracious: on which account they may be deemed the most useful instruments in nature for eradicating these noxious and destructive vermin.

GRANATE, or GARNET: a genus of fossils ranked among the siliceous earths; but, according to M. Magellan, analogous to gems, all of them being composed of the siliceous, argillaceous, and calcareous earths, with a greater or lefs proportion of iron. The opaque and black garnets contain about a fifth part of iron; but the diaphanous ones only 1/10, according to Bergman. The garnets, properly so called, contain a greater quantity of siliceous earth than the chalcedons, and both are now justly ranked with the siliceous earths. The general properties of the garnet, according to Cronstedt, are as follow: 1. It is more fusible as it contains less metallic matter, and is more transparent or glassy in its texture. 2. Mixed with salt of lead, it may, on a piece of charcoal, be converted into glass by the blow-pipe, which cannot be done with a flint. 3. The most transparent garnet may, without any addition, be brought to a black opaque flag by the same means. 4. It is never, as far as is hitherto known, found pure, or without some mixture of metal, especially iron, which may be extracted by the common methods. 5. Th\[\ldots\]
GRANATE. See Garnet.

GRAND, a term rather French than English, tho' used on many occasions in our language. It has the same import with great, being formed of the Latin grandis. In this sense we say, the grand-master of an order, the grand-master of Malta, of the five-masons, &c. So are the grand-master, grand-grand-master, grand-grand-master, &c. grand-father, grand-mother, &c.

In the French polity and outforns there are several officers thus denominated, which we frequently retain in English; as grand almoner, grand ecuyer, grand chamberlain, grand veyer, &c.

GRAND-AFZI. See Assise.

GRANDDIFFORT (diferitio magna), in English law, a writ of ditrectis, so called on account of its extent, which reaches to all the goods and chattels of the party within the county. This writ lies in two cases: either when the tenant or defendant is attached and appears not, but makes default; or where the tenant or defendant hath once appeared, and after makes default. On such occasions, this writ lies by common law, in lieu of a petit cape.

GRAND GALE, among painters, a term used to express that there is something in the picture very great and extraordinary, calculated to fartride, please, and instruct. Where this is found, they say, the painter was a man of grand gale; and they use the words sublima and marvellous, when they speak of a picture, in much the same sense.

GRAND JURY, lancent, sargent, &c. See JURY, &c. GRANDEE, is understood of a lord of the first rank or prime quality.

In Spain, the term grande is used absolutely to denote the prince lords of the court, to whom the king has once given leave to be covered in his presence; there are some grandees for life only; made by the king's say-ing, Be covered for thyself and heirs. These last are reputed far above the former.

There are some who have three or four grandeeships in their family.

GRANDEUR and SUBLIMITY. These terms have a double signification: they commonly signify the quality or circumstance in objects by which the emotions of grandeur and sublimity are produced; sometimes the emotions themselves.

In handling the present subject, it is necessary that the impression made on the mind by the magnitude of an object, abstracting from its other qualities, should be acute. And because the operation of some difficulty, the safest method of judging is, to choose a plain object that is neither beautiful nor deformed, if such a one can be found. The plainest that occurs, is a huge mass of rubbiffh, the ruins perhaps of some extensive building; or a large heap of flones, such as are collected together for keeping in memory a battle or other remarkable event. Such an object, which in miniature would be perfectly indif ferent, makes an impression by its magnitude, and appears agreeable. And supposing it so large as to fill the eye, and prevent the attention from wandering up on other objects, the impression it makes will be so much the deeper. See ATTENTION.

But though a plain object of that kind be agreeable, it is not termed grand; it is not entitled to that character, unless, together with its size, it be possessed of other qualities that contribute to beauty, such as regularity, proportion, order, or colour; and according to the number of such qualities combined with magnitude, it is more or less grand. Thus St Peter's church at Rome, the great pyramid of Egypt, is a most towering above the clouds, a great arm of the sea, and above all a clear and serene sky, are grand; because, beside their size, they are beautiful in an eminent degree. On the other hand, an overgrown whale, having a disagreeable appearance, is not grand. A large building agreeable by its regularity and proportions, is grand; and yet a much larger building delicient of regularity, has not the least tincture of grandeur. A single regiment in battle array, makes a grand appearance; which the surrounding crowd does not, though perhaps ten for one in number. And a regiment where the men are all in one livery, and the horses of one colour, makes a grander appearance, and consequently strikes more terror, than where there is confusion of colour and drefs. Thus greatness or magnitude is the circumstance that distinguishes grandeur from beauty: agreeableness is distinguishing the genus, of which beauty and grandeur are species.

The emotion of grandeur, duly examined, will be found an additional proof of the foregoing doctrine. That this emotion is pleasant in a high degree, requires no other evidence but one to have seen a grand object: and if an emotion of grandeur be pleasant, its cause or object, as observed above, must infallibly be agreeable in proportion.

The qualities of grandeur and beauty are not more dfficnt, than the emotions are which these qualities produce in a spectator. It is observed in the article BEAUTY, that all the various emotions of beauty have one common character, that of sweetnefs and gésity. The emotion of grandeur has a different cha-

N
Demands not strict regularity.

Though regularity, proportion, order, and colour, contribute to grandeur as well as to beauty, yet these qualities are not by far so essential to the former as to the latter. To make out that proportion, some preliminaries are requisite. In the first place, the mind, not being totally occupied with a small object, can give its attention at the same time to every minute part; but in a great or extensive object, the mind, being totally occupied with the capital and striking parts, has no attention left for those that are little or indifferent. In the latter, two similar objects appear not so similar when viewed at different distances; the similar parts of a very large object, cannot be seen but at distant distances; and for that reason, its regularity, and the proportion of its parts, are in some measure lost to the eye; neither are the irregularities of a very large object so conspicuous as of one that is small. Hence it is, that a large object is not so agreeable by its regularity, as a small object; nor so disagreeable by its irregularities.

These considerations make it evident, that grandeur is satisfied with a less degree of regularity, and of the other qualities mentioned, than is requisite for beauty; which may be illustrated by the following experiment. Approaching to a small conical hill, we take an overlook of the hill to be considerably enlarged, so as to make as less sensible of its regularity, it will upon that account appear less beautiful. It will not, however, appear less agreeable, because some slight emotion of grandeur comes in place of what is lost in beauty. And at last, when the hill is enlarged to a great mountain, the small degree of beauty that is left, is sunk in its grandeur. Hence it is, that a towering hill is delightful, if it have but the lightest resemblance of a cone; and a chain of mountains not lefs fo, though deficient in the accuracy of order and proportion. We require a small surface to be smooth; but in an extensive plain, considerable inequalities are overlooked. In a word, regularity, proportion, order, and colour, contribute to grandeur as well as to beauty; but with a remarkable difference, that in passing from small to great, they are not required in the same degree of perfection. This remark serves to explain the extreme delight we have in viewing the face of nature, when sufficiently enriched and diversified with objects. The bulk of the objects in a natural landscape are beautiful, and some of them grand: a flowing river, a spreading oak, a round hill, an extended plain, are delightful: viz. the emotion of beauty; but the emotion of grandeur is so different from these mentioned, as to merit a peculiar name.

The same observation is applicable to works of art. In a small building, the slightest irregularity is disagreeable; but in a magnificent palace, or a large Gothic church, irregularities are less regarded. In an epic poem, we pardon many negligence that would not be permitted in a sonnet or epigram. Notwithstanding such exceptions, it may be justly laid down for a rule, That in works of art, order and regularity ought to be governing principles; and hence the observation of Longinus, "In works of art we have regard to exact proportion; in those of nature, to grandeur and magnificence." The same reflections are in a good measure applicable to sublimity: particularly that, like grandeur, it is a species of agreeableness; that a beautiful object placed high, appearing more agreeable than formerly, produces in the spectator a new emotion, termed the emotion of sublimity: and that the perfection of order, regularity, and proportion, is less required in objects placed high, or at a distance, than at hand.

The pleasurable emotion raised by large objects, has not escaped the poets:

He doth behold the narrow world
Like a Colossus: and we petty men
Walk under his huge legs.

Cleopatra. I dreamt there was an emperor Antony:
Oh fuch another sleep, that I might see
But fuch another man!
His face was as the heavens—and therein fluck
A fun and moon, which kept their course, and lighted
The little O' th' earth.
His legs bestride the ocean, his rear'd arm
Credited the world.

Majesty
Dies not alone—but, like a gulf, deth draw
What's near it with it. It's a rally wheel
Fixed on the summit of the highest mount,
To whom huge fpekes ten thousand letter things
Are mortis'd and adjourn'd—which, when it falls,
Each small amenity, petty confequence,
Attends the build'd round ruin.

The poets have also made good use of the emotion produced by the elevated situation of an object:
Quod ille lyricus statibus inferes,
Sublimi ferial fidera vertice.

Oh thou! the earthly author of my blood,
Whoft youthful spirit, in me regenerate,
Both with a twofold vigour lift me up,
To reach at victory above my head.

Northumberland, thou ladder wherewithal
The mounting Bolingbrooke ascends my throne.

Antony. Why was I rais'd the metier of the world,
Hung in the skies; and blazing as a trave'ld,
Till all my fires were spent; and then cast downward
To be trod out by Caesar?

The description of Paradise in the fourth book of
Paradise
The fishermen that walk upon the beach
Appear like mice; and you tallttering back
Dinlim'd to her cock; her cock, a buoy.

Almost too small for fight. The murr'ning surge,
That on the unnumber'd idle pebbles chafes,
Cannot be hold to high. I'll look no more,
Left my brain turn, and the deficient fight
Tinkle down headlong. *King Lear,* act 4, sc. 6.

A remark is made above, that the emotions of grandeur and sublimity are nearly allied. And hence it is, that the one term is frequently put for the other: an increasing series of numbers, for example, producing an emotion similar to that of mounting upward, is commonly termed *a descending series*; a series of numbers gradually decreasing, producing an emotion similar to that of going downward, is commonly termed *a descending series*; we talk familiarly of going up to the capital, and of going down to the country: from a lesser kingdom we talk of going up to a greater; whence the *anabasis* in the Greek language, when one travels from Greece to Persia. We discover the same way of speaking in the language even of Japan; and its universality proves it the offspring of a natural feeling.

The foregoing observations leads us to consider grandeur and sublimity in a figurative sense, and as applicable to the fine arts. Hitherto these terms have been taken in their proper sense as applicable to objects of light only: and it was of importance to bestow some pains upon that article; because, generally speaking, the figurative sense of a word is derived from its proper sense, which holds remarkably at present. Beauty, in its original signification, is confined to objects of light; but as many other objects, intellectual as well as moral, raise emotions resembling that of beauty, the reference of the effects of beauty to objects of sense we extend the term beauty to these objects. This equally accounts for the terms grandeur and sublimity taken in a figurative sense. Every emotion, from whatever cause proceeding, that resembles an emotion of grandeur or elevation, is called by the same name: thus generosity is said to be an *elevated* emotion, as well as great courage; and that firmness of soul which is superior to misfortunes obtains the peculiar name of *magnanimity.* On the other hand, every emotion that confines the mind, and fixeth it upon things trivial or of no importance, is termed *low.* By its resemblance to an emotion produced by a little or low object of light: thus an appetite for trifling amusements is called *low taste.* The same terms are applied to characters and actions: we talk familiarly of an *elevated* genius, of *great* man, and equally to *littlenesses* of mind: some actions are *great* and *elevated,* and others are *little* and *groveling*.

Sentiments, and even expressions, are characterized in the same manner: an expression or sentiment that raises the mind is designated *great* or *elevated,* and hence the *sublime* in poetry. In such figurative terms, we lose the distinction between *great* and *elevated* in their proper sense; for the resemblance is not to entice us to preserve these terms distinct in their figurative application. We carry this figure still farther. Elevation, in its proper sense, imports superiority of place, and lowness, inferiority of place: and hence a man of superior talents, of superior rank, of inferior parts, of inferior taste, and such like. The veneration we have for our ancestors, and for the ancients in general, being similar to the emotion produced by an

---

*How fearful
And dizzy 'tis, to cast one's eye so low!
The rocks and gashes, that wing the midway air,
Show scarce so gros as beetles. Half-way down
Hangs one that gathers fampire; dreadful trade!

Methinks he seems no bigger than his head.*
The resemblance in feeling between real and figurative grandeur is humorously illustrated by Addison in an essay criticizing upon English tragedy. *"The ordinary method of making an hero is to clap a huge plume of feathers upon his head, which rises so high, that there is often a greater length from his chin to the top of his head than to the sole of his foot. One would believe, that we thought a great man and a tall man the same thing. As the superb ornamental upon the head make a great man, a princes generally receives her grandeur from those additional incumbrances that fall into her tail: I mean the broad sweeping train that follows her in all her motions; and finds constant employment for a boy who stands behind her to open and spread it to advantage." The Scythians, impressed with the fame of Alexander, were astonished when they found him a little man.

A gradual progress from small to great is not less remarkable in figurative than in real grandeur or elevation. Every one must have observed the delightful effect of a number of thoughts or sentiments, artfully disposed like an ascending series, and making impressions deeper and deeper: such disposition of members in a period is termed a climax.

Within certain limits grandeur and sublimity produce their strongest effects, which lessen by excess as well as by defect. This is remarkable in grandeur and sublimity taken in their proper sense; the grandest emotion that can be raised by a visible object is where the object can be taken in at one view; if so immense as not to be comprehended but in parts, it tends rather to distract than satisfy the mind (A): in like manner, the strongest emotion produced by elevation is where the object is seen distinctly; a greater elevation lessens in appearance the object, till it vanishes out of sight with its pleasant emotions. The fame is equally remarkable in figurative grandeur and elevation; which shall be handled together, because, as observed above, they are often distinguishing. Sentiments may be so strained as to become obscure, or to exceed the capacity of the human mind: against such licence of imagination, every good writer will be upon his guard. And therefore it is of greater importance to observe, that even the true sublime may be carried beyond that pitch which produces the highest entertainment. We are undoubtedly susceptible of a greater elevation than can be inspired by human actions the most heroic and magnanimous; witness what we feel from Milton's description of superior beings: yet every man must be sensible of a more constant and sweet elevation when the history of his own species is the subject: he enjoys an elevation equal to that of the greatest hero, of an Alexander or a Caesar, or an Equamondus: he admires the heroes in their sublime sentiments and most hazardous exploits, with a magnanimity equal to theirs; and finds no stretch to preserve the same tone of mind for hours together without sinking. The case is not the same in describing the actions or qualities of superior beings: the reader's imagination cannot keep pace with that of the poet; the mind, unable to support itself in a strained elevation, falls as from a height; and the fall is immoderate like the elevation: where that effect is not felt, it must be prevented by some obscurity in the conception, which frequently attends the descriptions of unknown objects. Hence the St Francises, St Dominics, and other tetrarch suffants among the Roman Catholics. A mind unable to raise itself to the Supreme Being self-existent and eternal, or to support itself in a strained elevation, finds itself more at ease in using the intercession of some saint whose piety and penances while on earth are supposed to have made him a favourite in heaven.

A strained elevation is attended with another inconvenience, that the author is apt to fall suddenly as well as the reader; because it is not a little difficult to descend, sweetly and easily, from such elevation to the ordinary tone of the subject. The following passage is a good illustration of that observation:

(A) It is justly observed by Addison, that perhaps a man would have been more astonished with the majesty of the air that appeared in one of Lycurgus's statues of Alexander, though no bigger than the life, than he might have been with Mount Athos, had it been cut into the figure of the hero, according to the proposal of Phidias, with a river in one hand and a city in the other. *Spelh. N° 415.*
GRA [109]

In the description of a storm, to figure Jupiter throwing down huge mountains with his thunderbolts, is hyperbolically sublime, if we may use the expression: the tone of mind produced by that image is so distant from the tone produced by a thick flower of rain, that the sudden transition must be unpleasant.

Objects of sight that are not remarkably great nor high, scarce raise any emotion of grandeur or of sublime: and the same holds in other objects; for we often find the mind roused and animated, without being carried to that height. This difference may be discerned in many sorts of music, as well as in some musical instruments: a kettle-drum roules, and a hautboy is animating; but neither of them inspires an emotion of sublimity: revenge animates the mind in a considerable degree; but if we never produce an emotion that can be termed grand or sublime; and perhaps no disagreeable passion ever has that effect.

No desire is so universal than to be exalted and honoured; and upon that account, chiefly, are we ambitious of power, riches, titles, fame, which would suddenly lose their relish did they not raise us above others, and command submission and deference: and it may be thought, that our attachment to things grand and lofty, proceeds from their connection with our favourite passion. This connection has undoubtedly an effect; but that the preference given to things grand and lofty must have a deeper root in human nature, will appear from considering, that many below their time upon low and trifling amusements, without having the least tenerine of this favourite passion: yet these very perfons talk the same language with the rest of mankind; and prefer the more elevated pleasures: they acknowledge a more refined taste, and are ashamed of their own as low and grovelling. This sentiment, constant and universal, must be the work of nature; and it plainly indicates an original attachment in human nature to every object that elevates the mind: some men may have a greater relish for an object not of the highest rank; but they are conscious of the preference given by mankind in general to things grand and sublime, and they are sensible that their peculiar taste ought to yield to the general taste.

What is said above suggests a capital rule for reaching the sublime in such works of art as are susceptible of it; and that is, to present those parts or circumstances only which make the greatest figure, keeping out of view every thing trivial or, for the mind, elevated by an important object, cannot, without relinquish, be forced down to below any share of its attention upon trifles. Such judicious selection of capital circumstances, is by an eminent critic fyled grandeur of manner*. In none of the fine arts is there so great a scope for this rule as in poetry; which, by that means, enjoys a remarkable power of flattening upon objects and events an air of grandeur: when we are spectators, every minute object presents itself in its order; but in describing at second hand, these are laid aside, and the capital objects are brought close together. A judicious taste in thus selecting the most interesting incidents, to give them an united force, accounts for a fact that may appear surprizing; which is, that we are more moved by spirited narrative at second hand, than by being spectators of the event itself, in all its circumstances.

Longinus † exemplifies the foregoing rule by a comparison of two passages.

Ye pow'r's, what madness! how on ships to fail! (Tremendous thought! can thoughtless mortals fail?) For frozen seas they quit the pleasing plain, Plant woods in waves, and dwell amidst the main. Far o'er the deep (a trackless path) they go, And wander oceans in pursuit of wo. No false their hearts, no rest their eyes can find, On heaven their looks, and on the waves their mind; Sun are their spirits, while their arms they rear, And gods are wearied with their fruitless prayer.

Burh as a wave that from the cloud impends, And swell'd with tempests on the ship descends. White are the decks with foam: the winds aloud Howl o'er the masts, and dought through every spout. Pales, trembling, tir'd, the sailors freeze with fear, And instant death on every wave appears.

In the latter passage, the most striking circumstances are selected to fill the mind with terror and affectment. The former is a collection of minute and low circumstances, which scatter the thought, and make no impression; it is at the same time full of verbal antitheses and low conceits, extremely improper in a scene of disharmony.

The following description of a battle is remarkably sublime, by collecting together in the sweet words, those circumstances which make the greatest figure.

"Like autumn's dark storms pouring from two echoing hills, towards each other approached the heroes; as two dark streams from high rocks meet and roar on the plain, loud, rough, and dark in battle, meet Lochlin and Linisfail. Chief mixes his strokes with chief, and man with man; steel founds on steel, and helmets are cleft on high: blood bursts and smokes around: thirings murmur on the polished yew; darts ruth along the sky: spears fall like sparks of flame that gild the flomy face of night."

"As the noise of the troubled ocean when roll the waves on high, as the last peal of the spring heaven, such is the noise of battle. Though Càrime's hundred bards were there, fcele were the voice of a hundred bards to send the deaths to future times; for many were the deaths of the heroes, and wide poured the blood of the valiant." FINGAL.

The following passage in the 4th book of the Iliad is a description of a battle wonderfully ardent, "When now gathered on either side, the hoofds plunged together in sight; shield is hardly laid to shield; spears crash on the brazen corsets; billy buckler with buckler meets; loud tumult rages over all; groans are mixed with hoasts of men; the slain and slayer join in noise; the earth is floating round with blood. As when two rushing flames from two mountains come roaring down, and throw together their rapid waters below, they roar along the gulpful vale; the startled shepherd hears the sound as he staks o'er the distant hills: so, as they mixed in fight, from both armies clamour with loud terror arose." But such general descriptions are not frequent in Homer. Even his single combats are rare. The fifth book is the longest account of a battle that is in the Iliad; and yet contains nothing but a long catalogue of chiefs killing chief

* Spectator, No. 475.

† Claud. 8.
The clouds are split into a thousand small parts in the light; the most eminent architects have governed themselves by the same rule in all their works.

Another rule chiefly regards the sublime, though it is applicable to every sort of literary performance intended for amusement; and that is, to avoid as much as possible abstract and general terms. Such terms, similar to mathematical signs, are contrived to express our thoughts in a concise manner; but images which are the life of poetry, cannot be raised in any perfection but by introducing particular objects. General terms, that comprehend a number of individuals, must be excepted from that rule: our kindred, our clan, our country, and words of the like import, though they scarce raise any image, have, however, a wonderful power over the passions: the greatness of the complex object overbalances the obscurity of the image.

Grandeur, being an extreme vivid emotion, is not readily produced in perfection but by reiterated impressions. The effect of a single impression can be but momentary; and if one feel suddenly somewhat like a swelling or exaltation of mind, the emotion vanishes as soon as felt. Single thoughts or sentiments are often cited as examples of the sublime; but their effect is far inferior to that of a grand subject displayed in its capital parts. We shall give a few examples, that the reader may judge for himself. In the famous action of Thermopylae, where Leonidas the Spartan king, with his chosen band, fighting for their country, were cut off to the last man, a saying is reported of Dianeces, one of the band, which, expressing cheerful and undisturbed bravery, is well intuited to the first place in examples of that kind: talking of the number of their enemies, it was observed, that the arrows shot by such a multitude would intercept the light of the sun; "So much the better (says he), for we then shall in fight the shades."

Samerfes. Ah! Warwick, Warwick, were thou as we are, We might recover all our losses again.

The Queen from France has brought a puissant power. Ev'n now we heard the news. Ah! could we then fly! Warwick. Why, I then would not fly. Third part, Henry VI, act. 5, sc. 3.

Such a sentiment from a man expiring of his wounds, is truly heroic; and must elevate the mind to the greatest height that can be done by a single expression: It will not suffer in a comparison with the famous sentiment Qu'il mourut of Corneille: the latter is a sentiment of indignation merely, the former of firm and cheerful courage.

To cite in opposition many a sublime passage, enriched with the finest images, and drenched in the most nervous expressions, would scarce be fair. We shall produce but one instance, that of Shakespear, which sets a few objects before the eye, without much pomp of language: it operates its effect by representing these objects in a climax, razing the mind higher and higher till it feel the emotion of grandeur in perfection:

The cloud-capt tow'rs, the gorgeous palaces, The solemn temples, the great globe itself, Yea, all which it inheres, shall dissolve, &c.

The cloud-capt tow'rs produce an elevating emotion, heightened by the gorgeous palaces; and the mind is carried still higher and higher by the images that follow.
The cloud-capt tow'r's, the gorgeous palaces,
The solemn temples, the great globe itself,
Yes, all which it inherit, shall dissolve,
And like the baseless fabric of a vision
Leave not a wreck behind—

The elevation of the mind in the former part of this beautiful passage, makes the fall great in proportion, when the most humble of all images is introduced, that of an utter dissolution of the earth and its inhabitants. The mind, when warmed, is more susceptible of impressions than in a cool state; and a depressing or melancholy object listened to, makes the strongest impression when it reaches the mind in its highest state of elevation or cheerfulness.

But a humbling image is not always necessary to produce that effect: a remark is made above, that in describing inferior beings, the reader's imagination, unable to support itself in a strained elevation, falls often as from a height, and sinks even below its ordinary tone. The following instance comes luckily in view; for a better cannot be given: "God said, Let there be light, and there was light." Longinus quotes this passage from Moses as a shining example of the sublime; and it is scarce possible, in fewer words, to convey so clear an image of the infinite power of the Deity: but then it belongs to the present subject to remark, that the emotion of sublimity raised by this image is but momentary; and that the mind, unable to support itself in an elevation so much above nature, immediately sinks down into humility and veneration for a Being so far exalted above groveling mortals. Every one is acquainted with a dispute about that passage between two French critics *, the one positively affirming it to be sublime, the other as positively denying. What has been remarked, shows, that both of them have reached the truth, but neither of them the whole truth: the primary effect of the passage is undoubtedly an emotion of grandeur: which so far justifies Boileau: but then every one must be sensible, that the emotion is merely a flash, which, vanishing instantaneously, gives way to humility and veneration. That indirect effect of sublimity justifies Huet, on the other hand, who being a man of true piety, and probably not much carried by imagination, felt the humbling passions more sensibly than his antagonist did. And laying aside difference of character, Huet's opinion may perhaps be defended as the more solid; because, in such images, the depressing emotions are the more sensibly felt, and have the longer endurance.

The straining an elevated subject beyond due bounds, and beyond the reach of an ordinary conception, is not a vice so frequent as to require the correction of criticism. But false sublimine is a rock that writers of more fire than judgment commonly split on; and therefore a collection of examples may be of use as a beacon to future adventurers. One species of false sublime, known by the name of bombast, is common among writers of a mean genius: it is a serious endeavour, by strained description, to raise a low or familiar subject above its rank; which, instead of being sublime, fails not to be ridiculous. The mind, indeed, is extremely prone, in some animating passions, to magnify its objects beyond natural bounds: but such hyperbolical description has its limits: and when carried beyond the impulse of the propensity, it degenerates into burlesque. Take the following examples:

* Boileau and Huet.

** False sublime.
And both were the laity, wherein to lay up the full gallop, or farmer."

GRANGE, an ancient term for a barn or place wherein to lay up and thresh corn. The word is formed of the Latin grana; or of granum, "grain, corn," &c. Hence also granger or grangier, "a grange-keeper or farmer."

GRANICUS, a small river near the Hellefpoint in Lesser Asia, remarkable for the first victory gained by Alexander the Great over the armies of Darius. — Authors disagree very much about the number of the Persians, though all agree that they were vastly more numerous than the Greeks. Jufcin and Orosius tell us, that the Persian army consisted of 600,000 foot and 20,000 horse; Arrian makes the foot amount to 200,000; But Diodorus tells us, that they were not more than 100,000 foot and 10,000 horse. The Macedonian army did not exceed 30,000 foot and 5000 horse. The Persian cavalry lined the banks of the Granicus, in order to oppose Alexander wherever he should attempt a passage; and the foot were posted behind the cavalry on an easy ascent. Parmenio would have had Alexander to allow his troops some time to refresh themselves; but he replied, that, after having crossed the Hellefpoint, it would be a disgrace to him and his troops to be stopped by a rivulet. Accordingly a proper place for crossing the river was not sooner found, that he commanded a strong detachment of horse to enter; he himself followed with the right wing, which he commanded in person; the trumpets in the mean time sounding, and loud shouts of joy being heard through the whole army. The Persians let fly such showers of arrows against the detachment of Macedonian horse, as caused some confusion; several of their horses being killed or wounded. As they drew near the bank a most bloody engagement ensued; the Macedonians attempting to land, and the Persians putting them back into the river. Alexander, who observed the confusion they were in, took the command of them himself; and landing in spite of all opposition, obliged the Persian cavalry, after an obstinate resistance, to give ground. However, Spithrobates, governor of Ionia, and fon-in-law to Darius, still maintained his ground, and did all that lay in his power to bring them back to the charge. Alexander advanced full gallop to engage him; neither did he decline the combat; and both were slightly wounded at the first encounter. Spithrobates having thrown his javelin without effect, advanced fword in hand to meet his antagonist, who ran him through with his pike as he raised his arm to discharge a blow with his fcyliner. But Rosaces, brother to Spithrobates, at the same time gave Alexander such a furious blow on the head with his battle-ax, that he beat off his plume, and slightly wounded him through the helmet. As he was ready to repeat the blow, Citius with one stroke of his fcyliner cut off Rosaces's head, and thus in all probability saved the life of his sovereign. The Macedonians then, animated by the example of their king, attacked the Persians with new vigour, who soon after betook themselves to flight. Alexander did not pursue them; but immediately charged the enemy's foot with all his forces, who had now passed the river. The Persians, disheartened at the defeat of their cavalry, made no great resistance. The Greek mercenaries retired in good order to a neighbouring hill, whence they sent deputies to Alexander desiring leave to march off unmolested. But he, instead of coming to a parley with them, rushed furiously into the middle of this small body; where his horse was killed under him, and he himself in great danger of being cut in pieces. The Greeks defended themselves with incredible valour for a long time, but were at last almost entirely cut off. In this battle the Persians are said to have lost 20,000 foot and 2500 horse, and the Macedonians only 55 foot and 60 horse.

GRANITE, in natural history, a distinct genus of stones, composed of separate and very large concretions rudely compounded together; of great hardnes, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire. Of this genus there are three species: 1. The hard white granite, with black spots, commonly called moorstone. This is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running into one another, but each pure and distinct, and firmly adhering, but at the same time the whole forming an unconnected stone. 2. The hard red granite variegated with black and white, and common in Egypt and Arabia. 3. The pale whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

Some of these kinds of stones are found in almost every country, and in many places they are found of immense bigness. The largest mass of this kind in the known world, lying as an unconnected stone, is near the Cape of Good Hope in Africa, and of which we have the following description in the Philosophical Transactions, vol. 68, p. 102, given by Mr Anderson in a letter to Sir John Pringle. "The stone is so remarkable, that it is called by the people here the Tower of Babel, and by some the Pearl Diamond. It either takes the last name from a place near which it is situated, or it gives names to the tract of cultivated land called the Pearl. It lies upon the top of a ridge of low hills, beyond a large plain, at the..."
Granite. the distance of about thirty miles from the Cape Town; beyond which, at a little distance, is a range of hills of a much greater height. It is of an oblong shape, and lies north and south. The south end is highest; the east and west sides are steep and high; but the top is rounded, and slopes away gradually to the north end, so that you can ascend by that way, and enjoy a most extensive prospect of the whole country. I could not precisely determine its circumference, but it took us above half an hour to walk round it; and by making every allowance for the rugged way, and footing a little, I think the most moderate computation must make it exceed half a mile. The same difficulty occurred with respect to knowing its height; but I think, that, at the south end, it is nearly equal to half its length: or, were I to compare it to an object you are acquainted with, I should say it equalled the dome of St. Paul’s church.

“I am uncertain whether it ought to be considered as the top of the hill, or a detached stone, because there is no positive proof of either, unless we were to dig about its base; but it would certainly impress every beholder, at first sight, with the idea of its being one stone, not only from its figure, but because it is really one solid uniform mass from top to bottom, without any interruption; which is contrary to the general character of the high hills of this country, they being commonly divided, or composed of different strata, at least if we may judge from the rows of plants or shrubs which grow on the sides of the steep rock, and, as I suppose, are produced from the small quantity of earth interposed between them. It has indeed a few fissures, or rather impressions, which do not reach deeper than four or five feet; and near its north end a stratum of a more compact stone runs across, which is not above twelve or fourteen inches thick, with its surface divided into little squares, or oblongs, disposed obliquely. This stratum is perpendicular; but whether it cuts the other to its base, or is superficial, I cannot determine. Its surface is also so smooth that, it does not appear to have formerly been joined to, or separated from, any other part by violence; as is the case with many other large fragments; but enjoys the exact situation where it was originally placed; and has undergone little change from being exposed for so many successive ages to the calcining power of a very hot climate.”

A part of this stone being examined by Sir William Hamilton, he determined it to be a granite, and of the same nature as the top of the hill, or a detached stone, because there is a predominance of quartzo-felspar, and mica; the grey ones of white quartz, grey or violet felt-spar, and black mica. The black granites commonly contain chlorite instead of felt-spar; and the green usually contain green quartz.

On exposing granite to the flame of a blow-pipe, the component ingredients separate from one another. Sir Gerhard having melted some in a crucible, found the felt-spar run into a transparent glass; below it the mica lay in form of black flag, the quartz remaining unaltered. It melted somewhat better when all the three were powdered and mixed together; though even then the quartz was still discernible by a magnifying glass. Hence we may explain the reason why grains of a white colour are sometimes found in volcanic lavas. The mixture of mica prevents the felspar or quartz from splitting or cracking; and hence its insusceptibility and use in furnace-building.

Granites are seldom flaty or laminated. In those which are of a close texture, the quartz and felspar predominate. They take a good polish; for which reason the Egyptians formerly, and the Italians still work them into large pieces of ornamental architecture, for which they are extremely fit, as not being liable to decay in the air. Farber, in his letters from Italy, mentions a kind of stone named granitones, composed of felt-spar and mica: a substance of this kind, which moulders in the air, is found in Finland; which is said to contain salt-petre, and sometimes common salt. In that country it is called repariri. Warton describes 18 species of granites, besides many others akin to this genus. Those described by Cronstedt are, 1. Loose or friable, which comes from France, and is used at the brass-works for casting that metal in. 2. Hard or compact, of which there are two varieties, red and grey. The former is met with of two kinds: viz. fine-grained from Swappari in Lapland, or coarse-grained from the province of Dalne in Sweden. The grey, with other colours, is met with on the coast round Stockholm and Norland in Sweden.

GRANITELLO, a genus of stones of the order of petrae, belonging to the class of faxa. There are two species, 1. That composed of different particles, found in several of the mountainous parts of Sweden. In some of these there is a predominance of quartzo-felspar particles, in others of micaceous; in which last case the stone is flaty, and easily split. 2. Granitello, composed of convoluted particles. This is met with of different colours, as whitish grey, greenish, and reddish.

Both these kinds of stones are used in building furnaces, on account of the powerful resistance they make to the fire; but the latter is preferable to the other, on account of its containing a little of a refractory clayish substance. It is likewise of great use in mills, where the fellow is a coarse sandstone.

GRANIVOROUS, an appellation given to animals which feed on corn or seeds. These are principally of the bird kind.

GRANT, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, &c.

GRANT (Francis), Lord Cullen, an eminent lawyer.
Granter and judge in Scotland, was descended from a younger branch of the family of the Grants of Grant in that kingdom, and was born about the year 1660. When he commenced advocate, he made a distinguished figure at the revolution, by opposing the opinion of the old lawyers, who warmly urged on the inability of the convention of estates to make any disposition of the crown. The abilities he showed in favour of the revolution recommended him to an extensive practice; in which he acquired so much honour, that when the union between the two kingdoms was to be accomplished, queen Anne unexpectedly, and without application, created him a baronet, with a view of securing his interest in that measure; and upon the same principle, the soon after created him a judge, or one of the lords of session. From this time, according to the custom of Scotland, he was styled from the name of his estate, Lord Cullen; and the fame good qualities that recommended him to this honourable office, were very conspicuous in the discharge of it; which he continued for 20 years with the highest reputation, when a period was put to his life by an illness which lasted but three days. He expired without any agony on March 16th 1726.—His character is drawn to great advantage in the Biographia Britannica; where it is observed, among other remarks to his honour, "That as an advocate he was indefatigable in the management of business; but at the same time that he spared no pains, he would use no craft. He had so high an idea of the dignity of his profession, that he held it equally criminal to neglect any honest means of coming at justice, or to make use of any arts to elude it. In respect to fortune, though he was modest and frugal, and had a large practice, yet he was far from being avaricious. His private charities were very considerable, and grew in the same proportion with his profits. He was, besides, very scrupulous in many points; he would not suffer a just cause to be lost through a client's want of munificence. He was such an enemy to oppression, that he never denied his assistance to such as labouring under it; and with respect to the clergy of all professions (in Scotland,) his conscience obliged him to serve them without a fee. When his merit had raised him to the bench, he thought himself accountable to God and man for his conduct in that high office; and that deep sense of his duty, at the same time that it kept him strictly to it, encouraged and supported him in the performance. Whenever he was free to speak, the paper of cause was remarkably full, for his reputation being equally established for knowledge and integrity, there were none, who had a good opinion of their own pretensions, but were moved to bring them before him, and not many who did not fit down satisfied with his decision. This prevailed more especially after it was found that few of his sentences were reversed; and when they were it was commonly owing to himself: for if, upon mature reflection, or upon new reasons offered at the rehearing, he saw any just ground for altering his judgment, he made no scruple of declaring it; being persuaded, that it was more manly, as well as more just, to follow truth, than to support opinion; and his conduct in this respect had a right effect; for instead of lessening, it raised his reputation. He would not, however, with all this great flock of knowledge, experience, and probity, trust himself in matters of blood, or venture to decide in criminal cases on the lives of his fellow-creatures; which was the reason that, though often solicited, he could never be prevailed upon to accept of a seat in the judiciary court.—In his private character he was as amiable as he was respectable in his public. He was charitable without ostentation, disinterested in his friendships, and beneficent to all who had anything to do with him. He was not only strictly just, but so free from any species of vanity, that his lady, who was a woman of great prudence and discretion, finding him more intent on the business committed to him by others than on his own, took upon herself the care of placing out his money; and to prevent his postponed, as he was apt to do, such kind of affairs, when securities offered, he caused the circumstances of them to be stated in the form of cafes, and so procured his opinion upon his own concerns as if they had been those of a client. He was so true a lover of learning, and was so much addicted to his studies, that, notwithstanding the multiplicity of his business while at the bar, and his great attention to his charge when a judge, he nevertheless found time to write various treatises on very different and important subjects: Some political, which were remarkably well-timed, and highly serviceable to the government; others of a more extensive nature, such as his essays on law, religion, and education, which were dedicated to George II. when prince of Wales; by whose command, his then secretary, Mr Samuel Molyneux, wrote him a letter of thanks, in which were many gracious expressions, as well in relation to the piece as to its author. He composed, besides these many discourses on literary subjects, for the exercise of his own thoughts, and for the better discovery of truth; which went no farther than his own closet, and from a principle of modesty were not communicated even to his most intimate friends."
Granulated Cambridge. In 1696, his comedy called the She-gal-
lunts was acted at the theatre-royal in Lincolns-in-
fields, as his tragedy called Heroic Love was in the
year 1698. In 1702 he translated into English the
second Olymian of Demosthenes. He was member for
the county of Cornwall in the parliament which met in
1710; was afterwards secretary of war, comptroller of
the household, then treasurer, and sworn one of the
privy-council. The year following he was created
baron Lanfdowne. On the accession of king George I.
in 1714, he was removed from his treasurer’s place;
and the next year entered his protest against the bills
for attainting lord Bolingbroke and the duke of Or-
mond. He entered deeply into the scheme for rais-
ing an insurrection in the west of England; and be-
ing seized as a suspected person, was committed to the
Tower, where he continued two years. In 1719, he
made a speech in the house of Lords, against the bill
to prevent occasional conformity. In 1722, he with-
drew to France, and continued abroad almost ten years.
At his return in 1732, he published a fine edition of his
works in 2 vols quarto. He died in 1735, leaving no
male issue.

Granville, a sea-port town of France, in Lower
Normandy, partly seated on a rock and partly on a
plain. It gave the title to an English earl, now
extinct.

W. Long. 1. 32. N. Lat. 48. 58.

Granulated, something that has undergone
granulation. See the next article.

Granulation, in chemistry, an operation by
which metallic substances are reduced into small grains,
or roundish particles; the use of which is, to facilitate
their combination with other substances.—This opera-
tion is very simple; it consists only in pouring a
melted metal slowly into a vessel filled with water,
which is in the mean time to be agitated with a broom.
With melted copper, however, which is apt to ex-
plode with great violence on the contact of water,
some precautions are to be observed, of which an ac-
count is given under the article Chemistry, n° 11468.
Lead or tin may be granulated by pouring them when
melted into a box; the internal surface of which is to
be rubbed with powdered chalk, and the box strongly
shaken till the lead has become solid. Metals are gra-
nulated, because their ductility renders them inca-
pable of being pounded, and because filing is long
and tedious, and might render the metal impure by
an admixture of iron from the file.

Grape, the fruit of the vine. See Vine and
Wine. See also Curants and Raisins.

Grape-shot, in artillery, is a combination of small
shot, put into a thick canvas bag, and corded strongly
together, so as to form a kind of cylinder, whose di-
амe is equal to that of the ball adapted to the ca-
non. The number of shot in a grape varies according
to the service or size of the guns: in sea-service nine
is always the number; but by land it is increased to
any number or size, from an ounce and a quarter in
weight to three or four pounds. In sea-service the
bottoms and pins are made of iron, whereas those used
by land are of wood.

Grapes, in the manage, a term used to signify the
arrests or mangy tumours that happen in the horse’s
legs.

Graphometer, a mathematical instrument,
otherwife called a Semi-circle; the use of which is to
observe any angle whose vertex is at the centre of the
infrument in any plane (though it is most commonly
horizontal, or nearly so), and to find how many de-
grees it contains. See Geometry, p. 674, prop. xi. &c.

Graphel, or Grappling, a sort of small an-
chor, fitted with four or five flukes or claws, and
commonly used to ride a boat or other small vesel.

Fire-grappling, an instrument nearly resembling
the former, but differing in the construction of its
flukes, which are furnished with strong bars on
their points. These machines are usually fixed on the
yard-arms of a ship, in order to grapple any adver-
sary whom the intends to board. They are, however,
more particularly useful in Fire-ships for the purposes
described in that article.

Grass, in botany, is defined to be a plant having
simple leaves, a stem generally jointed and tubular, a
hufky calyx (called gluma), and the seed single. Hence
wheat, oats, barley, &c. are properly graises, accord-
ing to the definition given; while clover and some
other similar plants are not graises, though so frequently
called by that name.—Of graises, the leaves are food
for cattle, the small feed for birds, and the larger
graist chiefly for man. And it is observable, that
nature has so provided, that cattle (in grazing) seldom
eat the flower intended to produce feed, unless com-
pelled by hunger.

For the culture of the different sorts of grain, see
Agriculture, n° 122. & seq.; and for that of the
graises commonly so called, see the same article, n°
175, & seq. and the references below.

Culmiferous graises might be divided into two ge-
eral classes, for the purporses of the farmer, that it
might be of use for him to attend to, viz. 1st, Those
which, like the common annual kinds of corn, run
chiefly to seed-stalks; the leaves gradually decaying as
these advance towards perfection, and becoming to-
tally withered or falling off entirely when the seeds are
ripe. Rye-graiz belongs to this class in the strictest
sense. To it likewise may be assigned the vernal-
graises, dog’s-tail graises, and fine bent-graises. 2dly, Those
whose leaves continue to advance even after the seed-
stalks are formed, and retain their verdure and fucce-
sence during the whole seafon, as is the case with the
feine and poa tribes of graises, whose leaves are as
green and succulent when the seeds are ripe and the
flower-stalks fading, as at any other time.

"It is wonderful, Mr Stillingfleet remarks, to see • Trefis rel-
ating to Nat. Hist.
the how long mankind have neglected to make a proper ad-
Vantage of plants of such importance, and which, in
almost every country, are the chief food of cattle.

The farmer, for want of distinguishing and feeding
graises for feed, fills his pastures either with weeds or
bad or improper graises; when, by making a right
choice, after some trials, he might be sure of the best
graises, and in the greatest abundance that his land
admits of. At present, if a farmer wants to lay down
his land to graises, what does he do? he either takes
his feed indiscriminately from his own foul hay-rick,
or sends to his next neighbour for a supply. By this
means, besides a certain mixture of all sorts of rubbiih,
which must necessarily happen, if he chances to have
a large proportion of good feed, it is not unlikely but
that what he intends for dry land may come from moist,
Agriculture.

Now, would the farmer be at the pains of separating once in his life half a pint or a pint of the different kinds of grasses-seeds, and take care to sow them separately, in a very little time he would have wherewithal to flock his farm properly, according to the nature of each soil, and might at the same time spread these seeds separately over the country, by supplying the feeding-thraps. The number of grasses fit for the farmer is, I believe, small, perhaps half a dozen or half a score are all he need to cultivate; and how small the trouble would be of such a task, and how great the benefit, must be obvious to every one at first sight. Would not any one be looked on as wild who should sow wheat, barley, oats, rye, peas, beans, vetches, buck-wheat, turnips, and weeds of all sorts together; yet how it is much less absurd to do what is equivalent in relation to grasses? Does it not import the farmer to have good hay and grass in plenty; and will cattle thrive equally on all sorts of grasses? We know the contrary. Horses will scarcely eat hay which is not perfectly ripe, and even quite dry. It is the farmer to have good hay and stock; only that it might be of use upon all sorts of pastures which have been recommended as the most profitable, viz.

1. Hordeum murinum, Rye-grass vulgo. [Rye-grasses properis is the Secale villosum. Perennial, beardless, Lolium perenne, is also, in some counties of England, improperly called rye-grasses.] See Agriculture, p. 179.

2. Festuca rubra, Purple Fescue-grass. See Agriculture, p. 54.

3. Festuca ovina, Sheep silt. See Agriculture, pp. 36—58. This is perhaps the most valuable grass of all. It is observed to grow and thrive on lands of all qualities and in all situations, from the driest upland pastures to the very moist parts of meadows. It does not remain with its feet till some time after they are ripe, and even quite dry. It makes the thickest and closest pile of any of them, and furnishes a good value of grass in proportion to its leaves. It flowers in June, and is ripe in July.

5. Alopecurus bulbosus, Bulbous Foxtail-grass, is recommended by Dr Anderson, as promising on some occasions to afford a valuable pasture-grass. It is chiefly, he observes, to delight in a moist soil, and therefore promises to be only fit for a meadow pasture grass. The quality that first recommended it to his notice, was the unusual firmness that its matted roots gave to the surface of the ground, naturally soft and moist, in which it grew; which seemed to promise that it might be of use upon chalky soils, chiefly in preventing them from being much poached by the feet of cattle which might pasture upon them. Molay soils especially are so much hurt by poaching, that anything that promises to be of use in preventing it deserves to be attended to.

6. Poa pratensis, Great Meadow-grass, seems to approach in many respects to the nature of the purple-fescue; only that its leaves are broader, and not so long; being only about a foot or 16 inches at their greatest length. Like it, it produces few feed-flaks and many leaves, and is an abiding plant. It affects chiefly the dry parts of meadows, though it is to be found on moat good pastures. It is very retentive of its seeds, and may therefore be suffered to remain till the flaks are quite dry. It blooms the beginning of June, and its seeds are ripe in July.

7. Poa compressa, Creeping Meadow-grass, according to Dr Anderson, seems to be the most valuable grass of any of this genus. Its leaves are firm and succulent, of a dark Saxa-green colour, and flowers upon one another, as to form the richest pile of pasture-grasses. The flower-flaks, if suffered to grow, appear in sufficient quantities; but the growth of these does not prevent the growth of the leaves, both advancing together during the whole summer; and when the flaks fade, the leaves continue as green as before. Its leaves are much larger and more abundant than the common meadow-grasses, Poa trivialis; and therefore it better deserves to be cultivated.

8. Anthoxanthum odoratum, Vernal grass, grows very commonly on dry hills, and likewise on found rich meadow-land. It is one of the earliest grasses we have; and from its being found on such kinds of pastures as sheep are fond of, and from whence excellent mutton comes, it is most likely to be a good grass for sheep-pastures. It gives a grateful odour to hay. In one respect, it is very easy to gather, as it sheds its seeds upon the leaf rubbing. A correspondent of the Bath Society, however, mentions a difficulty that occurs in collecting them, owing to its being surrounded with taller grasses at the time of its ripening, and being almost hid among them. If it be not carefully watched when nearly ripe, it escapes, and gathered within a few days after it comes to maturity, great part of the seed will be lost. The twisted elatic awns, which adhere to the seed, lift them out of their receptacles with the leaf motion from the wind, and the straw and ear remain quite erect. It is found mostly in the moist parts of meadows; very little of it on dry pastures. It flowers about the beginning of May, and is ripe about the middle of June.

9. Cynosurus cristatus, Crested Dog's-tail Grass. Mr Stillington imagines this grass to be proper for parks, from his having known one, where it abounds, that is famous for excellent venison. He recommends it also, from experience, as good for sheep; the best mutton he ever tasted, next to that which comes from hills where the purple and sheep fescue are the finest bent and the silver hair grasses abound, having been from sheep fed with it. He adds, that it makes a very fine turf upon dry sandy or chalky soils: but unless swept over with the scythe, its flowering-STEMS will look brown;
The fame may be faid of thefe two grasfs as of the preceding one.

14. *Festuca fluitans*, Flote Fescue. In a piece published in the Amojnmatas Academicae, vol. 3, intitled Stmata Effulenta, we are informed, that "the feeds of this grasf are gathered yearly in Poland, and from hence carried into Germany; and fometimes into Sweden, and fold under the name of manna feeds. Threfe are much ufed at the tables of the great, on account of their nourishing quality and agreeable taste. It is wonderful (adds the author), that these feeds have hitherto been neglected, since they are fo easily collected and cleaned." There is a clamour on the ear of the fiole-fefcelle, when the feeds are ripe, that tastes like honey; and for this reafon perhaps they are called manna feeds.

Linnaeus (Flor. Seue, art. 95.) fays that the bran of this grasf will cure horfes troubled with botts, if kept from drinking for fome hours.

Concerning this grasf we have the following information by Mr Stillingfleet. "Mr Dean, a very fenible farmer at Hutfomb, Bermfhire, affidured me that a field, always lying under water, of about four acres, that was occupied by his father when he was a boy, was covered with a kind of grasfs, that maintained five farm-horfes in good heart from April to the end of harvest, without giving them any other kind of food, and that it yielded more than they could eat. He, at my defire, brought me some of thefes, which proved to be the flote-fescue with a mixture of the marfh-bent; whether this laft contributes much towards fur-riihing fo good purfure for horfes, I cannot fay. They both throw out roots at the joints of the stalks, and therefore are likewife to grow to a great length. In the index of doubious plants at the end of Ray's Synop-phis, there is mention made of a grasf under the name of *gramen cannum supinum longiflimum*, growing not far from Saliphury, 24 feet long. This muft by its length be a grasf with a creeping falk; and that there is a grasf in Wilthire growing in watery meadows, so valuable, that an acre of it fets from 10 to 12 pounds, I have been informed by feveral perfons. Thefe circum-fances incline me think it muft be the flote-fescue; but whatever grasfs it be, it certainly muft deserve to be inquired after."

15. *Alpecepear pratenfis*, Meadow Fontail. Linnaeus fays that this is a proper grasf to sow on grounds that have been drained.—Mr Stillingfleet was informed, that the flot bay which comes to London is from the meadows where this grasfs abounds. It is scarce in many parts of England, particularly Herefordfhir, Bermfhire, and Norfolk. It might be gathered at almost any time of the year from hay ricks, as it does not feed its feeds without rubbing, which is the cafe of bot few grasfs. It is among the moft graceful of all grasfs to cattle. It is ripe about the latter end of June.

16. *Poa annua*, Annual Meadow Grasf. This grasf (fays Mr Stillingfleet) makes the finest of turfs. It grows every where by way sides, and on rich found commons. It is called in some parts the Suffolk grasf. I have feen whole fields of it in High Suffolk without any mixture of other grasfs; and as some of the flot falt-butter we have in London comes from that county, it is moft likely to be the flot grasf for the dairy. I have feen a whole park in Suffolk covered with this grasf; but whether it affords good venion, I cannot tell, having never tasted of any from it. I should rather think not, and that the bell pailure for fheep is alfo the bell for deer. However, this wants trial. I remarked on Malvern-hill fomething particular in relation to this grasf. A walk that was made there for the convenience of the water drinkers, in lefs than a year was covered in many places with it, though I could not find one fingle plant of it besides in any part of the hill. This was no doubt owing to the frequent reading, which above all things makes this grasf florifh; and therefore it is evident that riding muft be very serviceable to it. It has been objected, that this grasf is not free from bents, by which word is meant the flowing-items. I anfwer, that this is moft certainly true, and that there is no grasf without them. But the flowers and items do not grow fo foon brown as thoef other grasfs; and being much florter, they do not cover the radical leaves fo much; and therefore this grasf affords a more agreeable turf without mov- ing, than any other whatever that I know of."
Grasses are made, for the most part, not by sowing grass seeds, but by laying turfs; and indeed the turfs from a fine common or down are much preferable to sown grasses: but if walks or plots are to be made by sowing, the best way is to procure the feed from those pastures where the grass is naturally fine and clear; or else the trouble of keeping it from spurry or bent grass will be very great, and it will scarce ever look handsome.

In order to sow grass walks, the ground must be first dug; and when it has been drenched and laid even, it must be very carefully raked over, and all the clobs and ftones taken off, and then covered over an inch thick with good mud.

This being done, the seed is to be fown pretty thick, that it may come up close and short; it must then be raked over again, to cover the seed, that if the weather should happen to be windy, it may not be blown away. It ought also to be observed, that where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil or Dutch clover sown with it; for this will make a fine turf much fooner than any other sown grass, and will continue a better verdure than any other of any places that are well filled, or where nothing improves grass so much as turf.

In order to keep grass-plats or walks handsome, and in good order, you may low in autumn fresh feed over any places that are not well filled, or where the grass is dead: but nothing improves grass so much as mowing and constant rolling.

When turf is laid in gardens, it is a general practice to cover the surface of the ground under the turf, either with sand or very poor earth: the design of this is to keep the grass fine, by preventing its growing too rank. This is proper enough for very rich ground: but it is not so for such land as is middling, or but poor; for when this is practized in such places, the grass will soon wear out and decay in patches.

When turf is taken from a common or down, such ought to be chosen as is free from weeds: and when it is designed to be used for years without renewing, the dresting should be laid upon it every other year, either of very rotten dung, ashes, or, where it can be easily procured, very rotten tan; but these dressings should be laid on early in the winter, that the rain may wash them into the ground, otherwise they will occasion the grass to burn, when the warmth of the summer begins.

When grass is sod-dressed, and well rolled and mowed, it may be kept very beautiful for many years; but where it is not dressed, or fed with sheep, it will rarely continue handsome more than eight or ten years.

Grasshopper, in zoology, a species of Gryllus. See Gryllus.

Gratarolus (William), a learned physician in the 16th century, was born at Bergamo in Italy; and taught physic with reputation at Padua: but having embraced the Protestant religion, he retired to Switzerland; where he was made professor of physic. He died at Basle in 1568, aged 52. He wrote several curious works in Latin; amongst which are, 1. The manner of preferring and improving the memory. 2. Of preferring in health travellers, men of letters, magistrates, and studious persons, &c.

Grates for Fires, are composed of ribs of iron placed at small distances from one another, so that the air may have sufficient access to the fuel, and the accumulation of the ashes, which would choke the fire, may be prevented. Grates seem peculiarly adapted to the use of pit-coal, which requires a greater quantity of air to make it burn freely than other kinds of fuel. The hearths of the Britons seem to have been fixed in the centre of their halls, as is yet practiced in some parts of Scotland, where the fire is nearly in the middle of the house, and the family sit all around it. Their fire place was perhaps nothing more than a large stone, depressed a little below the level of the ground, and thereby adapted to receive the ashes. About a century ago, it was only the floor of the room, with the addition of a bank or hob of clay. But it was now changed among the gentlemen for a portable fire-pan, raised upon low supports, and fitted with a circular grating of bars. Such were in use among the Gauls in the first century, and among the Welsh in the tenth.

Gratian, the son of Valentinian I. by his first wife, was declared Augustus by his father at the city of Amiens in 365, and succeeded him in 367; a prince equally exalted for his wit, eloquence, modesty, charity, and zeal against heretics. He affiliated Theodosius with him in the empire, and advanced the poet Antonius to the consulship. He made a great daughter of the Germans at Strafford: and hence was famed Memmius. He was the first emperor who refused the title of Pontifex Maximus, upon the score of its being a Pagan dignity. He was assassinated by Andragathius in 375, in the 24th year of his age.

Gratian, a famous Benedictine monk, in the 12th century, was born at Chiufi, and employed near twenty-four years in compounding a work, intitled Decretum, or Concordantia Diffordantium Canonum, because he there endeavoured to reconcile the canons which seemed contradictory to each other. This work he published in 1151. As he is frequently mistaken, in taking one canon of one council, or one passage of one father, for another, and has often cited false decreals, several authors have endeavoured to correct his faults; and chiefly Anthony Augalwine, in his excellent work, intitled, De emendatione Gratiani. To the decreals of Gratian, the popes principally owed the great authority they exercised in the thirteenth and following centuries.

Gratings, in a ship, are small edges of sawed plank, framed one into another like a lattice or prison grate, lying on the upper deck, between the main-mast and fore-mast, serving for a defence in a close fight, and also for the coolness, light, and convenience of the ship's company.

Gratiola, a genus of the monography order, belonging to the diandra clas of plants. The corolla is irregular; there are two bar- ren flama; the capsule is bilocular; the calyx has seven leaves, with the two exterior ones peltate. There are four species; the most remarkable of which is the officinalis, or common hedge-hyssop. This grows naturally on the Alps and other mountainous parts of Europe. It hath a thick, fibrous, creeping root, which propagates very much, when planted in a proper soil and situation. From this arise several upright square stalks, garnished with narrow
narrow spear-shaped leaves, placed opposite. The flowers are produced on the side of the stalks at each joint; they are shaped like those of the foxglove, but are small, and of a pale yellowish colour. This herb has an emetic and purgative virtue; to answer which intentions, it was formerly used by the common people in England, but was never much prescribed by the physicians, and at last fell totally into disuse. Of late however, it has been the subject of a dissertation by Dr James Kotzevski of Warsaw, in Poland; who gives some remarkable accounts of its effects in mania and obstinately veneral cases. It was given in powder, or in extract, to the quantity of half a dram of the first, and a whole dram of the second, at each dose. From the cases related in his dissertation, the author draws the following conclusions: 1. The gratiola may be given with safety both to male and female patients. 2. In all disorders proceeding from a superabundance of phlegm in the fluids, it appears to be a most effectual remedy. 3. In consequence of this, it is had recourse to with very great advantage in melancholy and mania arising from that state of the system. 4. It powerfully promotes purging, vomiting, sweat, and urine; and is therefore much superior mounted him upon a good horse, with however, its proper objections. That the sublimest gratitude. It is a virtue which is touched with the kindness of a human benevolence, is capable of being affected by the divine goodnesses, and of becoming, under the influence of that affection, a source of the purest and most exalted virtue. The love of God is the sublimest gratitude. It is a mistake therefore, to imagine, that this virtue is omitted in the Scriptures; for every precept, which commands us to love God because he first loved us, presupposes the principle of gratitude, and directs it to its proper object. It is impossible to particularize the several expressions of gratitude, which vary with the character and situation of the benefactor, and with the opportunities of the person obliged; for this variety admits of no bounds. It may be observed, however, that on one part gratitude can never oblige a man to do what is wrong, and what by consequence he is previously obliged not to do: On the other part, it argues a total want of every generous principle, as well as of moral probity, to take advantage of that ascendency, which the conferring of benefits jolly creates, to draw or drive those whom we have obliged into mean or dishonest Gratitude-compliances.

The following pleasing example of genuine gratitude is extracted from Hakewill’s Apol. 1. 4. c. 1. p. 436.

—Francis Frescobald, a Florentine merchant, in Italy, had gained a plentiful fortune, of which he was liberal handed to all in necessity; which being well known to others, though concealed by himself, a young stranger applied to him for charity. Signior Frescobald, seeing something in his countenance more than ordinary, overlooked his tattered clothes; and compassionating his circumstances, asked him “What was he, and of what country?” “I am (answered the young man) a native of England; my name is Thomas Cromwell, and my father-in-law is a poor sheer-man. I left my country to seek my fortune; came with the French army that were routed at Gaillon, where I was a page to a footman, and carried his pike and hurtzner after him.” Frescobald commiserating his necessities, and having a particular respect for the English nation, clothed him gently; took him into his house till he had recovered strength by better diet; and, at his taking leave, mounted him upon a good horse, with 16 ducats of gold in his pockets. Cromwell expressed his thankfulness in a very sensible manner, and returned by land towards England; where, being arrived, he was preferred into the service of Cardinal Wolsey. After the Cardinal’s death, he worked himself to effectually into the favour of King Henry VIII. that his majesty made him a baron, vicount, earl of Essex, and at last made him lord high chancellor of England. In the mean time, Signior Frescobald, by repeated losses at sea and land, was reduced to poverty; and calling to mind (without ever thinking of Cromwell), that some English merchants were indebted to him in the sum of 15,000 ducats, he came to London to procure payment. Travelling in pursuit of this affair, he fortunately met with the lord chancellor as he was riding to court; who thinking him to be the same gentleman that had done him such great kindness in Italy, he immediately alighted, embraced him, and with tears of joy asked him, If he was not Signior Francis Frescobald, a Florentine merchant? “Yes, Sir (said he), and your most humble servant.” “My servant! (said the Chancellor) No; you are my special friend, that relieved me in my wants, laid the foundation of my greatness, and, as such, I receive you; and, since the affairs of my sovereign will not now permit a longer conference, I beg you will oblige me this day with your company at my house to dine with me.” Signior Frescobald was surprized and astonished with admiration who this great man should be that acknowledged such obligations; and so passionately expressed a kindnes for him: but, contemplating a while his voice, his mead, and carriage; he concludes it to be Cromwell, whom he had relieved at Florence; and therefore not a little overjoyed, goes to his house, and attended his coming. His lordship came soon after; and immediately taking his friend by the hand, turns to the lord high admiral and other noblemen in his company, saying, “Don’t your lordships wonder that I am so glad to see this gentleman? This is he who first contributed to my advancement.” He then
Gratitude. then told them the whole story; and, holding
by the hand, led him into the dining-room, and placed
him next himself at table. The company being
gone, the Chancellor made use of this opportunity to
know what affair had brought him into England. Fre­
cobald in a few words gave him the true state of his
circumstances: To which Cromwell replied, "I am for­
ry for your misfortunes, and I will make them as
easy to you as I can; but, because men ought to be just
before they are kind, it is fit I should repay the debt I
owe you." Then leading him into his closet, he lock­
ed the door; and opening a coffer, first took out 16
ducats, delivering them to Frecobald, and said, "My
friend, here is the money you lent me at Florence, with
ten pieces you laid

with such true feeling of the physician's character,
that the author screamed with approbation. His
raptures were soon checked; for the mimic told him,
with the emphasis of sensibility, that he would sooner
die than prostitute his talents to the rendering such
genuine humanity a public laughing stock. The play­
er's name was Griffin."
GRATZ, a handsome strong town of Germany,
and capital of Styria, with a castle seated on a rock,
and an university. The Jesuits have a college here;
and there are a great number of handsome palaces,
and a fine arsenal. The castle stands on a very lofty
hill, and communicates with the river by means of a
deep well. The emperors-dowager was obliged to re­
tire hither during the war of 1741 and 1742. It
is seated on the river Mauer, in E. Long. 16. 25. N. Lat.
47-4.
GRATIUS, a Latin poet, cotemporary with Ovid,
the author of a poem intitled Cyngnetae, or the
Manner of hunting with dogs; the best edition of which
is that of Leyden, 12mo, with the learned notes of
Janus Ulitius.
GRAVE, in grammar, a species of accent opposite
to acute. The grave accent is expressed thus (');
and flows, that the voice is to be depressed, and the
syllable over which it is placed pronounced in a low
deep tone.
GRAVE, in music, is applied to a sound which is in
a low or deep tone. The thicker the chord or string,
the more grave the tone or note, and the smaller the
acuter. Notes are supposed to be the more grave, in
proportion as the vibrations of the chord are less quick.
GRAVE, in the Italian music, serves to denote the
flowing movement.
GRAVE is also used for a tomb, wherein a person de­
funct is interred.
Graves, among the Jews, were generally out of the
city, though we meet with instances of their interring
the dead in towns. Frequent mention is made of
graves upon mountains, in highways, in gardens, and
private houses. So that nothing on this head feems
to have been determined. The fame may be observed
with respect to the Greeks. The Thebans had a law
that every person who built an house should provide a
burial ground. Men who had distinguished themselves
were frequently buried in the public forum. The moft
general custom was, however, to bury out of the city,
chiefly by the highway side. The Romans were for­
bidden by the law of the 12 tables to bury or to burn
the dead in the city; but some we find had their fe­
pulchres in Rome, though they paid a fine for the in­
dulgence.
GRAVE, a very strong town of the Netherlands, in
Dutch Brabant, seated on the river Maas, beyond
which there is a fort. E. Long. 5. 41. N. Lat. 51. 46.
GRAVEL, in natural history and gardening, a con­
geries of pebbles, which, mixed with a stiff loam,
makes laving and elegant gravel-walks; an ornament
peculiar to British gardens, and which gives them an
advantage over those of other nations.
GRAVEL, in medicine. See the Index subjoined to
that article; and see ALKALI, n. 17.
GRAVEL-Walks. To make these properly, the bot­
tom should be laid with lime-rubbish, large flint-stones,
or any other hard matter, for eight or ten inches thick, to keep weeds from growing through, and over this the gravel is to be laid six or eight inches thick. This should be laid rounding up in the middle, by which means the larger stones will run off to the sides, and may be raked away; for the gravel should never be fenced before it is laid on. It is a common mistake to lay these walks too round, which not only makes them uneasy to walk upon, but takes off from their apparent breadth. One inch in five feet is sufficient proportion for the rise in the middle; so that a walk of 20 feet wide should be four inches higher at the middle than at the edges, and so in proportion. As soon as the gravel is laid, it should be raked, and the large stones thrown back again; then the whole should be rolled both lengthwise and crosswise; and the person who draws the roller should wear shoes with flat heels, that he may make no holes; because holes made in a new walk are not easily remedied. The walks should always be rolled three or four times in very hard showers, after which they will bind more firmly than otherwise they could ever have been made to do.

Gravel, with some loam among it, bides more firmly than the rawer kinds; and when gravel is naturally very hard and sharp, it is proper to add a mixture of loam to it. The best gravel for walks is such as abounds with smooth round pebbles, which, being mixed with a little loam, are bound so firmly together, that they are never afterwards injured either by wet or dry weather. These are not so liable to be turned up by the feet in walking, as the more irregularly shaped pebbles, and remain much more firmly in their places after rolling.

GRAVELINES, a very strong sea-port town of the Netherlands in the French Flanders, with a castle and harbour. It was ceded to France by the treaty of the Pyrenees, and is seated in a marshy country on the river Aa, near the sea, in E. Long. 2° 15'. N. Lat. 50° 59'.

GRAVELY LAND, or SOIL, that abounding with gravel or sand, which easily admits of heat and moisture; and the more loamy such lands are, the more barren they prove.

GRAVENAC, a town of Germany, in the circle of Susebia, and capital of a county of the same name. E. Long. 8° 15'. N. Lat. 48° 22'.

GRAVER, in the art of engraving, a tool by which all the lines, scratches, and shades, are cut in copper, &c. See Engraving.

GRAVESANDE (William James), was born of an ancient and honourable family at Delft in Holland, in 1688. He studied the civil law at Leyden, but mathematical learning was his favourite amusement. When he had taken his doctor's degree in 1707, he settled at the Hague, and practised at the bar, in which situation he cultivated an acquaintance with learned men; with a society of whom, he published a periodical review intitled Le Journal Litteraire, which was continued without interruption from the year 1713 to the year 1722, when he died. The most considerable of his works are, "A treatise on perspective: An introduction to the Newtonian philosophy, or a treatise on the elements of physics confirmed by experiments; A treatise on the elements of algebra, for the use of young students," and "A course of logic and metaphysics." He had intended to have presented the Gravesend, public with a system of morality, but his death prevented the execution. The ministers of the republic consulted him on all occasions wherein his talents were requisite; and his skill in calculation was often of service to them; as was his address in deciphering, for detecting the secret correspondence of their enemies. As professor of mathematics and astronomy at Leyden, none ever applied the powers of nature with more success, or to more useful purposes.

GRAVESEND, a town of Kent in England, situated on the banks of the Thames. It is 23 miles from London; and has a blockhouse well mounted with cannon, to command the ships and river, directly opposite to Tilbury fort in Essex. The town was plundered and burnt by the French and Spaniards in the reign of Richard II. to compensate which, the king, at the request of the abbot of St Mary Le-Grace of Tower-hill, to whom he had granted a manor there called Parrockes, vested it and Milton with the sole privilege of carrying passengers by water from hence to London at 4s. the whole fare, or 2d. a head; which was confirmed by Henry VIII.; but now the fare is 9d. a head in the tilt-boat, and 1s. in the wherry. The former must not take in above 40 passengers, the latter no more than 8. Coaches ply here at the landing of people from London, &c. to carry them to Rochester, at 1s. 6d. each. This town and Milton were incorporated by queen Elizabeth by the name of the parriees (now the mayor), jurats, and inhabitants of Gravesend and Milton: And, as Gravesend is the place where most passengers through Kent from foreign parts take boat for London, that queen, in order to show the grandeur of the metropolis of her kingdom, ordered the lord mayor, aldermen, and city companies, to receive all ambassadors and eminent strangers here in their formalities, and to attend them to London in barges if by water; or if they choose to come by land, they were to meet them on horseback on Blackheath in their livery-gowns. The towns for several miles round are supplied from hence with garden stuffs; of which great quantities are also sent to London, where the sagacity of Gravesend is preferred to that of Battersea. All outward-bound ships are obliged to anchor in this road till they have been visited by the customs officers; and for this purpose a sentry is stationed at the block-house fires a signal; but the homeward-bound all pass by without notice, unless it be to put waiters on board, if they are not supplied beforehand. As the outward-bound generally take in provisions here, the place is full of seamen, who are all in a hurry. The whole town being burnt down in 1727, 5000l. was granted by the parliament in 1731 for rebuilding its church, as one of the 50 new ones. In 1624, one Mr Pinnock gave 21 dwelling-houses here, besides one for a master-weaver, to employ the poor; and here is a charity-school for 24 boys, who are both taught and clothed. The town-house was erected in 1764, and in 1772 an act of parliament empowered the inhabitants to pave and light their streets.

GRAVINA, a town of Italy, in the kingdom of Naples, and Terra di Bari, with a bishop's see, and the title of a duchy. E. Long. 17° N. Lat. 41°.

GRAVINA (John Vincent), an eminent scholar, and illustrious lawyer of Italy, born at Roggiana in 1664.
GRA

GRA

GRA

GRA

as the branded or blackened grey, which has spots quite black dispersed here and there. The dappled grey, which has spots of a darker colour than the rest of the body. The light or silver grey, wherein there is but a small mixture of black hairs. The red or iron grey, which has but a small mixture of white. And the brownish or sandy-coloured grey, where there are bay-coloured hairs mixed with the black.

Gray, a town of France, in the Francia Compte, and capital of the bailiwick of Amont. It is a trading place, and seated on the river Saine, in E. in Long. 5. 41. N. Lat. 47. 30.

Gray (Lady Jane). See Grey.

Gray (Thomas), an admired English poet, was the youngest and only surviving son of a reputable citizen of London, and was born in Cornhill in 1716. He was educated at Eton, where he contracted a friendship with Mr Horace Walpole, and with Mr Richard West, son of the Lord chancellor of Ireland. Mr West and Mr Gray were both intended for the bar, but the former died early in life, and the latter was diverted from that pursuit by an invitation to accompany Mr Walpole in his travels; which he accepted without any determined plan for his future life. During Mr Gray's travels, he wrote a variety of letters to Mr West and to his parents, which are printed with his poems; and when he returned, finding himself in narrow circumstances, yet with a mind indisposed for active employment, he retired to Cambridge, and devoted himself to study. Soon after his return, his friend West died; and the melancholy impressed on him by this event may be traced in his admired "Elegy written in a country churchyard," which is thought to have been begun, if not finished, at this time; though the conclusion, as it stands at present, is certainly different from what it was in the first manuscript copy. The first impulse of his sorrow for the death of his friend gave birth to a very tender sonnet in English, on the Petrarchian model; and also to a sublime apostrophe in hexameters, written in the genuine strain of classical majesty, with which he intended to begin one of his books De Principiis cogitandi.

From the winter of the year 1742, to the day of his death, his principal residence was at Cambridge: from which he was seldom absent any considerable time, except between the years 1750 and 1762; when, on the opening of the British Museum, he took lodgings in Southampton-row, in order to have recourse to the Harlían and other manuscripts there deposited, from which he made several curious extracts, amounting in all to a tolerable-sized folio, at present in the hands of Mr Walpole.

About the year 1747, Mr Mason, the editor of Mr Gray's poems, was introduced to him. The former had written, a year or two before, some imitations of Milton's juvenile poems, viz. A Monody on the death of Mr Pope, and two pieces intituled Il Bellesoq and Il Pacifico on the peace of Aix-la-Chapelle; and the latter revised them, at the request of a friend. This laid the foundation of an intimacy which continued without interruption to the death of Mr Gray.

About the year 1750, Mr Gray had put his last hand to his celebrated Elegy written in a country church-yard, and had communicated it to his friend Mr Walpole, whose good taste was too much charmed with
with it to suffer him to with-hold the light of it from his acquaintance. Accordingly it was shown about for some time in manuscript, and received with all the applause it so justly merited. At last the publisher of one of the magazines having obtained a surreptitious copy of it, Mr Gray wrote to Mr Walpole, declaring that he would put his own manuscript into the hands of Mr Dodley, and order him to print it immediately. This was the start popular of all the author’s publications. It ran through eleven editions in a very short space of time; was finely translated into Latin by Mr Meffirs Andly and Roberts; and in the same year by Mr Lloyd.

From July 1659 to the year 1762, he generally resided in London, with a view, as we have already observed, of having recourse to the British Museum. In July 1758, his grace the duke of Grafton wrote him a polite letter, informing him, that his majesty had been pleased to offer to him the professorship of Modern History in the University of Cambridge, then vacant by the death of Mr Laurence Brocket. This place was valuable in itself, the salary being 400l. a year; but what rendered it particularly acceptable to Mr Gray was its being given him without any solicitation. He was indeed remarkably disinterested in all his pursuits. Though his income, before this addition, was very small, he never read or wrote with a view of making his labours useful to himself. He may be said to have been one of those few persons of the annals of literature, especially in the poetical class, who are devoid of self interest, and at the same time attentive to economy: and also was among mankind in general one of those very few economists, who possess that talent, untinured with the frightful train of avarice. When his circumstances were at the lowest, he gave away such sums in private charity, as would have done credit to an ampler purse. But what chiefly deterred him from seeking any advantage by his literary pursuits, was a certain degree of pride, which led him to despise the idea of being thought an author by profession.

However, it is probable, that early in life he had an intention of publishing an edition of Strabo; for his papers contain a great number of his uncle Antrobus, he was a certain degree of pride, which, if it have not the same grace, have undoubtedly equal dignity. He endeavoured to trace this mode of building from the time it commenced through all the various changes, and to establish its perfection in the reign of Henry VIII. and ended in that of Elizabeth. For this purpose, he did not so much depend upon written accounts, but upon internal evidence which the buildings themselves give of their respective antiquity; since they constantly furnish to the well informed eye, arms, ornaments, and other marks, by which their several ages may be ascertained. On this account he applied himself to the study of heraldry as a preparatory science; and has left behind him a copious number of genealogical papers, more than sufficient to prove him a complete master of it. By these means he arrived at so very extraordinary a pitch of sagacity, as to be enabled to pronounce, at first sight, on the precise time when every particular part of any cathedral was erected. But the favourite study of Mr Gray for the last ten years of his life was natural history, which he then rather refumed than began; as by the instructions of his uncle Antrobus, he was a considerable botanist at 15. The marginal notes which he has left on Linnaeus and other writers on the vegetable, animal, and fossile kingdoms, are very numerous, which latter he considered are on Hudson’s Flora Anglica, and the tenth edition of the Systena Nature; which latter he interleaved and filled almost entirely. While employed on zoology, he read Aristotle’s treatise on that subject with great care, and explained many difficult passages of that obscure ancient by the lights he had received from modern naturalists. In a word, excepting pure mathematics, and the studies dependent on that science, there was hardly any part of human learning in which he had not acquired a competent skill, and in most of them a consummate mastery. To this account of his literary character we may add, that he had a fine taste in painting, prints, gardening, and music; and was moreover a man of good-breeding, virtue, and humanity.

He died in 1771; and an edition of his poems, with memoirs of his life and writings, were published in 1775, by Mr Macon. This gentleman, however, instead of employing his own pen in drawing Mr Gray’s character, has adopted one drawn by the Rev. Mr Temple, rector of Mamhead in Devonshire, in a letter to Mr Bofwell; to whom the public are indebted for communicating it. “Perhaps (says Mr Temple) he was the most learned man in Europe. He was equally acquainted with
with the elegant and profound parts of science, and
that not superficially but thoroughly. He knew every
branch of history, both natural and civil; had read all
the original historians of England, France, and Italy;
and was a great antiquarian. Criticism, metaphysics,
moral politics, made a principal part of his plan of
fludy; voyages and travels of all sorts were his favour-
able amusements; and he had a fine taste in painting,
prints, architecture, and gardening. With such a
fame knowledge, his conversation must have been
equally instructive and entertaining; but he was also
a good man, a well-bred man, a man of virtue and hu-
manity. There is no character without some speck,
some imperfection; and I think the greatest defect in
his was an affection in delicacy, or rather effemina-
ty, and a visible fatisficient, or contempt and disdain
of his inferior sciences. He also had, in some de-
gree, that weakness which disfigured Voltaire so much
in Congreve: though he seemed to value others chiefly
according to the progress they had made in know-
ledge; yet he could not bear to be considered himself
merely as a man of letters; and though without birth,
or fortune, or station, his desire was to be looked up-
on as a private independent gentleman, who might be
read for his amusement. Perhaps, it may be said, What
signifies so much knowledge, when it produces so little?
Is it worth taking so much pains to leave no memo-
rial but a few poems? But let it be considered, that
Mr Gray was, to others, at least innocently employed:
to himself, certainly beneficially. His time passed
agreeably; he was every day making some new ac-
quiertion in science; his mind was enlarged, his heart
softened, and his virtue strengthened, the world and
mankind were shown to him without a mask; and he
was taught to consider every thing as trudging, and un-
worthy the attention of a wise man, except the pur-
fuit of knowledge, and the practice of virtue in that
state wherein God hath placed us."

GRAYLING, in ornithology, a species of Salmo.

In angling for this fish your hook must be armed
upon the thanks with a very narrow plate of lead, which
should be flinderest at the bent of the hook, that the
bait (which is to be a large gudgeon, the uppermost
wing of which must be pulled off) may come over to
the more easily. At the point let there be a cad-
bait in a continnual motion. The jag-tail, which is
a worm of a pale flesh-colour, with a yellow tag on its
tail, is an excellent bait for the grayling in March and
April.

GREASE, a swelling and goutiness of the legs
of a horse. See Farriery, § xxxvi.

GREAT, a term of comparison, denoting a thing
to have more extension than some other to which it is
referred. Thus we say, a great space, a great distance,
a great figure, a great body, &c.

GREAT is likewise used figuratively in matters of
morality, &c. to signify ample, noble, elevated, extra-
ordinary, important, &c. Thus we say, Shakespeare
was a great genius, Da Vinci a great painter, Galileo
a great philosopher, Bolso a great critic, &c.

GREAT is also a title or quality appropriated to cer-
tain princes and other illustrious personages. Thus
we say, the great Turk, the great Mogul, the great
cham of Tartary, the great duke of Florence, &c.

GREAT is also a surname bestowed on several kings
and emperors. Thus we say, Alexander the great;
Cyrus the great; Charles the great, or Charlemagne;
Henry the great of France, &c.

GREAT is also applied to several officers who have
pre-eminence over others. Thus we say, the lord
great chamberlain; the great marshal of Poland, &c.

GREATER TONE, in music. See Tone.

GREATVES (John), an eminent physician and
antiquary, was the eldest son of John Greatis rector of
Colombe, near Alresford in Hampshire, and born in
1602. He was educated in Balliol College in Oxford,
from which he removed to Merton. He was after-
wards, on the foot of his great merit, chosen geo-
metry professor of Gresham College. His ardent thir-
t of knowledge soon carried him into several parts of
Europe, where he eagerly seized every opportunity of
improving it. His next voyage was into the eastern
countries; where nothing remarkable in the heavens,
earth, or even subterraneous places, seems to have
escaped his nice observation. He, with indefatigable
industry, and even at the peril of his life, collected
a considerable number of Arabic, Peric, and Greek,
manuscripts, for archbishop Laud. Of these he knew
the value, as he could master of the languages in
which they were written. He also collected for
that prelate many oriental gems and coins. He took
a more accurate survey of the pyramids than any tra-
veller who went before him. On his return from the
East, he visited several parts of Italy a second time.
During his stay at Rome, he made a particular inquiry
into the true state of the ancient weights and measures.
Soon after he had finished his second voyage, he was
chosen Savilian professor of astronomy at Oxford. He
was eminently qualified for his professorship, as the
works of ancient and modern astronomers were fa-
familier to him. His books relating to oriental learn-
ing, his Pyramideographia, or a description of the pyra-
midis in Egypt, his Epocha Celebrius, and other curious
useful pieces, of which Mr Ward has given us a
catalogue, shew him to have been a great man. Those
which he intended to publish would have shown him
to be a greater; but he was flopped in his great
career by death in 1642.

GREECE, in ornithology. See Columb.

GREECE, the present Romelia, and in many re-
spects one of the most defervingly celebrated coun-
tries in the world, was anciently bounded on the north
by Macedonia and the river Stymphal; on the west by
the Pontian sea; on the south by the Mediterranean;
and on the east by the Egcan sea and Archipelago. It
extended from the Strymon, by which it was parted
from Thrace, to the promontory of Temanus, the south-
most point of Peloponnesus, now the Morea, about
6° 20' of latitude, or nearly 440 English miles, and in
breath from east to west about 359 miles.

The general names by which the inhabitants of this
country were known to the ancients were those of
Græci, or Graeci, from whence the name of Greece
is plainly derived. These names are thought to come from
Græco, the father, or (according to some) the son, of
Thebas, who gave name to Thebais; but some mo-
dern critics choose to derive it from Kagan, the name
with Rom, the son of Pelag, by the transposition of a
letter to soften the sound. These names were after-
wards changed for Achæ and Helphus; the first, as is
supposed,
 Greeks were people in that of der tioned, the fon of Deucalion, and father of Dorus, universally allowed to have been that of Ioloes, which peopled colonies gave this name to all the Japhet, by the daughter of Erichtheus the grand­fol· lver of the daughter of the man named, Iolus, which the Arcadians, the most ancient people in Greece, derived from their pretended founder Pelafgius; who is said to have got such footing in Peloponnesus, that the whole peninsula from him was called Pelasgia. But the most ancient name of all is universally allowed to have been that of Iones, which the Greeks themselves derived from Ion the fon of Xuthus; or, as the fable hath it, of Apollo, by Creusa the daughter of Erichtheus the grandson of Deucalion. Jophues, however, affirms, that their original is of much older date; and that Javan, the fon of Japhet, and grandson of Noah, was the first who peopled those countries; which Bochart hath also rendered very probable. It is true, indeed, that among the Greeks themselves, only the Athenians, and fuch colonies as sprang from them, were called Iones; but it is also plain beyond exception, that other nations gave this name to all the inhabitants of Greece.

The inhabitants of Greece in the first ages, even by the confeffion of their own historians, appear to have been favage scarce a degree removed from brutes. They lived indifferently on every fruit, herb, or root that came in their way; and lay either in the open fields, or at telt sheltered themselves in dens, caves, and hollow trees; the country itself in the mean time remaining one continued uncultivated defert. The firft improvement they made in their way of living, was the exchanging of their old food for the more wholesome acorns, building huts for themselves to sleep in, and covering their bodies with the skins of beafts. For all this it feems, they were beholden to Pelafgius abovementioned (suppofed by fome to be Pel leg fpo•ken of in Scripture), and who was highly reverenced by them on that account. This reformation in their way of life, however, it feems wrought none in their manners. On the contrary, they who had nothing to fight for but a hole to sleep in, began now to envy and rob one another of these slender acquisitions. Thus, in process of time, put them under a necessity of joining themselves into companies under one head, that they might either more safely plunder their neighbours, or preserve what they had got. Laws they had none, except that of the fword: fo that thofe only lived in safety who inhabited the moft barren and craggy places; and hence Greece for a long time had no telted inhabitants, the weakest being always turned out by the strongest. Their gigantic fize and strength, if we may believe Plutarch added much to their influence and cruelty, that they femed to glory in committing the greatest acts of violence and barbarity on thofe that unhappily fell into their hands.

The next advance towards civilization, was their forming themselves into regular societies, to cultivate the lands, and build themfelves towns and cities for their safety. Their original barbarity and mutual vio­lences against each other naturally prevented them from uniting as one nation, or even into any confiderable community: and hence the great number of states into which Greece was originally divided. The most remarkable of these small principalities mentioned in history are the following: In Peloponnesus were thofe of Sieyon, Argos, and Mefenfia, Achaia Propria, Arcadia, and Laconia. In Grecia Propria (that part of Greece which lay without Peloponnesus), were thofe of Attica, Megara, Beotia, Locris, Ephine­mida, Doris, Phocis, Locris, Ozolea, and Etolia. In Epirus were the Molofli, Amphiboli, CaUipolos, Dracopes, Chacoes, Thrifopteri, Almen, and Acarnani. In Thessaly were thofe of Thessaliotis, Epi­olis, Pelaflgiotis, Magnesia, and Phthia. All thofe have at one time or other been severally governed by kings of their own, though we only find the names of many of them mentioned in the histories of the more confiderable kingdoms of Sparta, Attica, thebes, &c.

The erection of these kingdoms, however, for some time, did not much alter the cafe; the inhabitants of the new kingdoms plundered and destroyed one another without mercy. Attica was the only place in any degree free from these incursions, because it was naturally deftitute of everything that could in­vite a plundering enemy; but thofe cities fared much worse which were situated on the sea-coasts, because they were in continual danger of being plundered either by sea or land: for pirates at that time did not infall all thofe seas than robbers did the land. And this was one main caufe why moft of the ancient cities of Greece were situated at some confiderable distance from the shore; but even in thofe, as all their safety con­fisted in the refiftance they could make againft an invader, their habituals were under a necessity of going constantly armed, and being ever on their guard. Another mischief arising from thofe continual piracies and robberies was, that they occasioned the far greater part of the lands to be uncultivated, fo that the people only planted and fowed as much as was barely neceffary for their prefent support; and where there was fuch an universal neglect of agriculture, there could be as little room for any discoveries in other useful arts and trades. Hence, when other na­tions, as the Jews, Egyptians, Midianites, Phornici­ans, &c. had improved themselves to a very high degree, the Greeks feem to have been utter strangers to every useful art.

During this period of favage barbarity, the moft renowned Grecian heroes, as Hercules, Theseus, &c. performed their exploits; which, however exaggerated by poetie fiction, no doubt had a foundation in truth. Some indeed are of opinion that the Grecian heroes are entirely fictitious, and their exploits derived from thofe of the Hebrew worthies, fuch as Sam­fon, Gideon, &c. Yet, confidering the extreme de­gree of barbarity which at that time prevailed through­out Greece, it feems not at all improbable that fome perfons of extraordinary strength and courage might undertake the cafe of the opprefed, and travel about like the more modern knights-errant in quest of ad­ventures.

The firft expedition in which we find the Greeks united, was that againft Troy, the particulars of which are recited under the article Troy. Their success here (which happened about 1184 B.C.) cost them very dear; vast numbers of their bravest warriors being slain; great numbers of the survivors being cast away
away in their return; and many of those who had the
good luck to get back again, being loon after murder-
ed, or driven out of their country. It is probable,
however, that their having flaid for such a long time
in Asia, might contribute to civilize the Greeks some-
what sooner than what they otherwise would have
been; and accordingly from this time, we find their
historians begin to notice them, and as it were begin-
ing to emerge out of darkness. The continual wars, in-
deed, in which they were engaged among themselves,
no doubt, for a long time, prevented them from mak-
ing any considerable progress in those arts in which
they afterwards made great progress. These wars,
which indeed never ceased as long as the Greeks pre-
ferred their liberty, rendered them brave, and skilled
in the military art, above all other nations; but at the
same time they effectually prevented them from mak-
ing permanent conquests, and confined them within the
bounds of their own country; while the different states
were one way or other so equally balanced, that scarce
one of them was able perfectly to subdue another. The
Spartans, however, having, with great difficulty, re-
duced the kingdom of Mecleone, and added its terri-
tories to their own, became the leading people in
Greece. Their superiority was long disputed by A-
thens; but the Peloponnesian war at last determined
that point in favour of the Spartans, when the city of
Athens was taken, and its walls demolished by Lyfan-
der the Spartan general. See ATTICA, no. 164.—By
the battle of Leuctra, the Spartans lost that superiori-
y which they had maintained for 500 years, and
which now devolved on the Thebans. After the death
of Epaminondas, the celebrated Theban general, how-
ever, as no person was found possessed of his abili-
ties, the Thebans were again obliged to yield the superi-
ority to the Spartans. But by this time the Greeks
had become acquainted with the luxuries and elegan-
cies of life; and all the rigour of their original laws
could not prevent them from valuing these as highly
as other people. This did not indeed abate their val-
our, but heightened their mutual animosities; at the
same time that, for the sake of a more easy and com-
fortable life, they became more disposed to submit to
a master. The Persians, whose power they had long
dreaded, and who were unable to reftit them by force
of arms, at last found out (by the advice of Alcibi-
ades) the proper method of reducing the Grecian
power; namely, by affisting them by turns, and sup-
plying one state with money to fight against another,
till they should all be so much reduced, that they
might become an easy prey. Thus the Greeks were
weakened, though the Persians did not reap any ben-
efit from their weakness. Philip of Macedon entered
into the same political views; and partly by intrigue,
partly by force, got himself declared Generalissimo
of Greece. His successor Alexander the Great
completed their subjection; and by destroying the city
of Thebes, and exterminating its inhabitants, struck
such terror throughout Greece, that he was as ful-
ly obeyed by all the states as by any of the rest of his
subjects. During his absence in Persia, however,
they attempted, when he was off the Macedonian yoke,
to rise in revolt by his general Antipater. The news of
Alexander's death was to them a matter of the utmost
joy; but their mutual animosities prevented them
from joining in any solid plan for the recovery of their
liberties, and hence they continued to be oppressed by
Alexander's successors, or other tyrants, till Aratus,
an Achaen, about 268. B. C. formed a design of get-
ting his country free from these oppressors. He per-
uaded a number of the smaller republics to enter into a
league for their own defence, which was called the
Achaean league; and notwithstanding that the repub-
lies, taken singly, had very little strength, they not
only maintained their independency, but soon became
formidable when united. This association continued
to become daily more and more powerful; but received
a severe check from Cleomenes, king of Sparta, which
obliged them to call in Antigonus to their assistance.
This prince overcame Cleomenes at the battle of Sel-
falia, and afterwards made himself master of Sparta.
Thus he became a more formidable enemy than the
one he had conquered, and the recovery of the Gre-
cian liberties was incomplete.

Soon after this, the Greeks began to feel the weight
of a power more formidable than any which they had
formerly experienced; namely, the insidious and haughty republic first intermeddled with the,
Grecian affairs, under pretence of setting them at
liberty from the oppression of Philip of Macedon.
This, by a proper union among themselves, they might
have accomplished; but in this they acted as though
they had been infatuated; receiving with the utmost
joy the decree of the Roman conful, who declared
them free; without considering, that he who had thus
given them liberty, might take it away at his pleasure.
This lesson, however, they were soon taught, by the
total reduction of their country to a Roman province;
and from this time, the Greeks began to suffer under the tyranny of the Turks, and their sufferings
were completed by the taking of Conflantinople in
1453. Since that time, they have groaned under the
yoke of a most despotic government; so that all traces of their former valour, ingenuity, and learning, are
now in a manner totally extinct.

Modern Greece comprehends Macedonia; Albania,
now called Armaut; Epirus; Thessaly, now Jana;
Achaia, now Livadia; the Peloponnesus, now Morea;
the Peloponnesus, now Morea; together with the islands on its coast, and in the Ar-
chipelago. The continent of Greece is seated between
the 36th and 43d degrees of north latitude; and be-
tween the 19th and 27th degrees of longitude, east
of London. To the north it is bounded, by Bulgaria
and Servia, from which it is divided by a ridge of
mountains; to the south, by the Mediterranean sea;
to the east, by Romania and the Archipelago; and
the west, by the Adriatic, or gulph of Venice. Its
length is said to be about 400 miles, and its utmost
breadth about 20 miles. It is a country that is
productive and healthy; and the soil fruitful, though badly
cultivated; yielding corn, wine, delicious fruits, and
abounding with cattle, fowls, and venison. As to re-
ligion,
ligion, Christianity was planted in Greece soon after the death of our Saviour, and flourished there for many ages in great purity; but since the Greeks became subject to the Turkih yoke, they have sunk into the most deplorable ignorance, in consequence of the slavery and thraldom under which they groan, and their religion is now greatly corrupted. It is indeed little better than a heap of ridiculous ceremonies and absurdities. The head of the Greek church is the patriarch of Constantinople; who is chosen by the neighbouring archbishops and Metropolitans, and confirmed by the emperor or grand vizir. He is a person of great dignity, being the head and director of the eastern church. The other patriarchs are those of Jerusalem, Antioch, and Alexandria. Mr Tournefort tells us, that the patriarchates are now generally set to sale, and bestowed upon those who are the highest bidders. The patriarchs, metropolitans, archbishops, and bishops, are always chosen from among the Calyfers or Greek monks. Before the patriarchs receive their patents and the caftan, which is a veil of finley-wooletry, or some other stuff, presented by the grand signior to ambassadors and other persons newly invested with some considerable dignity, they are obliged to make large presents to the vizir, &c. The income of the patriarch of Constantinople is paid to amount to no less than one hundred and twenty thousand guilders, of which he pays the one half by way of annual tribute to the Ottoman Porte, adding six thousand guilders besides as a present at the feast of Bairam. The next peer to a bishop among the clergy is an archimandrite; who is the director of one or more convents, which are called *mandræ*; then come the abbot, the arch-priest, the priest, the deacon, the under-deacon, the chanter, and the lector. The secular clergy are subjected to no rules, and never rise higher than high-priest. They are allowed to marry once; but it must be with a virgin, and before they are ordained. They have neither glebe nor tythes, but depend on the perquisites that arise from their office; and they seldom preach but in Lent. The Greeks have few nunneries; but a great many convents of monks, who are all priests, and students excepted, obliged to follow some handicraft employment, and lead a very obscure life. The Greeks deny the supremacy of the pope, and abhor the worship of images; but have a multitude of pictures of saints in their churches, whom they pray to as mediators. Their faiths are very severe. They believe also in the doctrine of transubstantiation, and that the Holy Ghost does not proceed from the Son. They admit not of purgatory, says Mr Thevenot: but yet they allow a third place, where they lay the blessed remain, in expectation of the day of judgment. At mass they consecrate with leavened bread; and communicate under both kinds, as well the priests, and as well women and children as men. When they carry the sacrament to the sick, they do not prostrate themselves before it, nor expose it to be adored; neither do they carry it in procession, or have any particular feast in honour of it. Baptism is performed among them by plunging the whole body of the child thrice into water. Immediately after baptism, they give it confirmation and the communion; and seven days after that, it undergoes the ceremony of ablution. When a priest is married, among other ceremomies, the bridegroom and bride drink each two glasses of wine; then the glass is given to the priest, who merrily drinks off the rest of the wine, and breaking the glasses, says, so may the bridegroom break the virginity of the bride. As to the charafter of the modern Greeks, they are said to be very covetous, hypocritical, treacherous, great pederasts, and at the same time revengeful to the highest degree; but very superstitious. They are so much defpised by the Turks, that these do not value even a Greek who turns Moslem. The Turks are remarkable for their taciturnity, they never use any unnecessary words; but the Greeks, on the contrary, are very talkative and lively. The Turks generally pralifie what their religion enjoins, but the Greeks do not; and their misery puts them upon a thousand mean shifts and scandalous practices, authorized by bad example, and perpetuated from father to fon. The Greek women have fine features and beautiful complexion: their countenances still very much resemble those of the ancient Greek statues.

GREEK, or GRECIAN, any thing belonging to ancient Greece.

The Greek language, as preferred in the writings of the celebrated authors of antiquity, as Homer, Hesiod, Demosthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expressions, suitable to the genius and occasions of a polite and learned people, who had a taste for arts and sciences. In it, proper names are figurative; which is the reason that the modern languages borrow so many terms from it. When any new invention, instrument, machine, or the like, is discovered, recourse is generally had to the Greek language: the facility wherewith words are there compounded, affording such as will be expressive of its use: such are, barometer, hygrometer, microscope, telescope, thermometer, &c. But of all sciences, medicine most abounds with such terms; as diaphoretic, diagnost, diarrhoea, hemorrhage, hydrophobia, phthisia, atrophy, &c. Besides the copiousness and significance of the Greek, wherein it excels most, if not all, other languages, it has also three numbers, viz. a singular, dual, and plural: also a multitude of tenses in its verbs, which makes a variety in discourse, prevents a certain dryness that always accompanies too great an uniformity, and renders that language peculiarly proper for all kinds of verse. The use of the participles, of the aorist and preterite, together with the compound words already mentioned, give it a peculiar force and brevity without taking any thing from its perspicuity.

It is no easy matter to assign the precise difference between the modern and ancient Greek; which consists in the terminations of the nouns, pronouns, verbs, &c. not unlike what obtains between some of the dialects of the Italian or Spanish. There are also in the modern Greek many new words, not to be met with in the ancient. We may therefore distinguish three ages of the Greek tongue: the first of which ends at the time when Constantinople became the capital of the Roman empire; the second lasted from that period to the taking of Constantinople by the Turks; and the third from that time to this.

Greek Bible. See Bible.

Greek Church, is that part of the Christian church, which
which is established in Greece, extending likewise to some other parts of Turkey. See GREECE.—It is thus called in Europe, Asia, and Africa, in contradistinction from the Latin or Romish church, as also the Eastern church, in distinction from the Western.

The Romanists call the Greek church the Greek schism: because the Greeks do not allow the authority of the pope, but depend wholly, as to matters of religion, on their own patriarchs. They have treated them as schismatics ever since the revolt, as they call it, of the patriarch Photius.

Greek monks and Nuns, of whatsoever order, consider St. Basil as their founder and common father, and esteem it the highest crime to deviate in the least from his constitutions. There are several beautiful convents with churches, in which the monks perform divine service day and night. Some of the monks are cannibales, or live together, wear the same habit, eat at the same table, and perform the same exercises and employments.

Greek Orders, in architecture, are the Doric, Ionic and Corinthian; in contradistinction to the two Latin orders, the Tuscan and Composite. See ORDER.

GREEN, one of the original prismatic colours, exhibited by the refraction of the rays of light. See CHROMATICS AND COLOUR.

GREEN, among painters and dyers. See COLOUR-MAKING, &c. &c.

GREEN-Cloth, a board or court of justice held in the compting-house, of the British king's household, composed of the Lord Steward and officers under him, who sit daily. To this court is committed the charge and oversight of the king's household in matters of justice, and government, with a power to correct all offenders, and to maintain the peace of thencever, or jurisdiction of the court-royal; which is every way about two hundred yards from the front gate of the palace where his majesty resides.

It takes its name, board of green cloth, from a green cloth spread over the board where they sit.

Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

Clerks of the Green Cloth were two officers of the board of green cloth, who appointed the diet of the king and his household; and kept all records, legers, and papers relating thereto; make up bills, parcels, and debentures for salaries, and provisions and necessaries for the officers of the buttery, pantry, cellar, &c. They also waited upon foreign princes when entertained by his majesty. But this has been lately abolished.

GREEN Finch, in ornithology, the English name of the greenfinch fringilla, with the wings and tail variegated with yellow. See FRINGILLA.

GREEN-House, or CONSERVATORY, a house in a Garden, courted for sheltering and preserving the most curious and tender exotic plants, which in our climate will not bear to be exposed to the open air, especially during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

The length of greenhouses must be proportioned to the number of plants intended to be preserved in them, and cannot therefore be reduced to rule: but their depth should never be greater than their height in the clear; which, in small or middling houses, may be 16 or 18 feet; but in large ones from 20 to 24 feet; and the length of the windows should reach from about one foot and a half above the pavement, and within the same distance of the ceiling, which will admit of a cornice round the building over the heads of the windows. Their breadth cannot be in proportion to their length; for if in the largest building they are more than seven or seven feet and a half broad, they will be extremely heavy and inconvenient.

The piers between the windows must be as narrow as may be to support the building; for which reason they should either be of stone or hard burnt bricks. If the piers are made of stone, they should be 30 inches wide in front, and sloped off behind to about 18 inches, by which means there will be no corners to take off the rays of the sun. If they are of brick, they will require to be at least three feet in front, but they should in the same manner sloped off behind. Over the greenhouse may be rooms for drying and preserving feeds, roots, &c. and behind it a place for tools and other purposes; and both these behind, and the rooms above, will be of great use in keeping off the frosts, so that the wall between these need not be of more than two bricks and a half in thickness.

The floor of the greenhouse, which should be laid either with Bremen squares, Purbeck stone, or flat tiles, must be raised two feet above the surface of the adjoining ground, or if the situation be damp, at least three feet; and if the whole is arch'd with low brick arches under the floor, they will be of great service in preventing damp; and under the floor, about two feet from the front, it will be very advisable to make a flue of ten inches wide and two feet deep; this should be carried the whole length of the house, and then returned back along the hinder part, and there be carried up into funnels adjoining to the tool-house, by which the smoke may be carried off. The fire-place may be contrived at one end of the house, and the door at which the fuel is put in, as also the ash-gate, may be contrived to open into the tool-house, and the fuel being laid in the same place, the whole is out of sight. Bradley advises, that the front of greenhouses, in the colder parts of England, be built in a sweep or semicircle, so that one part or other of it may receive the sun's rays all day. The use of fires must, however, be very sparing in this place; and it is not one winter in three or four that will require them in any part, only when the weather is very severe, and the frost cannot well be kept out any other way, this is an expedient that is good to have in readiness, as it may save a whole house of plants. Within side of the windows, in front of the greenhouse, there should be good strong shutters, made with hinges, to fold back close to the piers, that they may not obstruct the ray of the sun. The back part of the house should be either laid over with flueco or plastered with mortar, and whitewashed, in order to prevent the frosty air from penetrating through the walls. When the greenhouse is wainscoted, the walls should be plastered with lime and hair behind the wainscot, to keep out the cold, and the wainscot, as well as the ceiling, and every part within the house, should be painted white, for the reflection of the sun's rays. There must be a number of trellis with forms of wood upon them, to support the pots of plants; the tallet to be placed hindmost, the lowest within four feet of the windows; and
the rows of plants should rise gradually, so that the heads of the second row should be entirely above the first; and behind them there should be a space of at least five feet, for the convenience of watering the plants, and for a free circulation of air. It has been observed, that the placing of the euphorbiums, cacti, and other succulent plants among orange-trees, and other common greenhouse-plants, is always destructive of them, by making them receive an improper sort of effluvia, which plants of that kind imitate very freely. They should therefore be placed in two wings built at each end of the greenhouse; which, if, well contrived, will be a great beauty as well as use to the building. These wings may be made capable of a greater warmth also by more flues, and may be made to contain a hot-bed of tanners bark for the raising many of the tender plants, natives of warm climates. 

Whilist the front of the greenhouse is exactly south, one of the wings may be made to face the south-east and the other the south-west. By this disposition the heat of the sun is reflected from one part of the building to the other all day, and the front of the main greenhouse is guarded from the cold winds. These two wings may be so contrived as to maintain plants of different degrees of hardines, which may be easily effected by the situation and extent of the fire-place, and the manner of conducting the flues: the wing facing the south-east is evidently the most proper for the warmest stoves; this may be divided in the middle by a partition of glass, with glass-doors opening from one division to the other. In each of these there should be a fire-place, with flues carried up against the back-wall, through which the smoke should be made to pass as many times the length of the house as the height will admit of the number of flues; for the longer the smoke is in passing, the more heat will be given to the house with a less quantity of fuel. The other wing, facing the south-west, should be divided and furnished with flues in the same manner; and thus different degrees of heat may be obtained, according to the seasons and the particular sorts of plants that are to be preserved. If there are no fheeds behind these wings, the walls should not be less than three bricks thick; and the back part, having sloping roofs, which are covered with tiles or slates, should be lined with reeds, &c. under the covering. The sloping glass-panes of these houses should be made to slide and take off, so that they may be drawn down more or less in warm weather to admit air to the plants; and the upright glass-panes in front may be so contrived as that every other may open as doors upon hinges, and the alternate glass-panes may be divided into two; the upper part of each should be so contrived as to be drawn down like shutters, so that either of them may be used to admit air in a greater or less quantity as there may be occasion.

As to the management of the plants herein, Mortimer recommends the opening of the mould about them from time to time, and sprinkling a little fresh mould in them, and a little warm dung on that; as also to water them when the leaves begin to wither and curl, and not oftener, which would make them fade and be sickly; and to take off such leaves as wither and grow dry.

Green-Silver, the name of an ancient enclom within Greenland; the manor of Writtle in the county of Essex in England; which is, that every tenant whose fore-door opens to Greenbury shall pay an half-penny yearly to the lord, by the name of green-silver.

Green-Wax, is used where cliates are delivered to the sheriffs out of the exchequer, under the seal of that court, made in green wax, to be levied in the several counties. This word is mentioned in the 45d Stat. Ed. III. c. 9. and 7 Hen. IV. c. 4.

Greenland, a general name by which are denoted the most easterly parts of America, stretching towards the north pole, and likewise some islands to the northward of the continent of Europe, lying in very high latitudes.

This country is divided into West and East Greenland. West Greenland is now determined by the latest maps to be a part of the continent of America, though upon what authority is not very clear. That part of it which the Europeans have any knowledge of is bounded on the west by the strand of the Strait of Davis, and on the east by the northern part of the Atlantic Ocean. It is a very mountainous country, and some parts of it to high that they may be discerned 30 leagues off at sea. The inland mountains, hills, and rocks, are covered with perpetual snow; but the low lands on the sea-side are clothed with verdure in the summer season. The coast abounds with inlets, bays, and large rivers; and is surrounded with a vast number of islands of different dimensions. In a great many places, however, on the eastern coast especially, the shore is inaccessible by reason of the floating mountains of ice. The principal river, called Baaf, falls into the sea in the 64th degree of latitude, where the first Danish lodge was built 1741; and has been navigated above 40 miles up the country.

West Greenland was first peopled by Europeans in the eighth century. At that time a company of Icelanders, headed by one Ericke Rande, were by accident driven on the coast. On his return he represented the country in such a favourable light, that some families followed him thither, where they soon became a colony from Iceland, and by the name of Groenland, or Greenland, on account of its verdant appearance. This colony was converted to Christianity by a missionary from Norway, fent thither by the celebrated Olaf, the first Norwegian monarch who embraced the true religion. The Greenland settlement continued to increase and thrive under his protection; and in a little time the country was provided with many towns, churches, convents, bishops, &c. under the jurisdiction of the archbishop of Drontheim. A considerable commerce was carried on between Greenland and Norway; and a regular intercourse maintained between the two countries till the year 1406, when the last bishop was sent over. From All correspondence was cut off, and all knowledge of Greenland has been buried in oblivion.

This strange and abrupt cessation of all trade and commerce has been attributed to various causes; but the most probable is the following. The colony, from its first settlement, had been harassed by the natives, a barbarous and savage people; agreging in customs, garb, and appearance, with the Eqquimaux found about Hudson's Bay. This nation, called Schreblinges,
Greenland. at length prevailed against the Iceland settlers who inhabited the western district, and exterminated them in the 14th century; inasmuch, that when their brethren of the eastern district came to their assistance, they found nothing alive but some cattle and flocks of sheep running wild about the country. Perhaps they themselves afterwards experienced the same fate, and were totally destroyed by the Scherlings, whose descendants still inhabit the western parts of Greenland, and from tradition confirm this conjecture. They affirm that the houses and villages, whose ruins still appear, were inhabited by a nation of strangers, whom their ancestors destroyed. There are reasons, however, for believing that there may be still some descendants of the ancient Iceland colony remaining in the eastern district, though they cannot be visited by land, on account of the stupendous mountains, perpetually covered with snow, which divide the two parts of Greenland; while they have been rendered inaccessible by sea, by the Vaft quantity of ice driven from Spitzbergen, or East Greenland. One would imagine that there must have been some considerable alteration in the northern parts of the world since the 15th century, so that the coast of Greenland is now become almost totally inaccessible, though formerly visited with very little difficulty. It is also natural to ask, By what means the people of the eastern colony mounted the abovementioned obstacles when they went to the assistance of their western friends; how they returned to their own country; and in what manner historians learned the success or their expedition? Concerning all this we have very little satisfactory information.

All that can be learned from the most authentic records is, that Greenland was divided into two districts, called West Bygd and East Bygd: that the western division contained four parishes and two villages: that the eastern district was still more flourishing, as being nearer to Iceland, sooner settled, and more frequented by shipping from Norway. There are also many accounts, though most of them romantic and slightly affected, which render it probable that part of the eastern colony still subsisted, who, at some time or other, may have given the imperfect relation abovementioned.

This colony, in ancient times, certainly comprised twelve extensive parishes, one hundred and ninety villages; a bishop's fees, and two monasteries. The present inhabitants of the western district are entirely ignorant of this part, from which they are divided by rocks, mountains, and deferts, and still more effectually by their apprehension; for they believe the eastern Greenlanders to be a cruel, barbarous nation, that destroy and eat all strangers who fall into their hands. About a century after all intercourse between Norway and Greenland had ceased, several ships were sent successively by the kings of Denmark in order to discover the eastern district; but all of them miscarried. Among these adventurers, Mogens Heinon, after having surmounted many difficulties and dangers, got off the land; which, however, he could not approach. At his return, he pretended that the ship was arrested in the middle of her course by certain rocks of loadstone at the bottom of the sea. The Greenland fame year, 1576, in which this attempt was made, has been rendered remarkable by the voyage of Captain Martin Frobisher, sent upon the same errand by Queen Elizabeth. He likewise described the land; but could not reach it, and therefore returned to England; yet not before he had failed sixty leagues in the firth which still retains his name, and landed on several islands, where he had some communication with the natives. He had likewise taken possession of the country in the name of Queen Elizabeth; and brought away some pieces of heavy black stone, from which the refiners of London extracted a certain proportion of gold. In the ensuing spring he undertook a second voyage, at the head of a small squadron, equipped at the expense of the public; entered the firths a second time; discovered upon an island a gold and silver mine; bestowed names upon different bays, islands, and headlands; and brought away a loading of ore, together with two natives, a male and a female, whom the English kidnapped.

Such was the success of this voyage, that another armament was fitted out under the auspices of Admiral Frobisher, consisting of 15 sail, including a considerable number of soldiers, miners, smelters, carpenters, and bakers, to remain all the winter near the mines in a wooden fort, the different pieces of which they carried out in the transports. They met with boisterous weather, impenetrable fogs, and violent currents upon the coast of Greenland, which retarded their operations until the season was far advanced. Part of their wooden fort was lost at sea; and they had neither provision nor fuel sufficient for the winter. The admiral therefore determined to return with as much ore as he could procure: of this they obtained large quantities out of a new mine, to which they gave the name of the Counts of Sufleis. They likewise built an house of stone and lime, provided with ovens; and here, with a view to conciliate the affection of the natives, they left a quantity of small morrice-bells, knives, beads, looking-glasses, leaden pictures, and other toys, together with several loaves of bread. They buried the timber of the fort where it could be easily found next year; and sawed corn, pease, and other grain, by way of experiment, to know what the country would produce. Having taken these precautions, they failed from thence in the beginning of September; and after a month's stormy passage, arrived in England: but this noble design was never prosecuted.

Christian IV. king of Denmark, being desirous of discovering the old Greenland settlement, sent three ships thither, under the command of Captain Godfke Lindenow; who is said to have reached the east coast of Greenland, where he traded with the savage inhabitants, such as they are still found in the western district, but few of signs of a civilized people. Had he actually landed in the eastern division, he must have perceived some remains of the ancient colony, even in the ruins of their convents and villages. Lindenow kidnapped two of the natives, who were conveyed to Copenhagen; and the same cruel fraud (a) was practiced.

(a) Nothing can be more inhuman and repugnant to the dictates of common justice than this practice of tearing away poor creatures from their country, their families, and connections: unless we suppose them altogether
Greenland, titled by other two ships which failed into Davis’s Straights, where they discovered divers fine harbours, and delightful meadows covered with verdure. In some places they are said to have found a considerable quantity of ore, every hundred pounds of which yielded twenty-six ounces of silver. The fame Admiral Lindenow made another voyage to the coast of Greenland in the year 1606, directing his course to the westward of Cape Farewell. He coasted along the straits of Davis; and having made some observations on the face of the country, the harbours and islands, returned to Denmark. Carsten Richards, being detached with two ships on the same discovery, deserted the high land on the eastern side of Greenland; but was hindered by the ice from approaching the shore.

Other expeditions of the same nature have been planned and executed with the same bad success, under the auspices of a Danish company of merchants. Two ships returned from the western part of Greenland loaded with a kind of yellow sand, supposed to contain a large proportion of gold. This being assayed by the goldsmiths of Copenhagen, was condemned as useless, and thrown overboard; but from a small quantity of this sand, which was preserved as a curiosity, an expert chemist afterwards extracted a quantity of pure gold. The captain, who brought home this adventure, was so chagrined at his disappointment, that he died of grief, without having left any directions concerning the place where the sand had been discovered. In the year 1654, Henry Moller, a rich Dane, equipped a vessel under the command of David de Nelles, who failed to the west coast of Greenland, from which he carried away three women of the country. Other efforts have been made, under the encouragement of the Danish king, for the discovery and recovery of the old Iceland colony in Greenland; but all of them miscarried, and people began to look upon such expeditions as wild and chimerical. At length the Greenland colony at Bergen in Norway, transported a colony to the western coast, about the 64th degree of latitude; and these Norwegians failed in the year 1712, accompanied by the Reverend Hans Egede, to whose care, ability, and precision, we owe the best and most authentic account of modern Greenland. This gentleman endeavoured to reach the eastern district by coasting towards the north, and continual storms, obliged him to return; and as he could not even find the Strait of Forbisher, he concluded that no such place ever existed. In the year Greenland, 1724, a ship being equipped by the company, failed on this discovery, with a view to land on that side opposite to Iceland; but the vast shoals of ice, which barred the passage of the coast, rendered this scheme impracticable. His Danish majesty, in the year 1728, caused horses to be transported to Greenland, in hope that the settlers might by their means travel over land to the eastern district; but the icy mountains were found impassable. Finally, lieutenant Richards, in a ship which had wintered near the new Danish colony, attempted, in his return to Denmark, to land on the eastern shore; but all his endeavours proved abortive.

Mr. Egede is of opinion, that the only practicable method of reaching that part of the country, will be to coast north-about in small vessels, between the great flakes of ice and the shore; as the Greenlanders have declared, that the currents continually rushing from the bays and inlets, and running north-westwards along the shore, hinder the ice from adhering to the land; so that there is always a channel open, through which vessels of small burden might pass, especially if lodges were built at convenient distances on the shore, for the convenience and direction of the adventurers.

That part of the country which is now visited and settled by the Danes and Norwegians, lies between the 64th and 65th degrees of north latitude; and thus far it is said the climate is temperate. In the summer, which continues from the end of May to the middle of September, the weather is warm and comfortable, while the wind blows easterly; though even at this time storms frequently happen, which rage with incredible violence; and the sea coasts are inflected with fogs that are equally disagreeable and unhealthy. Near the shore, and in the bays and inlets, the low land is clothed with the most charming verdure; but the inland mountains are perpetually covered with ice and snow. To the northward of the 65th degree of latitude the cold is progressively intense; and towards the end of August all the coast is covered with ice, which never thaws till April or May, and sometimes not till the latter end of June. Nothing can exhibit a more dreadful, and at the same time a more dazzling appearance, than those prodigious masses of ice that surround the whole coast in various forms, reflecting a multitude of colours from the sun-beams, and calling to mind the enchanted scenes of romance. Such prospects they yield in calm weather; but when the wind begins together defilute of natural affection; and that this was not the case with those poor Greenlanders, some of whom were brought alive to Copenhagen, appears from the whole tenor of their conduct, upon their first capture, and during their confinement in Denmark. When first captivated, they rent the air with their cries and lamentations; they even leaped into the sea; and, when taken on board, for some time refused all sustenance. Their eyes were continually turned towards their dear country, and their faces always bathed in tears. Even the countenance of his Danish majesty, and the cares of the court and people, could not alleviate their grief. One of them was perceived to shed tears always when he saw an infant in the mother’s arms; a circumstance from whence it was naturally concluded, that he had left his wife with a young child in Greenland. Two of them went to sea in their little canoes in hope of reaching Greenland; but none of them were retaken. Other two made the same attempt; but were driven by a storm on the coast of Schonen, where they were apprehended by the peasants, and reconveyed to Copenhagen. One of them afterwards died of a fever, caught in fishing pearl, during the winter, for the governor of Kolding. The rest lived some years in Denmark; but at length feeling no prospect of being able to revisit their native country, they sunk into a kind of melancholy disorder, and expired.
Greenland, begins to blow, and the waves to rise in vast billows, the violent shocks of those pieces of ice dazzling against one another fill the mind with horror. Greenland is seldom visited with thunder and lightning, but the Aurora Borealis is very frequent and bright. At the time of new and full moon, the tide rises and falls upon this coast about three fathoms; and it is remarkable, that the springs and fountains on shore rise and fall with the flux and reflux of the ocean.

The soil of Greenland varies like that of all other mountainous countries. The hills are very barren, being indeed frozen throughout the whole year; but the valleys and low grounds, especially near the sea, are rich and fruitful. The ancient Norwegian chronicles inform us, that Greenland formerly produced a great number of cattle; and that considerable quantities of butter and cheese were exported to Norway; and, on account of their peculiar excellency, set apart for the king's use. The same histories inform us, that some parts of the country yielded excellent wheat; and that large oaks were found here, which carried acorns as big as apples. Some of these oaks still remain in the southern parts, and in many places the marks of ploughed land are easily perceived. At present, however, the country is destitute of corn and cattle, though in many places it produces excellent pasture; and if properly cultivated, would probably yield grain also. Mr Egede fowed some barley in a bay adjoining to the Danish colony. It sprang up so fast, that by the latter end of July it was in the full ear; but being nipped by a night-frost, it never arrived at maturity. This seed was brought from Bergen; where the summer is of greater heat and duration than in Greenland; but in all probability the corn which grows in the northern parts of Norway would also thrive here. Turnips and coleworts of an excellent taste and flavour are also produced here. The sides of the mountains near the bays are clothed with wild thyme, which diffuses its fragrance to a great distance. The herb tormentil is very common in this country, and likewise many others not described by the botanists. Among the fruits of Greenland we number juniper-berries, blue-berries, bil-berries, and bramble-berrries.

Greenland is thought to contain many mines of metal though none of them are wrought. To the southward of the Danish colony are some appearances of a mine of copper. Mr Egede once received a lump of ore from one of the natives; and here he found calcite of a yellow colour. He once sent a considerable quantity of sand of a yellow colour, intermixed with streaks of vermilion, to the Bergen company. They probably found their account in this present; for they desired him by a letter to procure as much of that sand as possible: but he was never able to find the place where he saw the first specimen. It was one of the smallest among a great number of islands; and the mark he had set up was blown down by a violent storm. Possibly this might be the same mineral of which Captain Frobisher brought to much to England. This country produces rock-crystals both red and white, and whole mountains of the albesos or incom-bustible flax. Around the colony, which is known by the name of Good Hope, they find a kind of buffard marble of various colours, which the natives form into bowls, lamps, pots, &c. All that has been said of Greenland: the fertility of Greenland, however, must be understood only of that part which lies between the 60th and 65th degrees of latitude. The most southern parts are totally destitute of herbs and plants. The wretched inhabitants, cannot find grast in sufficient qualities to stuff into their shoes to keep their feet warm, but are obliged to buy it from those who inhabit the more southern parts.

The animals which abound most in Greenland are, rein-deer, foxes, hares, dogs and white bears. The hares are of a white colour, and very fat; the foxes are of different colours, white, greyish, and bluish; and smaller than those of Denmark and Norway. The natives keep a great number of dogs, which are large, white, or speckled, and rough, with ears standing upright, as is the case with all the dogs peculiar to cold climates. They are timorous and stupid, and neither bay nor bark, but sometimes howl diversely. In the northern parts the natives yoke them in fedges; which, though heaven laden, they will draw on the ice at the rate of 70 miles in a short winter's day. These poor animals are very ill rewarded for their service; being left to provide for themselves, except when their masters happen to catch a great number of seals. On these occasions the dogs are regaled with the blood and entrails; at other times they feebite, like wild-beasts, upon muscles and berries. Here also are found great numbers of ravens, eagles of a prodigious size, falcons, and other birds of prey; and likewise a kind of linnet, which warbles very melodiously. Whales, sword-fish, porpoises, &c. abound on the coasts; also holybut, turbut, cod, haddock, &c. The more dubious animals also, called mermaids, sea-serpents, and krakens, said to be found on the coast of Norway, are said likewise to dwell in these seas. Mr Egede affiries us, that in the year 1734, the sea-serpent was seen off the new Danish colony, and raised its head mast high above the surface of the water. See Kraken, Mermaid, and Sea-Serpents.

The people who now inhabit the western coast of Greenland, and who, without doubt, are the descendents of the ancient Schelings, who exterminated the first Icelandic colony, bear a near resemblance to the Samoedes and Laplanders in their persons, complexion, and way of life. They are short, brawny, and inclined to corpulency; with broad faces, flat noses, thick lips, black hair and eyes, and a yellowish-tawny complexion. They are for the most part vigorous and healthy, but remarkably short-lived; few of them reaching the grand climateric; and many dying in their infancy, and in the prime of youth. They are subject to a weaknes in the eyes, occasioned by the piercing winds and the glare of the snow in the wintertime. The leprosy is known among them, but is not contagious. Those that dwell in the northern parts are miserably tormented with dysenteries, rheums, and pulmonary disorders, boils, and epilepsy. The smallpox being imported among them from Copenhagen in the year 1734, made terrible havoc among these poor people, who are utterly destitute of any knowledge of the medicinal art, and depend entirely for allusion upon the anekskats or conjurers. In their dispositions the Greenlanders are cold, phlegmatic, indolent, and slow of apprehension; but very quiet, orderly, and good.
Greenland.

They live peaceably together; and have every thing in common, without strife, envying, or animosity. They are civil and hospitable, but very different in their social customs. They never wash themselves with water; but lick their paws like the cat, and then rub their faces with them. They eat after their dogs without washing their dishes; devour the lice which devour them; and even lick the sweat, which they scrape off from their faces with their knives. The women wash themselves with their own urine, which they imagine makes their hair grow; and in the winter-time go out immediately after, to let the liquor freeze upon their skin. They will often eat their victuals off the dirty ground, without any vehicle to hold them in; and devour rotten flesh with the greatest avidity. In times of scarcity they will stuff on pieces of old skin, reeds, sea-weed, and a root called taglermet, dressed with trail oil and fat. The dung of rein-deer taken from the intestines, the entrails of partridges, and all sorts of offal, are counted dainties among these savages; and of the scrapings of seals skins they make delicate pan-cakes. At first they could not taste the Danish provisions without abhorrence; but now they are become extremely fond of bread and butter, though they still retain an aversion to tobacco and spirits; in which particular they differ from almost all savages on the face of the earth.

The Greenlanders commonly content themselves with one wife; who is condemned, as among other savage nations, to do all the drudgery, and may be corrected, or even divorced, by the husband at pleasure. Heroes, however, and extraordinary personages, are indulged with a plurality of wives. Their young women are generally chaste and bashful; but at some of their feasts, in the midst of their jollity, a man retires with his neighbour’s wife behind a curtain made of skins; and all the guests, thus coupled, retire in their turns. The women think themselves happy if an angekut or prophet will thus honour them with his caresses. These people never marry within the prohibited degrees of consanguinity, nor is it counted decent in a couple to marry who have been educated in the same family. — They have a number of ridiculous and superstitious customs; among which the two following are the most remarkable. While a woman is in labour, the goolips hold a chamber-pot over her head, as a charm to hasten the delivery. When the child is a year old, the mother licks and lobbies it all over, to render it as the imagines, more strong and hearty.

All the Greenlanders hitherto known speak the same language, though different dialects prevail in different parts of the country. They never wash themselves with double compounds; and is so gutural, that the pronunciation of many words is not to be learned except by those who have been accustomed to it from their infancy. The letters C, D, F, Q, and X, are not known in their alphabet. Like the North Americans, and inhabitants of Kamtschats, they have a great number of long polyyllables. Their words, nouns as well as verbs, are inflected at the end by varying the terminations without the help of articles; but their language being found defective, they have adopted a good many words from the Norwegian dialect. Notwithstanding the endeavours of the Danith missionaries, they have no great reason to boast of the profelytes Greenland have made of the natives Greenland. These savages pay great deference and respect to the Danes, whom indeed they obey as their masters, and hear the truths of the Christian religion expounded without doubting the veracity of their teachers; but at the same time they listen with the most mortifying indifference, without being in the least influenced by what they have heard. They believe in the immortality of the soul, and the existence of a spirit whom they call Tornagarfik; but of whom they have formed the most ridiculous notions. The Angekuts, who are supposed to be his immediate ministers, differ concerning the principles of his existence; some affirming that he is without form or shape; others, that he has the shape of a bear; others, that he has a large human body with only one arm; while others affirm that he is no larger than a man’s finger, with many other absurdities of a similar kind. They have also a peculiar kind of mythology, by which they believe all the elements to be full of spirits, from among which every one of their prophets is supplied with a familiar which they name Tornack; and who is always ready when summoned to his assistance.

The Greenlanders are employed all the year round either in fishing or hunting. At sea they pursue the whales, morays, seals, fish for eating, and sea-fowl. On shore they hunt the rein-deer in different parts of the country. They drive these animals, which feed in large herds, into a narrow circle or defile, where they are easily taken with arrows. Their bow is made of fir-tree, wound about with the twisted sinews of animals: the string is composed of the same stuff; or of seal skin: the arrow is a good third in length, pointed with a bearded iron, or a sharp bone; but those with which they kill birds are blunt, that they may not tear the flesh. Sea-fowls they kill with lances, which they throw to a great distance with surprising dexterity. Their manner of catching whales is quite different from that practised by the Europeans. About 50 persons, men and women, sit out in one long boat, which is called a rose-boat, from one woman, because it is rowed by females only. When they find a whale, they strike him with harpoons, to which are fastened with long lines some seals skins blown up like bladders. These, by floating on the surface, not only discover the back of the whale, but hinder him from diving under water for any length of time. They continue to pursue him until he loses strength, when they pierce him with spears and lances till he expires. On this occasion they are clad in their spring coats consisting of one piece, with gloves, boots, caps made of seal skin: closely laced and fewed that they keep out water. Thus accoutred, they leap into the sea; and begin to slice off the fat, even under water, before the whale is dead. — They have many different ways of killing seals; namely, by flicking them with a small harpoon equipped also with an air-bag; by watching them when they come to breathe at the air-holes in the ice, and striking them with spears; by approaching them in the diggings of their own species, that is, covered with a seal skin, creeping upon the ice, and moving the head from side to side as the seals are accustomed to do. By this stratagem the Greenlander makes towards the unsuspecting
Greenland, pecating seal, and kills him with a spear. The Greenlanders angle with lines made of whale-bone cut very small, by means of which they succeed wonderfully. The Greenland canoe, like that used in Nova Zembla and Hudson’s bay, is about three fathoms in length, pointed at both ends, and three quarters of a yard in breadth. It is composed of thin rafts fastened together with the sinews of animals. It is covered with dressed seal-skins both below and above, in such a manner that only a circular hole is left in the middle, large enough to admit the body of one man. Into this the Greenlander thrusts himself undoubtedly Spitzbergen. The sea, left in the middle, large feals, made of the same materials, but more durable; and above, in such manner to bring to Copenhagell, outfiripped a pinnace of 16 oars, the northward as far as the current ran along. This obstacle for a canoe, fitted with a paddle broad at both ends, he will venture out to sea in the most stormy weather to catch feals and sea-fowl; and if he is overfet, he can easily raise himself by means of his paddle. A Greenland canoe, fitted out with a pinnace, which carried a triangular sail made of the membranes and entrails of seals, and is managed the continent of the coast of Spitzbergen. The sea, as Cil:cular, with the finews of animals, whereas in Greenland is about three yards made of whale-bone country from N. Lat 78° to 80° 15′, which was undoubtedly Spitzbergen. The sea in the neighbourhood of the islands of Spitzbergen abounds very much with whales, and is the common resort of the whole-fishing ships from different countries, and the country itself is frequently visited by these ships, but till the late voyage of the Hon. Capt. Phipps, by order of his Britannic majesty, the situation of it was erroneously laid down. It was imagined that the land stretched to the northward as far as 82° of north latitude; but Capt. Phipps found the most northerly point of land, called Seven Islands, not to exceed 80° 30′ of latitude. Towards the coast he saw other lands lying at a distance, so that the Spitzbergen plainly appeared to be surrounded by water on that side, and not joined to the continent of Asia, as former navigators had supposed. The north and west coasts also he explored, but was prevented by the ice from going far to the northward as he wished. The coast appeared neither habitable nor accessible. It is formed of high, barren, black rocks, without the least marks of vegetation; in many places bare and pointed; in others covered with snow, appearing even above the clouds. The valleys between the high cliffs were filled with snow and ice. “This prospect,” says Capt. Phipps, “would have suggested the idea of perpetual winter, had not the mildness of the weather, the smooth water, bright fun-shine, and constant day-light, given a cheerfulness and novelty to the whole of this romantic scene.”

The current ran along this coast half a knot an hour, north. The height of one mountain seen here was found by geometrical mensuration to be at one time 130 fathom, sandy bottom, not far from the shore, and well sheltered from all winds. Close to this harbour is an island called Amsterdam Island, where the Dutch used formerly to boil their whale-oil; and the remains of some convenience erected by them for that purpose tend to be the original discoverers, and called the Greenland country Spitzbergen, or Sharp Mountains, from the many sharp-pointed and rocky mountains with which it abounds. They alleged that the coast discovered by Sir Hugh Willoughby was some other country; which accordingly the Hollanders delineated on their maps and charts by the name of Willoughby Land; whereas in fact no such land ever existed; and long before the voyage of these Dutchmen, Stephen Barrows, an English shipwrecker, had coasted along a desolate country from N. Lat 76° to 80° 15′, which was undoubtedly Spitzbergen. The sea in the neighbourhood of the islands of Spitzbergen abounds very much with whales, and is the common resort of the whole-fishing ships from different countries, and the country itself is frequently visited by these ships, but till the late voyage of the Hon. GREENLAND, a sea-port town in Scotland, and one of the ports of the city of Glasgow. It is distant 22 miles from that city; and was formerly called the Bay of St. Lawrence. The Frith of Clyde here expands into a fine bayon four miles wide, and is landlocked on all sides. Greenock is a burgh of barony, and the best built town on all the coast. It is the chief refort of the herring fishe, and otherwise a place of great trade and very populous.—The harbour was made by Sir John Shaw of Greenock, whose ancestor built the church; and the family had here a castle.

GREENWICH, a town of the county of Kent, in England, pleasantly situated on the bank of the Thames, about five miles east from London. Here was formerly a royal palace, built by Humphry duke of Gloucester, enlarged by Henry VII. and completed by Henry VIII. The latter often chose this town for his place of residence; as did also the queens Mary and Elizabeth, who were born in it. The fame duke Humphry began a tower on the top of the steep hill in the park, which was finished by Henry VII. but afterwards demolished, and a royal observatory erected in its place by Charles II. furnished with mathematical instruments for astronomical observations, and a deep dry well for observing the stars in the day time. The palace being afterwards much neglected, King Charles II. (who had enlarged the park, walled it about and planted it), pulled it down, and began another, of which he lived to see the first wing magnificently finished. But king William III. in 1694, granted it, with nine acres of ground thereto belonging, to be converted into a royal hospital for old and disabled seamen, the widows and children of those who lost their lives in the service, and for the encouragement of navigation. The wing, which cost king Charles 36,000 l. is now the first wing of the hospital towards London. The front to the Thames consists of two ranges of stone-built houses with the range of the house in the centre of the area, but detached from any part of the hospital. These buildings perfectly correspond with each other, and have their tops crowned with a stone balustrade. The buildings which are facing the area, correspond with them, though in a finer and more elegant style; and have domes at their ends, which are 120 feet high, supported on coupled columns. Under one of these is the hall, which is finely painted by Sir James Thornhill, and contains many royal portraits; and under the other the chapel, which by accident was destroyed by fire. This fire broke out in the hospital on the second of January 1779, and totally consumed the dome at the S. Ecuador of the building, with the chapel which was the most elegant in the world, the great dining-hall, and eight wards containing the lodgings of near 600 pensioners. The dome was rebuilt about the year 1785; but the repair of the whole damage is not yet completed. On the sides of the grate which open to these buildings from the park, are placed a large terrestrial and celestial globe, in which the stars are gilt; and in the centre of the area is a statue of George II. About 2000 old disabled seamen are maintained in this hospital. Besides private benefactions, to the amount of near L. 60,000 (which appear in tables hung up at the entrance of the hall), the parliament, in the year
Oreenwith 173 '1, fettled his estate, to the value of £6000 per annum. All strangers who see it, pay twopence a month; and this income is applied to the support of the musical school for the sons of sailors. For the better support of which, every seaman in the royal navy, and in the merchant service, pays sixpence a month, fopped out of their pay, and delivered in at the six-penny receiver's office in Tower-hill. On this account, a seaman, who can produce an authentic certificate of his being disabled, and rendered unfit for service, by defending any ship belonging to his Majesty's British subjects, or in taking any ship from the enemy, may be admitted into this hospital, and receive the same benefits from it as if he had been in his Majesty's immediate service. Besides the seamen and widows abovementioned, about 100 boys, the sons of seamen, are bred up for the service of the royal navy; but there are no out-pensioners as at Chelsea. Each of the mariners has a weekly allowance of seven loaves, weighing 16 ounces each; three pounds of beef, two of mutton, a pint of peas, a pound and a quarter of cheese, two ounces of butter, fourteen quart's of beer, and one shilling a-week tobacco money: the tobacco money of the bosomates is two shillings and sixpence a-week each, that of their mates one shilling and sixpence, and that of the other officers in proportion to their rank; besides which, each common pensioner receives once in two years, a suit of blue cloth, a hat, three pairs of stockings, two pair of shoes, five neck-cloths, three shirts, and two night caps. Out of all that is given for showing the hall, only three-pence in the shilling is allowed to the person that shows them; the rest makes an excellent fund for the yearly maintenance of not less than 20 poor boys, who are the sons of mariners that have been either slain or disabled in the service of their country. The park is well stocked with deer, and affords as much variety, in proportion to its size, as any in the kingdom: but the views from the Observatory and the one-tree hill are beautiful beyond imagination, particularly the former. The projection of these hills is so bold, that you do not look down upon a gradually falling slope or flat inclines, but at once upon the tops of the fishing trees, which grow in knots and clumps out of deep hollows and imbrowned dells. The cattle which feed on the lawns, which appear in breaks among them, seem moving in a region of fairy land. A thousand natural openings among the branches of the trees break upon little picturesque views of the swelling turf, which, when illumined by the sun, have an effec pleasing beyond the power of fancy to paint. This is the foreground of the landscape: a little farther, the eye falls on that noble structure the hospital, in the midst of an amphitheatre of wood; then the two reaches of the river make that beautiful :perpective which forms the Life of Dogs, and presents the floating millions of the Thames. To the left appears a fine tract of country, leading to the capital, which there finishes the prospect. The parish-church of Greenwich, rebuilt by the commissioners for erecting the 50 new churches, is a very handsome structure, dedicated to St Alphage, archbishop of Canterbury, who is said to have been slain by the Danes in the year 1012 on the spot where the church now stands. There is a college at the end of the town, fronting the Thames, for the maintenance of 20 decayed old house-keepers, 12 out of Greenwich, and eight who are to be alternately chosen from Snottisham and Castle-Rising in Norfolk. This is called the duke of Norfolk's College, though it was founded and endowed in 1613 by Henry earl of Northampton the duke of Norfolk's brother, and by him committed to the care of the Mercers company. To this college belongs a chapel, in which the earl's body is laid; which, as well as his monument, was removed hither a few years ago from the chapel of Dover castle. The pensioners, besides meat, drink, and lodging, are allowed one shilling and sixpence a week, with a gown every year, linen once in two years, and hats once in four years. In 1560, Mr Lambard, author of the Perambulation of Kent, also built an hospital, called queen Elizabeth's college, said to be the first erected by an English Protestant. There are likewise two charity-schools in this parish. The river Thames is here very broad, and the channel deep; and at some very high tides the water is salt. This is the chief harbour for the king's yachts. The town contains about 1500 houses; and a market on Wednesday and Saturday was erected here in 1737; the direction of which is in the governors of the royal hospital, to which the profits arising from it were to be appropriated.

GREGORIOUS, among zoologists, a term applied to such animals as do not live solitary, but associate in herds or flocks.

GREGORIAN CALENDAR, that which shows the new and full moon, with the time of Easter, and the movable feasts depending thereon, by means of epacts disposed through the several months of the Gregorian year. See CHRONOLOGY, n° 24.

GREGORIAN Telescope. See OPTICS, (Index.)

GREGORIAN Year. See CHRONOLOGY, n° 24.

GREGORY the Great, was born at Rome, of a patrician family. He discovered such abilities in the exercise of the senatorial employments, that the emperor Julian appointed him prefect of Rome. Pope Pelagius II. sent him nuncio to Constantinople, to demand succours against the Lombards. When he thought of enjoying a solitary life, he was elected pope by the clergy, the senate, and the people of Rome. Besides his learning and diligence in instructing the church, both by writing and preaching, he had a very happy talent in winning over princes in favour of the temporal as well as spiritual interest of religion. He undertook the conversion of the English, and sent over some monks of his order, under the direction of Augustine their abbot. His morality with respect to the chastity of churchmen was very rigid, ascertaining that a man who had ever known a woman ought not to be admitted to the priesthood; and he always caufed the candidates for it to be examined upon that point. He likewise vigorously exerted himself against such as were found guilty of calumny. However, he flattered the emperor Phocas, while his hands were yet reeking with the blood of Mauritius, and of his three children, who had been butchered in his sight. He likewise flattered Brunschaut, a very wicked queen of France. He is accused of destroying the noble monuments of ancient Roman magnificence, that those who visited the city might not attend more to the triumphant arches than to holy things; and burnt a multitude of heathen books, Livy in particular. He died in 604.

GREGORY of Nazianzen, given the Divus, was
Gregory, one of the most illustrious ornaments of the Greek church in the fourth age. He was made bishop of Constantinople in 379; but finding his election contested by Timotheus archbishop of Alexandria, he voluntarily resigned his dignity about 382, in the general council of Constantinople. His works are extant, in two volumes, printed at Paris in 1602. His style is said to be equal to that of most of the celebrated orators of ancient Greece.

Gregory (Theodorus), surnamed Thaumaturgus, on account of his miracles, was the scholar of Origen; and was elected bishop of Neocaesarea, the place of his birth, about the year 240, during his absence. He assisted at the council of Antioch, in 255, against Paulus Samoetanus; and died in 270. He had the satisfaction of leaving only seventeen idolaters in his diocese, where there were but seventeen Christians when he was ordained. There is still extant of him, A gratuitous oration to Origen, A canonical epistle, and some other works.

Gregory, bishop of Nyssa, one of the fathers of the church, and author of the Nicene creed, was born in Cappadocia, about the year 331. He was chosen bishop of Nyssa in 372, and banished by the emperor Valens for adhering to the council of Nice. He was nevertheless afterwards employed by the bishops in several important affairs, and died in 376. He wrote Commentaries on the Scriptures; Sermons on the mysteries; Moral discourses; Dogmatical treatises; Panegyrics on the saints; some letters on church-discipline; and other works. His style is very allegorical and affected.

Gregory of Tours, or Georgius Florentinus Gregorius, one of the most illustrious bishops and celebrated writers of the sixth century, was defended from a noble family in Auvergne. He was educated by his uncle Gallus, bishop of Clermont; and distinguished himself so much by his learning and virtue, that a friend of his was chosen bishop of Tours. He afterwards went to Rome to visit the tomb of the apostles, where he contracted a friendship with Gregory the Great, and died in 595. This author was extremely curious with regard to miracles. He wrote, 1. The history of France. 2. The lives of the saints; and other works. The best edition is that published by Father Rumar, 1699.

Gregory (James), one of the most eminent mathematicians of the last century, was a fellow of the Rev. Mr John Gregory minister of Drumoak in the county of Aberdeen, and was born at Aberdeen in 1638. His mother was a daughter of Mr David Anderon of Finzeagh, a gentleman who posseid a singular turn for mathematical and mechanical knowledge. This mathematical genius was hereditary in the family of the Anderons, and from them seems to have been transmitted to their descendants of the name of Gregory. Alexander Anderon, cousin german of the above-mentioned David, was professor of mathematics at Paris in the beginning of the 17th century, and published there in 1672, Supplementum Apollonii redivi, &c. The mother of James Gregory inherited the genius of her family; and observing in her son, while yet a child, a strong propensity to mathematics, she instructed him herself in the elements of that science. He received his education in the languages at the grammar school of Aberdeen, and went through the usual course of academical studies in the Marischal college.

At the age of 24 he published his treatise, intitled Optica Promota, seu abrid radiorum reflexorum at reflectorum mysterior, geometricae nduncta; cui subeditur appendix utilissimorum astronomie problematiorem solvendum exhibens, London 1665: a work of great genius, in which he gave the world an invention of his own, and one of the most valuable of the modern discoveries, the construction of the reflecting telescope. This discovery immediately attracted the attention of the mathematicians, both of Britain and other countries, who were soon convinced of its great importance to the sciences of optics and astronomy. The manner of placing the two specula upon the same axis appearing to Sir Isaac Newton to be attended with the disadvantage of losing the central rays of the larger speculum, he proposed an improvement on the instrument, by giving an oblique position to the smaller speculum, and placing the eye-glasses in the side of the tube. But it is worth remarking, that the Newtonian construction of that instrument was long abandoned for the original or Gregorian, which is at this day universally employed where the instrument is of a moderate size; though Mr Herchel has preferred the Newtonian form of the construction of those immense telescopes, which of late years he has so successfully employed in observing the heavens.

The university of Padua being at that time in high reputation for mathematical studies, James Gregory went thither soon after the publication of his first work; and fixing his residence there for some years, he published, in 1667, Vera Circuli et Hyperboli quadraturæ, in which he propounded another discovery of his own, the invention of an infinitely converging series for the areas of the circle and hyperbola. To this treatise, when republished in 1668, he added a new work, intituled, Geometria pars universalis, in quāvis quantitatum curvarum, rectificationem, &eummutationem, ejusque determinationem, in which he is allowed to have shown, for the first time, a method for the solution of algebraic problems. These works engaged the notice, and procured Mr Gregory the correspondence, of the greatest mathematicians of the age, Newton, Huygens, Halley, and Wallis; and their author being soon after chosen a fellow of the royal society of London, contributed to enrich the Philosophical Transactions at that time by many excellent papers. Through this channel, in particular, he carried on a dispute with Mr Huygens, upon the occasion of his treatise on the quadrature of the circle and hyperbola, to which that able mathematician had flouted some objections. Of this controversy, it is unnecessary to enter into particulars. It is sufficient to say, that, in the opinion of Leibnitz, who allows Mr Gregory the highest merit for his genius and discoveries, Mr Huygens has pointed out, though not errors, some considerable deficiencies in the treatise above mentioned, and shown a much simpler method of attaining the end in view.

In 1668, Mr James Gregory published at London another work intituled Exercitationes Geometricæ which contributed still to extend his reputation. About this time he was elected professor of mathematics in the university of St Andrew's; an office which he held for
Gregory. six years. During his residence there, he married, in 1669, Mary, the daughter of George Jalilefon the celebrated painter, whom Mr Walpole has termed the Vandyke of Scotland, and who was fellow-disciple with that great artist in the school of Rubens at Antwerp.

In 1674, he was called to Edinburgh, to fill the chair of mathematics in that university. This place he had held for little more than a year, when, in October 1675, being employed in showing the satellites of Jupiter through a telescope to some of his pupils, he was suddenly struck with total blindness, and died a few days after, at the early age of 37.

He was a man of an acute and penetrating genius. His temper seems to have been warm, as appears from the conduct of his dispute with Mr Huygens; and, conscious perhaps of his own merits as a discoverer, he seems to have been jealous of losing any portion of his reputation by the improvements of others upon his inventions.

Gregory (David), Savilian professor of astronomy at Oxford, whom Dr Smith has termed sapientissimi ingenii mathematici, was the eldest son of Mr Gregory of Kinnaird, brother of the abovementioned Mr James Gregory.

He was born at Aberdeen in 1661, and received the earlier parts of his education in that city. He completed his studies at Edinburgh; and, being possessor of the mathematical papers of his uncle, foot distinguished himself likewise as the heir of his genius. In the 23d year of his age, he was elected professor of mathematics in the university of Edinburgh; and published, in the same year, Exercitatio Geometrica de dimensionibus figurarum, sive exemplum methodi generalis dimensionis quaedam figurarum, Edinburgh, 1684, 4to. He was very early the excellence of the Newtonian philosophy; and had the merit of being the first who introduced it into the schools by his public lectures at Edinburgh.

He had (says Mr Whitton*) already caused several of his scholars to keep acts, as we call them, upon several branches of the Newtonian philosophy; while we at Cambridge, poor wretches, were ignominiously studying the fictitious hypothesis of the Cartesian.†

In 1691, on the report of Dr Bernard's intention of resigning the Savilian professorship of astronomy at Oxford, David Gregory went to London; and being patronized by Sir Isaac Newton, and warmly befriended by Mr Flamstead the astronomer royal, he obtained the vacant professorship, for which Dr Halley was a competitor. This rivalry, however, instead of animosity, laid the foundation of friendship between these eminent men; and Halley soon after became the college of Gregory, by obtaining the professorship of geometry in the same university. Soon after his arrival in London, Mr Gregory had been elected a fellow of the royal society; and, previously to his election in the Savilian professorship, had the degree of doctor of physic conferred on him by the university of Oxford (A).

In 1693 he published in the Philosophical Transactions a resolution of the Florentine problem de T. fiur- divine veliformi quadribusi; and he continued to communicate to the public, from time to time, many ingenious mathematical papers by the same channel. In 1695, he printed at Oxford Catalogue et Dissertations Sphaericæ Elementa; a work which, as he informs us in his preface, contains the substance of some of his public lectures read, eleven years before, at Edinburgh. This valuable treatise was republished first with additions by Dr William Brown, with the recommendation of Mr Jones and Dr Defaguiriers; and afterwards by the latter of these gentlemen, with an appendix containing an account of the Gregorian and Newtonian telescopes, together with Mr Hadley's tables for the construction of both those instruments. It is not unworthy of remark, that, in the end of this treatise, there is an observation which shows, that what is generally believed to be a discovery of a much later date, the construction of achromatic telescopes, which has been carried to great perfection by Mr Dollond and Mr Ramsden, had suggested itself to the mind of David Gregory, from the reflection on the admirable contrivance of nature in combining the different humours of the eye. The passage is as follows: "Quod siob difficultates physisicas in speculis idoneis torno clarorandi et poliendi, etiamum lentibus uti oporeat, fortasse media diverse denititatis ad lentam objectivam componentem adhibere utile foret, ut a natura factum observavimus in oculi fabrica, ut cristallinos humor (tere ejusdem cum virto virtutis ad radios lucis refringendos) aqueo et vitreo (aque quad refractionem haud absumilibus) conjungitur, ad imaginem quam diffinte fieri poterit, a natura nihil frustra molleente, in oculi fundo depingendum." Catopt. et Disolpl. Sphaer. Elem. Oxon. 1695, p. 98.

In 1702 our author published at Oxford, Astronomiae Physicae et Geometriae Elementa; a work which is accounted his master-piece. It is founded on the Newtonian doctrines, and was esteemed by Sir Isaac Newton himself as a most excellent explanation and defence of his philosophy. In the following year he gave to the world an edition in folio of the works of Euclid in Greek and Latin; in prosecution of a design of his predecessor Dr Bernard, of printing the works of all the ancient mathematicians. In this work, although it contains all the treatises attributed to Euclid, Dr Gregory has been careful to point out such as he found reason, from internal evidence, to believe to be the productions of some inferior geometrician. In prosecution of Dr Bernard's plan, Dr Gregory engaged, soon after, with his colleague Halley, in

(‡) On obtaining the above professorship, he was succeeded in the mathematical chair at Edinburgh by his brother James, likewise an eminent mathematician; who held that office for thirty-three years, and retiring in 1725 was succeeded by the celebrated Maclaurn. A daughter of this professor James Gregory, a young lady of great beauty and accomplishments, was the victim of an unfortunate attachment, which furnished the subject of Mallet's well-known ballad of William and Margaret.

Another brother, Charles, was created professor of mathematics at St Andrew's by queen Anne in 1707. This office he held with reputation and ability for thirty-two years; and, resigning in 1739, was succeeded by his son, who eminently inherited the talents of his family, and died in 1763.
Gregory, in the publication of the Conics of Apollonius; but he had proceeded but a little way in this undertaking when he died, in the 40th year of his age, at Maidenhead in Berkshire, A.D. 1710. To the genius and abilities of David Gregory, the most celebrated mathematicians of the age, Sir Isaac Newton, Dr Halley, and Dr Keill, have given ample testimonies. Besides those works published in his lifetime, he left in manuscript, A Short Treatise of the Nature and Arithmetic of Logarithms, which is printed at the end of Dr Keill's translation of Commandine's Enulid, and a Treatise of Practical Geometry which was afterwards translated, and published in 1745, by Mr MacLaurin.

Dr. David Gregory married, in 1695, Elizabeth, the daughter of Mr Oliphant of Langtown in Scotland. By this lady he had four sons, of whom, the eldest, David, was appointed regius professor of modern history at Oxford by king George I. and died in 1767, in an advanced age, after enjoying for many years the dignity of dean of Christ church in that university.

Gregory (Dr John), professor of medicine in the university of Edinburgh, was the son of Dr James Gregory professor of medicine in King's college Aberdeen, and grandson of James the inventor of the Gregorian telescope. His father was first married to Catharine Forbes, daughter of Sir John Forbes of Monymusk; by whom he had six children, most of whom died in infancy. He married afterwards Anne Chalmers, only daughter of the Rev. Mr George Chalmers principal of King's college, by whom he had two sons and a daughter. John, the youngest of the three, was born at Aberdeen, June 3, 1724. Losing his father when only in the 7th year of his age, the care of his education devolved on his grandfather Principal Chalmers, and on Dr Sinclair on the three Gregory, who, upon the resignation of their father a short time before his death, had been appointed to succeed him in the professorship of medicine in King's college. He likewise owed much in his infant years, and during the whole course of his studies, to the care and attention of his cousin, the celebrated Dr Reid, now of the university of Glasgow. The rudiments of our author's classical education he received at the grammar-school of Aberdeen; and, under the eye of his grandfather, he completed in King's college, his studies in the Latin and Greek languages, and in the sciences of ethics, mathematics, and natural philosophy. His master in philosophy and mathematics was Mr Thomas Gordon, the present philosophy professor of King's college, who has ably filled an academical chair for above half a century.

In 1742, Mr Gregory went to Edinburgh, where the school of medicine was then rising to that celebrity which has since so remarkably distinguished it. Here he attended the anatomical lectures of the elder Dr Monro, of the materia medica and botany, and of Dr Parham on chemistry. The medical society of Edinburgh, instituted for the free discussion of all questions relative to medicine and philosophy had begun to meet in 1737. Of this society we find Mr Gregory a member in 1742, at the time when Dr Mark Akenside, his fellow student, and intimate companion, was a member of the same institution.

In the year 1745 our author went to Leyden, and attended the lectures of those celebrated professors Gaußius, Albinus, and Van Royen. While at this place he had the honour of receiving from the King's college of Aberdeen, his alma mater, whom he regarded as a favourite son, an unqualified degree of doctor of medicine; and soon after, on his return thither from Holland, he was elected professor of philosophy in the same university. In this capacity he read lectures during the years 1747, 1748, and 1749, on the mathematics, on experimental philosophy, and on moral philosophy. In the end of 1749, however, he chose to resign his professorship of philosophy, his views being turned chiefly to the practice of physic, with which he apprehended the duties of this professorship, occupying a great portion of his time, too much interfered. Previously, however, to his settling as a physician at Aberdeen, he went for a few months to the Continent; a tour, of which the chief motive was probably amusement, though, to a mind like his, certainly not without its profit in the enlargement of ideas, and an increased knowledge of mankind.

Some time after his return to Scotland, Dr Gregory married, in 1752, Elisabeth daughter of William Lord Forbes; a young lady who, to the exterior endowments of great beauty and engaging manners, joined a very superior understanding, and an uncommon share of wit. With her he received a handsome addition of fortune; and during the whole period of their union, which was but for the space of nine years, enjoyed the highest portion of domestic happiness. Of her character it is enough to say, that her husband, in that admired little work, A father's Legacy to his Daughters, the last proofs of his affection for them, declares, that, "while he endeavours to point out what they should be, he draws but a very faint and imperfect picture of what their mother was." The field of medical practice at Aberdeen being at that time in a great measure pre-occupied by his elder brother Dr James Gregory, and others of some note in their profession, our author determined to try his fortune in London. Thither accordingly he went in 1754; and being already known by reputation as a man of genius, he found an easy introduction to many persons of distinction both in the literary and polite world. The late George Lord Lyttleton was his friend and patron. An attachment, which was founded on a striking similarity of manners, of tastes, and of dispositions, grew up into a firm and permanent friendship; and to that nobleman, to whom Dr Gregory was wont to communicate all his literary productions, the world is indebted for the publication of the Comparative View of the State and Faculties of Man, which made him first known as an author. Dr Gregory likewise enjoyed the friendship of the late Edward Montague, Esq; and of his lady, the celebrated champion of the Fame of Shakespeare against the cavils and calumnies of Voltaire. At her assemblies, or conversazioni, the reftor of taste and genius, our author had an opportunity of cultivating an acquaintance with many of the most distinguished literary characters of the present times.

In 1754 Dr Gregory was chosen fellow of the roy-
to this work, he signified his intention of comprehending in it the whole series of diseases of which he treated in his lectures on the Practice of Physic; but this intention he did not live to accomplish, having brought down the work no further than to the end of the class of Febrile Diseases.—In his academical lectures Dr. Gregory never attempted to mislead the student by flattering views of the perfection of the science; but was, on the contrary, anxious to point out its defects; wisely judging, that a thorough sensé of the imperfection of an art or science is the first step towards its improvement. In this view he was careful to expound the fallacies of the several theories and hypotheses which have had the most extensive currency, and perpetually inculcated the danger of systematizing with limited experience, or an imperfect knowledge of facts. Yet in the work last mentioned it will appear, from the order in which he has treated of the several diseases, that he did not entirely neglect the systematic arrangements of other authors. These, however, he warned his pupils, that he had not adopted from any conviction of the rectitude of those theories to which they referred, but only as afraid that degree of method, and regularity of plan, which is found to be the best help to the study of any science. Considering a rational theory of physic to be as yet a desideratum, it was his object to communicate to his pupils the greatest portion of practical knowledge, as the only basis on which such a theory could ever be reared. His method, in treating of the several diseases, was first to mention those symptoms which are understood among physicians to characterize or define a disease; proceeding from the general to the more particular series of symptoms and their occasional varieties; to point out accurately the diagnostic symptoms, or those by which one disease is essentially distinguished from others that resemble it, and to mark likewise the prognostics by which a physician is enabled to conjecture the probable event of a disease, whether favourable or otherwise. He then proceeded to specify the various canons, predispensing occasional, and proximate; accounting as far as he thought could be done on just principles, for the appearance of the several symptoms; and, finally, he pointed out the general plan of cure, the particular remedies to be employed, and the cautions requisite in the administration of them. Thus desirous of establishing the science of medicine upon the solid foundation of practice and experience; and knowing that many things affirmed as facts by medical writers have been built upon a very careless observation, while confirming a favourite theory; and that, on the other hand, many real and important facts have, from the same spirit of system, been explained away and discredited; he constantly endeavoured, both by his precept and example, to inculcate to his pupils the necessity of extreme caution either in admitting or in denying medical facts, or what are commonly given as such. To the desire of enforcing this necessary caution is owing that multitude of queries respecting matters of fact, as well as matters of opinion, which occurs in the Elements of the Practice of Physic.

Dr. Gregory, soon after the death of his wife, and, as he himself says, "for the amusement of his solitary hours,"
The preceding years of his life, this work is a most amiable display of the piety and goodness of his heart, and his constant knowledge of human nature and of the world. It manifests such solicitude for their welfare, as strongly recommends the advice which he gives. He speaks of the female sex in the most honourable terms, and labours to increase its estimation, whilst he plainly, yet genteelly and tenderly, points out the errors into which young ladies are prone to fall. It is particularly observable, in what high and honourable terms he speaks of the Holy Scriptures, of Christian worship, and faithful ministers; how warmly he recommends to his daughters the vigorous and devout worship of God in public and private. He dwells largely on that temper and behaviour, which were particularly suited to their education, rank, and circumstances; and recommends that gentleness, benevolence, and modesty, which adorn the character of the ladies, and do particular honour to their sex. His advice, with regard to love, courtship, and marriage, are peculiarly wise, and interesting to them. They show what careful observation he had made on female domestic conduct, and on the different effects of polishing or wanting the virtues and qualities which he recommends. There is something peculiarly curious, animated, and useful, in his directions to them, how to judge of, and manifest an honourable passion in, and towards the other sex, and in the very accurate and useful distillation which he makes between true and false delicacy. Nothing can be more striking and affecting, nothing more likely to give his paternal advice their desired effect, than the respectful and affectionate manner in which he mentions his lady their mother, and the irreparable loss which he and they sustained by her early death. In short, in this tract, the professor shines with peculiar lustre as a husband and father, and it is admirably adapted to promote domestic happiness.

These letters to his daughters were evidently written under the impression of an early death, which Dr Gregory had reason to apprehend from a constitution subject to the gout, which had begun to show itself at irregular intervals even from the 15th year of his age. His mother, from whom he inherited that disease, died suddenly in 1770, while sitting at table. Dr Gregory had prognosticated for himself a similar death, an event of which, among his friends, he often talked, but had no apprehension of the nearness of its approach. In the beginning of the year 1773, in conversation with his son the present Dr James Gregory, the latter remarking, that having for the three preceding years had no return of a fit, he might make his account with a pretty severe attack at that season; he received the observation with some degree of anger, as he felt himself then in his usual state of health. The prediction, however, was too true; for having gone to bed on the 9th of February 1773, with no apparent disorder, he was found dead in the morning.

His death had been instantaneous, and probably in his sleep; for there was not the smallest discomposure of limb or of feature,—a perfect euthanasia.

Dr Gregory, in person, was considerably above the middle size. His frame of body was compacted with symmetry, but not with elegance. His limbs were not active; he flopped somewhat in his gait; and his countenance, from a fullness of feature and a heaviness of eye, gave no external indication of superior power of mind or abilities. It was otherwise when engaged in conversation. His features then became animated, and his eye most expressive. He had a warmth of tone and of gesture which gave a pleasing interest to every thing which he uttered: But, united with this animation, there was in him a gentleness and simplicity of manner, which, with little attention to the exterior and regulated forms of politeness, was more engaging than the most finished address. His conversation flowed with ease; and, when in company with literary men, without affording a display of knowledge, he was liberal of the stores of his mind. He possessed a large share of the social and benevolent affections, which, in the exercise of his profession, manifested themselves in many nameless, but important, attentions to those under his care; attentions which, proceeding in him from an extended principle of humanity, were not squared to the circumstances or rank of the patient, but ever bestowed most liberally where they were most requisite. In the care of his pupils, he was not satisfied with a faithful discharge of his public duties. To many of these strangers in the country, and far removed from all who had a natural interest in their concerns, it was matter of no small importance to enjoy the acquaintance and countenance of one so universally respected and esteemed. Through him they found an easy introduction to an enlarged and elegant society; and, what to them was still more valuable, they experienced in him a friend who was ever easy of access, and ready to affit them to the utmost with his counsel and patronage. The same spirit of philanthropy endeared him in a particular manner to his intimate friends; and, whomsoever he might be ranked most of the Scottih literati of his time. Some time after his death, the professorship of the Theory of Medicine was bestowed upon his eldest son the present Dr James Gregory; who has since succeeded to the Practical Chair, lately filled by that other most eminent professor Dr Cullen.

G R E- hound. See Cant.—Among a litter of gre-hound puppies, the best are always those which are lightest. These will make the nimblest dogs as they grow up. The gre-hound is best for open countries where there is little covert. In these places there will sometimes be a course after a hare of two or three miles or more, and both the dogs and the game in sight all the while. It is generally supposed that the gre-hound bitch will beat the dog in running: but this seems to be an error; for the dog is both longer made, and considerably stronger, than the bitch of the same kind. In breeding these dogs, the bitch is principally to be regarded; for it is found by experience, that the best dog and a bad bitch will not get so good puppies as an indifferent dog with a good bitch. The dog and bitch should be as nearly as may be of the same...
same age; and for the breeding of fine and perfect dogs, they should not be more than four years old. An old bitch may be used with a young dog, but the puppies of a young bitch and an old dog will never be good for anything.

The general food for a gre-hound ought to be chippings or rasings of bread, with soft bones and gristles; and those chippings ought always to be soaked in beef or mutton broth.

The proper exercise of a gre-hound is courting him three times a-week, and rewarding him with blood; which will animate him in the highest degree, and encourage him to persecute his game. But the hare also should ever have fair play. She should have the law, as it is called; that is, have leave to run about twelve score yards before the dog is slipped after her; that he may have some difficulty in the course, and not pick up the game too easily. If he kills the hare, he must never be suffered to tear her; but the must be taken from him, his mouth cleaned of the wool, and the liver and lights given him by way of encouragement. Then he is to be led home, and his feet washed with butter and beer, and about an hour after he is to be fed.

When the dog is to be taken out to course, he should have nothing in the morning but a toast and butter, and then he is to be kennelled till taken out to the field. The kennelling these dogs is of great use, always giving them spirits and nimbleness when they are set loose; and the better way of managing a fine gre-hound, is never to let him stir out of the kennel, except at the times of feeding, walking, or courting.

GRENADA, one of the Caribbee islands, lying in W. Long. 61. 40. N. Lat. 12. o. It is the last of the Windward Caribbees; and lies 30 leagues north of new Andalusia, on the continent. According to some it is 24 leagues in compass; according to others, only 22: and it is said to be 30 miles in length, and in some places 15 in breadth. The chief port, formerly called Louis, now St. George's Islands on the west side of the island, in the middle of a large bay, with a sandy bottom. The island is so prodigious that so many vast vessels, from 300 to 400 tons, may ride secure from storms; and that 100 ships, of 1000 tons each, may be moored in the harbour. A large round bason, which is parted from it by a bank of sand, would contain a considerable number of ships, if the bank was cut through: but by reason of it the large ships are obliged to pass within 50 paces of one of the mountains lying at the mouth of the harbour; the other mountain lying about half a mile distant. The island abounds with wild game and fish, it produces also very fine timber, but the cocoa-tree is observed not to thrive here so well as in the other islands. A lake on a high mountain, about the middle of the island, supplies it with fresh-water streams. Several bays and harbours lie round the island, some of which might be fortified to great advantage; so that it is very convenient for shipping, not being subject to hurricanes. The soil is capable of producing tobacco, sugar, indigo, peache, and millet.

In 1638, M. Poincy, a Frenchman, attempted to make a settlement in Grenada; but was driven off by the Caribbeans, who referred to this island in greater numbers than to the neighbouring ones, probably on account of the game with which it abounded. In 1650, M. Parquet, governor of Martinico, carried over from that island 200 men, furnished with presents to reconcile the savages to them; but with arms to subdue them, in case they should prove insubordinate. The savages are said to have been frightened into submission by the number of the Frenchmen: but, according to some French writers, the chief not only welcomed the new-comers; but, in consideration of some knives, hatchets, scissors, and other toys, yielded to Parquet the sovereignty of the island, referring to themselves their own habitations. The Abbe Raynal informs us, that these first French colonists, imagining they had purchased the island by these trifles, allured the sovereignty, and soon acted as tyrants. The Caribbeans, unable to contend with them by force, took their usual method of murdering all those whom they found in a defenceless state. This produced a war; and the French settlers having received a reinforcement of 300 men from Martinico, forced the savages to retire to a mountain; from whence, after exhausting all their arrows, they rolled down great logs of wood on their enemies. Here they were joined by other savages from the neighbouring islands, and again attacked the French, but were defeated anew; and were at last driven to such desperation, that 40 of them, who had escaped from the slaughter, jumped from a precipice into the sea, where they all perished, rather than fall into the hands of their implacable enemies. From thence the rock was called la mort des Jautmans, from the word leapers; which name it still retains. The French then destroyed the habitations and all the provisions of the savages; but fresh supplies of Caribbeans arriving, the war was renewed with great vigour and great numbers of the French were killed. Upon this they resolved totally to exterminate the nates; and having accordingly attacked the savages unawares, they inhumanly put to death the women and children, as well as the men; burning all their boats and canoes, to cut off all communication between the few survivors and the neighbouring islands. Notwithstanding all these barbarous precautions, however, the Caribbeans continued their depredations, from 200 to 400 men; and their frequent irruptions at last obliged Parquet to sell all his property in the island to the Count de Cerillac in 1657. The new proprietor, who purchased Parquet's property for 30,000 crowns, fent thither a person of brutal manners to govern the island. He behaved with such infupportable tyranny, that most of the colonists retired to Martinico; and the few who remained condemned him to death after a formal trial. In the whole court of justice that tried this miscreant, there was only one man (called Archangeli) who could write. A farrier was the person who impeached him; and he, instead of the signatures, sealed with a horse-shoe; and Archangeli, who performed the office of clerk, wrote round it these words in French, "Mark of Mr de la Rie, counsel for the court."

It was apprehended that the court of France would not ratify a sentence passed with such unusual formalities; and therefore most of the judges of the governor's crime, and witnesses of his execution, disappeared. Only those remained whose obsequies screened them from the pursuit of the laws. By an amicable
G R E N A D A

251 white people, 33 free savages or mulattoes, and 525 slaves. The useful animals were reduced to 64 horses and 350 head of horned cattle. The whole culture consisted of 3 plantations of sugar and 52 of indigo. — The island had been fold in 1664 to the French West India company for 100,000 livres.

This unfavourable state of the affairs of Grenada was changed in 1714. The change was owing to the flourishing condition of Martinico. The richest of the ships from that island were sent to the Spanish coasts, and in their way touched at Grenada to take in refreshments. The trading privileges, who undertook this navigation, taught the people of that island the value of their soil, which only required cultivation. Some traders furnished the inhabitants with slaves and utensils to erect sugar plantations. An open account was established between the two colonies. Grenada was clearing its debts gradually by its rich produce; and the balance was on the point of being closed, when the war in 1744 interrupted the communication between the two islands, and at the same time stopped the progress of the sugar-plantations. This loss was supplied by the culture of coffee, which was purveyed during the hostilities with all the activity and eagerness that industry could inspire. — The peace of 1748 revived all the labours, and opened all the former sources of wealth. In 1753 the population of Grenada consisted of 1262 white people, 175 free negroes, and 11,991 slaves. The cattle amounted to 2208 horses or mules, 2456 head of horned cattle, 3278 sheep, 902 goats, and 331 hogs. The cultivation rose to 83 sugar plantations, 2,725,600 coffee-trees, 115,300 cocoa-trees, and 800 cotton-plants. The provisions consisted of 5,740,450 bushels of cassada, 953,596 banana trees, and 145 squares of potatoes and yams. The colony made a rapid progress, in proportion to the excellence of its soil; but in the course of the last war but one, the island was taken by the British. At this time one of the mounts at the side of St George's harbour was strongly fortified, and might have made a good defence, but surrendered without firing a gun; and by the treaty concluded in 1763 the island was ceded to Britain. On this cession, and the management of the colony after that event, the Abbé Raynal has the following remarks. — "This long train of evils [the ambition and mismanagement of their countrymen] has thrown Grenada into the hands of the English, who are in possession of this conquest by the treaty of 1763. But how long will they keep this colony? Or, will it never again be restored to France? — England has not made a fortunate beginning. In the first enthusiasm raised by an acquisition, of which the highest opinion had been previously formed, every one was eager to purchase estates there. They fold for much more than their real value. This caprice, by expelling old colonists who were inured to the climate, has sent about L. 1,553,000 out of the mother-country. This imprudence has been followed by another. The new proprietors, misled, no doubt, by national pride, have substituted new methods to those of their predecessors. They have attempted to alter the mode of living among their slaves. The negroes, who from their very ignorance are more attached to their customs than other men, have revolted. It hath been found necessary to send out troops, and to shed blood. Grenada. The whole colony was filled with suspicions. The masters who had laid the SLAVES with using violent methods, were afraid of being burnt or mangled in their own plantations. The labours have declined, or been totally interrupted. Tranquillity has at length been restored. The number of slaves has been increased as far as 40,000, and the produce has been raised to the treble of what it was under the French government. The plantations will still be improved by the neighbourhood of a dozen of islands, called the Grenadines or Grenadillos, that are dependent on the colony. They are from three to eight leagues in circumference, but do not afford a single spring of water. The air is wholesome. The ground, covered only with thin bushes, has not been screened from the sun. It exhales none of those noxious vapours which are fatal to the husbandman. Caricaon, the only one of the Grenadines, which the French have occupied, was at first frequented by turtle fishermen; who, in the leisure afforded them by so easy an occupation, employed themselves in clearing the ground. In the course of time, their small number was increased by the accestion of some of the inhabitants of Guadalupe; who, finding that their plantations were destroyed by a particular sort of ants, removed to Caricaon. The island blossomed from the liberty that was enjoyed there. The inhabitants collected about 1200 slaves, by whose labours they made themselves a revenue of near 20,000l. a-year in cotton. — The other Grenadines do not afford a prospect of the same advantages, though the plantation of sugar is begun there. It has succeeded remarkably well at Bequia, the largest and most fertile of these islands, which is no more than twotwelve leagues distant from St Vincent." —

In the year 1779 the conquest of this island was accomplished by D'Eftaign the French admiral, who had been prevented from attempting it before by his engagement against St Vincent. Immediately after his conquest of St Lucia, however, being reinforced by a squadron under M. de la Motte, he set sail for Grenada with a fleet of 26 sail of the line and 12 frigates, having on board 10,000 land forces. He arrived on the second of July; and landed 3000 troops, chiefly Irish, being part of the brigade composed of natives of Ireland in the service of France. These were conducted by Count Dillon, who disposed them in such a manner as to surround the hill that overlooks and commands George's Town, together with the fort and harbour. To oppose these, Lord McCartney, the governor, had only about 150 regulars, and 300 or 400 armed inhabitants; but though all resistance was evidently vain, he determined nevertheless to make an honourable and gallant defence. The preparations made were such as induced D'Eftaign himself to be present at the attack; and, even with his vast superiority of force, the first attack on the entrenchments proved unsuccessful. The second continued two hours; when the garrison were obliged to yield to the immense disparity of numbers which assailed them, after having killed or wounded 300 of their antagonists. Having thus made themselves masters of the intrenchments on the hill, the French turned the cannon of the fort towards the fort which lay under it; on which the governor demanded a capitulation. The terms, however, were
GRENADINES, or GRENAULTS. See the preceding article.—It is there mentioned that the Grenadines do not afford a single drop of fresh water. A small spring however has been lately discovered in the principal island Caricacon, by digging; but being of great value, it is kept locked by the proprietor Mr Mayes. The capital of that island is called Hillborough, in which there is a small church.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chinese use as a red colour in some of their most useful articles, particularly for that colour which is called oil-red, or red in oil. The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no such thing as silver-coined money, but they use in commerce bars or mazas of silver, these they pay and receive in large bargains; and among a nation so full of fraud as the Chinese, it is no wonder that these are too often adulterated with too great an alloy of copper. They pass, however, in this state in the common payments. There are some occasions, however, such as the paying the taxes and contributions, on which they must have their silver pure and fine: on this occasion they have recourse to certain people, whole sole business it is to refine the silver, and separate it from the copper and the lead it contains. This they do in furnaces made for the purpose, and with very convenient vessels. While the copper is in fusion, they take a small brush, and dip the end of it into water; then striking the handle of the brush, they sprinkle the water by degrees upon the melted copper; a sort of pellicle forms itself by this means on the surface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large vessel of cold water, it forms that red powder which is called the grenaille; they res-
GRENOBLE, a large, populous, and ancient town of Dauphiny in France, with a bilious fever. It contains a great number of handsome buildings, particularly the churches and convents. The leather and gloves that are made here are highly esteemed. The leather and gloves that are made here are highly esteemed.

GREVILLE (Folke), lord bishop of Bath, president of the Privy Council, and one of the most learned of English noblemen, was born in the year 1554, and descended from the noble families of Beauchamps of Powick and Wilmot by de Broc. In company with his cousin Sir Philip Sidney, he began his education at a school in Shrewsbury: thence he went to Oxford, where he remained for some time a gentleman commoner, and then removed to Trinity-College in Cambridge. Having left the university, he visited foreign courts, and thus added to his knowledge of the ancient languages a perfect knowledge of the modern. On his return to England he was introduced to Queen Elizabeth by his uncle Robert Greville, at that time in her majesty's service, and by Sir Henry Sidney, lord president of Wales, was nominated to some lucrative employments in that principality.

In the year 1581, when the French commissioners who came to treat about the queen's marriage with the Duke of Anjou were sumptuously entertained with tilts and tournaments, Mr Greville, who was one of the champions, signified himself, as to "win the reputation of a most valiant knight." He continued a constant attendant at court, and a favourite with the queen to the end of her reign; during which he obtained the office of treasurer of marine, and also a grant of the manor of Wedgnoke. As to his knowledge of the modern languages, he was well acquainted with the ancient and several modern languages; he had a very comprehensive knowledge of all affairs relating to commerce, whether foreign or domestic; and his successors were not less, being in his time esteemed the highest commoner in England. He

REVIEWED queen Elizabeth's mercantile affairs so constantly, that he was called the royal merchant; and his house was sometimes appointed for the reception of foreign princes upon their first arrival at London. Greville (see)
the following inscription to be engraved upon the tomb: "Fulke Greville, servant to queen Elizabeth, councillor to king James, and friend to Sir Philip Sidney. Trophæum Pœnsunt." He wrote several works both in verse and prose; among which are, 1. Two tragedies, Alaham and Muffapha. 2. Treatise of Human Learning, &c. in verse, folio. 3. The Life of Sir Philip Sidney. 4. An inquisition upon Fame and Honour, in 86 fannas. 6. Cecilius, a collection of 109 songs. 7. His remains, consisting of political and philosophical poems.

GREVIIUS. See Grevius.

GREW (Nehemiah), a learned English writer, in the 17th century, had a considerable practice as a physician in London, and succeeded Mr. Oldenburgh in the office of secretary to the royal society. In this capacity partizan to an order of council, he drew up a catalogue of the natural and artificial rarities belonging to the society, under the title of Methodus Regali Societatis, &c. 1681. He also wrote, besides several pieces in the Philosophical Transactions, 1. The Comparative Anatomy of the Stomach and Guts, folio. 2. The Anatomy of Plants, folio. 3. Tabulæi de fæculis Cathartici naturæ et usi. 4. Cosmologia Sacra, or a Discourse of the Universe as it is the Creature and Kingdom of God, folio.

GREWIA, in botany: A genus of the polyandria order, belonging to the gynandria clafs of plants; and in the natural method ranking under the 37th order, Columinaræ. The calyx is pentaphyllous; there are five petals, each with a necrariferous scale at the base; the berry is quadrilocular.

Species. 1. The occidentalis, with oval crested leaves, has long been preferred in many curious gardens both in England and Holland. It is a native of the Cape of Good Hope, and grows to the height of 10 or 12 feet. The stem and branches greatly resemble those of the small leaved elm, the bark being smooth, and of the same colour with that when young. The leaves are also very like those of the elm, and fall off in autumn. The flowers are produced singly along the young branches from the wings of the leaves, and are of a bright purple colour. 2. The Africana, with oval spear-shaped serrated leaves, is a native of Senegal in Africa, from whence its seeds were brought by Mr. Adanson. In Britain it rises with a fibrous stalk five or six feet high, sending out many lateral branches, with a brown hairy bark, and garnished with spear-shaped serrated leaves; but the plants have not flowered in Britain.

Gulter and usf. The first sort, though a native of a warm climate, will bear the open air in Britain; only requiring to be sheltered in a green-house during the winter-time. It may be propagated by cuttings or layers planted in pots filled with soft loamy earth. The second sort is tender, and must be kept constantly in a warm bark-lace. In summer, they require a large share of the free air to be admitted to them; and should have water three or four times a-week in warm weather; but in the winter they must be sparingly watered. The negroes of Senegal highly value a decoction of the bark of this last species, and use it as a never-failing remedy against venereal complaints.

GREY, or Gray colour. See Gray.

GREY (Lady Jane), a most illustrious and unfortunate lady, descended of the blood-royal of England by both parents, was the eldest daughter of Henry Grey marquis of Dorset and Frances the daughter of Charles Brandon lord Suffolk, by Mary the dowager of Louis XII. king of France, who was the youngest daughter of Henry VII. king of England. She was born in the year 1537, at Broadgate, her father's seat in Leicestershire. She discovered an early propensity to all kinds of good literature; and having a fine genius improved under the tuition of Mr. Elmer, she made a most surprising progress in the languages, arts, and sciences. She understood perfectly both kinds of philosophy, and could express herself very properly at least in the Latin and Greek tongues; and we are informed by Sir Thomas Chaloner (in Strype's Memorial, Vol. III. p. 93.), that she was well versed in Hebrew, Chaldee, Arabic, French, and Italian; "and (he adds) she played well on instrumental music, wrote a curious hand, and was excellent at the needle."

Chaloner also tells us, that she accompanied her musical instruments with a voice exquisitely sweet in itself affiIced with all the graces that art could bestow.

In the year 1553, the dukes of Suffolk and Northumberland, who were now, after the fall of Somerset, arrived at the height of power, began, on the decline of the king's health, to think how to prevent that reverse of fortune which, as things then stood, they foresaw must happen upon Edward's death. To obtain this end, no other remedy was judged sufficient but a change in the succession of the crown, and transferring it into their own families, by rendering Lady Jane queen. Those most excellent and amiable qualities which had rendered her dear to all who had the happiness to know her, joined to her near affinity to the king, subjected her to become the chief tool of an ambition so notoriously not her own. Upon this very account she was married to lord Guilford Dudley, fourth son of the duke of Northumberland, without discovering to her the real design of the match; which was celebrated with great pomp in the latter end of May; and such a change in the succession of the crown, that he contributed bounteously to the expense of it from the royal wardrobe. The young king Edward VI died in July following; and our fair queen, with infinite reluctance, overpowered by the importunities of her ambitious friends, allowed herself to be proclaimed queen of England, on the strength of a deed of settlement extorted from that prince by her father-in-law the duke of Northumberland, which set aside the succession of queen Mary, queen Elizabeth, and Mary queen of Scots. Her regal pageantry continued but a few days. Queen Mary's undoubted right prevailed; and the unfortunate Lady Jane Grey and her husband were committed to the Tower, and on the 13th of November arraigned and found guilty of high treason. On the 12th of February following they were both beheaded on Tower-hill. Her magnanimity in this dreadful catastrophe was astonishing. Immediately before her execution, she addressed herself to the weeping multitude with amazing composure and coherency: she acknowledged the justice of the law, and died in charity with that wretched world which she had so much reason to execrate. Thus
did the pious Mary begin her reign with the murder of an innocent young creature of 18; who for simplicity of manners, purity of heart, and extensive learning, was hardly ever equalled in any age or country. But, alas! Jane was an obstinate heretic.—A few days before her execution, Fleckenham, the queen's chaplain, with a pious intention to rescue her poor soul from eternal misery, paid her frequent visits in the Tower, and used every argument in his power to convert her to the Popish religion; but he found her so much his superior in argument, that he gave up the contest; resigning her body to the block, and her soul to the devil.

Her writings are, 1. Four Latin Epistles; three to Bullenger, and one to her sister lady Catharine. The last were written, the night before her execution, in a blank leaf of a Greek Testament. Printed in a book intitled Epistle Helvetiae Reformatoribus, vol. ad eos scriptae, et alii, Tigouri, 1742, 8vo. 2. Her conference with Fleckenham. (Ballard). 3. A letter to Dr Harding, her father's chaplain. Printed in the Phoenix, vol. ii. p. 28. 4. A Prayer for her own use during her confinement. In Fox's acts and monuments. 5. Four Latin verses; written in prison with a pin. They are as follows:

Non aliena putes, homini que obstingere possunt:
Sors hominum mibi, tunc erit illa tibi.

Jane Dudley.

Deo juvante, nil nocet livor malus;
Et non juvante, nil iustus labor gravis.

Post tenebras fero lucem.

6. Her speech on the scaffold. (Ballard). It began thus: "My Lords, and you good Christian people who come to see me die; I am under a law, and by that law, as a never-err'ing judge, I am condemned to die: not for any thing I have offended the queen's sudden death, have followed the excess of this law, as a protestor of Law at Wittenberg; whence he passed to Dresden, and was at last recalled to Leipfic to succeed M. Menece. He died in 1734. Besides several academical dissertations, he wrote, 1. Principia jurisprudentiae naturalis, a small work much esteemed; 2. Opera juris publici et privati.

GRIEBNER (Michael Henry), a learned civilian of Germany, was born at Leipfic in 1682. After writing some time in the journal of Leipfic, he was made professor of Law at Wittenberg; whence he passed to Dresden, and was at last recalled to Leipfic to succeed M. Menece. He died in 1734. Besides several academical dissertations, he wrote, 1. Principia jurisprudentiae naturalis, a small work much esteemed; 2. Opera juris publici et privati.

GRIEF, or Sorrow. The influence of this passion on the body is very great. Its effects resemble in several instances those of fear, with, however, some variations, owing perhaps to its being in general of longer duration. Grief diminishes the bodily strength in general, and particularly the force of the heart and circulation; as appears by the frequent sighs and deep respirations which attend it, which seem to be necessary exertions, in order to promote the passage of the blood through the lungs. It diminishes periphraxis, obstructs the menstrual discharge, produces paleness of the skin, and edematous complaints, and chittus of the glandular parts. It aggravates the fever, and the malignity of putrid and contagious distempers, and renders people more apt to receive the infection of them. When it comes on suddenly, and in a great degree, it causes a palpitation of the heart, and renders the pulse irregular. Blindness, gangrene, and sudden death, have followed the excess of this fermentation. Its effects of changing the colour of the hair are well known. Opiates, if not given in large doses, are good cordials in this case.

GRIEVELM, in botany: A genus of the pentagyria order, belonging to the decandria class of plants. The calyx is quinqued; there are five petals; the effects of changing the colour of the hair are well known. Opiates, if not given in large doses, are good cordials in this case.

GRIERSON (Constantia), born of poor parents in the county of Kilkenny in Ireland, was one of the most learned women on record, though she died at the age of 27, in 1733. She was an excellent Greek and Latin scholar; and underfoot history, divinity, philosophy, and mathematics. She proved her skill in Latin by her dedication of the Dublin edition of Tacitus to lord Carteret, and by that of Terence to his son; to whom she also addressed a Greek epigram. She wrote many elegant English poems, several of which were inserted by Mrs Barber among her own. When lord Carteret was lord lieutenant of Ireland, he obtained a patent for Mr Grierfon to be the king's printer; and to reward the uncommon merit of his wife, caused her life to be included in it.

GRIFFON (Griphus, Grifus). In the natural history of the ancients, the name of an imaginary bird of the eagle kind. They represented it with four legs, wings, and a beak; the body representing an eagle, and the lower a lion; they supposed it to watch over gold mines, hidden treasures, &c.
Grimaldi, Francesco, an eminent painter, generally known by the appellation of Bolognese, was born at Bologna in 1606, where he became a disciple of Annibal Caracci, and proved an honour to that illustrious master. From the school of Annibal he went to complete his studies at Rome, and improved himself daily, by copying the works of those artists in which he observed the greatest excellence, until his superior talents recommended him to the favour of Innocent X. Grimaldi, secondly, if not the first, corporation in England. It had anciently three convents and a castle. It is governed by a mayor, high steward, recorder, twelve aldermen, twelve common councilmen, two bailiffs, two coroners, a town clerk, and three sergeant-at-mace. The mayor holds a court here on Tuesday, and the bailiffs on Friday. Here are several streets of good houses, and a church that looks like a cathedral. It was a place of great trade before its harbour was choked up; yet the road before it is a good station for ships that wait for a wind to get out to sea. Its chief trade is in coals and salt brought by the Humbers.

GRINDING, or TRITURATION, the act of breaking or comminuting a solid body, and reducing it into powder. See PULVERIZATION and LEVIGATION.

The painters' colours are ground on a marble or porphyry, either with oil or gum-water.

Grinding is also used for rubbing or wearing off the irregular parts of the surface of a body, and reducing it to the defined figure, whether that be flat, concave, or the like.

The grinding and polishing of glass is a considerable art; for which see Glass-Grinding. For the grinding of optical glasses, see Optics, the Mechanical Part.

The grinding and polishing of glass is a considerable art; for which see Glass-Grinding. For the grinding of optical glasses, see Optics, the Mechanical Part.

GRI

Built and endowed with the malignant influence of that evil spirit, when they see their features and muscles, make horrid grimaces, and at last imitate all the appearance of epileptics.

GRISONs, a people situated among the Alps, and allies of the Swiss. Their country is bounded on the north by the counties of Sursans and Blidenz, the canton of Glaris, and the principality of Lichtenstein; on the south by the canton's Italian bailiwicks, the county of Chavonne, and the Valteline; on the east by the territories of Venice and Milan; and on the west by some of the Italian bailiwicks, and the canton of Uri. It is divided into three leagues, viz. the Grisonor grey league, the league of the house of God, and that of the ten jurisdictions; which unite and form one republic. The two first lie towards the south, and the third towards the north. The length of the whole is above 70 miles, and the breadth about 60. The inhabitants are said to have had the name of Grifons from the grey coats they wore in former times. This country, lying among the Alps, is very mountainous; but the mountains yield good pasture for cattle, sheep, and goats, with some rye and barley: in the valleys there is plenty of grain, pulse, fruits, and wine. This country also abounds with hogs and wild-fowl; but there is a scarcity of fish and fowl, and their horses are mostly purchased of foreigners. The principal rivers are the Rhine, the Inn, and the Adda. Here are also several lakes, most of which lie on the tops of the hills. The language of the Grisons is either a corrupt Italian or the German. Each of the leagues is subdivided into several leffer communities, which are too many democracies; every male above 16 having a share in the government of the community, and a vote in the election of magistrates. Deputies from the several communities constitute the general diet of the Grison leagues, which meets annually, and alternately at the capital of each league; but they can conclude nothing without the consent of their constituents. This country was ancienly a part of Rhetia. After the extinction of the Roman empire in the west, it was some time subject to its own dukes, or those of Swabia. Then the bishop of Coire, and other petty princes, dependent on the emperors of Germany, became masters of great part of it: at last, by the extinction of some, purchase, voluntary grants, and force, it got rid of all its lords, and ered itself into three distinct republics, each of which, as we observed already, is subdivided into a certain number of communities, which are a sort of republics, exercising every branch of sovereignty, except that of making peace or war, sending embassies, concluding alliances, and enacting laws relating to the whole country, which belong to the provincial diets of the several leagues. The communities may be compared to the cities of Holland, and the diets of the several leagues to the provincial states. The particular diets are composed of a deputy from each community; and both in them and the communities every thing is determined by a majority of votes. In the communities, every male above 16 has a vote. Besides the annual provincial diets for choosing the chiefs and other officers, and deliberating on the affairs of the several leagues, there are general diets for what concerns all the three leagues or whole body. In both these, the
representatives can do nothing of themselves, but are tied down to the instructions of their principals. There is a general seal for all the three leagues; and each particular league has a separate seal. Besides the stated times of meeting, extraordinary diets are sometimes summoned, when either the domestic affairs of the state or any foreign minister require it. In the general diets, the Grey League has 28 votes; that of the House of God, 23; and that of the Ten Jurisdictions, 15. These leagues, at different times, have entered into close alliances with the neighbouring cantons and their associates. The bailiwicks belonging in common to the three leagues are those of the Valte-line, Chieavene, Bormio, Meyenfeld, Malans, and Jennins; the officers of which are nominated successively by the several communities every two years. The yearly revenue arising to the Grisons from their bailiwicks is said to amount to about 13,500 florins. The public revenues altogether are but small, though there are many private persons in the country that are rich. However, in case of any extraordinary emergency, they tax themselves in proportion to the necessity of the service and the people’s abilities. They have no regular troops, but a well-disciplined militia; and upon occasion, it is said, can bring a body of 30,000 fighting men into the field: but their chief security arises from the narrow paffes and high mountains by which they are surrounded.

Of the jurifprudence, religion, &c. of the Grisons, the following account is given by Mr Coxe in his travels in Switzerland. Throughout the three leagues the Roman law prevails, modified by the municipal customs. The courts of justice in each community are composed of the chief magistrate, who presides, and a certain number of jurymen, chosen by the people: they have no regular salaries, but receive for their attendance a small sum, arising in some communities from the expenses of the process, which are defrayed by the criminals; in others from a share of the fines. They enjoy the power of pardoning or diminishing the penalty, and of receiving a composition in money. This mode of proceeding supposes what is as absurd in theory as it is contrary to experience, that judges will incline to mercy when it is their interest to convict; or will impartially inflict punishment, even when injurious to their own private advantage. The prisoners are examined in private; frequently tortured for the purpose of forcing confession; when the judges either divide the fines, or remit the punishment for a composition. In some districts a criminal trial is a kind of festival to the judges, for whom a good repast is provided at the expense of the prisoner if convicted; and thus the following allusion, in Garth’s Difpenfary, applied with more wit than truth to our courts of justice, is literally fulfilled:

‘And wretches hang, that jurymen may dine.’

Capital punishments, however, are extremely rare; a circumstance arising not from a want of severity in the penal statutes, or from a propensity to mercy in the judges; but because the latter draw more advantages from finning than executing an offender. In a word, to use the expression of Burnet, which is as true at present as it was in his time, ‘Many crimes go unpunished, if the persons who commit them have either great credit or much money.’ It is remarkable, that torture is more frequently applied, and for smaller delinquencies, in these independent republics, than in the subject provinces. The infliction of it depends entirely upon the arbitrary will of the judges; a majority of whom may order it for an offence which is not capital, nor even punishable by corporal penalties. Thus it is not uncommon, in those communities where fines are divided among the judges, to torture women of loose conduct, for the purpose of compelling them to confess with whom they have been connected; for as such offences are punishable by fines, the more persons are convicted, the larger share of money is distributed among the judges for the trouble of their attendance. Even in the districts where the fines are paid to the community, torture is often no less wantonly inflicted, because, when the prisoner is not found guilty, the expenses of the process fall upon the public, and the judges receive little remuneration. Even in the civil courts most causes are decided by bribing the judges; and appeals in those communities, wherein they are admitted, scarcely serve any other end than to enlarge the sphere of corruption; Coire, and a few other places, are excepted from this general reflection.

The religion of the Grisons is divided into catholic and reformed. The doctrines of the reformation were first preached about the year 1524, and received at Fleisch a small village in the Ten Jurisdictions upon the confines of Sargans; from thence they were extended to Mayenfeld and Malans, and soon afterwards through the whole valley of Pretigau. The new opinions spread with such celerity, that before the end of the 16th century they were embraced by the whole league of the Ten Jurisdictions (excepting part of the community of Alvenew), the greatest part of the House of God, and a few communities in the Grey League. The difference of religion nearly excited a civil war between the two sects, as well at the first introduction of the reformation as at the beginning of the troubles in the Valteline. In the latter instance, the two parties rote in arms; but the Catholics being overpower-d by the Protestants, matters were amicably adjusted. Since that period all religious concerns have been regulated with perfect cordiality. According to the general consent of the three leagues, each community being absolute within its little territory, has the power of appointing its own particular worship, and the inhabitants are free to follow either the Catholic or Reformed persuasion. In the administration of civil affairs religion has no interference: the deputies of the general diet may be members of either communion, as chosen by the communities which they represent. By this moderate and tolerating principle, all religious diffentions have been suppressed as much as possible; and the most perfect amity subsists between the two sects.

In spiritual concerns, the Catholics for the most part are under the jurisdiction of the bishop of Coire. For the affairs of the Reformed churches, each league is divided into a certain number of districts, the ministers whereof assemble twice every year: these assemblies are called colloquia. Each colloquium has its president, and each league a superintendent called a dean. The supreme authority in spiritual concerns is vested in the synod, which is composed of the three deans, and the clergy of each league; the synod assemblies every year alternately in each of the three leagues. Candidates for
for holy orders are examined before the synod. The necessary qualifications for admission into the church ought to be the knowledge of Hebrew, Greek, and Latin; but this rule is not strictly adhered to; many being ordained without the least acquaintance with either of those languages. Formerly Latin was solely used, as well in the debates of the synod as for the purpose of examining the candidates; but at present that tongue grows more and more into disuse, and German is employed in its stead.

The number of reformed parishes in the whole three leagues amounts to 135, in the following proportion:

- In the Grey League 46, in that of God's House 53, and in the League of Ten Jurisdictions 36. The ministers of these churches enjoy but very small salaries. The richest benefices do not perhaps yield more than L. 20, or at most L. 25 per annum, and the poorest sometimes scarcely L. 6. This scanty income is attended with many inconveniences. It obliges the clergy who have families to follow some branch of traffic, to the neglect of their ecclesiastical studies, and to the degredation of their professional character. Another inconvenience is superadded to the narrowness of their income. In most communities the ministers, though confirmed by the synod, are chosen by the people of the parish, and are solely dependent on their bounty. For these reasons, the candidates for holy orders are generally extremely ignorant. They cannot support that expense which is requisite to pursue their studies; they are not animated with the expectation of a decent competence; and, from the dependence of their ecclesiastical studies, and the probability of their professional character.

For these reasons, the candidates for holy orders are generally extremely ignorant. They cannot support that expense which is requisite to pursue their studies; they are not animated with the expectation of a decent competence; and, from the dependence of their ecclesiastical studies, and the probability of their professional character.

GRIST, in country affairs, denotes corn ground, or ready for grinding.

GRIT (argillaceous), a genus of argillaceous earth. Its texture is more or less porous, equable, and rough to the touch. It does not give fire with steel, nor effervesce with acids. When fresh broken and breathed upon, it exhales an earthy smell. Mr Kirwan mentions two kinds; one from Hollington near Utzeter, of a yellowish or whitish grey, and about the specific gravity of 2.85. Another, from Kneeply in Staffordshire, is of the specific gravity of 2.68; and is unsuitable for being used for firestones. According to Fabroni the grit-flone is of greater or less hardness, mostly of a grey, and sometimes of a yellowish colour, composed of a silicious and micaceous sand, but rarely of a sparrie kind; with greater or smaller particles closely compacted by an argillaceous cement. It gives some sparkles with steel, is indissoluble for the most part in acids, and vitrifiable in a strong fire. It is used for millstones and whetstones; and sometimes for filtering flames and for building.

GROATS, in country affairs, oats after the hulls are off, or great oat-meal.

GROCERS, anciently were such persons as engaged in all merchandise that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

GROENDAST, or SPITZBERGEN. See GREENLAND.

GROGRAM, a kind of stuff made of silk and cotton.

GROIN, that part of the belly next the thigh.—In the Philosophical Transactions we have an account of a remarkable case, where a peg of wood was extracted from the groin of a young woman of 21, after it had remained 16 years in the stomach and intestines, having been accidentally swallowed when she was about five years of age. Vide Vol. LXVII. p. 459.

GROIN, among builders, is the angular curve made by the intersection of two semi-cylinders or arches; and is either regular or irregular. — A regular groin is that tongue grows more and more into disuse, and German is employed in its stead.

GROSS, a foreign money, in divers countries, answering to the English groat.

Gross is used among us for the quantity of twelve dozen.

Gross weight, is the weight of merchandizes and goods, with their dust and drofs, as also of the bag, cafe, celf, &c. wherein they are contained; out of which gross weight, allowance is to be made of tare and tret.

GROSS, or GROSSUS, in our ancient law writers, denotes a thing absolute, and not depending on another. Thus, vidain in gross, villainus in grofo, was a servant, who did not belong to the land, but immediately to the person of the lord; or a servile person not appendant or annexed to the land or manor, and to go along with the tenures as appurtenant to it; but like other personal goods and chattels of his lord, at his lord’s pleasure and disposal.

Gross, advowson in. See ADYSONSON.

GROSE-BEAN, in zoology, a name by which we commonly call the coccotreufia, called also at other times the how finch. This is the Loxia coccothraustes in the Linnaean fylen.

GROSE-BEAK, in ornithology; a species of Loxia.

GROSSULARIA. See RIBES.

GROTESQUE, or GROTESK, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprife and ridicule. The name arises hence, that figures of this kind were so much used to adorn the gratts wherein the tombs of eminent persons or families were inclosed. Such was that of Ovid, whose grato was discovered near Rome about one hundred years ago.

GROYTUS (Hugo), or more properly Hugo de Groote, one of the greatest men in Europe, was born at Delft in 1582. He made so rapid a progress in his studies, that at the age of 15 he had attained a great knowledge in philosophy, divinity, and civil law; and a yet greater proficiency in polite literature, as appeared by the commentary he had made at that age on Martianus Capella. In 1598, he accompanied the Dutch ambassador into France, and was honoured with several marks of efteeem by Henry IV. He took his degree of doctor of laws in that kingdom; and at his return to his native country, devoted himself to the bar, and pleaded before he was 17 years of age. He was not 24 when he was appointed attorney-general. In 1613 he settled in Rotterdam, and was nominated syndic of that city; but did not accept of the office, till a promise was made him that he should not be removed from it. This prudent precaution he took from his foreseeing, that the quarrels of the divines on the doctrine of grace, which had already given rise to many factions in the state, would occasion revolutions in the chief cities. The same year he was sent into England, on account of the divisions that reigned between the traders of the two nations, on the right of fishing in the northern seas; but he could obtain no satisfaction. He was afterwards sent to England, as it is thought, to peruddle the king and the principal divines to favour the Arminians; and he had several conferences with king James on that subject. On his return to Holland, his attachment to Barneveld involved...
The ancient authors referred to dens and grottos, to apply themselves the more attentively to meditation.

Okey-hole, Elder-hole, Peake's-hole, and Pool's-hole are famous among the natural caverns or grottos of Britain.

The entrance to Okey-hole, on the south side of Mendip-hills, is in the fall of the hills, which is beset all about with rocks, and has near it a precipitate descent of near twelve fathoms deep, at the bottom of which there continually issues from the rocks a considerable current of water. The naked rocks above the entrance show themselves about thirty fathoms high, and the whole ascent of the hill above is about a mile, and is very steep. As you pass into this vault, you go at first upon a level, but advancing farther, the way is found to be rocky and uneven, sometimes ascending, and sometimes descending. The roof of this cavern, in the highest part, is about eight fathoms from the ground, and in many particular places it is so low, that a man must stoop to get along. The breadth is not less various than the height, for in some places it is five or six fathoms wide, and in others not more than one or two.

It extends itself in length about two hundred yards. People talk much of certain stones in it, resembling men and women, and other things; but there is little matter of curiosity in these, being only harmless lumps of a common spar. At the farthest part of the cavern there is a good stream of water, large enough to drive a mill, which puts all along one side of the cavern, and at length slides down about six or eight fathoms among the rocks, and then prefiling through the crevices of them, discharges itself into the valley. The river within the cavern is well floored with eels, and has some torrents in it; and these cannot have come from without, there being no great fall near the entrance. In dry summers, a great number of frogs are seen all along this cavern, even to the farthest part of it; and on the roof of it, at certain places, hang vast numbers of bats, as they do in almost all caverns, the entrance of which is either level, or but slightly ascending or descending; and even in the more perpendicular ones they are sometimes found, provided they are not too narrow, and are sufficiently high. The cattle that feed in the pastures through which this river runs, have been known to die suddenly sometimes after a flood; this is probably owing to the waters having been impregnated, either naturally or accidentally, with lead ore.

Elden-hole is a huge profound perpendicular chasm, three miles from Buxton, ranked among the natural wonders of the Peak. Its depth is unknown, and is pretended to be unflammable. Cotton tells us it founded 824 yards; yet the plunger fell down. But he might easily be deceived, unless his plummet was really very heavy; the weight of a rope of that length might well make the landing of the plummet scarce perceivable.

Peake's-hole, and Pool's hole, called also the Devil A—/, are two remarkable horizontal springs under mountains; the one near Castleton, the other just by Buxton. They seem to have owed their origin to the
springs which have their current through them; when
the water had forced its way through the horizontal
 fissures of the strata, and had carried the loose earth
away with it, the loose stones must fall down of course;
and where the strata had few or no fissures, they re-
maincd entire; and so formed these very irregular
arches, which are now so much wondered at. The
water which passes through Pool's-hole is impregnated
with particles of lime-flour, and has incrusted the
whole cavern in such a manner that it appears as one
solid rock.

In grottos are frequently found crystals of the rock,
flaëmites, and other natural conglomations, and those
often of an amazing beauty. M. Homberg conjectures,
from several circumstances, that the marble pilar-
ars in the grotto of Antiparos vegetate or grow.
That author looks on this grotto as a garden, whereof
the pieces of marble are the plants; and endeavours to
show, that they could only be produced by some vege-
tative principle. See Antiparos.

At Foligno in Italy is another grotto consisting of
pillars and orders of architecture of marble, with their
ornaments, &c. fearfully inferior to those of art; but
they all grow downwards: so that if this too be a gar-
den, the plants are turned upside down.

Grotto del Cani, a little cavern near Pozznoli, four
leagues from Naples, the streams whereof are of a
mephitical or noxious quality; whence also it is called
bosca venumula, the poisonous mouth. See Mephit.

"Two miles from Naples (says Dr Mead), just by
the Lago d'Agnano, is a celebrated mofeta, commonly
called la Grotta del Cani, and equally destructive to all
within the reach of its vapours. It is a small grotto
about eight feet high, twelve long, and eight broad; from
the ground arise a thin, subtle, warm fume, visible
within the reach of its air, which from time immemorial hath
issuèd out of the earth in that place in very great quantity, the causes of which
cannot yet be investigated from any of the modern
discoveries concerning that species of air. It proves
pernicious when breathed in too great quantity, by
rarefying the blood too much; and hence the best
method of recovering persons apparently killed by fix-
ed air, is to apply a great degree of cold all over their
bodies, in order to condenfe the blood as much as pos-
ible. This is the reason why the dogs recover when
thrown into the lake Aghano, as above mentioned.
See the articles Blood and Damps.

Grott del Serpi, is a subterranean cavern near the
village of Saffa, eight miles from the city of Brac-
cano in Italy, described by Kircher thus: "The grotto
del serpi is big enough to hold two persons. It is
perforated with several fullary apertures, somewhat in
manner of a sieve; out of which, at the beginning of
the spring season, issues a numerous brood of young
snakes of divers colours, but all free from any parti-
cular poisonous quality. In this cave they expel
their fumes; here lepers, paralytics, arthritics, and
ephelantine patients become quite naked; where, the warmth of the subterranean
fumes resolving them into a sweat, and the serpents
clinging warily all around, licking and fucking
them, they become so thoroughly freed of all their
vicious humours, that, upon repeating the operation
for some time, they become perfectly restored."

This cave Kircher visited himself; and found it
warm, and every way agreeable to the description
given of it. He faw the holes, and heard a murmur-
ing hissing noise in them. Though he missed
seeing the serpents, it not being the season of their
creeping out; yet he saw a great number of their
carcasses, or thoughts, and an ell growing hard by
laden with them.

The discovery of this cave was by the cure of a le-
per going from Rome to fome baths near this place,
losing his way, and being benighted, he happened
upon this cave. Finding it very warm, he pulled off
his clothes; and being weary and sleepy, had the good
fortune not to feel the serpents about him till they had
wrought his cure.

Milky Grotto, Crypta Larentis, a mile distant from
1

Grotto.
the ancient village of Bethlehem, is said to have been thus denominated on occasion of the blessed Virgin, who let fall some drops of milk in giving suck to Jesus in this grotto. And hence it has been commonly sup-
poded, that the earth of this cavern has the virtue of
replenishing milk to women that are grown dry, and even
curing fevers. Accordingly, they are always dig-
ing in it, and the earth is sold at a good rate to
as have faith enough to give credit to the fable. An

to it four parts of bees wax: when melted together,

Cements for artificial grottos may be made thus:

Take two parts of white rosin, melt it clear, and add
to it four parts of bees wax; when melted together, add
or three parts of the powder of the stone you
design to cement, or so much as will give the cement
the colour of the stone; to this add one part of
flower of sulphur: incorporate all together over a
gentle fire, and afterwards knead them with your
hands in warm water. With this cement the stones,
shells, &c. after being well dried before the fire, may
be cemented.

Artificial red coral branches, for the embellishment
of grottos, may be made in the following manner:

Take clear rosin, dissolve it in a bras-pan; to every
ounce of which add two drams of the finest vermilion:
when you have flirred them well together, and have
chopped your twigs and branches, peeled and dried,
take a pencil and paint the branches all over whilst
the composition is warm; afterwards shape them in imitation of natural coral. This done, hold the
branches over a gentle coal-fire, till all is smooth and even
as if polished. In the same manner white coral may
be prepared with white lead, and black coral with
lamp-black.

A grotto may be built with little expence, of glas,
cinders, pebbles, pieces of large flint, shells, mofs,
stones, counterfeit coral, pieces of chalk, &c. all
bound or cemented together with the above described
cement.

GROVE, in gardening, a small wood impervious to
the rays of the sun.

GROVES have been in all ages held in great veneration.
The profeuchæ, and high-places of the Jews, whither
they resort for the purposes of devotion, were probably situated in groves: See Joshua xxiv. 26. The profeuchæ in Alexandria, mentioned by Philo, had groves about them, because he complains that the Alexandrians, in a tumult against the Jews, cut down the trees of their profeuchæ.

The ancient Romans had a sort of groves near sev-
eral of their temples, which were consecrated to some
god, and called luciæ; by Antiphrasius, a non lucendo, as
being shady and dark. The veneration which the ancient
druids had for groves is well known.

Modern groves are not only great ornaments to
gardens; but are also the greatest relief against the
violent heat of the sun, affording shade to walk under
in the hottest parts of the day, when the other parts
of the garden are useless; so that every garden is de-
fective which has not shade.

Groves are of two sorts, viz. either open or close.
Open groves are such as have large shady trees, which
stand at such distances, as that their branches
approach so near to each other as to prevent the rays
of the sun from penetrating through them.

Close groves have frequently large trees standing
in them; but the ground under these are filled with
shrubs or underwood: so that the walks which are in
them are private, and screened from winds; by which
means they are rendered agreeable for walking, at
those times when the air is either too hot or too cool
in the more exposed parts of the garden. These are
often contrived so as to bound the open groves, and
frequently to hide the walls or other inclosures of the
garden: and when they are properly laid out,
with dry walks winding through them, and on the
sides of these sweet-smelling shrubs and flowers ir-
regularly planted, they have a charming effect.

Grove (Henry), a learned and ingenious Prela-
danian divine, was born at Taunton in Somersetshire,
in 1683. Having obtained a sufficient flock of clas-
fical literature, he went through a course of academ-
ical learning, under the Rev. Mr Warren of Taunton, who
had a flourishing academy. He then removed to Lon-
don, and studied some time under the reverend Mr
Rowe, to whom he was nearly related. Here he
contracted a friendship with several persons of merit,
and particularly with Dr Watts, which continued till
his death, though they were of different opinions in
several points warmly controverted among divines.

After two years spent under Mr Rowe, he returned
into the country, and began to preach with great re-
putation; when an exact judgment, a lively imagina-
tion, and a rational and amiable representation of
Christianity, delivered in a sweet and well governed
voice, rendered him generally admired; and the spi-
rit of devotion which prevailed in his sermons procure-
him the esteem and friendship of Mrs Singer, after-
wards Mrs Rowe, which she expressed in a fine ode
on death, addressed to Mr Grove. Soon after his begin-
ning to preach, he married; and on the death of Mr
Warren, was chosen to succeed him in the academy
at Taunton. This obliging him to

The Regulation of Dissenters, drawn up for the use of his pupils. About the same
time, he entered into a private dispute by letter with
Dr Samuel Clarke: but they not being able to con-
vince each other, the debate was dropped with ex-
pressions of great mutual esteem. He next wrote several
papers printed in the Spectator, viz. Numbers 388.
603. 626. 635. The last was republished, by the di-
rection of Dr Gibson bishop of London, in the Evi-
dences of the Christian Religion, by Joseph Addison,
Esq. In 1725, Mr James, his partner in the academy,
dying, he succeeded him in his pastoral charge at
Fullwood, near Taunton, and engaged his nephew
to undertake the other parts of Mr James's work as
 tutor; and in this situation Mr Grove continued till
his death, which happened in 1738. His great con-

Grove.
cern with his pupils, was to inspire and cherish in them a prevailing love of truth, virtue, liberty, and genuine religion, without violent attachments or prejudices in favour of any party of Christians. He repre-
sented truth and virtue in a most engaging light; and though his income, both as a tutor and a minifter, was insufficient to support his family, without breaking into his paternal estate, he knew not how to refuse the call of charity. Besides the above pieces, he wrote, 1. An Essay towards a Demonstration of the Soul's Immortality. 2. An Essay on the Terms of Christian Communion. 3. The Evidence of our Saviour's Resurrection considered. 4. Some Thoughts concerning the Proof of a Future State from Reason. 5. A Discourse concerning the Nature and Design of the Lord's Supper. 6. Wonders the First Spring of Action in the Deity. 7. A Discourse on Saving Faith. 8. Miscellaneous in Prose and Verse. 9. Many of his works, by subscription, in four volumes octavo, with the names of near 700 subscribers, among whom were some of the best judges of merit in the established church.

GROUND, in painting, the surface upon which the figures and other objects are represented. The ground is properly understood of such parts of a piece, as have nothing painted on them, but retain the original colour upon which the other colours are applied to make the representations. A building is said to serve as a ground to a figure when the figure is painted on the building.

The ground behind a picture in miniature, is commonly blue or crimson, imitating a curtain of satin or velvet.

GROUND, in etching, denotes a gumous composition fineaer over the surface of the metal to be etched, to prevent the aquafortis from eating, except in such places where this ground is cut through with the point of a needle. See the article Etching.

GROUND-Fishing, fishing under water without a float, only with a plumb of lead, or a bullet, placed above nine inches from the hook; which is better, because it will roll on the ground. This method of fishing is most proper in cold weather, when the fish swim very low.

The morning and evening are the chief seasons for the ground-line in fishing for trout; but if the day prove cloudy, or the water muddy, you may fish at ground all day.

GROUND-Tackle, a ship's anchors, cables, &c. and in general whatever is necessary to make her ride safe at anchor.

GROUND-Joy, in botany. See Glechoma.

GROUND-Fire, in botany. See Teucrum.

GROUNDSELL. See Senecio.

GROUP, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other. See Painting.—The word is formed of the Italian gruppo, a knot.

The Groups, a cluster of islands lately discovered in the South Sea. They lie in about S. Lat. 18° 12' and W. Long. 142° 42'. They are long narrow slips of land, ranging in all directions, some of them ten miles or upwards in length, but not more than a quarter of a mile broad. They abound in trees, particularly those of the cocoa-nut. They are inhabited by well-made people, of a brown complexion. Most of them carried in their hands a slender pole about 14 feet in length, pointed like a spear; they had likewise something shaped like a paddle, about four feet long. Their canoes were of different sizes, carrying from three to six or seven people, and some of them hoisted a sail.

GROUSE, or Grouse. See Tetrao.

GROUSE, or GREATHED (Robert), a learned and famous bishop of Lincoln, was born at Stow in Lincolnshire, or (according to others) at Stradbroke in Suffolk, in the latter part of the twelfth century. His parents were of poor rank, that when a boy he was reduced to do the meanest offices, and even to beg his bread; till the mayor of Lincoln, struck with his appearance and the quickness of his answers to certain questions, took him into his family, and put him to school. Here his ardor of learning, and admirable capacity for acquiring it, soon appeared, and procured him many patrons, by whose assistance he was enabled to prosecute his studies, first at Cambridge, afterwards at Oxford, and at last at Paris. In these three famous seats of learning, he spent many years in the most indefatigable pursuit of knowledge, and became one of the best and most universal scholars of the age. He was a great master not only of the French and Latin, but also of the Greek and Hebrew languages, which was a very rare accomplishment in those times. We are assured by Roger Bacon, who was intimately acquainted with him, that he spent much of his time for almost forty years in the study of geometry, astronomy, optics, and other branches of mathematical learning, in all which he very much excelled. Theology was his favourite study, in which he read lectures at Oxford with great applause. In the mean time, he obtained several preferments in the church, and was elected and consecrated bishop of Lincoln, A. D. 1235. In this station he became very famous, by the purity of his manners, the popularity of his preaching, the rigour of his discipline, and the boldness with which he reproved the vices and opposed the arbitrary mandates of the court of Rome; of this last it may be proper to give one example. Pope Innocent IV. had granted to one of his own nephews named Frederick, who was but a child, a provision to the first canon's place in the church of Lincoln that should become vacant, and sent a bull to the archbishop of Canterbury, and Innocent, then papal legate in England, commanding them to see the provision made effectual; which they transmitted to the bishop of Lincoln. But that brave and virtuous prelate, boldly, refused to obey this unreasonable mandate, and sent an answer to the papal bull containing the following sentence:—"If we except the sins of Lucifer and Antichrist, there neither is nor can be a greater crime, nor any thing more contrary to the doctrine of the gospel, or more odious and abominable in the sight of Jesus Christ, than to ruin and destroy the souls of men, by depriving them of the spiritual aid and ministry of their pastors. This crime is committed by those who command the benefices intended for the support of able pastors, to be bestowed on those who are incapable of..."
Growth.

Growth, performing the duties of the pastoral office. It is impossible therefore that the holy apostolic fee, which received its authority from the Lord Jesus Christ, for edification, and not for destruction, can be guilty of such a crime, or any thing approaching to such a crime, so hateful to God and so hurtful to men. For this would be a most manifest corruption and abuse of its authority, which would forfeit all its glory, and plunge it into the pains of hell.” Upon hearing this letter, his holiness became frantic with rage, poured forth a torrent of abuse against the good bishop, and threatened to make him an object of terror and abominiation to the whole world. “How dare (said he) this old, deaf, doating fool, disbelieve my testimony! It is given by Bale. He was contrite, devout, and solemn in the church; as a fodderer of the pope, and a support of the church of Rome; for he fell sick at his castle of Bougden that same year; and when he became sensible that his death was drawing near, he called his clergy into his apartment, and made a long discourse to them, to prove that the reigning Pope Innocent IV. was Antichrist. With this exertion his strength and spirits were so much exhausted, that he expired soon after, October 9, 1253. A contemporary historian, who was perfectly well acquainted with him, hath drawn a fine and bold reprimander of the pope and the king, an admonition of the prelates; a corrigent of the monks; an instructor of the clergy; a supporter of the stakes; a censor of the incontinent; a scourge and terror to the court of Rome; a diligent searcher of the scriptures; and a frequent preacher to the people. At his table he was hospitable, polite, and cheerful. In the church he was contrite, devout, and solemn; and in performing all the duties of his office he was venerable, active, and indefatigable. The illustrious Roger Bacon, who was most capable, and had the best opportunities of forming a true judgment of the extent of his learning, by perusing his works, and by frequently conversing with him, hath given this honourable testimony in his favour. “Robert Grouthead bishop of Lincoln, and his friend Friar Adam de Marisco, are the two most learned men in the world, and excel all the rest of mankind both in divine and human knowledge.” This most excellent and learned prelate was a very voluminous writer, and composed a prodigious number of treatises on a great variety of subjects in philosophy and divinity, a catalogue of which is given by Bale.

GROWTH, the gradual increase of bulk and stature that takes place in animals or vegetables, to a certain period. — The increase of bulk in such bodies as have no life, owing to fermentations excited in their substance, or to other causes, is called Expansion, Swelling, &c.

The growth of animals, nay even of the human spe-

cies, is subject to great variations. A remarkable instance of the last was observed in France in the year 1729. At this time the Academy of Sciences examined a boy who was then only seven years old, and who measured four feet eight inches and four lines high without his shoes. His mother observed the signs of puberty on him at two years old, which continued to increase very quick, and soon arrived at the usual standard. At four years old he was able to lift and toss the common bundles of hay into flures in the horses racks; and at six years old could lift as much as a sturdy fellow of twenty. But though he thus increased in bodily strength, his understanding was no greater than is usual with children of his age, and their play things were also his favourite amusements.

Another boy, a native of the hamlet of Bouzanquet, in the diocese of Alais, though of a strong constitution, appeared to be knit and stiff in his joints till he was about four years and a half old. During this time neither father was remarkable of him than an extraordinary appetite, which was satisfied no otherwise than by giving him plenty of the common aliment of the inhabitants of the country, consisting of rye-bread, cheese, bacon, and water; but his limbs soon becoming supple and pliable, and his body beginning to expand itself, he grew up in a extraordinary manner, that at the age of five years he measured four feet three inches; some months after, he was four feet eleven inches; and at six, five feet, and bulky in proportion. His growth was so rapid, that one might fancy he saw him grow: every month, his cloaths required to be made longer and wider; and what was still very extraordinary in his growth, it was not preceded by any sickness, nor accompanied with any pain in the groin or elsewhere. At the age of five years his voice changed, his beard began to appear, and at six he had as much as a man of thirty; in short, all the unquestionable marks of puberty were visible in him. It was not doubted in the country but this child was, at five years old, or five and a half, in a condition of beinggetting other children; which induced the rector of the parish to recommend to his mother, that she would keep him from too familiar a conversation with children of the other sex. Though his wit was riper than is commonly observable at the age of five or six years, yet its progress was not in proportion to that of his body. His mind and manner still retained something childish, though by his bulk and stature he resembled a complete man, which at first sight produced a very singular contrast. His voice was strong and manly, and his great strength rendered him already fit for the labours of the country. At the age of five years, he could carry to a good distance three measures of rye, weighing 84 pounds; when turned of six; he could lift up easily on his shoulders and carry loads of 750 pounds weight in good way off; and these exercises were exhibited by him as often as the curious engaged him thereto by some liberality. Such beginnings made people think that he would soon shoot up into a giant. A mountebank was already soliciting his parents for him, and flattering them with hopes of putting him in a way of making a great fortune. E't all these hopes suddenly vanished. His legs became crooked, his body shrunken, his voice grew feebly, and
fibly weaker, and he at last sunk into a total imbecility.

In the Paris Memoirs also there is an account of a girl who had her menstres at three months of age. When four years old, she was four feet six inches in height, and had her limbs well proportioned to that height, her breasts large and plump, and the parts of generation like those of a girl of eighteen; so that there is no doubt but that she was marriageable at that time, and capable of being a mother of children. These things are more singular and marvellous in the northern than in the southern climates, where the females come sooner to maturity. In some places of the East Indies, the girls have children at nine years of age.

Many other instances of extraordinary growth might be brought, but the particulars are not remarkably different from those already related. — It is at first sight astonishing how children of such early and prodigious growth do not become giants: but when we consider, that the signs of puberty appear so much sooner than they ought, it seems evident that the whole is only a more than usually rapid expansion of the parts, as in hot climates; and accordingly it is observed, that such children, instead of becoming giants, always decay and die apparently of old age, long before the natural term of human life.

GRUB, in zoology, the English name of the hexapod worms, produced from the eggs of beetles, and which at length are transformed into winged insects of the same species with their parents.

GRUBBING, in agriculture, the digging or pulling up of the stubs and roots of trees.

When the roots are large, this is a very troublesome and laborious task; but Mr Mortimer hath shewn how it may be accomplished in such a manner as to save great expense by a very simple and easy method. He proposes a strong iron hook to be made about two feet four inches long, with a large iron ring fastened to the upper part of it. This hook must be put into a hole in the side of the root, to which it must be fastened; and a lever being put into the ring, three men, by means of this lever, may wring out the root, and twist the sap-roots afunder. Stubbs of trees may also be taken up with the same hook, in which work it will save a great deal of labour, though not so much as in the other; because the stubs must be first elft with wedges, before the hook can enter the fides of them, to wrench them out by pieces.

GRUBENHAGEN, a town and castle of the duchy of Brunswick, in Lower Saxony, remarkable for its mines of silver, copper, iron, and lead. E. Long. 9. 30. N. Lat. 51° 16'.

GRUINARDS (from grui, "a crane"), the name of the fourteenth order in Linnaeus's Fragments of a Natural Method, consisting of geranium, and a few other genera which the author considers as allied to it in their habit and external structure.

GRUME, in medicine, denotes a concreted clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscidity and flagranting in the capillary vessels produces several disorders.

GRUPPO, or Turned Shaks, a musical grace, designed by Playford to consist in the alternate prolation of two tones in juxta-position to each other, with a close on the note immediately beneath the lower of them. See Shaks.

GRUS, in astronomy, a southern constellation, not visible in our latitude. The number of stars in this constellation, according to Mr Sharp's Catalogue, is 13.

GRUS, in ornithology. See Ardea.

GRUTER (James), a learned philologist, and one of the most laborious writers of his time, was born at Antwerp in 1590. He was but a child when his father and mother, being perfecuted for the Protestant religion by the duchefs of Parma, governours of the Netherlands, carried him into England. Heimbled the elements of learning from his mother, who was one of the most learned women of the age, and besides French, Italian, and English, was a complete midlref of Latin, and well skilled in Greek. He spent some years in the university of Cambridge; after which he went to that of Leyden to study the civil law; but at last applied himself wholly to polite literature. After travelling much, he became professor in the university of Heidelberg; near which city he died, in 1627. He wrote many works; the most considerable of which are, 1. A large collection of ancient inscriptions. 2. Thesaurus criticus. 3. Deliciae poetarum Gallorum, Italorum, & Belgiorum, &c.

GRUYERS, a town of Switerland, in the canton of Friburgh, with a pretty good castle. It is famous for its cheese, which is all its riches. E. Long. 7. 23. N. Lat. 46° 35'.

GRY, a measure containing one tenth of a line. A line is one-tenth of a digit, and a digit one-tenth of a foot, and a philosophical foot one-third of a pendulum, whose diadromes, or vibrations, in the latitude of 45 degrees, are each equal to one-second of time, or one-fifteenth of a minute. GRYLLUS, in zoology, the name of the cricket and locust kinds, which, together with the grasshoppers, make only one genus of insects, belonging to the order of hemiptera. The general characters of the genus are: The head is inflected, armed with jaws, and furnished with palp: The antennae in some of the species are fætaceous, in others filiform: The wings are deflected towards and wrapped round the sides of the body; the under ones are folded up, so as to be concealed under the elytra. All the feet are armed with two nails; and the hind ones are formed for leaping. The genus is subdivided into five different species, or families, as follows:

I. The Acride, Truxalis of Fabricius, or Cricket family properly so called; of which the characters are: Their head is of a conical form, and longer than the thorax; and their antennae are unifirm, or sword-shaped. Of this family there are eight species, none of them found in Britain.

II. The Bulle, or Acrisius of Fabricius: These are
are distinguished by a kind of crest or elevation on the thorax: their antennae are shorter than the thorax, and filiform; and their palpi are equal. — The grasshopper is of a dark-brown colour; sometimes sprinkled with spots of a yellow hue, and decreases to the extremity of the abdomen. This prolongation of the thorax stands instead of elytra, of which this insect is destitute. It has only wings under this projection of the thorax. Linnaeus mentions a spot in the thorax; which, however, is often wanting. This species is everywhere to be found which the"

...bulla-bipunctatus is of a dark-brown colour; sometimes sprinkled with spots of a higher hue. But the nureus and filiform; and their palpi are equal. — The gryllus is often wanting. This species is everywhere to be found where the

...end of the abdomen. There are 10 or 11 other species, inhabitants of Europe and America.

...third family, called Acheté, are distinguished by two bristles, situated above the extremity of their abdomen; by having three flewmata; and by the tarsi being composed of three articulations. This family is in many places called Cricket, on account of the sound which the insect makes. There are 28 species enumerated in the new edition of the Systema naturae; of which the most remarkable are...

...Gryllus, or the field cricket, as it is often called, likes best to appear out of its subterraneous habituation. In White's Natural History of Selbourne, a very pleasing account is given of the manners and economy of these insects; which, however, are so shy and cautious, he observes, that it is no easy matter to get a sight of them; for, feeling a person's footsteps as he advances, they hop short in the midst of their song, and retire backwards nimbly into their burrows, where they lurk till all suspicion of danger is over. At first it was attempted to dig them out with a spade, but without any great success; for either the bottom of the hole was inaccessible from its terminating under a great stone; or else, in breaking up the ground, the poor insect was inadvertently squeezed to death. Out of one of so bruised a multitude of eggs were taken, which were long and narrow, of a yellow colour, and covered with a very tough skin. More gentle means were then used, and proved successful: "a pliant stalk of grass, gently introducted into the caverns, will probe their windings to the bottom, and quickly bring out the inhabitant; and thus the humane inquirer may gratify his curiosity without injuring the object of it. It is remarkable, that though these insects are furnished with long legs behind, and brawny thighs for leaping, like grasshoppers; yet when driven from their holes they show no activity, but crawl along in a shiftable manner, so as easily to be taken: and again, tho' provided with a curious apparatus of wings, yet they never exert them when there seems to be the greatest occasion. The males only make that thrilling noise perhaps out of rivalry and emulation, as is the case with many animals which exert some shrill note during their breeding time: it is raised by a brisk friction of one wing against the other. They are solitary beings, living singly male or female, each as it may happen; but there must be a time when the sexes have some intercourse, and then the wings may be useful perhaps during the hours of night. When the males meet they will fight fiercely, as our author found by some which he put into the crevices of a dry stone wall, where he wanted to have made them settle. For tho' they seemed disrelished by being taken out of their knowledge, yet the first that got possession of the chinks would seize on any that were obruped upon them with a vast row of serrated fangs. With their strong jaws, toothed like the fhears of a lober's claws, they perforate and round their curious regular cells, having no fore-claws to dig, like the mole-cricket. When taken in the hand, they never offer to defend themselves, tho' armed with such formidable weapons. Of such herbs as grow before the mouths of their burrows they eat indiscriminately; and on a little platform, which they make just by, they drop their dung; and never, in the day time, seem to stir more than two or three inches from home. Sitting in the entrance of their caverns they chirp all night as well as day from the middle of the month of May to the middle of July; in hot weather, when they are most vigorous, they make the hills echo; and in the stiller hours of darkness, may be heard to a considerable distance. In the beginning of the season their notes are more faint and inward; but become louder as the summer advances, and fixed away again by degrees. — Sounds do not always give us pleasure according to their sweetness and melody; nor do harsh sounds always displease. We are more apt to be captivated or disgusted with the associations which they promote, than with the notes themselves. Thus the thrilling of the field-cricket, though sharp and fridulous, yet marvellously delights some hearers, filling their minds with a train of summer ideas of every thing that is rural, verdurous, and joyous. About the tenth of March the crickets appear at the mouths of their cells, which they then open and bore, and shape very elegantly. All that ever I have seen at that season were in their pupa state, and had only the rudiments of wings, lying under a skin or coat, which must be cast before the insect can arrive at its perfect state; from whence I should suppose that the
old ones of last year do not always survive the winter. In August, their holes begin to be obliterated, and the insects are seen no more till spring. — Not many summers ago I endeavoured to transplant a colony to a terrace in my garden, by boring deep holes in the floring turf. The new inhabitants stayed some time, and fed and fed; but wandered away by degrees, and were heard at a farther distance every morning; so that it appears, that on this emergency they made use of their wings in attempting to return to the spot from which they were taken. — One of these crickets, when confined in a paper cage and set in the sun, and supplied with plants moistened with water, will feed and thrive, and become so merry and loud as to be irksome. As the heats of the dog-days. Though they are frequently confined in a paper cage and set in the sun, and supplied with plants moistened with water, will feed and thrive, and become so merry and loud as to be irksome.

When they become very active, and the mortality among them is great, they emit a shrill noise, which can be heard at a farther distance, and which is exceedingly unpleasant. Mr White informs us, who was once an eye-witness: "for a gardener at an house where he was on a visit, happening to be moving, on the 6th of that month, by the side of a canal, his foot struck too deep, poked off a large piece of turf, and laid open to view a curious scene of domestic economy:

" — — — ingentem late dedit ore fenorum:
"Apparet domus imus, et aris longa patecit:
"Apparent — — penetratae."
There were many caverns and winding passages leading to a kind of chamber, neatly smoothed and rounded, and about the size of a moderate snuff-box. Within this secret nursery were deposited near two eggs of a dirty yellow colour, and enveloped in a tough skin, but too lately excluded to contain any rudiments of young, being full of a viscous substance. The eggs lay but shallow, and within the influence of the sun, just under a little heap of fresh-moulded mould, like that which is raised by ants. When mole-cricketflies fell, they move "cursa undos" rising and falling in curves, like the other species mentioned before. In different parts of this kingdom people call them mole-cricketflies, earthworms, and one another, all very apposite names."

IV. The Tettigoniæ, Grasshoppers, or Locusts, armed at the tail: The females of this family are distinguished by a tubular dart at the extremity of their abdomen: in both sexes the antennæ are cetaceous, and longer than the abdomen; and the tarsi composed of four articulations. Of these insects there are six species enumerated in the Systema Naturæ. They leap by the help of their hinder legs, which are strong and much longer than the fore ones. Their walk is heavy, but they fly tolerably well. Their females deposit their eggs in the ground, by means of the appendices which they carry in their tail, which consist of two lamínæ, and penetrate the ground. They lay a great number of eggs at a time; and those eggs, united in a thin membrane, form a kind of group. The little larvae that spring from them are wholly like the perfect insects, excepting in size, and their having neither wings nor cytra, but only a kind of knobs, four in number, which contain both, but undisplayed. The unfolding of them only takes place at the time of the metamorphosis, when the insect has attained its full growth. In these insects, when examined internally, besides the gullet, we discover a small stomach; and behind that a very large one, wrinkled and furrowed within. Side, there is still a third: so that it is thought, and with some probability, that all the animals of this genus chew the cud, as they so much resemble ruminant animals in their internal conformation.

V. Locustæ (the Gryllis of Fabricius), or Locusta unarmatæ at the tail. This family is distinguished by having the tail purple, without the fetae of the Abhiceæ, or the tube of the Tettigoniæ: their antennæ are filiform, and one half as long as the abdomen. They have three femelina, and three joints to the tail. To part of this description, however, there is an exception in the gryllus locusta-grofhus, the antennæ of which are of a cylindrical form. According to Mr Barbut, "few species vary so much in size and colour. Some of these insects are twice as long as others; the antennæ in most are filiform, but in this particular species cylindrical, composed of about 24 articulations, and one fourth of the length of the body. As to colour, the small individuals are nearly quite red spotted with black, with the under part of the body only of a greenish yellow. The larger subjects are all over a greenish hue, the under part being of a deeper yellow; only the inside of the hinder thighs is red. But what characterizes this species is, the form of the thorax, which has, above, a longitudinal elevation, attended by one on each side, the middle whereof drawing high

VOL. VIII.

to the first, forms a kind of X. Moreover, between the claws that terminate the feet there are small spunge, but larger in this species than the rest. This species is to be met with everywhere in the country. The larvæ of caterpillars very much resemble the perfect insects, and commonly dwell under ground." Of this tribe, 118 other species are enumerated in the Systema Naturæ, natives of different parts of the globe; besides a considerable number noted as unacertained with regard to their being distinct species or only synonyms or varieties of some of the others.

All the Gryllis, except the first family which feed upon other insects, live upon plants; the achei chieflly upon the roots, the tettigoniæ and locusta upon the leaves.

The diminution of Locusta into families (IV. V.), as above characterized, is extremely proper; and the difference of organization upon which it is founded has been observed to be adapted to the mode and the places in which the insects lay their eggs. But by taking the wings into consideration, there might have been formed three tribes or divisions, instead of two, upon the same natural foundation. Thus according to the observations of the Abbé Pouget, those which have their abdomen furnished with the tube or darts above mentioned, stay their eggs in a still spot of earth which instrument perforates. During the operation, the dart opens; and, being hollow and grooved on each side, within, the egg slides down along the grooves, and is deposited in the hole. Of those which have the tail simple, i.e. which have no darts, some have long wings, and some very short. The long-winged fort lay their eggs on the bare ground, and have no use for a perforating instrument; but they cover them with a glutinous substance, which fixes them to the soil, and prevents their being injured either by wind or waters. Those, again, which have short wings deposit their eggs in the sand: and to make the holes for this purpose, they have the power of elongating and retracting their abdominal rings, and can turn their body as on a pivot; in which operation long wings would have been a material impediment.

The annals of most of the warm countries are filled with accounts of the devastations produced by locusts, which sometimes make their appearance in clouds of vast extent. They seldom visit Europe in such swarms as formerly; yet in the warmer parts of it are still formidable. Those which have at uncertain intervals visited Europe in our memory, are supposed to have come from Africa: they are a large species about three inches long. The head and horns are of a brownish colour; it is blue about the mouth, as also on the inside of the larger legs. The shield which covers the back is greenish: and the upper side of the body brown, spotted black, and the under side purple. The upper wings are brown, with small dusky spots, and one larger spot at the tips. The under wings are more transparent, and of a light brown tinted with green, but there is a dark cloud of spots near the tips. Those insects are bred in the warm parts of Asia and Africa, from whence they have often taken their flight into Europe, where they committed terrible devastations. They multiply faster than any other animal in the creation, and are truly terrible in the countries where they breed. Some of them were seen in different
but all this was repairs the damage; but in Europe this ces, however, where they alight, they destroy every journey, and are therefore more voracious dead, as devouring the corn and grass. In the vor. Their bite is thought to contaminate have been equalled by the putrefying carcases of other to the ay.

that was green, they multitude of locusts. After having eaten up every tilloll. To nse the expression of the husbandman, they were covered with them and totally ravaged. The fires put out by the great numbers of swarms that succeeded each other. A day or two after one of these was in motion, others that were just hatched came to glean after them, gnawing off the young branches, and the very bark of the trees. Having lived near a month in this manner, they arrived at their full growth, and threw off their worm-like state, by eating their skins. To prepare themselves for this change, they fixed their hinder part to some bush or twig, or corner of a stone, when immediately, by an undulating motion used on this occasion, their heads would first appear, and soon after the rest of their bodies. The whole transformation was performed in seven or eight minutes time, after which they remained for a little while in a languishing condition; but as soon as the sun and air had hardened their wings, and dried up the moisture that remained after casting off their former flough, they returned to their former greediness, with an addition both of strength and agility. But they did not now continue in one place, but were dispersed in all directions. After laying their eggs, they directed their course northward, and probably perished in the sea.—In that country, however, the amazing fertility of the soil and warmness of the climate generally render the depredations of these insects of little consequence; besides that many circumstances concur to diminish their number. Though naturally herbivorous, they often fight with each other, and the victor devours the vanquished. They are the prey, too, of terents, lizards, frogs, and the carnivorous birds. They have been found in the stomachs of the eagle and different kinds of owls. They are also used as food by the Moors, who go to hunt them, fry them in oil or butter, and sell them publicly at Thebes and other places.

in the year 1750, a cloud of locusts was seen to enter Russia in three different places, and from thence they spread themselves over Poland and Lithuania in such astonishing multitudes, that the air was darkened and the earth covered with their numbers. In some places they were seen lying dead, heaped upon each other to the depth of four feet; in others, they covered the surface like a black cloth; the trees bent with their weight, and the damage which the country sustained exceeded computation.

in 1754, 1755, 1756, and 1757, great devastations were committed in Spain by a species of locusts, of which we have the following description by Don Guillerimo Bowles, published in D'Ilson's Travels through that country. "The locusts are continually seen in the southern parts of Spain, particularly in the pafures and remote uncultivated districts of Estremadura, but in general are not taken notice of, if not very numerous, as they commonly feed upon wild herbs, without preying upon gardens and cultivated lands, or making their way into houses. The peasants look at them with indifference while they are frisking about in the field, neglecting any measure to destroy them till the danger is immediate and this favourable moment to remedy the evil is elapsed. Their yearly number is not very considerable, as the males are far more numerous than the females. If an equal proportion were allowed only for ten years, their numbers would be so great as to destroy the whole vegetative system. Beasts and birds would starve for want of subistence, and even mankind would become a prey to their ravenous appetites. In 1754, their increase was so great from the multitude of females, that all La Mancha and Portugal were covered with them and totally ravaged. The horrors of famine were spread even farther, and affiiled the.
...in an alluvial fertile soil, where the fruits are generally of a large size, and often of a singular beauty. Among them, melons are particularly celebrated for their deliciousness.

The amours of these creatures are objects of surprise and admiration, and their union is such that it is difficult to separate them. When this separation is voluntary, after having lasted some hours, they are so exhausted, that the male retires immediately to the water for refreshment, where, losing the use of his limbs, he found perishes, and becomes an easy prey to the fish; having given life to his offspring at the expense of his own. The female, disembarrassed, the not without violent struggles, spends the remainder of her days in some solitary place, busy in forming a retreat under ground, where she can secure her eggs, of which she generally lays about 40, secreting them by her fugacity from the intemperature of the air, as well as the more immediate danger of the plough or the plaudor of the plaudor; one fatal blow of which would destroy all the hopes of a rising generation. The manner of building this cell is equally surprising. In the hinder part of her body, nature has provided her with a round smooth instrument, eight lines in length, which at its head is as big as a writing quill, diminishing to a hard sharp point, hollow within like the tooth of a viper, but only to be seen with a lens. At the root of this vehicle there is a cavity, with a kind of bladder, containing a glutinous matter, of the same colour, but without the consanguinity or tenacity of that of the flink-worm, as I found by an experiment, made for the purpose, by an infusion in vinegar, for several days, without any effect. The orifice of the bladder corresponds exactly with the instrument which serves to eject the glutinous matter. It is hid under the skin of the belly, and its interior surface is united to the moveable parts of the belly, and can partake of its motions, forming the most admirable contexture for every part of its operations, as she can dispose of this ingredient at pleasure, and eject the fluid, which has three very excellent properties: first, being indissoluble in water, it prevents its young from being drowned; next, it refills the heat of the sun, otherwise the structure would be destroyed by its inhabitants; lastly, it is proof against the frost of winter, so as to preserve a necessary warmth within. For greater security, this retreat is always contrived in a solitary place: for though a million of locusts were to light upon a cultivated field, not one would deposit its eggs there; but wherever they meet a barren and loneome situation, there they are sure to repair and lay their eggs.

These locusts seem to devour, not so much from a ravenous appetite, as from a rage of destroying everything that comes in their way. It is not surprising, that they should be found of the most juicy plants and fruits, such as melons, and all manner of garden fruits and herbs, and feed also upon aromatic plants, such as lavender, thyme, rosemary, &c. which are so common in Spain, that they serve to heat ovens; but it is very singular, that they equally eat mustard seed, onions, and garlic; nay even hemlock; and the most rank and poisonous plants, such as the thorn apple and deadly nightshade. They will even prey upon crowfoot, whose causticity burns the very hides of beasts; and such is their universal taste, that they do not prefer the innocent mallow to the bitter furze, or rue to wormwood, confuming all alike, without predilection or flavour, with this remarkable circumstanee, that during the four years they committed such havoc in Extremadura, the love-apple, or Tylosemon folatiamusic Linnaeus, was the only plant that escaped their rapacious tooth, and claimed a respect to its root, leaves, flowers, and fruit. Naturalists may search for their motives, which I am at a loss to discover; the more as I saw millions of them light on a field near Almaden, and devour the woolen and linen garments of the peasants, which were lying to dry on the ground. The curate of the village, a man of veracity, at whose house I was, assured me, that a tremendous body of them entered the church, and devoured the silk garments that adorned the images of the saints, not sparing even the varnish on the altars. The better to discover the nature of such a phenomenon, I examined the stomach of the locust, but only found one thin and soft membrane, with which, and the liquor it contains, it destroys and dissolves all kind of substances, equally with the most caustic and venemous plants; extracting from them a sufficient and salutary nourishment.

Out of curiosity to know the nature of so formidable a creature, I was urged to examine all its parts with the utmost exactness: its head is of the face of a pea, though longer, its forehead pointing downwards like the handsome Andalician horse, its mouth large and open, its eyes black and rolling, added to a timid aspect not unlike a hare. With such a dastardly countenance who would imagine this creature to be the scourge of mankind! In its two jaws it has four incisive teeth, whose sharp points traverse each other like saws, their mechanism being such as to gape or to cut. This armed, what can resist a legion of such enemies? After devouring the vegetable kingdom, they were, in proportion to their strength and numbers, to become carnivorous like wapts, they would be able to defy whole flocks of sheep, even to the dogs and shepherds; just as we are told of ants in America, that will overcome the fiercest serpents.

The locust spends the months of April, May, and June, in the place of its birth: at the end of June its wings have a fine rose colour, and its body is strong. Flying then in their prime, they assemble for the last time, and burn with a desire to propagate their species; this is observed by their motions, which are unequal in the two sexes. The male is restless and folicitous, the female is coy, and eager after food, flying the approaches of the male, so that the morning is spent in the courtship of the one and the retreat of the other. About ten o'clock, when the warmth of the sun has cleared their wings from the dampness of the night, the females seem uneasy at the approach of the males, who continuing their pursuit, they rise together two feet high, forming a black cloud that darkens the rays of the sun. The clear atmosphere of Spain becomes gloomy, and the finest summer day of Extremadura more dismal than the winter of Holland. The rustling of so many millions of wings in the air, seems like the trees of a forest agitated by the wind. The first direction of this formidable column is always against the wind, which if not too strong, the column will extend about a couple of leagues. The locusts then make a halt, when the most dreadful havoc begins; their senfe of smell being so delicate, they can find at that distance a corn field or a garden, and after demolishing it, rise again in pursuit of another: this may be said to be done in an instant. Each seems to have, as it were,
GRYPHION (Sebastian), a celebrated printer of Lyons in France, was a German, and born at Suabia near Augsburg in 1494. He reformed the art of printing at Lyons, which was before exceedingly corrupt; and the great number of books printed by him are valued by the connoisseurs. He printed many books in Hebrew, Greek, and Latin, with new and very beautiful types; and his editions are no less accurate than beautiful. The reason is, that he was a very learned man, and perfectly versed in the languages of such books as he undertook to print. Thus a certain epigrammatist has observed, that Robert Stephens was a very good corrector, Colinæus a very good printer, but that Gryphius was both an able printer and corrector. This is the epigram:

"Inter tota mortuus librorum qui adhuc, tres sunt
Iulianus: longum estam turbis fama
Ephratam filium, pulchrum Colinæus, utrumque
Gryphius adeo mente magna factus."

He died 1556, in his 63d year: and his trade was carried on honourably in the fame city by his son, Anthony Gryphius. One of the most beautiful books of Sebastian Gryphius is a Latin Bible: it was printed 1550, with the largest types that had then been seen, in 2 Gryphion vols folio.

GRYPHITES, in natural history, in English crow's stone, an oblong foliaceous shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward. They are frequently found in gravel or clay-pits in many countries. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so; and the plates of which they are composed, are in some smaller and thinner, in others thicker and larger, and in specimens of the same kind.

GUADALAJARA, or GUADALAXARA, a town of Spain, in New-Castile, and district of Alcalá, seated on the river Heráez. W. Long. 2. 45. N. Lat. 40. 56.

GUADALOAJARA, a considerable town of North America, and capital of a rich and fertile province of the same name, with a bishop's see. W. Long. 114. 59. N. Lat. 20. 20.

GUADALAVIAR, a river of Spain, which rises on the confines of Arragon and New Castile, and, running by Turvel in Arragon, crosses the kingdom of Valencia, passes by the town of the same name, and soon after falls into the Mediterranean sea, a little below Valencia.

GUADALQUIVER, one of the most famous rivers of Spain, rises in Andalusia, near the confines of Granada, and running quite through Andalusia, by the towns of Baixa, Andaxar, Cordova, Seville, and St. Lucar, falls at left into the bay of Cadiz.

GUADALOupe, a handfome town in Spain, in Etrimadura, with a celebrated convent, whose structure is magnificent, and is immensely rich. It is seated on a rivulet of the same name. E. Long. 3. 50. N. Lat. 39. 15.

GUADALUPE, one of the Caribbean islands, belonging to the French, the middle of which is seated about N. Lat. 16. 30. W. Long. 61. 20.

This island, which is of an irregular figure, may be about 80 leagues in circumference. It is divided into two parts by a small arm of the sea, which is not above two leagues long, and from 15 to 40 fathoms broad. This canal, known by the name of the Salt River, is navigable, but will only carry vessels of 50 tons burden.

That part of the island which gives its name to the whole colony is, towards the centre, full of craggy rocks, where the cold is so intense, that nothing will grow upon them but fern, and some useless shrubs covered with moss. On the top of these rocks, a mountain called la Souphiere, or the Brimsfe Mountain, rises to an immense height. It exhales, through various openings, a thick black smoke, intermixed with sparks that are visible by night. From all these hills flow numberless springs, which fertilize the plains below, and moderate the burning heat of the climate by a refreshing stream. It is celebrated, both by the gallant, which formerly used to touch at the Windward Islands, had orders to renew their provision with this pure and wholesome water. Such is that part of the island properly called Guadalup. That which is commonly called Grand...
GUA

Guadalupe. Grand Terre, has not been so much favoured by nature. It is indeed less rugged; but it wants springs and rivers. The soil is not so fertile, or the climate so wholesome or so pleasant.

No European nation had yet taken possession of this island, when 550 Frenchmen, led by two gentlemen named Loline and Duplessis, arrived there from Dieppe on the 28th of June 1635. They had been very imprudent in their preparations. Their provisions were very chosen, that they were spoiled in the passage, and they had drifted so few, that they were exhausted in two months. They were supplied with more from the mother-country, St Christopher's, whether from scarcity or design, refused to spare them any; and the first attempts in husbandry made in the country, could not as yet afford any thing. No resource was left for the colony but from the savages; but the superficialities of a people, who cultivate but little, and therefore had never laid up any stores, could not be very considerable. The new comers, not content with what the savages might freely and voluntarily bring, came to a resolution to plunder them; and hostilities commenced on the 16th of January 1636.

The Caribbs, not thinking themselves in a condition openly to repel an enemy who had so much the advantage from the superfluities of their arms, destroyed their own provisions and plantations, and retired to Grand Terre, or to the neighbouring islands. From thence the most desperate came over to the island from which they had been driven, and concealed themselves in the thickest parts of the forests. In the day time, they shot with their poisoned arrows, or knocked down with their clubs, all the Frenchmen who were scattered about for hunting or fishing. In the night, they burned the houses and destroyed the plantations of their unjust spoilers.

A dreadful famine was the consequence of this kind of war. The colonists were reduced to graze in the fields, to eat their own excrements, and to dig up dead bodies for their subsistence. Many who had been slaves at Algiers, held in abhorrence the hands that had broken their fetters; and all of them cursed their existence. It was in this manner that they atoned for the crime of their invasion, till the government of Aubert brought a peace with the savages at the end of the year 1640. The remembrance, however, of hardships endured in an invaded island, proved a powerful incitement to the cultivation of all articles of immediate necessity; which afterwards induced an attention to those of luxury consumed in the mother-country. The few inhabitants who had escaped the calamities they had drawn upon themselves, were soon joined by some disaffected colonists from St Christopher's, by Europeans fond of novelty, by sailors tired of navigation, and by some sea-captains, who prudently chose to commit to the care of a grateful soil the treasures they had saved from the dangers of the sea. But still the prosperity of Guadalupe was stopped or impeded by obstacles arising from its situation.

The facility with which the pirates from the neighbouring islands could carry off their cattle, their slaves, their very crops, frequently brought them into a desperate situation. Intemperate broils, arising from jealousies of authority, often disturbed the quiet of the planters. The adventurers who went over to the windward islands, disdaining a land that was fitter for Guadalupe agriculture than for naval expeditions, were easily drawn to Martinico by the convenient roads it abounds with. The protection of those intrepid pirates brought to that island all the traders who flattered themselves that they might buy up the spoils of the enemy at a low price, and all the planters who thought they might safely give themselves up to peaceful labours. This quick population could not fail of introducing the civil and military government of the Caribbee islands into Martinico. From that time the French ministry attended more seriously to this than to the other colonies, which were not so immediately under their direction; and hearing chiefly of this island, they turned all their encouragements to that way.

It was in consequence of this preference, that in 1700 the number of inhabitants in Guadalupe amounted only to 3825 white people, 235 savages, free negroes, mulattoes, and 6725 slaves, many of whom were Caribbs. Her cultures were reduced to 60 small plantations of sugar, 66 of indigo, a little cocoa, and a considerable quantity of cotton. The cattle amounted to 1620 horses and mules, and 3699 head of horned cattle. This was the fruit of 60 years labour. But her future progress was as rapid as her first attempts had been slow.

At the end of the year 1755, the colony was peopled with 9643 whites, 41,140 slaves of all sex, and of both sexes. Her saleable commodities were the produce of 334 sugar-plantations, 15 plots of indigo, 46,840 items of cocoa, 11,700 of tobacco, 2,257,725 of coffee, 1,274,447 of cotton. For her provisions she had 29 squares of rice or maize, and 1219 of potatoes or yams, 2,028,520 banana trees, and 32,577,950 trenches of castor. The cattle of Guadalupe consisted of 4946 horses, 2924 mules, 125 calves, 13,716 head of horned cattle, 11,162 sheep or goats, 2444 hogs. Such was the state of Guadalupe when it was conquered by the British in the month of April 1759.

France lamented this loss; but the colony had reason to comfort themselves for this disgrace. During a siege of three months, they had seen their plantations destroyed, the buildings that served to carry on their works burnt down, and some of their slaves carried off. Had the enemy been forced to retreat after all these devastations, the island was ruined. Deprived of all affiance from the mother-country, which was not able to send her any succours, and expecting nothing from the Dutch (who, on account of their neutrality, came into her roads), because they had nothing to offer them in exchange, she could never have subsisted till the ensuing harvest.

The conquerors delivered them from these apprehensions. The British, indeed, are no merchants in their colonies. The proprietors of lands, who mostly reside in Europe, send to their representatives whatever they want, and draw the whole produce of the estate by the return of their ships. An agent settled in some sea-port of Great Britain is intrusted with the furnishing the plantation and receiving the produce. This was impracticable at Guadalupe; and the conquerors in this respect were obliged to adopt the custom of the conquered. The British, informed of the advantage the French made of their trade with the colonies,
Andalusia, and falls into the bay or gulf of Cadiz between Càntaro Marino and Agramonte.

GUADIX, a town of Spain, in the kingdom of Granada, with a bishop's see. It was taken from the Moors in 1253, who afterwards retook it, but the Spaniards again got possession of it in 1489. It is situated in a fertile country, in W. Long. 2. 12. N. Lat. 37. 5. 

GUAJACUM, LIGNUM VITÆ, or Pockwood: A genus of the monogany order, belonging to the deciduous class of plants; and in the natural method ranking under the 14th order, Cruciferae. The calyx is quill-shaped and unequal; the petals five, and inserted into the calyx; the capsule is angulated, and tri- or quinquelocular.

Species. 1. The officinale, or common lignum vitae used in medicine, is a native of the West India Islands and the warmer parts of America. There it becomes a large tree, having a hard, brittle, brownish bark, not very thick. The wood is firm, solid, ponderous, very recondite, of a blackish yellow colour in the middle, and of a hot aromatic taste. The smaller branches have an agh-coloured bark, and are garnished with leaves divided by pairs of a bright green colour. The flowers are produced in clusters at the end of the branches, and are composed of oval concave petals of a fine blue colour. 2. The candium, with many pairs of oblong lobes, has many small lobes placed along the mid-rib by pairs of a darker green colour than those of the foregoing fort. The flowers are produced in loose bunches towards the end of the branches, and are composed of oval concave petals of a fine blue colour, with petals fringed on the edges. This species is also a native of the West India Islands, where it is called báilard lignum vitae. 3. The Afrum, with many blunt-pointed leaves, is a native of the Cape of Good Hope. The plants retain their leaves all the year, but have never yet flowered in Britain.

Culture. The first species can only be propagated by seeds, which must be procured from the countries where it naturally grows. They must be sown fresh in pots, and plunged into a warm hot-bed, where they will come up in six or eight weeks. While young, they may be kept in a hot-bed of tan-bark under a frame during the summer; but in autumn they must be removed into the bark-flute, where they should constantly remain. The second fort may be propagated the same way; but the third is to be propagated by layers, and will live all the winter in a good green-house.

Uses. The wood of the first species is of very considerable use both in medicine and in the mechanical arts. It is compact and heavy as to sink in water. The outer part is often of a pale yellowish colour; but the heart is blacker, or of a deep brown. Sometimes it is marbled with different colours. It is so hard as to break the tools which are employed in fell ing it; and is therefore seldom used as firewood, but is of great use to the sugar-planters for making wheels and cogs to the sugar-mill. It is also frequently wrought into bowls, mortars, and other utensils. It is brought over hither in large pieces of four or five hundred weight each; and from its hardness and beauty is in great demand for various articles of turnery ware.

The wood, gum, bark, fruit, and even the flowers of...
Guaiacum. of this tree, have been found to possess medicinal virtues; but it is only the three first, and more particularly the wood and resin, which are now in general use in Europe. The wood has little or no smell, except when heated, or while rasping, and then a slight aromatic one is perceived. When chewed, it imparts a mild acrimony, biting the palate and tongue. Its pungency resides in its resinous matter, which it gives out in some degree to water by boiling, but spirit extracts it wholly.

Of the bark there are two kinds: one smooth, the other unequal on the surface: they are both of them weaker than the wood; though, while in a recent state, they are strongly cathartic.

The gum, or rather gummy resin, is obtained by wounding the bark in different parts of the body of the tree, or by what has been called jagging. It exudes copiously from the wounds, though gradually; and when a quantity is found accumulated upon the several wounded trees, hardened by exposure to the sun, it is gathered and packed in small kegs for exportation. This resin is of a friable texture, of a deep greenish colour, and sometimes of a reddish hue; it has a pungent acrid taste but little or no smell, unless heated. The tree also yields a spontaneous exudation from the bark, which is called the native gum, and is brought to us in small irregular pieces, of a bright semipellucid appearance, and differs from the former in being much purer.

In the choice of the wood, which is the freshest, most ponderous, and of the darkest colour, is the best; the largest pieces are to be preferred too; and the best method is to rasp them as wanted, for the finer parts are apt to exhale when the raspings or chips are kept a while.

In choosing the resin, prefer those pieces which have chips of the bark adhering to them, and that easily separate therefrom by a quick blow. The resin is sometimes sophificated by the negroes with the gum of the manchinel tree; but this is easily detected by dissolving a little in spirit of wine or rum. The true gum imparts a whistful or milky tinge, but the manchinel gives a greenish cast. Much advices a few drops of spirit, nitri dulce, to be added to the spirituous portion, and then to be diluted with water, by which the gum is to be precipitated in a blue powder; but the adulteration will appear floating in white froth, &c.

Guaiacum was first introduced into Europe as a remedy for the venereal disease; and appears to have been used in Spain so early as 1508. The great successes attending its administration before the proper use of mercury was known, brought it into such repute, that it is said to have been sold for even old crowns a pound. It did not, however, continue to maintain its reputation; but was found so generally to fail where the disease was deep-rooted, and was at length superseded by mercury, to which it now only serves occasionally as an adjunct in the decumum tignorum, of which guaiacum is the chief ingredient.

The general virtues of guaiacum are those of a warm stimulating medicine; strengthening the stomach and other visceras, and remarkably promoting the urinary and cuticular discharges: hence, in catarrhal defedations, and other disorders proceeding from obstructions of the excretory glands, and where sluggish ferous humours abound, they are eminently useful; rheumatic and other pains have often been relieved by them. They are also laxative. The resin is the most active of these drugs, and the efficacy of the others depends upon the quantity of this part contained in them. The resin is extracted from the wood in part by watery liquors, but much more perfectly by spirituous ones. The watery extract of this wood, kept in the shops, proves not only less in quantity, but considererably weaker than one made with spirit. This last extract is of the same quality with the native resin, and differs from that brought to us only in being purer. The gum or extracts are given from a few grains to a scruple or half a dram, which last dose proves for the most part considerably purgative. The official preparations of guaiacum are, an extract of the wood, a solution of the gum in redistilled spirit of wine and a solution in volatile spirit, and an empyreumatic oil distilled from the wood. The resin dissolved in rum, or combined with water, by means of mucilage or the yolks of eggs, or in form of the volatile mixture or elixir, is much employed in gout and chronic rheumatism. The tincture or elixir has been given to the extent of half an ounce twice a day, and is sometimes usefully combined with laudanum.

GUAUOR, GUALLOR, or Cowaller, a large town of Indofian in Asia, and capital of a province of the same name, with an ancient and celebrated fortress: of great strength. It is situated in the very heart of Hindofian Proper, being about 80 miles to the south of Agra, the ancient capital of the empire, and 150 from the nearest part of the Ganges. From Calcutta it is, by the nearest route, upwards of 800 miles, and 910 by the ordinary one; and about 280 from the British frontiers. Its latitude is 26° 14', and longitude 78° 26', from Greenwich.

In the ancient division of the empire it is clased in the Souah of Agra, and is often mentioned in history. In the year 1008, and during the two following centuries, it was thrice reduced by famine. It is probable that it must in all ages have been deemed a military post of the utmost consequence, both from its situation in respect to the capital, and from the peculiarity of its site, which was generally deemed impregnable. With respect to its relative position, it must be considered that it stands on the principal road leading from Agra to Malwa, Guzerat, and the Decan; and that too near the place where it enters the hilly tract which advances from Bandleund, Malwa, and Agimere, to a parallel with the river Jumna, throughout the greatest part of its course. And from all these circumstances of general and particular situation, together with its natural and acquired advantages as a fortress, the possession of it was deemed as necessary to the ruling emperors of Hindofian as Dover-castle might have been to the Saxons and Normans kings of England. Its palace was used as a state prison as early as 1317, and continued to be such until the downfall of the empire.—On the final disembarkation of the empire, Guuleor appears to have fallen to the lot of a rajah of the Jat tribe; who assumed the government of the district in which it is immediately situated, under the title of Rana of Gohlud or Gold. Since that period it has changed masters more than once: the Mahratta, whose dominions extend to the neighbourhood of
it having sometimes possessed it; and at other times the Rana: but the means of transfer were always either famine or treachery, nothing like a siege having ever been attempted.

Gualeor was in the possession of Madosjee Scindia, a Maharatta chief, in 1779, at the close of which year the council-general of Bengal concluded an alliance with the Rana; in consequence of which, four battalions of sepoys of 500 men each, and some pieces of artillery, were sent to his assistance, his district being over-run by the Marhatters, and himself almost shut up in his fort of Gohud. The grand object of his alliance was to penetrate into Scindia's country, and finally to draw Scindia himself from the western side of India, where he was attending the motions of general Godard, who was then employed in the reduction of Guzerat; it being Mr. Hastings's idea, that when Scindia found his own dominions in danger, he would detach himself from the confederacy, of which he was the principal member, and thus leave matters open for an accommodation with the court of Peonah. It fell out exactly as Mr. Hastings predicted. Major William Popham was appointed to the command of the little army sent to the Rana's assistance; and was very successful as well in clearing his country of the enemy, as in driving them out of one of their own most valuable districts, and keeping possession of it; and Mr. Hastings, who justly concluded that the capture of Gualeor, if practicable, would not only open the way into Scindia's country, but would also add to the reputation of our arms in a degree much beyond the risk and expense of the undertaking, repeatedly expressed his opinion to major Popham, together with a wish that it might be attempted; and-founded his hopes of success on the confidence that the garrison would probably have in the natural strength of the place. It was accordingly undertaken; and the following account of the place, and the manner of getting possession of it, was written by captain Jonathan Scott, at that time Persian interpreter to major Popham, to his brother major John Scott.

"The fortresses of Gualeor stand on a vast rock of about four miles in length, but narrow, and of unequal breadth, and nearly flat at the top. The sides are so steep as to appear almost perpendicular, and for a whole day was not naturally so, it has been scraped away; and the height from the plain below is from 200 to 300 feet. The rampart conforms to the edge of the precipice all around; and the entrance to it is by steps running up the side of the rock, defended on the side next the country by a wall and bastions, and farther guarded by seven stone gateways, at certain distances from each other. The area within is full of noble buildings, reservoirs of water, wells, and cultivated land; so that it is really a little district in itself. At the north-west foot of the mountain is the town, pretty large, and well built; the houses all of stone. To have besieged this place would be vain, for nothing but a surplice or blockade could have carried it."

A tribe of banditti from the district of the Rana had been accustomed to rob about this town, and once in the dead of night had climbed up the rock and got into the fort. This intelligence they had communicated to the Rana, who often thought of availing himself of it, but was fearful of undertaking an enterprise of such moment with his own troops. At length he informed major Popham of it, who sent a party of the robbers to conduct some of his own spies to the spot. They accordingly climbed up in the night, and found that the guards generally went to sleep after their rounds. Popham now ordered ladders to be made; but with so much secrecy, that until the night of the prise only myself and a few others knew it. On the 3d of Augst., in the evening, a party was ordered to be in readiness to march under the command of captain William Bruce; and Popham put himself at the head of two battalions, which were immediately to follow the forming party. To prevent as much as possible any noise in approaching or ascending the rock, a kind of shoes of woolen cloth were made for the sepoys, and stuffed with cotton. At eleven o'clock the whole detachment marched from the camp at Rey-pour, eight miles from Gualeor, through unfrequented paths, and reached it a little before day-break. Just as captain Bruce arrived at the foot of the rock, he saw the lights which accompanied the rounds moving along the rampart, and heard the sentinels cough (the mode of signifying that all is well in the Indian camp or garrison), which might have damped the spirit of many men; but served only to inspire him with more confidence, as the moment for action, that is, the interval between the palling the rounds, was now ascertained. Accordingly when the lights were gone, the wooden ladders were placed against the rock, one of the robbers first mounted, and returned with an account that the guard was retiring to sleep. Lieutenant Cameron, our engineer, next mounted, and tied a rope-ladder to the battlements of the wall; this kind of ladder being the only one adapted to the purpose of scaling the wall in a body (the wooden ones only serving to ascend from crag to crag of the rock, and to assist in fixing the rope-ladders). When all was ready, captain Bruce, with 20 sepoys, grenadiers, ascended without being discovered, and squatted down under the parapet; but before a reinforcement arrived, three of the party had to little recollection as fire on some of the garrison who happened to be lying asleep near them. This had nearly destroyed the whole plan by scattering the sepoy, who was retreating to sleep. Lieutenant Cameron, our engineer, next mounted, and tied a rope-ladder to the battlements of the wall; this kind of ladder being the only one adapted to the purpose of scaling the wall in a body (the wooden ones only serving to ascend from crag to crag of the rock, and to assist in fixing the rope-ladders). When all was ready, captain Bruce, with 20 sepoys, grenadiers, ascended without being discovered, and squatted down under the parapet; but before a reinforcement arrived, three of the party had to little recollection as fire on some of the garrison who happened to be lying asleep near them. This had nearly destroyed the whole plan by scattering the sepoy, who was retreating to sleep. GUA [169] GUA

Guam. 1780; and which, before the capture of it by the British, was pronounced by the princes of Hindostan, as far as their knowledge in the military art extended, to be impregnable. In 1783 Madajee Scindia besieged this fortresst, then possessed by the Rana of Goohud, with an army of 70,000 men, and effected the reduction by the treachery of one of the Rana's officers, who formed the plan of admission of a party of Scindia's, while they were immediately supported by another party, who attacked an opposite quarter, and got admission also.

GUAM, the largest of the Ladrone islands in the South Sea, being about 40 leagues in circumference. It is the only one among the innumerables islands that lie scattered in the immense South Sea which has a town built in the European style, with a regular fort, a church, and civilized inhabitants. The air is excellent, the water good, the garden stuffs, and fruits are exquisite, the flocks of buffaloes innumerable, as are those of goats and hogs, and all kinds of poultry abound in an astonishing degree. There is no port in which worn-out sailors can be more speedily restored, or find better or more plentiful refreshments, than in this.

But Guam did not formerly enjoy this state of abundance. When it was first discovered by Magellan in 1521, with the other eight principal islands that lie north of it, which, with a multitude of smaller ones, form together that archipelago known by the name of the Ladrones, they were all crowded with inhabitants, but afforded no refreshments to navigators except fish, bananas, cocoa-nuts, and bread fruit; and even these could not be procured but by force, amidst flowers of the arrows and lances of the natives. The Spaniards carried thither from America the first flock of cattle, of fowls, of plants, and seeds, and fruits, as well as garden stuffs, which are all now found in such abundance.

The Ladrone islands, and Guam in particular, were covered with inhabitants when they were discovered. It is said that Guam alone contained upon its coasts more than 20,000 people. These men were ferocious savages and bold thieves, as all the islanders in the south seas are, undoubtedly because they were unacquainted with the rights of property; but they were so savage, so incapable of supporting the yoke of civilization, that the Spaniards, who undertook to bring them under the regulations of law and order, have seen their numbers almost annihilated within the space of two centuries. Under the government of their missionnaires, these fierce islanders, after having long defended, by cruel wars, the right of living like wild beasts under the guidance of infatué, being at last obliged to yield to the superioriety of the Spanish arms, gave themselves up to despair: they took the resolution of administering potions to their women, in order to procure abortions, and to render them sterile, that they might not bring into the world, and leave behind them, beings that were not free, according to the ideas that they had of liberty. A resolution so violent, and so contrary to the views and intentions of nature, was perfidiously in with so much obblivion in the nine Ladrone islands, that their population, which at the time of the discovery consisted of more than 60,000 souls, does not now exceed 800 or 900 in the whole extent of the archipelago. About 20 or 30 years ago, the scattered fragments of the original natives were collected and established in the island of Guam, where they now begin to recover by the wise precautions, and prudent, though tardy, exertions of a government more adapted to the climate of these islands and to the genius of their inhabitants.

The principal settlement, which the Spaniards call the town of Agana, is situated about four leagues north-east of the landing-place, on the sea-shore, and at the foot of some hills not very high, in a beautiful well-watered country. Besides this, there are 21 smaller settlements of Indians round the island, all on the sea-shore, composed of five or six families, who cultivate fruits and grain, and employ themselves in fishing.

The centre of the island is still uncleared. The trees are not very tall, but they are fit for the building of houses and of boats. The forests are in general very thick. The Spaniards at first cleared certain portions of land to turn them into savannahs for the feeding of cattle. The formation of savannahs consists in multiplying within the forests small cleared spots separated only by thickets and rows of trees, and kept clean from shrubs of every kind. The Spaniards sow these spots with grass seeds, and other indigenous plants that are fit for pasturage. These meadows, being effectually shaded on every quarter, preserve their freshness, and afford the flocks and herds a shelter from the sun and the great heat of the noon. The cattle that were formerly brought to the savannahs of Guam from America have multiplied astonishingly: they are become wild, and must be shot when wanted, or taken by stratagem.

The woods are likewise full of goats, of hogs, and fowls, which were all originally brought thither by the Spaniards, and are now wild. The flesh of all these animals is excellent. In the savannahs, and even in the heart of the forests, there is a vast multitude of pigeons, of parrots, of thrushes, and of blackbirds.

Among the indigenous trees of the country, the most remarkable are, the cocoa-nut tree and the bread-fruit tree. The woods are also filled with guavas, bananas, or plantanes of many varieties, citrons, lemons, and oranges, both sweet and bitter; and the small dwarf thorny citrus-orange with red fruit. The sugar-bush abounds in all the Ladrone islands; and as it is constantly in flower, as well as the citron and orange-shrubs, with many other of the indigenous plants, they perfume the air with the most agreeable scents, and delight the eye with the richest colours.

The rivers of Guam, which are either rivulets or torrents, abound in fish of an excellent quality: the Indians, however, eat none of them, but prefer the inhabitants of the sea. The turtle, which grow here as large as those in the island of Ascension, are not eaten either by the Indians or Spaniards.

The cultivated crops lately introduced are, the rice, the maize, the indigo, the cotton, the cocoa, the sugar-cane, which have all succeeded. That of the maize, especially, is of astonishing fertility; it is common to find in the fields where this grain is cultivated plants of twelve feet high, bearing eight or ten spikes from nine to ten inches in length, set round with well-filled seeds. The gardens are stored with mangoes.
GUA [ 170 ] GAU

GUAMANGA and pine-apples. The former is one of the finest fruits imaginable: it was brought from Manilla, and may be eaten in great quantity without any bad consequences. Horses have been brought to Guam from Manilla, and asses and mules from Acapulco. The Indians have been taught to tame and domesticate the ox, and to employ him in the draught.

This island, the land of which rises gradually from the sea-shore towards the centre by a gentle acclivity, is not very mountainous. The inhabitants say, that its soil is equally rich and fertile over the whole island, except in the northern part, which forms a peninsula almost defitute of water. But in the rest, you cannot go a league without meeting a rivulet. Upon penetrating a little way into the interior part of the country, to the east and the south of Agana, many springs of fine water are found, forming at little distances, basons of pure water, which, being shaded by thick trees, produce a most agreeable coolness in spite of the heat of the climate.

The indigenous inhabitants are such as they were described by Magellan; of small stature, sufficiently ugly, black, and in general dirty, though they are continually in the water. The women are for the most part handsome, well made, and of a reddish colour. Both sexes have long hair. This feamy people have become by civilisation gentle, passionate, and dancing much, but labour little. They are addicted to drunkenness, for they drink freely of the wine of the cocoa-nut. They love holidays and dancing much, but labour little. They are fond of sweetmeats, of small apples, and cakes. Horses are taught to tame and preserve of any thing; the art of observing what passes, in order to prevent surprize; or the care, precaution, and attention, we make use of to prevent any thing from happening contrary to our intentions or inclinations.

GUARD, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy. In garrison the guards are relieved every day; hence it comes that every soldier mounts guard once every three or four days in time of peace, and much oftener in time of war. See Honours.

Advanced Guard, is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger. The guards are either made stronger or weaker, according to situation, the danger to be apprehended from the enemy, or the nature of the country.

VAN GUARD. See Advanced Guard.

Artillery Guard, is a detachment from the army to secure the artillery when in the field. Their corps de garde is in the front of the artillery park, and their sentries dispersed round the same. This is generally a 48-hours guard; and upon a march, this guard marches in the front and rear of the artillery, and must be sure to leave nothing behind: if a gun or waggon breaks down, the officer that commands the guard is to leave a sufficient number of men to assist the gunners and marines in getting it up again.

Artillery Quarter-Guard, is frequently a non-commissioned officer's guard from the royal regiment of artillery, whose corps de garde is always in the front of their encampment.

Artillery Rear-Guard, consists in a corporal and six men, posted in the rear of the park.

Corps de Garde, are soldiers entrusted with the guard of a post, under the command of one or more officers. This word also signifies the place where the guard mounts.

Grand Guard; three or four squadrons of horse, commanded by a field-officer, posted at about a mile or a mile and a half from the camp, on the right and left wing, towards the enemy, for the better security of the camp.

Forage Guard, a detachment sent out to secure the foragers, and who are posted at all places, where either the enemy's party may come to disturb the foragers, or where they may be spread too near the enemy, so as to be in danger of being taken. This guard consists both of horse and foot, and must remain on their posts till the foragers are all come off the ground.

Main Guard, is that from which all other guards are detached. Those who are for mounting guard assemble at their respective captain's quarters, and march from hence to the parade, in good order; where, after the whole guard is drawn up, the small guards are detached to their respective posts: then the flagbearers throw lots for their guards, who are all under
under the command of the captain of the main guard. This guard mounts in garrison at different hours, according as the governor please.

Piguet-guard, a good number of horse and foot, always in readiness in case of an alarm: the horses are generally saddled all the time, and the riders booted.

The foot draw up at the head of the battalion, frequently at the beating of the tattoo; but afterwards return to their tents, where they hold themselves in readiness to march upon any sudden alarm. This guard is to make resistance in case of an attack, until the army can get ready.

Baggage-guard, is always an officer's guard, who has the care of the baggage on a march. The waggons should be numbered by companies, and follow one another regularly: vigilance and attention in the passage of hollow ways, woods, and thickets, must be strictly observed by this guard.

Quarter-guard, is a small guard commanded by a subaltern officer, posted in the front of each battalion, at 222 feet before the front of the regiment.

Rear-guard, that part of the army which brings up the rear on a march, generally composed of all the old grand guards of the camp. The rear-guard of a party is frequently eight or ten horse, about 500 paces behind the party. Hence the advance guard going out upon a party, form the rear-guard in their retreat.

Rear-guard, is also a corporal's guard placed in the rear of a regiment, to keep good order in that part of the camp.

Standard-guard, a small guard under a corporal, out of each regiment of horse, who mount on foot in the front of each regiment, at the distance of 20 feet from the streets, opposite the main-street.

French-guard, only mounts in the time of a siege, and sometimes consists of three, four, or six battalions, according to the importance of the siege. This guard must oppose the besieged when they rally out, protect the workmen, &c.

Provost-guard, is always an officer's guard that attends the provost in his rounds, either to prevent desertion, marauding, robbing, &c. See Provost.

Guard, in fencing, implies a posture proper to defend the body from the sword of the antagonist.

Ordinary guards, such as are fixed during the campaign, and relieved daily.

Extraordinary guards, or detachments, which are only commanded on particular occasions; either for the further security of the camp, to cover the foragers, or for convoys, ejects, or expeditions.

Guards, also imply the troops kept to guard the king's person, and consist both of horse and foot.

Horse guards, in England, are gentlemen chosen for their bravery, to be entrusted with the guard of the king's person; and were divided into four troops, called the 1st, 2d, 3d, and 4th troop of horse-guards. The first troop was raised in the year 1660, and the command given to lord Gerard; the second in 1661, and the command given to Sir Philip Howard; the third in 1663, and the command given to Charles de la Ferté; the fourth in 1692, and the command given to sir George Newburgh. Each troop had one colonel, two lieutenant-colonels, one cornet and major, one guidon and major, four exponents and captains, four brigadiers and lieutenants, one adjutant, four sub-brigadiers and cornets, and 60 private men. But the four troops are now turned into two regiments of life-guards.

Horse-Grenadier guards, are divided into two troops, called the 5th and 6th troops of horse-grenadier guards. The first troop was raised in 1693, and the command given to lieutenant-general Cholmondeley; the second in 1702, and the command given to lord Forrester. Each troop has one colonel, one lieutenant-colonel, one guidon or major, three exponents and captains, three lieutenants, one adjutant, three cornets, and 60 private men.

Teemen of the guard, first raised by Henry VII. in the year 1485. They are a kind of pompous foot-guards to the king's person; and are generally called by a nickname the Beef-eaters. They were anciently 250 men of the first rank under gentry; and of larger stature than ordinary, each being required to be six feet high. At present there are but 100 in constant duty, and 70 more not on duty; and when any one of the 100 dies, his place is supplied out of the 70. They go dressed after the manner of king Henry VIII. time. Their first commander or captain was the earl of Oxford, and their pay is 25. 2d. per day.

Foot-guards are regiments of foot appointed for the guards of his majesty and his palace. There are three regiments of them, called the 1st, 2d, and 3d regiments of foot-guards. They were raised in the year 1660; and the command of the first was given to colonel Ralfel, that of the second to general Monk, and the third to lord Linlithgow. The first regiment is at present commanded by one colonel, one lieutenant-colonel, three majors, 23 captains, one captain-lieutenant, 31 lieutenants, and 24 ensigns; and contains three battalions. The second regiment has one colonel, one lieutenant-colonel, two majors, 14 captains, one captain-lieutenant, 18 lieutenants, 16 ensigns; and contains only two battalions. The third regiment is the same as the second.

The French guards are divided into three within, and those without, the palace.—The first are the gardes du corps, or body-guards; which consist of four companies, the first of which companies was anciently Scots. The Scots guards, infra.

The guards without are the gens d'armes, light-horse, musqueters, and two other regiments, the one of which is French and the other Swiss.

New arrangements, however, have taken place in this department as well as others since the late revolution.

Scott guards, a celebrated band, which formed the first company of the ancient gardes du corps of France. It happened from the ancient intercourse between France and Scotland, that the natives of the latter kingdom had often distinguished themselves in the service of the former. On this foundation the company of Scots guards, and the company of Scots gendarmes, were instituted. Both of them owed their institution to Charles VII. of France, by whom the first standing army in Europe was formed, anno 1454; and their fates cannot but be interesting to Scotchmen. See Gendarmes.

Valour, honour, and fidelity, must have been very conspicuous features of the national character of the
Scots, when so great and civilized a people as the French could be induced to chose a body of them, foreigners as they were, for guarding the persons of their sovereigns.—Of the particular occasion and reasons of this predilection, we have a recital by Louis XII, a succeeding monarch. After setting forth the service which the Scots had performed for Charles VII., in expelling the English out of France, and reducing the kingdom to his obedience, he adds—"Since which reduction and for the service of the Scots upon that occasion, and for the great loyalty and virtue which he found in them, he selected 200 of them for the guard of his person, of whom he made an hundred men at arms, and an hundred life-guards: And the hundred men at arms are the hundred lances of our ancient ordinances; and the life-guard men are those of our guard, who still are near and about our person."—As to their fidelity in this honourable station, the historian, speaking of Scotland, says, "The French have feancient a friendship and alliance with the Scots, that of 400 men appointed for the king's life-guard, there are an hundred of the said nation who are the nearest to his person, and in the night keep the keys of the apartment where he sleeps. There are, moreover, an hundred complete lances and two hundred yeomen of the said nation, besides several that are dispersed thro' the companies: and for so long a time as they have served in France, never hath there been one of them found that hath committed or done any fault against the king or their state; and they make use of them as of their own subjects."

The ancient rights and privileges of the Scottish life-guards were very honourable; especially of the twenty-four first. The author of the Ancient Alliance says, "On high holidays, at the ceremony of the royal touch, the erection of knights of the king's order, the reception of extraordinary ambassadors, and the public entries of cities, there must be six of their number next to the king's person, three on each side: and the body of the king must be carried by them only, wherefoever ceremony requires. They have the keeping of the keys of the king's lodging at night, the keeping of the choir of the chapel, the keeping the boats where the king passes the rivers; and they have the honour of bearing the white silk fringe in their arms, which in France is the coronne couleur. The keys of all the cities where the king makes his entry are given to their captain in waiting or out of waiting. He has the privilege, in waiting or out of waiting, at ceremonies, such as coronations, marriages, and funerals of the kings, and at the baptism and marriage of their children, to take duty upon him. The coronation-robe belongs to him: and this company, by the death or change of a captain, never changes its rank, as do the three others."

This company's first commander, who is recorded as a per son of great valour and military accomplishments, was Robert Patillock, a native of Dundee; and in the band, ever ardent to distingwith itself, continued in great reputation till the year 1578. From the year 1612, the Scots guards were left attended, and their privileges came to be invaded. In the year 1612, they remonstrated to Louis XIII. on the subject of the injustice they had suffered, and set before him the services they had rendered to the crown of France. Attempts were made to re-establish them on their ancient foundation; but no negotiation for this purpose was effectual. The troops of France grew jealous of the honours paid them: the death of Francis II., and the return of Mary to Scotland, at a time when they had much to hope, were unfortunate circumstances to them: the change of religion in Scotland, was an additional blow: and the accession of James VI. to the throne of England, disturbed altogether the interests of France and Scotland. The Scots guards of France had therefore, latterly, no connection with Scotland but the name."

Guard-Boat, a boat appointed to row the rounds amongst the ships of war which are laid up in any harbour, &c. to observe that their officers keep a good looking out, calling to the guard-boat the palsies, and not suffering her crew to come on board, without having previously communicated the watch-word of the night.

Guard-Ship, a vessel of war appointed to superintend the marine affairs in a harbour or river, and to see that the ships which are not commissioned have their proper watchward kept duly, by sending her guard-boats around them every night. She is also to receive seamen who are imprisoned in the time of war.

Guardian, in law, a person who has the charge of any thing; but more commonly it signifies one who has the custody and education of such persons as have not sufficient discretion to take care of themselves and their own affairs, as children and idiots. Their business is to take the profits of the minor's lands to his use, and to account for the same; they ought to sell all movables within a reasonable time, and to convert them into land or money, except the minor is near of age, and may want such things himself; and they are to pay interest for the money in their hands, that might have been so placed out; in which case it will be presumed that the guardians made use of it themselves. They are to sustain the lands of the heir, without making deduction of anything thereon, and to keep it safely for him: if they commit waste on the lands, it is a forfeiture of the guardian ship, 3 Edw. 1. And where persons, as guardians, hold over any land, without the consent of the person who is next intitled, they shall be adjudged trespassers, and shall be accountable; 6 Ann. cap. xviii.

Guardian, or Warden, of the Cinque-ports, is an officer who has the jurisdiction of the five ports, with all the power that the admiral of England has in other places.

Camden relates, that the Romans, after they had settled themselves and their empire in Britain, appointed a magistrate, or governor, over the east parts, where the cinque-ports lie, with the title of comes illo­riti Saxonici per Britanniam; having another, who bore the like title, on the opposite side of the sea. Their business was to strengthen the sea-coast with munition, against the outrages and robberies of the barbarians; and that antiquity takes the warden of the Cinque-ports to have been erected in imitation thereof. The wardenship is a place of value, sufficed worth 700l. per annum.

Guardian of the Spiritualities, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant. A guardian of the spi-
spiritualities may likewise be either fixed in law, as the archbishop is of any diocese within his province, or by delegation, as he whom the archbishop or vicar-general for the time appoints. Any such guardian has power to hold courts, grant licenses, dispensations, probates of wills, &c.

GUADELEON, in botany: A genus of the monogynia order, belonging to the oenantha class of plants. The calyx is quadrifid; the petals four; the nectarium cylindrical, having the anthec in its mouth; the calyx is quadrangular, and quadrivulgar; the seeds solitary.

GUARDIANI (Battista), a celebrated Italian poet, born at Ferrara, in 1576. He was great-grandson to Guarino of Verona, and was secretary to Alphonso Duke of Ferrara, who intrusted him with several important commissions. After the death of that prince, he was successively secretary to Vincenzio de Gonzaga, to Ferdinand de Medici grand duke of Tuscany, and to Francis Maria de Feltri duke of Urbino. But the only advantages he reaped under these various dignities, were great encomiums on his wit and com-positions. He was well acquainted with polite literature; and acquired immortal reputation by his Italian poems, especially by his Pastor Fido, the most known and admired of all his works, and of which there have been innumerable editions and translations. He died in 1612.

GUARDIA, or GUARDA, a town of Portugal, in the province of Beira, with a bishop's see. It contains about 2300 inhabitants, is fortified both by art and nature, and has a stately cathedral. W. Long. 5° 17'. N. Lat. 40° 26'.

GUARDSiba, a town of Italy, in the kingdom of Naples, and in the Gonado-di-Molife, with a bishop's see. E. Long. 15° 53'. N. Lat. 51° 50'.

GUARIGAL, or GUERgua, a town of Africa, and capital of a small kingdom of the same name, in Blededugerd, on the south of Mount Atlas. E. Long. 9° 55'. N. Lat. 28° 0'.

GUARIGA, in natural history, the name of a species of monkey found in the West Indies. See SIMIA.

GUSTALLA, a strong town of Italy, in the dukedom of Mantua, with the title of duchy, remarkable for a battle between the French and Imperialists in 1724. It was ceded to the duke of Parma in 1748, by the treaty of Aix-la-Chapelle. It is situated near the river Po, in E. Long. 10° 33'. N. Lat. 44° 45'.

GUATIMALA, the audience of, in North America, and in New Spain, is above 750 miles in length, and 450 in breadth. It abounds in chocolate, which they make use of instead of money. It has 12 provinces under it: and the native Americans, under the dominions of Spain, profess Christiinity; but it is mixed with a great many of their own superstitions. There is a great chain of high mountains, which run across it from E. to W. and it is subject to earthquakes and storms. It is however very fertile; and produces, besides chocolate, great quantities of cochineal and cotton.

GUATIMALA, a province of North America, in New Spain, and in the audience of the same name; bounded on the W. by Soconusco, on the N. by Verapaz and Honduras, on the E. by Nicaragua, and on the S. by the south sea. St. Jago de Guatimala is the capital of the whole audience.

GUATIMALA, a large and rich town of North America, in New Spain; and capital of a government of the same name, with a bishop's see, and an university. It carries on a great trade, especially in chocolate. W. Long. 91° 30'. N. Lat. 14° 0'.

GUATIMALA, the Volcano of, is a mountain, which throws out fire and smoke. St Jago de Guatimala was almost ruined by it in 1541. It was afterwards rebuilt at a good distance from this dreadful mountain. A few years ago, however, it was again destroyed, with circumstances more terrible perhaps than any mentioned in history.

GUAVA, in botany. See Psidium.

GUAXACA, a province of North America, in New Spain, which is very fertile in wheat, Indian corn, cochineal, and cafia. It is bounded by the gulph of Mexico on the north, and by the south sea on the south. It contains mines of gold, silver, and crystal. Guaxaca is the capital town.

GUAXACA, a town of North America, in the Audience of Mexico, and capital of the province of the same name, with a bishop's see. It is without walls, and does not contain above 2000 inhabitants; but it is rich, and they make very fine sweet meats and chocolate. It has several rich convents, both for men and women. W. Long. 100°. N. Lat. 17° 45'.

GUAYRA, a district of the province of La Plata, in South America, having Brafil on the east, and Paraguay on the west.

GUBEN, a handome town of Germany, in Lower Lusatia, seated on the river Neiße, and belonging to the house of Sax-Merlenburg. E. 14° 59'. N. Lat. 51° 15'.

GUBER, a kingdom of Africa, in Negroland. It is surrounded with high mountains; and the villages, which are many, are inhabited by people who are employed in taking care of their cattle and sheep. There are also abundance of artificers, and linen-weavers, who fend their commodities to Tombuto. The whole country is overflowed every year by the inundations of the Niger, and at that time the inhabitants sow their rice. There is one town which contains 8000 families, among whom are many merchants.

GUVIO, a town of Italy, in the territory of the church, and in the duchy of Urbino, with a bishop's see. E. Long. 12° 41'. N. Lat. 45° 18'.

GUDGEON, in ichthyology; a species of cyprius, see Cyprinus.

This fish, though small, is of so pleasant a taste, that it is very little inferior to smelt. They spawn twice in the summer; and their feeding is much like the barbels in stems and on gravel, flying all manner of flies: but they are easily taken with a small red worm, fishing near the ground; and being a leather-mouthed fish, will not easily get off the hook when struck. The gudgeon may be filled with a float, the hook being on the ground; or by hand, with a running line on the ground, without cork or float. But although the small red worm abovementioned is the best bait for this fish, yet waps, gentles, and caddis will do very well. You may also fish for gudgeons with two or three hooks at once, and find very pleasant sport, where they rife any thing large. When you angle for them, stir up the sand or gravel with a long pole; this will make them gather to that place, bite faster, and with more eagerness.

Sea-Gudgeon, Rock fish; or Black Cod. See Gobius.
The Guelphs and GibeJins filled Italy with blood and carnage for many years. The Guelphs stood for the Pope, against the emperor. Their title is referred by some to Conrad III, in the twelfth century; by others, to that of Frederic I.; and by others, to that of his successor Frederic II. in the thirteenth century.

The name of Guelph is commonly said to have been formed from Wolfe, or Wolfe, on the following occasion: the emperor Conrad III. having taken the duchy of Bavaria from Wolfe VI. brother of Henry duke of Bavaria, Wolfe, affiicted by the forces of Roger king of Sicily, made war on Conrad, and thus gave birth to the faction of the Guelfs.

Others derive the name Guelfs from the German Wulf, on account of the grievous evils committed by that cruel faction: others deduce the denomination from that of a German called Guelfe, who lived at Pilsen, and adding that his brother, named Gibel, gave his name to the GibeJins. See the article GIBELINS.

GUELDERTLAND, one of the united provinces, bounded on the W. by Utrecht and Holland, and on the E. by the bishopric of Munster and the duchy of Cleves, on the N. by the Zuyder sea and Overysel, and on the S. it is separated from Brabant by the Meus. Its greatest extent from N. to S. is about 47 miles, and from W. to E. near as much; but its figure is very irregular. The acre of its greatest extent is about 211. Its greatest extent is about 47 miles, and from W. to E. near as much; but its figure is very irregular. The air here is much healthier and clearer than in the maritime provinces, the land lying higher. Excepting some part of what is called the Vechte, the soil is fruitful. It is watered by the Rhine, and its three branches, the Waal, the Yssel, and the Leek, besides lesser streams. In 1792, it was raised to a county by the emperor Henry IV. and in 1339 to a duchy by the emperor Louis of Bavaria. It had dukes of its own till 1528, when it was yielded up to the emperor Charles V. In 1797, it acceded to the union of Utrecht. It is divided into three districts, each of which has its states and diets. Those for the whole province are held twice a year at the capital towns. The province sends 10 deputies to the states-general. Here are computed 285 Calvinist ministers, 14 Roman Catholic congregations, 4 of the Lutheran persuasion, besides 3 of Orangists. The places of most note are Nijmegen, Zutphen, Arnhem, Harderwyk, Loo, &c.

GUELDRES, astrong town of the Netherlands, in the duchy of the same name. It was ceded to the king of Prussia by the peace of Utrecht, and is feared among marines. E. Long. 6. 21. N. Lat. 51. 50.

GUERCINO. See Bargier.

GUERICKE, or Gueriche, (Otho), the most celebrated mathematician of his time, was born in 1602. He was the inventor of the air pump; and author of several works in natural philosophy, the chief of which is Experimenta Magdeburgica. He died in 1686.

GUERNEY, an island in the English channel, on the coast of Normandy, subject to Britain; but (as well as the adjacent islands) governed by its own laws. See JERSEY. It extends from east to west, in the form of a harp, and is thirteen miles and a half from the south-west to north-east, and twelve and a half, where Guettarda, broadest, from east to west. The air is very healthy, and the soil naturally more rich and fertile than that of Jersey; but the inhabitants neglect the cultivation of the land for the sake of commerce: they are, however, sufficiently supplied with corn and cattle, both for their own use and that of their ships. The island is well fortified by nature with a ridge of rocks, one of which abounds with emery, used by lapidaries in the polishing of stones, and by various other artificers. Here is a better harbour than any in Jersey, which occasions its being more reforted to by merchants; and on the south side the shore bends in the form of a crescent, enclosing a bay capable of receiving very large ships. The island is full of gardens and orchards; whence cider is so plentiful, that the common people use it instead of small beer, but the more wealthy drink French wine.

GUETTARDA, in botany: A genus of the heptandria order, belonging to the monotypia class of plants; and in the natural ranking under the 18th order, Trifolium. The male calyx is cylindrical; the corolla cleft into seven parts, and funnel-shaped. The female calyx cylindrical; the corolla cleft into seven parts; one pistil, and the fruit a dry plum.

GUIANA, a large country of South America, is bounded on the east and north by the Atlantic ocean, and the river Oroonoko; on the fourth, by the river of the Amazons; and on the west, by the provinces of Grenada and New-Andalusia, in Terra-Firma, from which it is separated both on the west and north by the river Oroonoko. It extends above 1200 miles from the north-east to the south-west, that is, from the mouth of the river Oroonoko to the mouth of the river of Amazons, and near 600 in the contrary direction.

Most geographers divide it into two parts, calling the country along the coast Caribbeano Proper, and the interior country Guiana Proper: the last is also styled El Dorado by the Spaniards, on account of the immense quantity of gold it is supposed to contain.

The Portuguese, French, and Dutch, have all settlements along the coast. What lies south of Cape North belongs to the first of these nations; the coast between Cape North and Cape Orange is possessed by the natives; French Guiana, Old Cayenne, or Equinoctial France, extending from Cape Orange, 240 miles along the coast, to the river Maroni; where the Dutch territory begins, and extends to the mouth of the Oroonoko.

Along the coast, the land is low, marshy, and subject to inundations in the rainy season, from a multitude of rivers which descend from the inland mountains. Hence it is, that the atmosphere is suffocating, hot, moist, and unhealthy, especially where the woods have not been cleared away. Indeed, the Europeans are forced to live in the most disagreeable situations, and to establish colonies at the mouths of the rivers, amidst flinking marshes, and the putrid ooze of salt marshes, for the convenience of exportation and navigation.

"Dutch Guiana (according to an account lately published by a gentleman who resided several years at Surinam as a physician) was first discovered by Columbus in 1498. It lies between the 7th of north and
and the 5° of south latitude, and between the 33° and 60° of longitude west from London. It is bounded on the north and east, by the Atlantic; on the west, by the rivers Oroonoko and Negro; and on the south, by the river of Amazonas.

It is now divided between the Spaniards, Dutch, French, and Portuguese, but, except its sea-coast, and lands adjacent to its rivers, it has hitherto remained unknown to all but its original natives; and even of these, it is only the Dutch territories that foreigners have any knowledge of; for those of the Spaniards, French, and Portuguese, are inaccessible to them.

"This country, on account of the diversity and fertility of its soil, and of its vicinity to the equator, which passes through it, affords almost all the productions of the different American countries between the tropics, besides a variety peculiar to itself." Dutch Guiana was formerly the property of the English, who made settlements at Surinam, where a kind of corrupt English is still spoken by the negroes. The Dutch took it in the reign of Charles the Second, and it was ceded to them by a treaty in 1674, in exchange for what they had poissied in the province now called New-York.

The land for 50 miles up the country from the sea-coast is flat; and during the rainy seasons, covered two feet high with water. This renders it inconveniently fertile; the earth, for 12 inches deep, being a stratum of perfect manure: an attempt was once made to carry some of it to Barbadoes; but the wood-ants so much injured the vessel, that it never was repeated. The excessive richness of the soil is a disadvantage, for the canes are too luxuriant to make good sugar; and therefore, during the first and second crop, are converted into rum.

There are some trees on this part; but they are small and low, confiding chiefly of a small species of palm, interspersed with a leaf, nearly 30 feet long, and three feet wide, which grows in clusters, called a Troolie; and, at the edges of running-water, with mangroves.

Farther inward, the country rifes; and the soil, though still fertile, is less durable. It is covered with forests of valuable timber, that are always green; and there are some sandy hills, though no mountains; in the French territories, however, there are mountains, according to the reports of the Indians, for they have never been visited by any other people.

In this country the heat is seldom disagreeable: the trade-winds by day, the land breezes in the evening, and the invariable length of the nights, with gentle dews, refresh the air, and render it temperate and balmy.

There are two wet seasons and two dry, of three months each, in every year; and, during more than a month in each wet season, the rain is incessant. The dry seasons commence six weeks before the equinoxes, and continue six weeks after. The wet seasons are more wholesome than the dry, because the rains keep the waters that cover the low lands, near the sea, fresh; and in motion; but during the dry season it flagellates, and, as it wanes, becomes putrid, sending up very unwholesome exhalations. Blossoms, green and ripe fruit, are to be found upon the same tree in every part of the year. There are some fine white and red agates in Guiana, which remain untouched; and mines of gold and silver, which the Dutch will not suffer to be wrought.

The inhabitants of Guiana are either natives, who are of a reddish brown; or negroes and Europeans; or a mixed progeny of these in various combinations. The natives are divided into different tribes; more or less enlightened and polished, as they are more or less remote from the settlement of the Europeans. They allow polygamy, and have no division of lands. The men go to war, hunt, and fish; and the women look after domestic concerns, spin, weave in their fashion, and manage the planting of cassava and manioca; the only things which in this country are cultivated by the natives. Their arms are bows and arrows; sharp poisoned arrows, blown through a reed, which they use in hunting; and clubs made of a heavy wood called iron-wood. They eat the dead bodies of those that are slain in war; and fell for slaves tho' they take prisoners; their wars being chiefly undertaken to furnish the European plantations. All the different tribes go naked. On particular occasions they wear caps of feathers; but, as cold is wholly unknown, they cover no part but that which distinguishes the sex. They are cheerful, humane, and friendly; but timid, except when heated by liquor, and drunkness is a very common vice among them.

Their houfes consist of four flakes set up in a quadrangular form, with two poles, bound together by split nibbes, and covered with the large leaves called treeleis. Their life is ambulatory; and their house, which is put up and taken down in a few hours, is all they have to carry with them. When they remove from place to place, which, as they inhabit the banks of the rivers, they go by water in small canoes, a few vesels of clay made by the women, a flat stone on which they bake their bread, and a rough stone on which they grate the roots of the cassava, a hammock, and a basket, are all their furniture and utensils; most of them, however, have a bit of a looking-glass framed in paper, and a comb.

Their poisoned arrows are made of splinters of a hard heavy wood, called cacario; they are about 12 inches long, and somewhat thicker than a coarse knitting needle: one end is formed into a sharp point; round the other is wound some cotton, to make it fit the bore of the reed through which it is to be blown. They will blow these arrows 40 yards with absolute certainty of hitting the mark, and with force enough to draw blood, which is certain and immediate death. Against this poison no antidote is known. The Indians never use these poisoned arrows in war, but in hunting only, and chiefly against the monkeys; the sight of an animal thus killed may be safely eaten, and even the poison itself swallowed with impunity.

GUIANA, a town, bay, and harbour of South America, in Peru, and capital of an audience of the same name. W. Long. 76° 57'; S. Lat. 2° 00'.

GUIARA, a sea-port town of South-America, and on the Caracca coast. The English attempted to take it in 1739 and 1743; but they were repulsed both times. W. Long. 55° 5'; S. Lat. 10° 59'.

GUICCHARDINI (Francisco), a celebrated historian, born at Florence in 1492. He professed the civil law with reputation, and was employed in several...
G U I

176

G U I

G uicci-  

ral embasses. Leo X. gave him the government of

Moderne and Reggio, and Clement VII. that of

Romagna and Bologna. Guicciardini was also lieute-

nant-general of the pope's army, and distinguished

himself by his bravery on several occasions; but Paul

III. having taken from him the government of Bo-

logna, he retired to Florence, where he was made

councillor of state, and was of great service to the

house of Medicis. He at length retired into the coun-

try to write the history of Italy, which he composed

in Italian, and which comprehends what passed from

the year 1494 to 1532. This history is greatly ef-

teeed; and was continued by John Baptift Adriani, his

friend. He died in 1540.

GUICCIARDINI (Lewis), his nephew, composed a

history of the Low Countries, and memoirs of the af-

fairs of Europe, from 1539 to 1560. He wrote with

great spirit against the persecution of the duke D'Alva,

for which he imprisoned him. Died in 1582.

GUIDES, in military language, are usually the

country people in the neighbourhood of an encamp-

ment; who give the army intelligence concerning the

country, the roads by which they are to march, and

the probable route of the enemy.

GUIDI (Alexander), an eminent Italian poet, born

at Pavia in 1650. Having a desire to see Rome, he

there attracted the notice of queen Christina of Swed-

en, who retained him at her court; he befie obtained

a considerable benefice from pope Innocent XI. and

a pension from the duke of Parma. For a good of-

fice he did the flate of Milan with prince Eugenio, he

was enrolled among the nobles and decorations of that

town; and died in 1712. Nature had been kinder to his

intellect than to his exterior form; his body was marbles,
of a small and crooked, his head was

his intellect; he died in 1642. There are several

defigins of this great master in print, etched by him-

self.

GUIDON, a fort of flag or standard borne by the

King's life-guard; being broad at one extreme, and

almost pointed at the other, and slit or divided into two.

The guidon is the ensign or flag of a troop of horse-

guards. See Guard.

GUIDON, the office that bears the gui-

don. The guidon is that in the horse-guards which

the ensign is in the foot. The guidon of a troop of

horse takes place next below the cornet.

GUIDONS, guidons, or fæcola guidonum was a com-

pany of priests established by Charlemagne, at Rome,
to conduct and guide pilgrims to Jerusalem, to visit

the holy places: they were also to affift them in cafe

they fell sick, and to perform the last offices to them
in case they died.

GUIENNE, the largest province of France, bound-

ed on the north by Saintogne, Angoumois, and Li-

mozin; on the eft by Limonin, Auvergne, and Lan-
guedoc; on the south by the Pyrenées, Lower Na-

varre, and Bearn; and on the west by the ocean. It

is about 225 miles in length, and 200 in breadth. It

is divided into the Upper and Lower. The Upper

comprehends Quercy, Rouergue, Armagnac, the terri-

tory of Comminges, and the county of Bigorre. The

Lower contains Bourdeaux, Perigord, Agenois, Con-
domos, Bazadois, the Lander, Proper Gaucny, and

the ditrif of Labour. The principal rivers are, the

Garonne, the Adour, the Tarn, the Aveiron, and the

Lot. Bordeaux is the capital town.

GUIDANDINA, the Nickar tree: A genus of

the monogyinia order, belonging to the decandria clas
of plants; and in the natural method ranking under

the 33d order, Lomentacca. The calyx is monophyl-

lous and salver-shaped; the petals, inserted into the

neck of the calyx, nearly equal. The feed-velvet a le-
gumen.

Species. 1. The bonduc, or yellow nickar. 2. The

boudeculla, or gray nickar. These are climbing plants,
natives of the Weft-Indies, where they rife to the height
of twelve or fourteen feet: the flowers come out at
the wings of the flakks; and are composed of five con-
cave yellow petals. They are succeded by pods
about three inches long and two broad, closely armed
with slender spines, opening with two valves, each
including two hard feeds about the size of children's
marbles, of a yellowish colour. 3. The morings, or

moronga nickar, is a native of the island of Ceylon,
and some places on the Malabar coast. It rifes to the
height of 25 or 30 feet, having flowers produced in
loose bunches from the side of the branches, and com-
poed of an unequal number of petals.

Cultur and Use. These plants being natives of
warm climates, require to be kept through the winter
in a stove in this country. They are propagated by
seeds; but those of the frift fort are so hard, that un-
til they are soaked two or three days in water befor
they are put into the ground, or put into the pots in the
ran-bed to soften their covers, they will remain for years without vegetating.—The roots of the third fort are scraped when young, and used
by the inhabitants of Ceylon and Malabar as those of
horse-radish are in Europe. The wood dyes a beauti-
ful blue colour. It is the lignum nephriticum, or nephri-
tic wood, of the dispensatories; and is brought over in
large, compad, ponderous pieces, without knots, of
a whithil or pale yellow colour on the outside, and dark
coloured or reddith within; the bark is usually rejec-
ted. This wood imparts to water or redifinfed spirit a
dark tincture; appearing, when placed between the
light and the light, of a grayish blue. In other situ-
ations blue: pieces of another wood are sometimes mixed
with it, which give only a yellow colour to water.

The nephritic wood has scarce any smell, and very lit-
tle taste. It stands recommended in difficulty of urine,
nephritic complaints, and all disorders of the kidneys
and urinary passages; and is said to have this peculiar
advant-
advantage, that it does not, like the warmer diuretics, heat or offend the parts. Practitioners, however, have not found these virtues warranted by experience.

GUILD, (from the Saxon gildan, to "pay"), signifies a fraternity or company, because every one was guildare, i.e. to pay something towards the charge and support of the company. As to the original of these guilds or companies: It was a law among the Saxons, that every Freeman of fourteen years of age should find sureties to keep the peace, or be committed: upon which certain neighbours, and should find sureties to keep the peace, or be committed. Saxons, that every freeman of families, enter into an association, for such meetings. But as to the precise time when these guilds had their origin in England, there is nothing of certainty to be found; since they were in use long before any formal licence was granted to them for such meetings. It seems to have been about the close of the eleventh century, says Anderson, in his History of Commerce, vol. i. p. 70, that merchant-guilds, or fraternities, which were afterwards styled corporations, came first into general use in many parts of Europe. Mr Madox, in his Firma Burgi, chap. i. § 9. thinks, they were hardly known to our Saxon progenitors, and that they might be probably brought into England by the Normans; although they do not seem to have been very numerous in those days. The French and Normans might probably borrow them from the free cities of Italy, where trade and manufactures were much earlier propagated, and where possibly such communities were first in use. These guilds are now companies joined together, with laws and orders made by themselves, by the licence of the prince.

GUILD, in the royal boroughs of Scotland, is still used for a company of merchents, who are freemen of the borough. See Borough.

Every royal borough has a dean of guild, who is the next magistrate below the bailiff. He judges of the controversies among men concerning trade; disputes between inhabitants touching buildings, lights, water-courses, and nuisances; calls courts, at which his brethren of the guild are bound to attend; manages the common stock of the guild; and amercies and collects fines.

GUILD, Guild, or Gold, is also used among ancient writers, for a copperation or mult, for a fault committed.

GUILD-HALL, or Guild-Hall, the great court of judicature for the city of London. In it are kept the mayor's court, the sheriff's court, the court of huffings, court of conscience, court of common-council, chamberlain's court, &c. Here also the judges sit upon nisi prius, &c.

GUILDFORD, or Guildford, a borough-town of Surrey, situated on the river Wye, thirty one miles south-west of London. Near it are the ruinous walls of an old castle, this having been in the Saxon times a royal villa, where many of the kings used to pass the festivals. Here is a corporation consisting of a mayor, recorder, aldermen, &c. which sent members to parliament ever since parliament had a being. The great road from London to Chichester and Portsmouth lies through this town, which has always been famous for good inns, the cleanliness of linen, and other excellent accommodations; and the affizes are often held here. Its manufacture formerly was cloth, of which there are still some small remains. Here is a school founded by king Edward VI. also an almshouse endowed with lands worth 300l. a year, of which 100l. is employed in setting the poor at work, and the other 200l. for the maintenance of a master, 12 brethren, and 8 sisters, who are to have 25. 6d. a-week. There are, besides, two charity schools for 30 boys and 20 girls. There were three churches in this town, but one of them fell down in April 1740. There is a fine circular course for horse-matches, which begins when the Newmarket races are ended. King William III. founded a plate of 100 guineas to be run for here every May, and used to honour the race with his presence, as did once king George I. The river Wey is made navigable to the town, and by it a great quantity of timber is carried to London, not only from this neighbourhood, but from Sussex and Hampshire woods, above 30 miles off, from whence it is brought hither in the summer by land carriage. This navigation is also of great support to Farnham market, corn bought there being brought to the mills on this river within seven miles distance, and, after being ground and dressed, is sent down in barges to London. The road from thence to Farnham is very remarkable, for it runs along upon the ridge of a high chalky hill, called St Catherine's, no wider than the road itself, from whence there is an extensive prospect, viz. to the N. and N. W. over Bagshot-Heath, and the other way into Sussex, and almost to the South Down. The town sends two members to parliament, and gives title of earl to the North family.

GUILEMET, in ornithology. See COLUMBUS.

GUILLIM, (John), of Welsh extraction, was born in Herefordshire, about the year 1505. Having completed his education at Brazen-nose college, Oxford, he became a member of the college of arms in London; and was made rouge croix pursuivant, in which post he died in 1583. He published, in 1679, a celebrated work, intitled the Display of Heraldry, folio, which has gone through many editions. To the fifth, which came out in 1679, was added A treatise of honor civil and military, by captain John Logan.

GUINEA, a large tract of country lying on the west side of the continent of Africa, extends along the coast three or four thousand miles, beginning at the river Senegal, situated about the 17th degree of north latitude (being the nearest part of Guinea as well to Europe as to North-America). From that river to the river Gambia, and in a southerly course to Cape Sierra Leone, is comprehended a coast of about 700 miles; being the same tract for which Queen Elizabeth granted charters to the first traders to that coast. From Sierra Leone, the land of Guinea takes a turn to the eastward, extending that course about 1500 miles, including those several divisions known by the names of the Grain Coast, the Ivory Coast, the Gold Coast, and the Slave...
Slave Coast, with the large kingdom of Benin. From thence the land runs southward along the coast about 1200 miles, which contains the kingdoms of Congo and Angola; where the trade for slaves ends. From which to the southermost cape of Africa, called the Cape of Good Hope, the country is settled by Caffres and Hottentots, who have never been concerned in the making or selling slaves.

1. Of the parts which are above mentioned, the first is that situated on the great river Senegal, which is said to be navigable more than 1400 miles, and is by travellers described to be very agreeable and fruitful. Mr Brue, principal factor for the French African company, who lived 16 years in that country, after describing its fruitfulnes and plenty Ilear the company, who lived 16 years in that country, after great and small cattle, and poultry numerous: the which lies about the Slave river Gambia, the voyage he made up the river Gambia, or in other parts of Africa, is navigable about 600 miles, which contains the kingdoms of Guinea.

* Allley's Collett. p. 38, 39.

The same author, in the account of a voyage he made up the river Gambia, the mouth of which lies about 300 miles south of the Senegal, and is navigable about 600 miles up the country, says, "that he was surprized to see the land so well cultivated; scarce a spot lay unimproved; the low lands divided by small canals were all fowed with rice, &c. the higher ground planted with millet, Indian corn, and confort of different sorts; their beef excellent; poultry plenty and very cheap, as well as all other commodities of life." Mr Moor, who was sent from England about the year 1725, in the service of the African company, and refided at James Fort on the river Gambia, or in other factories on that river, about five years, confirms the above account of the fruitfulness of the country. Captain Smith, who was sent in the year 1726 by the African company to survey their settlements throughout the whole coast of Guinea, says, "the country about the Gambia is pleasant and fruitful; provisions of all kinds being plenty and exceeding cheap. The country on and between the two aforementioned rivers is large and extensive, inhabited principally by those three negro nations known by the name of Jalois, Fulis, and Mandingos. The Jaloos possess the middle of the country. The Fulis principal settlement is on both sides of the Senegal; great numbers of these people are also mixed with the Mandingos, which last are mostly settled on both sides the Gambia. The government of the Jaloos is represented as under a better regulation than can be expected from the common opinion we entertain of the negroes. We are told in Allley's Collection, "that the king has under him several ministers of state, who assist him in the government of the state. The grand Jerofo is the chief justice through all the king's dominions, and goes in circuit from time to time to hear complaints and determine controversies. The king's treasurer exercises the same employment, and has under him alkairs, who are governors of towns or villages. That the kendi, or viceroy, goes the circuit with the chief justice, both to hear causes and inspect into the behaviour of the alkairs, or chief magistrate of every village in their several districts." Valconelas, an author mentioned in the Collection, says, "the ancientest are preferred to be the prince's counsellors, who keep always about his person; and the men of most judgment and experience are the judges."

The Fulis are settled on both sides of the river Senegal: their country which is very fruitful and populous, extends near 400 miles from east to west. They are generally of a deep tanney complexion, appearing to bear some affinity to the Moors, whofhe are known to be made slaves. They have chiefs of their own, who rule with much moderation. Few of them will drink brandy, or any thing stronger than water and sugar, being strict Mahometans. Their form of government goes on easy, because the people are of a good quiet disposition, and do well instructed in what is right, that a man who does ill is the abomination of all, and none will support him against the chief. In these countries the natives are not covetous of land, desiring no more than what they use; and as they do not plough with horses and cattle, they can live but very little; therefore the kings are willing to give the Fulis leave to live in their country and cultivate their lands. If any of their people are known to be made slaves, all the Fulis will join to redeem them; they also support the old, the blind, and lame, amongst themselves, and as far as their abilities go, they supply the necessaries of the Mandingos, great numbers of whom they have maintained in famine." The author, from his own observations, says, "They were rarely angry, and that he never heard them abuse one another."

The Mandingos are said by Mr Brue before mentioned, "to be the most numerous nation on the Gambia, besides which, numbers of them are dispersed over all these countries, by the most rigid Mahometans amongst the negroes, they drink neither wine nor brandy, and are palter than the other negroes. The chief of the trade goes through their hands. Many are industrious and laborsious, keeping their ground well cultivated, and breeding a good flock of cattle. Every town has an alkair, or governor, who has great power; for most of them having two common fields of clear ground, one for corn, and the other for rice, the alkair appoints the labour of all the people. The men work the corn ground, and the women and girls the rice ground; and as they all equally labour, so he equally divides the corn amongst them; and in case any are in want, the others supply them. This alkair decides all quarrels, and has the first voice in all conferences in town affairs." Some of these Mandingos, who are settled at Galem, far up the river Senegal, can read and write Arabic tolerably; and are a good hospitable people, who carry on a trade with the inland nations. "They are extremely populous in those parts, their women being fruitful, and they not suffering any person amongst them, but such as are guilty of crimes, to be made slaves." We are told from Jobson, "that the Mahometan Negroes say their prayers thrice a day. Each village has
has a priest who calls them to their duty. It is surprising (says the author), as well as commendable, to see the modesty, attention, and reverence they observe during their worship. He asked some of their priests the purport of their prayers and ceremonies; they answered always was, "that they adored God by profaning themselves before him: that by humbling themselves, they acknowledged their own insignificance, and farther intreated him to forgive their faults, and to grant them all good and necessary things, as well as deliverance from evil." Joubon takes notice of several good qualities in these negro priests, particularly their great forbearance. They gain their livelihood by keeping school for the education of the children. The boys are taught to read and write. They not only teach school, but rove about the country, teaching and instructing, for which the whole country is open to them; and they have a free course through all places, though the kings may be at war with one another.

The three fore-mentioned nations practise several trades, as smiths, potter, tailors, and weavers. Their smiths particularly work neatly in gold and silver, and make knives, hatchets, reaping hooks, spades, and flares to cut iron, &c. Their potters make neat tobacco pipes, and pots to boil their food. Some authors say that weaving is their principal trade: this is done by the women and girls, who spin and weave very fine cotton cloth, which they dye blue or black. Moore says, the Jalofs particularly make great quantities of the cotton cloth; their pieces are generally 27 yards long, and about nine inches broad, their looms being very narrow; these few neatly together, so as to supply the use of broad cloth.

It was in these parts of Guinea that Dr. Adanfon, correspondent of the Royal Academy of Sciences at Paris, was employed from the year 1759 to the year 1753, wholly in making natural and philosophical observations on the country about the rivers Senegal and Gambia. Speaking of the great heats in Senegal, he says, "it is to them that they are partly indebted for the fertility of their lands; which is so great, that, with little labour and care, there is no fruit nor grain but grows in great plenty."

"Of the soil on the Gambia, he says, "it is rich and deep, and amazingly fertile; it produces spontaneously, and almost without cultivation, all the necessaries of life, grain, fruit, herbs, and roots. Every thing matures to perfection, and is excellent in its kind." One thing which always surprized him, was the prodigious rapidity with which the sap of trees repairs any loss they may happen to sustain in that country; "And I was never (says he) more astonished, than when landing four days after the locusts had devoured all the fruits and leaves, and even the buds of the trees, to find the trees covered with new leaves, and they did not seem to me to have suffered much." "It was then (says the author) the first sensation; you might see them in shoals approaching towards land. Some of those shoals were 50 fathoms square, and the fish crowded together in such a manner, as to roll upon one another, without being able to swim. As soon as the negroes perceive them coming towards land, they jump into the water with a basket in one hand, and swim with the other. They need only to plunge and to lift up their basket, and they are sure to return loaded with fish." Speaking of the appearance of the country, and of the disposition of the people, he says, "which way forever I turned mine eyes on this pleasant spot, I beheld a perfect image of pure nature: an agreeable solitude, bounded on every side by charming landscapes; the rural situation of cottages in the midst of trees; the ease and indulgence of the negroes, reclined under the shade of their spreading foliage, the simplicity of their dress and manners; the whole revived in my mind the idea of our first parents, and I seemed to contemplate the world in its primitive state. They are, generally speaking, very good-natured, sociable, and obliging. I was not a little pleased with this my first reception; it convinced me, that there ought to be a considerable abatement made in the accounts I had read and heard every where of the savage character of the Africans. I observed, both in the negroes and Moors great humanity and sociableness, which gave me strong hopes that I should be very happy amongst them, and meet with the successes I desired in my inquiries after the curiosities of the country." He was agreeably amused with the conversation of the negroes, their fables, dialogues, and witty stories with which they entertain each other alternately, according to their custom. Speaking of the remarks which the natives made to him with relation to the stars and planets, he says, "it is amazing, that such a rude and illiterate people should reason so pertinently in regard to those heavenly bodies; there is no manner of doubt, but that with proper instruments, and a good will, they would become excellent astronomers."

2. That part of Guinea known by the name of the Grain and Ivory Coast, extends about 300 miles. The soil is said to be in general fertile, producing abundance of rice and roots; indigo and cotton thrive without cultivation, and tobacco would be excellent if carefully manufactured; they have fift in plenty; their flocks greatly increase; and their trees are loaded with fruit. They make a cotton cloth, which fells well on the coast. In a word, the country is rich, and the commerce advantageous, and might be greatly augmented by such as would cultivate the friendship of the natives. These are represented by some writers as a rude, treacherous people: whilst several other authors give them a very different character, describing them as sensible, courteous, and the fairest traders on the coast of Guinea. In the Collection, they are said to be averse to drinking to excess, and such..."
of the negroes, or are fomented by the Europeans, as those brought from the back country. Here we find the natives more reconciled to the European manners and trade; but, at the same time, much more inured to war, and ready to affult the European traders in procuring loadings for the great number of vessels which come yearly on those coasts for slaves.

This part of Guinea is agreed by historians to be in general, extraordinary fruitful and agreeable; producing (according to the difference of the soil) vast quantities of rice and other grain, plenty of fruit and roots, palm wine and oil, and fish in great abundance, with much tame and wild cattle. Bofman, principal factor for the Dutch at D'Elmina, "speaking of the country of Axim, which is situated towards the beginning of the Gold Coast," says, "The Negro inhabitants are generally very rich, driving a great trade with the Europeans for gold: That they are industriously employed either in trade, fishing, or agriculture; but chiefly in the culture of rice, which grows here in an incredible abundance, and is transported hence all over the Gold Coast: the inhabitants, in lieu, returning full fraught with miller, jams, potatoes, and palm oil." The same author, speaking of the country of Ante, says, "This country, as well as the Gold Coast, abounds with hills, enriched with extraordinary high and beautiful trees; its valleys, between the hills, are wide and extensive, producing in great abundance very good rice, miller, jams, potatoes, and other fruits, all good in their kind." He adds, "In short, it is a land that yields its manurers as plentiful a crop as they can wish, with great quantities of palm wine and oil, besides being well furnished with all sorts of tame as well as wild beasts; but that the last fatal wars had reduced it to a miserable condition, and stripped it of most of its inhabitants:"

The adjoining country of Petu, he says, "was formerly so powerful and populous, that it struck terror into all the neighbouring nations; but it is at present so drained by continual wars, that it is entirely ruined; there does not remain inhabitants sufficient to till the country, though it is so fruitful and pleasant, though the country of Ante just before described; frequently (says our author), when walking through it before the last war, I have seen it abound with fine well built and populous towns, agreeably enriched with vast quantities of corn, cattle, palm wine, and oil. The inhabitants all applying themselves without any distinction to agriculture; some grow corn, others prepare soil, and draw wine from palm trees, with both which it is plentifully stored."

Smith gives much the same account of the before-mentioned parts of the Gold Coast; and adds, "the country about D'Elmina and Cape Coast, is much the same for beauty and goodnesse, but more populous; and the nearer we come towards the Slave Coast, the more delightful and rich all the countries are; producing all sorts of trees, fruits, roots, and herbs, that grow within the torrid zone." Barbot also remarks, with respect to the countries of Ante and Adom, "That the soil is very good and fruitful in corn and other produce; which it affords in such plenty, that besides what serves for their own use, they always export great quantities for sale: they have a competent number of cattle, both tame and wild, and the rivers abundantly flowed.
The inland people are said to live in great union and friendship, being generally well tempered, civil, and tractable; not apt to shed human blood, except when much provoked; and ready to afill one another. In the Collection it is said, "That the fishing business is esteemed on the Gold Coast next to trading; that those who profess it are more numerous than those of other employments. That the greatest number of these are at Kommando, Mina, and Korman-tin; from each of which places, there go out every morning (Tuesday excepted, which is the Fifth day, or day of rest) five, fix, and sometimes eight hundred canoes, from 13 to 14 feet long, which spread themselves two leagues at sea, each fisherman carrying in his cabin a sword, with bread, water, and a little fire on a large flue to roast fish. Thus they labour till noon, when the sea breeze blowing fresby, they return on the shore, generally laden with fish; a quantity of which the inland inhabitants come down to buy, which they fell again at the country markets."

Smith says, "The country about Acra, where the English and Dutch have each a strong fort, is very delightful, and the natives courteous and civil to strangers." He adds, "That this place seldom fails of an extraordinary good trade from the inland country, especially for slaves, whereof several are supposed to come from very remote parts, because it is not uncommon to find a Malayian or two amongst a parcel of other slaves: The Malayans are generally natives of Malacca, in the East-Indies, situated several thousand miles from the Gold Coast." They differ very much from Guinea negroes, being of a tawny complexion, with long black hair.

Most parts of the slave coasts are represented as equally fertile and pleasant with the gold coast. The kingdom of Whidah has been particularly noted by travellers. Smith and Bofman agree, "That it is one of the most delightful countries in the world. The great number and variety of tall, beautiful, and shady trees, which seem planted in groves; the verdant fields everywhere cultivated, and no other division than by those groves, and in some places a small foot-path, together with a great number of villages, contribute to afford the most delightful prospect; the whole country being a fine, easy, and almost imperceptible ascent for the space of 40 or 50 miles from the sea. That the farther you go from the sea, the more beautiful and populous the country appears. That the natives were kind and obliging, and of industrious, that no place which was thought fertile could escape being planted, even within the hedges which inclose their villages. And that the next day after they had reaped, they fowed again."

Snelgraves also says, "The country appears full of towns and villages; and being a rich soil, and well cultivated, looks like an entire garden." In the Collection, the husbandry of the negroes is described to be carried on with great regularity. "The rainy season approaching, they go into the fields and woods, to fix on a proper place for sowing; and as here is no property in ground, the king's licence being obtained, the people go out in troops, and first clear the ground from bushes and weeds, which they burn. The field thus cleared, they dig it up a foot deep, and so let it remain for eight or ten days, till the rest of their neighbours have disposed their ground in the same manner. They then confult about sowing, and for that end assemble at the king's court the next day. The king's grain must be sown first. They then go again to the field, and give the ground a second digging, and sow their seed. Whilst "the king or governor's land is sowing, he sends out wine and flesh, ready dressed, enough to serve the labourers. Afterwards, they in like manner sow the ground allotted for their neighbours as diligently as that of the king's, by whom they are also fed; and to continue to work in a body for the public benefit till every man's ground is tilled and sowed. None but the kings, and a few great men, are exempted from this labour. Their grain soon sprouts out of the ground. When it is about a man's height, and begins to ear, they raise a wooden house in the centre of the field, covered with straw, in which they let their children to watch their corn, and fright away the birds."

Bofman speaks in commendation of the civility, kindness, and great industry of the natives of Whidah. This is confirmed by Smith, who says, "The natives here seem to be the most gentleman-like negroes in Guinea, abounding with good manners and ceremony to each other. The inferior pay the utmost deference and respect to the superior, as do wives to their husbands, and children to their parents. All here are naturally industrious, and find constant employment; the men in agriculture, and the women in spinning and weaving cotton. The men, whose chief talent lies in husbandry, are unacquainted with arms; otherwise, being a numerous people, they could have made a better defence against the king of Dahome, who subdued them without much trouble. According to the Collection, there are, throughout the gold coast, regular markets in all villages, furnished with provisions and merchandise, held every day in the week except Tuesday, whence they supply not only the inhabitants, but the European ships. The negro women are very expert in buying and selling, and extremely industrious; for they will repair daily to market from a considerable distance, loaded like pack-horses, with a child perhaps at their back, and a heavy burden on their heads. After selling their wares, they buy fish and other necessaries, and return home loaded as they came. There is a market held at Sabi every fourth day, also a weekly one in the province of Apolagus, which is so referred to, that there are usually 5 or 6000 merchants. Their markets are so well regulated and governed, that seldom any disorder happens; each species of merchandise and merchants have a separate place allotted them by themselves. The buyers may haggle as much as they will, but it must be without noise or fraud. To keep order, the king appoints a judge; who, with four officers well armed, inspect the markets, hears all complaints, and in a summary way decides all differences; he has power
power to seize, and fell as slaves, all who are cach-
ed in stealing or disturbing the peace. In these mar-
kets are to be found men, women, children, oxen, sheep,
goats, and fowls of all kinds; European cloths, linen
and woollen; printed calicoes, silk, grocery ware,
china, gold-dust, iron in bars, &c. In a word, most
fords of European goods, as well as the produce of
Africa and Asia. They have other markets, refem-
bring our fairs once or twice a year, to which all the
country repair; for they take care to order the day so
in different governments as not to interfere with each
other."

With respect to government, Smith says, "that the
gold coast and slave coast are divided into dif-
ferent districts, some of which are governed by their
chiefs or kings: the others, being more of the na-
ture of a commonwealth, are governed by some
of the principal men, called Caboceros; who, Bofman
says; are properly denominated civil fathers, whose pro-
vince is to take care of the welfare of the city or vil-
lage, and to appease tumults." But this order of go-

government has been much broken since the coming
of the Europeans. Both Bofman and Barbot mention
murder and adultery to be severely punished on the
coast, frequently by death; and robbery by a fine pro-
portional to the goods stolen.

The income of some of the kings is large. Bofman
says, "that the king of Whidah's revenues and duties
on things bought and sold are considerable; he having
the title of all things sold in the market, or imported
into the country." Both the abovementioned authors
say, the tax on slaves shipped off in this king's domi-
nions, in some years, amounts to near L. 20,000.

Bofman tells us, the Whidah negroes have a faint
idea of a true God, ascribing to him the attributes
of an almighty power and omnipresence: but God, they
say, is too high to condescend to think of mankind;
wherefore he commits the government of the world to
those inferior duties which they worship." Some au-
thors say, the wife of these negroes are sensible of
their mistake in this opinion; but dare not forsake
their own religion, for fear of the populace rising and
killing them. This is confirmed by Smith, who says,
"that all the natives of this coast believed there is one
true God, the author of them and all things; that
they have some apprehension of a future state; and
that almost every village has a grove, or public place
of worship, to which the principal inhabitants, on a
day, resort to make their offerings."

In the Collection it is remarked as an excellency in
the Guinea government, "that however poor they
may be in general, yet there are no beggars to be found
amongst them; which is owing to the care of their
chief men, whose province it is to take care of the wel-
fare of the city or village, it being part of their of-

cine to see that such people may earn their bread by
their labour; some are bet to blow the smith's be-
lows, others to prep palm oil, or grind colours for
their mats, and fell provision in the markets. The
young men are lifted to serve as soldiers, so that they
suffer no common beggar." Bofman ascribes a fur-
ther reason for this good order*, viz. "that when a
negro finds he cannot Dobst, he binds himself for
a certain term of money, and the master to whom he
is bound is obliged to find him necessaries; that the ma-
ster sets him a fort of task, which is not in the least
flavish, being chiefly to defend his master on oc-
casions, or in fowing time to work as much as himself
pleases."

Adjoining to the kingdom of Whidah are several
small governments, as Coto, great and small Popo,
Adrard, &c. all situated on the slave coast, where the
chief trade for slaves is carried on. These are go-
verned by their respective kings, and follow much the same
customs with those of Whidah, except that their prin-
cipal living is on plunder and the slave trade.

4. Next adjoining to the Slave Coast, is the king-
dom of Benin, which, though it extends but about
170 miles on the sea, yet spreads so far inland as to be
effected the most potent kingdom in Guinea. By
accounts, the oil and produce appear to be in a great
measure like those before described, and the natives
are represented as a reasonable good-natured people.
Arts says*, "they are a sincere, inoffensive people, and do
not injustice either to one another or to tran-
gers." Smith confirms this account, and says, "that p. 388.
the inhabitants are generally very good-natured, and
exceeding courteous and civil. When the Europeans
make them presents, which in their coming thither to
trade they always do, they endeavour to return them
doubly." Bofman tells us, "that his countrymen the
Dutch, who were often obliged to trust them till
they returned the next year, were sure to be honestly
paid their whole debts."

There is in Benin a considerable order in govern-
ment; theft, murder, and adultery, being severely
punished. Smith says, "their towns are governed
by officers appointed by the king, who have power
to decide in civil cases, and to raise the public taxes;
but in criminal cases, they must send to the king's
court, which is held at the town of Oedo or Great
Benin. This town, which covers a large extent of
ground, is about 60 miles from the sea." Barbot
tells us, "that it contains 30 streets, 20 fathom wide,
and almost two miles long, commonly extending in a
straight line from one gate to another; that the gates are
guarded by soldiers; that in these streets markets are
held every day, for cattle, ivory, cotton, and many
forts of European goods. This large town is divided into
several wards or districts, each governed by its respec-
tive king of a street, as they call them, to
nerv the inhabitants, and to keep good order. The inhabi-

tants are very civil and good natured, conde[n
ging to what the Europeans require of them in a civil way." The
same author confirms what has been said by others of
their justice in the payment of their debts; and adds,
"that they, above all other Guineans, are very ho-
net and just in their dealings; and they have such an
aversion for theft, that by the law of the country it is
punished with death."

We are told by the same author, "that the king of Benin is able upon occasion
to maintain an army of 100,000 men; but that, for
the most part, he does not keep 30,000. See the ar-
cicle BENIN.

5. The last division of Guinea from which slaves
are imported, are the kingdoms of Congo and Anglo-
a: these lie to the south of Benin, extending with
the intermediate land about 1200 miles on the coast.
Great numbers of the natives of both these kingdoms
profess the Christian religion, which was long since

* Bofman, p. 119.

* Smith, P. 193.
of the climate, a rice, that it hardly bears any price, with fruits, roots, and palm oil in plenty. The natives are generally a quiet people, who discover a good understanding, and behave in a friendly manner to strangers, being of a mild conversation, affable, and easily overcome with reason. In the government of Congo, the king appoints a judge in every particular division, to hear and determine disputes and civil causes; the judges imprison and release, or impose fines, according to the rule of custom, but in weighty matters, every one may appeal to the king, before whom all criminal causes are brought, in which he gives sentence; but seldom condemneth to death. The town of Leango stands in the midst of four lordships, which abound in corn, fruits, &c. Here they make great quantities of cloth of divers kinds, very fine and curious; the inhabitants are seldom idle; they even make needle-work caps as they walk in the streets. The slave trade is here principally managed by the Portuguese, who carry it far up into the inland countries. They are said to send off from these parts 15,000 slaves each year. At Angola, about the tenth degree of south latitude, ends the trade for slaves.

As all these countries lie between the tropics, the air is excessively hot, especially from the beginning of September to the end of March; which, with the coolness of the nights, the frequent thick, flinking, sulphurous mists, and the periodical rains, when the flat country is overflowed, makes it very unhealthy, especially to Europeans. The natives, however, are little affected with the unhealthy air. According to Barbot, they keep much within doors in tempestuous times; and when exposed to the weather, their skins being supplied and pores closed by daily anointing with palm oil, the weather can make little impression on them. They generally, therefore, enjoy a good state of health, and are able to procure to themselves a comfortable subsistence, with much less care and toil than is necessary in our more northern climate. They lead a life of ease; they are not subject to the cold or the heat, for the climate is of such a nature that they can cultivate the land, and the periodical rains, whereby the land is regularly moistened, and being in many places covered by rivers, which run from north to south, and fall into the Atlantic, render the country extremely fertile, and being in many places improved by culture, abound with grain and fruits, which grow naturally over their huts, and which they afford an agreeable shade, as they are abundantly flocked with good clean vessels for most household uses, being of different sizes, from half a pint to several gallons.

The distempers the Europeans are subject to on this coast, are fevers, fluxes, and colics, which are occasioned by indifferent water and bad air; their settlements lying near the coast, where the fogs and fumes arising from the ooze and salt marshes, and the flinking fih the natives dry on the beach, corrupt the air, and render it fatal to the foreigners. The most temperate men find it difficult to preserve their health; but a great many suffer their death by their intemperance, or negligence, exposing themselves to the cold air in the evening, after a very hot day. This sudden change, from one extreme to the other, has often very bad effects in hot climates.

Of mountains in Guinea, the most remarkable are those of Sierra Leone. The principal caps are those of Cape Blanco, Cape Verd, Cape Leon, Cape St Ann's, Cape Palmas, and Cape Three-Poons, Cape Formosa, Cape Monte, Cape St John, Cape Lopas, Cape Lede, and Cape Negro. The chief bays are the Cyprian or Cintra Bay, and the Bite of Guinea. Of the rivers, the most considerable are those of Coanzo and Ambriti, the Zanga, the Lunde, the Cameron, the Formosa, the Volta, the Sierra Leone, and the Sherbro. All these run from east to west (except the Volta, which runs from north to south), and fall into the Atlantic.

Besides gold, ivory, and slaves, Guinea affords indigo, wax, gum-fenega, gum-tragascanth, and a variety of other gums and drugs.

The most ancient account we have of the country is that of the negroes, particularly that part situated on the Guinea coast between the two great rivers of Senegal and Gambia, which are the third and seventh in length and the fourth and seventh in the extent of their mouths. These are the rivers of the southern coast of Africa, which have been distinguished by the name of Senegal and Gambia, and which are the principal rivers of that country. They rise in the interior of the continent, and flow into the Atlantic Ocean. The Senegal rises in the interior of the country, and flows into the Atlantic Ocean, where it discharges its waters. The Gambia rises in the interior of the country, and flows into the Atlantic Ocean, where it discharges its waters. The Gambia is a much larger river than the Senegal, and is navigable for a greater distance. The coast of Guinea is also distinguished by the name of the Gambia, which is the name of the river that crosses it.

The history of the negroes, particularly that part situated on the Guinea coast between the two great rivers of Senegal and Gambia, is written by John Leo, a Moor, born at Oronada in Spain, before the Moors were totally expelled from that kingdom. He resided in Africa; but being on a voyage from Tripoli to Tunis, was taken by some Italian corsairs, who finding him possessed of several Arabian books, besides his own manuscripts, apprehended him to be a man of learning, and as such presented him to Pope Leo X. This pope encouraging him, he embraced the Romish religion, and his description of Africa was published in Italian. From these writings we gather, that after the Mahometan religion had extended to the kingdom of Morocco, some of the promoters of it crossing the sandy deserts of Numidia, which separate that country from Guinea, found it inhabited by men, who, though under no regular government, and destitute of that knowledge which the Arabs were so well skilled in, lived in content and peace. The first author particularly remarks, 'that they never made war, or travelled abroad, but employed themselves in tending their herds, or laboured in the ground.' J. Leo says, p. 65. 'That they lived in common, having no property in land, no tyrant nor superior lord, but supported themselves in an equal state, upon the natural produce of the country, which afforded plenty of roots, game, and honey.'
That ambition or avarice never drove them into foreign countries to subdue or cheat their neighbours. Thus they lived without toil or superfluities. The ancient inhabitants of Morocco, who wore coats of mail, and used swords and spears headed with iron, coming amongst these harmless and naked people, soon brought them under subjection, and divided that part of Guinea which lies on the rivers Senegal and Gambia into 15 parts; those were the 15 kingdoms of the negroes, over which the Moors presided, and the common people were negroes. These Moors took the negroes, the Mahometan religion, and arts of life; particularly the use of iron, before unknown to them. About the 14th century, a native negro, called Heli Ischia, expelled the Moors conquerors; but though the negroes threw off the yoke of a foreign nation, they only changed a Libyan for a negro master. Heli Ischia himself becoming king, led the negroes on to foreign wars, and established himself in power over a very large extent of country. Since Leo's time, the Europeans have had very little knowledge of those parts of Africa, nor do they know what became of this great empire. It is highly probable that late boke into pieces, and the negroes again refumed many of their ancient customs; for in the account published by Moore, in his travels on the river Gambia, we find a mixture of the Moorish and Mahometan customs, joined with the original simplicity of the negroes. It appears by accounts of ancient voyages, collected by Hackluit, Purchas and others, that it was about 50 years before the discovery of America, that the Portuguese attempted to sail round Cape Bojador, which lies between their country and Guinea: this, after divers repulses occasioned by the violent currents, they effected; when landing on the western coasts of Africa, they soon began to make incursions into the country, and to seize and carry off the native inhabitants. As early as the year 1434, Alonzo Gonzales, the first who is recorded to have met with the natives, being on that coast, pursued and attacked a number of them, when some were wounded, as was also one of the Portuguese; which the author records as the first blood spilt by Christians in those parts. Six years after, the fame Gonzales again attacked the natives, and took 12 prisoners, with whom he returned to his vessels: he afterwards put a woman on shore, in order to induce the natives to redeem the prisoners; but the next day 150 of the inhabitants appeared on horses and camels, provoking the Portuguese to land; which they not daring to venture, the natives discharged a volley of stones at them, and went off. After this, the Portuguese still continued to send vessels on the coast of Africa: particularly we read of their falling on a village, whence the inhabitants fled, and, being pursued, 25 were taken: "He that ran belt (says the author), taking the most. In their way home they killed some of the natives, and took 55 more prisoners. Afterwards Dini lasanes Diagrama, with two other vessels, landed on the island Arguin, where they took 54 moors; then running along the coast 80 leagues farther, they at several times took 30 slaves; but here seven of the Portuguese were killed. Then being joined by several other vessels, Dini lasanes proposed to destroy the island, to revenge the loss of the seven Portuguese; of which the Moors being apprised, fied, so that no more than 12 were found, whereof only four could be taken, the rest being killed, as also one of the Portuguese. Many more captures of this kind on the coast of Barbary and Guinea are recorded to have been made in those early times by the Portuguese; who, in the year 1481, erected their first fort at D'Elmina on that coast, from whence they soon opened a trade for slaves with the inland parts of Guinea.

From the foregoing accounts, it is undoubted, that the practice of making slaves of the negroes owes its origin to the early incursions of the Portuguese on the coast of Africa, solely from an inordinate desire of gain. This is clearly evidenced from their own historians, particularly Cada Mofo, about the year 1455, who writes, "That before the trade was settled for purchasing slaves from the Moors at Arguin, sometimes vol. i. four, and sometimes more Portuguese vessels, were used p. 516. to come to that gulf, well armed; and, landing by night, would surprize some fisherman's villages: that they even entered into the country, and carried off Arabs of both sexes, whom they sold in Portugal." And also, "That the Portuguese and Spaniards, settlement four of the Canarian Islands, and go to the other island by night, and fell some of the natives of both sexes, whom they sold to be sold in Spain." After the settlement of America, those devastations, and the captivating the miserable Africans, greatly increased.

Anderfon, in his History of Trade and Commerce, p. 336, speaking of what passed in the year 1508, writes, "That the Spaniards had by this time found that the miserable Indian natives, whom they had made to work in their mines and fields, were not so obedient and proper for those purposes as negroes brought from Africa: wherefore they, about that time, began to import negroes for that end into Hifpaniola, from the Portuguese settlements on the Guinea coasts; and also afterwards for their finger-works." It was about the year 1551, towards the latter end of the reign of Edward VI. when some London merchants sent out the first English ship on a trading voyage to the coast of Guinea. This was soon followed by several others to the same parts; but the English not having then any plantations in the West-Indies, and consequently no occasion for negroes, such ships traded only for gold, elephants teeth, and Guinea pepper. This trade was carried on at the hazard of losing their ships and cargoes, if they had fallen into the hands of the Portuguese, who claimed an exclusive right of trade, on account of the several settlements they had made there. In 1554, we find captain Thomas Windham trading along the coast with 140 men, in three ships, and falling as far as Benin, which lies about 3000 miles down the coast, to take in a load of pepper. Next year John Lock traded along the coast of Guinea as far as D'Elmina, when he brought away considerable quantities of gold and ivory. He speaks well of the natives, and says, "That whoever will deal with them must behave civilly, for they will not traffic if ill used." In 1555, William Towerfon traded in a peaceable manner with the natives, who made complaint to him of the Portuguese, who were then settled in their castle at D'Elmina; saying, "They were bad men; who made them slaves if they could take them, putting iron on their legs."
This had example of the Portuguese was soon followed by some evil disposed Englishmen: for the same captain Towerow relates, "That in the course of his voyage, he perceived the natives near St. Elaine unwillling to come to him, and that he was at last attacked by them; which he understood was done in revenge for the wrong done them the year before by one captain Gainew, who had taken away the negro captain's son and three others, with their gold, &c. This caused them to join the Portuguese, notwithstanding their hatred of them, against the English." The next year captain Towerow brought these men back again; whereupon the negroes showed him much kindness. Quickly after this, another instance of the same kind occurred in the case of Captain George Fennor, who being on the coast with three vessels, was also attacked by the negroes, who wounded several of his people, and violently carried three of his men to their town. The captain sent a messenger, offering anything they desired for the ransom of his men: but they refused to deliver them; letting him know, "That three weeks before an English ship, which came in the road, had carried off three of their people; and that till they were brought again, they would not restore his men, even though they should give their three ships to relieve them." It was probably the evil conduct of the same, and some other Englishmen which was the occasion of what is mentioned in Hill's Naval History, viz. "That when captain Hawkins returned from his first voyage to Africa, queen Elizabeth sent for him, when she expressed her concern, left any of the African negroes should be carried off without their free consent; which declared would be detestable, and would call down the vengeance of heaven upon the undertakers." Hawkins made great promises, which nevertheless he did not perform; for his next voyage to the coast appears to have been principally calculated to procure negro slaves, in order to sell them to the Spaniards in the West Indies; which occasioned the same author to use these remarkable words: "Here began the horrid practice of forcing the Africans into slavery: an injustice and barbarity, which, so far as there is vengeance in heaven for the worst of crimes, will some time be the destruction of all who act or who encourage it." This captain Hawkins, afterwards Sir John Hawkins, seems to have been the first Englishman who gave public countenance to this wicked traffic; for Anderfon, before mentioned, at p. 401, fays, "That in the year 1562, captain Hawkins, affiled by subscription of sundry gentlemen, now fitted out three ships; and having learnt that negroes were a very good commodity in the Indies, he fixed on negroes; and sailed with them for Guinea; where he sold them, and his English commodities, and loaded his three vessels with hides, sugar, ginger, &c. with which he returned home anno 1563, making a prosperous voyage." As it proved a lucrative business, the trade was continued both by Hawkins and others, as appears from the Naval Chronicle, p. 55; where it is said, "That in the year 1564, captain John Hawkins, with two ships of 700 and 400 tons, sailed for Africa; that on the 10th of December they anchored to the South of Cape Verdi, where the captain manned the boat, and sent 80 men in armour into that country, to see if they could take some negroes: but the natives flying from them, they returned to their ships, and proceeded farther down the coast. Here they had certain days, engaging their men a shore, in about (as the author fays) to burn and spoil their towns and take the inhabitants. The land they observed to be well cultivated, there being plenty of grain and fruit of several sorts, and the towns pretty laid out. On the 25th, being informed by the Portuguese of a town of negroes called Byamba, where there was not only a quantity of gold, but 140 inhabitants, they resolved to attack it, having the Portuguese for their guides; but by mismanagement they took but ten negroes, having seven of their own men killed and 27 wounded. They then went farther down the coast; when having procured a number of negroes, they proceeded to the West Indies, where they sold them to the Spaniards," And in the same Naval Chronicle, at p. 76, it is said, "That in the year 1567, Francis Drake, before performing his voyage round the world, went with Sir John Hawkins in his expedition to the coast of Guinea, where taking in a cargo of slaves, they determined to steer for the Caribbean Islands." How queen Elizabeth suffered from grievances an infringement of the right of mankind to be perpetrated by her subjects, and how she was persuaded, about the 30th year of her reign, to grant patents for carrying on a trade from the north part of the river Senegal to 100 leagues beyond Siera Leone, which gave rise to the African Company, is hard to account for, any otherwise than that if any, vol. iv. p. 85, it arose from the misrepresentation made to her of the situation of the negroes, and of the advantages it was pretended they would reap from being made acquainted with the Christian religion. This was the case of Louis XIII. of France: who, Labat, in his account of the isles of America, tells us, "that extremely uneasy at a law by which the negroes of his colonies were to be made slaves; but it being strongly urged to him as the readiest means of converting the Christians, he acquiesced therewith." Nevertheless, some of the Christian powers did not so easily give way in this matter: for we find, "That Cardinal Cibo, one of the pope's principal ministers of state, wrote a letter on behalf of the college of cardinals, or great council at Rome, to the missionaries in Congo, complaining that the pernicious and abominable abuse of selling slaves was yet continued; requiring them to remedy the same if possible; but this the missionaries law little hopes of accomplishing, by reason that the trade of the country lay wholly in slaves and ivory." It has been urged in justification of this trade, that by purchasing the captives taken in battle, they save the lives of so many human creatures, who otherwise would be sacrificed to the implacable revenge of the victors. But this pretence has been refuted by an appeal to reason and fact. For if the negroes apprehended they should be cruelly put to death if they were not sent away: why, it is asked, do they manifest such reluctance and dread as they generally do, at being brought from their native country? Smith, in his Account, p. 28, says, "The Gambians abhor slavery, and will attempt any thing, though ever so desperate, to avoid it." And Thomas Phillip, in his account of a voyage he performed to the coast of Guinea, writes, "They (the negroes) are to lodge to
Guinea.

leave their own country, that they have often leaped out of the canoe, boat, or canoe, into the sea, and kept under water till they were drowning, to avoid being taken up." But had the fact even been otherwise, the above plea is urged with an extreme bad grace, when it is notorious that the very wars said to be productive of such cruelty were fomented by the infamous arts of the Europeans. From the foregoing accounts, as well as other authentic publications of this kind, it appears, that it was the unwarrantable lust of gain which first stimulated the Portuguese, and afterwards other Europeans, to engage in this horrid traffic. By the most unquestionable relations of those early times, the natives were an inoffensive people, who, when civilly used, traded amicably with the Europeans. It is recorded of those of Benin, the largest kingdom in Guinea, that they were a gentle, loving, peaceful, and religious people; and Reynolds says, "They found more sincere proofs of love and good will from the natives, than they could find from the Spaniards and Portuguese, even though they had relieved them from the greatest misery."

And from the same relations there is no reason to think otherwise, that they generally lived in peace amongst themselves; there occurring no accounts of any wars at that early period, nor of any savage captives taken in battle.

In fact it was long after the Portuguese had made a practice of violently forcing the natives of Africa into slavery, that we read of the different negotiations making war upon each other, and selling their captive.

And probably this was not the case, till those bordering on the coast, who had been used to supply the vessels with necessaries, had become corrupted by their intercourse with the Europeans, and were excited by drunkenness and avarice to join them in carrying on those wicked schemes, by which those unnatural wars were perpetrated; the inhabitants kept in continual alarms; the country laid waste; and, as Moore expresses it, "infinite numbers sold into slavery." But that the Europeans are the principal cause of these devastations, is particularly evidenced by one whole connection with the trade would rather induce him to reject it in the fairest colours, viz. Captain Smith, the peron sent in the year 1726 by the African company to survey their settlements; who, from the information he received of one of the factors who had resided ten years in that country, says, "That the differing natives account it their greatest unhappiness, that they were ever visited by the Europeans."

"That we Christians introduced the traffic of slaves; and that before our coming they lived in peace."

In the accounts relating to the African trade, we find this melancholy truth farther attested by some of the principal directors in the different factories; particularly A. Brue fays, "That the Europeans were far from desiring to act as peace-makers amongst the negroes; which would be acting contrary to their interest, since the greater the wars, the more slaves were procured." And William Bowson also remarks, "That one of the former commanders gave large sums of money to the negroes of one nation, to induce them to attack some of the neighbouring nations; which occasioned a battle which was more bloody than the wars of the negroes usually are." This is confirmed by J. Barbot, who says, "That the country of D'El-

mima, which was formerly very powerful and populous, was in his time so much drained of its inhabitants by the inconstant wars fomented amongst the negroes by the Dutch, that there did not remain inhabitants enough to till the country."

It has also been advanced as an argument in favour of keeping the negroes in bondage, that there are slaves in Guinea, and that those amongst us might be so in their own country. Not to dwell upon the inconsistency of our giving any countenance to slavery, because the Africans, whom we effeminate into a horrid and savage people, allow of it, and perhaps the more from our example; the very circumstance stated, when inquired into, must afford cause of blushing, rather than serve as a palliation of such iniquitous conduct: for it will appear, that the slavery endured in Guinea is by no means to be excused as that in the colonies. Captain Moore, speaking of the natives living on the river Gambia, says, "That some of the negroes have many house slaves, which are their great glory; that those slaves live so well and easy that it is sometimes a hard matter to know the slaves from their masters or mistresses. And that though in some parts of Africa they fell their slaves born in the family; yet on the river Gambia they think it a very wicked thing." The author adds, "He never heard of but one that ever sold a family slave, except for such crimes as they would barely be sold if they had been free." And in Clio's Collection, speaking of the condition of the negroes in that large extent of country farther down the coast, particularly denominated the Coast of Guinea, it is said, "They have not many slaves on the coast; none but the king or nobles are permitted to buy or sell any; so that they are allowed only what are necessary for their families, or till the ground." The same author adds, "That they generally use their slaves well, and seldom correct them."

From the foregoing account of the natural disposition of the negroes, and the fruitfulness of most parts of Guinea, which are confirmed by authors of candour, who, from their own knowledge, may well be concluded, that the negroes acquaintance with the Europeans might have been a happiness to them; but these forgetful of their duty as men and Christians, have conducted themselves in so iniquitous a manner, as must necessarily raise in the minds of the thoughtful and well disposed negroes the utmost scorn and detestation of the very name of Christians. All other considerations have given way to an inextinguishable desire of gain, which has been the principal and moving cause of the most detestable and barbarous scene that was perhaps ever acted upon the face of the earth; instead of making use of that superior knowledge with which the Almighty, the common Parent of mankind, had favoured them, to strengthen the principle of peace and good will in the breasts of the incautious negroes, the Europeans have, by their bad example, led them into excess of drunkenness, debauchery, and avarice: whereby every pallion of corrupt nature being inflamed, they have been easily prevailed upon to make war and capture one another, as well to furnish means for the excesses they have been habituated to, as to satisfy the greedy desire of gain in their profligate employers; who, to this intent have furnished them with prodigious quantities of arms and ammunition.
guinean. Thus they have been hurried into confusion, distress, and all the extremities of temporal misery; every thing, even the power of their kings, has been made subservient to this wicked purpose; for instead of being protectors of their subjects, some of those rulers, corrupted by the excessive love of spirituous liquors, and the tempting baits laid before them by the factors, have invaded the liberties of their unhappy subjects, and are become their oppressors.

Here it may be necessary to observe, that the accounts we have of the inhabitants of Guinea are chiefly given by persons engaged in the trade, who, from selfish interested views, have described them in such colours as were least likely to excite compassion and respect, and endeavoured to reconcile to mankind a violation of the rights of mankind to the minds of the purchasers; yet they cannot but allow the negroes to be possessed of some good qualities, though they are not so much as possible to be salved over them. A particular instance of this appears in Atley’s Collection, vol. ii. p. 73; where the author, speaking of the Mandingos settled at Galam, which is situated 300 miles up the Senegal, after saying that they carry on trade to all the neighbouring kingdoms, and amassed riches, adds, “That excepting the vices peculiar to the blacks, they are a good sort of people, honest, hospitable, just to their word, laborious, industrious, and very ready to learn arts and sciences.” Here it is difficult to imagine what vices can be peculiarly attendant on a people so well disposed as the author describes these to be. With respect to the charge some authors have brought against them, as being void of all natural affection, it is frequently contradicted by others. In vol. ii. of the Collection, p. 275 and 629, the negroes of North Guinea and the Gold Coast are said to be fond of their children, whom they love with tenderness. And Bofman says, p. 340: “Not a few in his country (viz. Holland) fondly imagine, that parents here sell their children, men their wives, and one brother the other; but those who think so, deceive themselves; for this never happens on any other account but that of necessity, or some great crime.” The same is repeated by J. Barbot, p. 326, and also confirmed by Sir Hans Sloane in the introduction to his natural history of Jamaica; where, speaking of the negroes, he says, “They are usually thought to be haters of their own children; and therefore it is believed that they sell and dispose of them to strangers for money: but this is not true; for the negroes of Guinea being divided into seven captainships, as well as the Indians of America, have wars; and besides those slain in battle, many prisoners are taken, who are sold as slaves, and brought thither: but the parents here, although their children are slaves for ever, yet have a great love for them, that no matters dare fell or give away one of their little ones, unless they care not whether their parents hang themselves or no.” J. Barbot, speaking of the occasion of the natives of Guinea being represented as a treacherous people, ascribes it to the Hollander’s (and doubtless other Europeans) usurping authority, and fomenting divisions between the negroes. At p. 110, he says, “It is well known that many of the European nations trading amongst these people, have very unjustly and inhumanly, without any provocation, stolen away, from time to time, abundance of the people, not only on this coast, but almost every where in Guinea, who have come on board their ships in a harrased and confining manner: thefe they have in great numbers carried away, and sold in the plantations, with other slaves which they had purchased.” And although some of the negroes may be justly charged with indolence and rapine, yet many others are frequently mentioned by authors as a careful, industrious, and even laborious people.

By an enquiry into the laws and customs formerly in use, and still in force amongst the negroes, particularly on the Gold Coast, it will be found, that provision was made for the general peace, and for the safety of individuals; even in W. Bofman’s time, long after the Europeans had established the slave-trade, the natives were not publicly enslaved, any other wise than in punishment for crimes, when prisoners of war, or by a violent exertion of the power of their corrupted kings. Where any of the natives were stolen in order to be sold to the Europeans, it was done secretly, or at least only connived at by those in power: this appears from Barbot and Bofman’s account of the matter, both agreeing that man-stealing was not allowed on the Gold Coast. The first says, “Kidnapping or stealing of human creatures is punished there, and even sometimes with death.” And Bofman, whose long residence on the coast enabled him to speak with certainty, says, “That the laws were severe against murder, thiev ery, and adultery,” and adds, “That man-stealing was punished on the Gold Coast with rigid severity, and sometimes with death itself.” However it may be concluded, that the sale of the greatest part of the negroes to the Europeans is supported by violence, in defiance of the laws, through the knavery of their principal men, who (as is too often the case with those in European countries), under pretence of encouraging trade, and increasing the public revenue, disregard the laws and customs, and speak of the conntry generally advife with their head-men, scarceIy.

Moore also mentions man-stealing as being disencouraged by the negro governments on the river Gambia, and speaks of the enslaving the peaceable inhabitants, as a violence which only happens under a corrupt administration of justice. He says, “The kings of that country generally advise with their head-men, fearfully doing any thing of consequence without consulting them first, except the king of Barfial, who being subject to hard-drinking is very absolute. It is to this king’s inelastic thirst for brandy, that his subjects and families are in so precarious a situation.” Whenever this king wants goods or brandy, he sends a messenger to the English governor at James’s Fort, to desire he would send a vessel there with a cargo; this news being not at all welcome, the governor sends accordingly, against the arrival of the vessel, the king goes and roundabout some of his enemies towns, seizing the people, and telling them for such commodities as he is in want of, which commonly are brandy, guns, powder, balls, pistols, and cutlasses, for his attendants and soldiers: and coral and silver for his wives and concubines. In case he is not at war with any neighbouring king, he then falls upon one of his own towns, which are numerous, and uses them in the same manner. He often goes with some of his troops by atown in the day time, and returning in the night, sets fire
to three parts of it, and putting guards at the fourth, there feizes the people as they run out from the fire; he ties their arms behind them, and marches them either to Joss or Cohone, where he sells them to the Europeans.

Mr. Brue, the French director, gives much the same account, and says, "That having received goods, he wrote to the king, that if he had a sufficient number of slaves, he was ready to trade with him. This prince, as well as the other negro monarchs, has always a sure way of supplying his deficiencies, by selling his own subjects, for which they seldom want a pretence. The king had recourse to the method, by seizing 300 of his own people, and sent word to the director that he had the slaves ready to deliver for the goods." It seems the king wanted double the quantity of goods which the factor would give him for these 300 slaves; but the factor refusing to trust him as he was already in the company's debt, and perceiving that this refusal had put the king much out of temper, he proposed that he should give him a licence for taking many more of his people as the goods he still wanted were worth; but this the king refused, saying, it might occasion a disturbance among his subjects. Except in the above instance and some others, where the power of the negro kings is unlawfully exerted over their subjects, the slave-trade is carried on in Guinea with some regard to the laws of the country, which allow of none to be sold but prisoners taken in their national wars, or people adjudged to slavery in punishment for crime, but the largeness of the country, the number of kingdoms or commonwealths, and the great encouragement given by the Europeans, afford frequent pretences and opportunities to the bold designing provincials of one kingdom, to surprise and seize upon not only those of a neighbouring government, but also the weak and helpless of their own; and the unhappy people, taken on such occasions, are, with impunity, sold to the Europeans. These practices are doubtless disapproved of by the most considerate amongst the negroes; for Bofman acquaints us, that even their national wars are not agreeable to such. He says, "If the person who occasioned the beginning of the war be taken, they will not customarily admit him to ransom, though his weight in gold should be offered, for fear he should in future form some new design against their repose."

We shall conclude this article with the following account of the shocking methods used in the carrying on of the slave trade, as described by factors of different nations.

Mr. Moore, a factor for the English African Company on the river Gambia, writes, "That there are a number of negro traders, called joueurs, or merchants, who follow the slave-trade as a busines: their place of residence is so high up the country as to be six weeks travel from James' Fort, which is situated at the mouth of that river. These merchants bring down elephants, and in some years 2000 slaves, most of which, they say, are prisoners taken in war. They buy them from the different princes who take them; many of them are Bombrongs and Petcharies; nations who each of them have different languages, and are brought from a vast way inland. Their way of bringing them is tying them by the neck with leather thongs, at about a yard distant from each other, 30 or 40 in a string, having generally a bundle of corn or elephants' teeth upon each of their heads. In their way from the mountains, they travel through very great woods, where they cannot for some days get water; so they carry in skin bags enough to support them for a time. I cannot (adds Moore) be certain of the number of merchants who follow this trade, but there may, perhaps, be about 100, who go up into the inland country with the goods which they buy from the white men, and with them purchase, in various countries, gold, slaves, and elephants' teeth. Besides the slaves which the merchants bring down, there are many bought along the river: These are either taken in war, as the former are, or men condemned for crimes; or else people stolen, which is very frequent. Since the slave trade has been used, all punishments are changed into slavery; there being an advantage on such condemnation, they fear for crimes very hard, in order to get the benefits of selling the criminal."

John Barbot, the French factor, in his account of the manner by which the slaves are procured, says, "The slaves fold by the negroes are for the most part prisoners of war, or taken in the incursions they make into their enemies' territories; others are stolen away by their neighbours, when found abroad on the road, or in the woods; or else in the corn fields, at the time of the year when their parents keep them there all the day to fear away the devouring small birds. Speaking of the transactions on that part of Guinea called the Gulf Coast, where the Europeans have the most factories, and from whence they bring away much the greater number of slaves, the same author says, "The inhabitants of Coto do much mischief in stealing those slaves they sell to the Europeans from the inland country.—That the inhabitants of Poro excel the former; being endowed with a much larger share of courage, they rob more successfully, by which means they increase their riches and trade." The author particularly remarks, "That they are encouraged in their practice by the Europeans: sometimes it happens, according to the successes of the inland excursions, that they are able to furnish 200 slaves, or more, in a few days."

And he says, "The inhabitants of Fida, or Whidah, are so expeditions in trading for slaves, that they deliver 1000 a month."—"Hit here happens to be no stock of slaves there, the factor must trust the blacks with his goods, to the value of 300 l. or 200 l. which goods they carry up into the inland country to buy slaves at all markets for above 600 miles up the country, where they are kept like cattle in Europe; the slaves sold there being generally prisoners of war, taken from their enemies like other booty, and perhaps some few sold by their own countrymen, in extreme want, or upon a famine, as also some as a punishment of heinous crimes." So far Barbot's account. That given by Bofman is as follows: "When the slaves which are brought from the inland countries come to Whidah, they are put in prison together, when we meet concerning buying them, they are all brought out together in a large plain, where, our surgeons, they are thoroughly examined, and that naked, both men and women, without the least distinction or modesty. Thos which are approved as good, are foton one side; in the mean while a burning fire, with the arms of

name

"---v---"
name of the company, lies in the fire, with which ours are marked on the breast. When we have agreed with the owners of the slaves, they are returned to their prisons; where, from that time forward, they are kept at our charge, and cost us two pence a day each slave, which serves to libel them like criminals on bread and water; so that to save charges, we send them on board our ships the very first opportunity: before which, their masters strip them of all they have on their backs, so that they come on board stark naked, as well women as men. In which condition they are obliged to continue, if the master of the ship is not so charitable (which he commonly is) as to belowe something on them to cover their nakedness. Six or seven hundred are sometimes put on board a vessel, where they lie as close together as it is possible for them to be crowded."

When the great income which arises to the negro kings on the Slave Coast, from the slaves brought through their several governments to be shipped on board the European vessels, is considered, we have no cause to wonder that they give so great a countenance to that trade. Bofman says, "That each ship which comes to Whidah to trade, reckoning one with another, either by toll, trade, or Custom, pays about 400l., and sometimes 50 ships come hither in a year." Barbot confirms the same, and adds, "That in the neighbouring kingdom of Aroh, the duty to the king is the value of 70 or 80 slaves for each trading ship, which is near half as much more as at Whidah. Nor can the Europeans concerned in the trade, with any degree of propriety, blame the African kings for countenancing it, while they continue to send vessels on purpose to take in the slaves which are thus stolen, and that they are permitted, under the sanction of national laws, to sell them to the colonies."

According to a late sensible writer, Mr. Ramsey, "the annual British export to these coasts is estimated at 500,000l., including a considerable quantity that is annually exchanged with American and other foreign traders there; about 5000 cool. of ivory, gold dust, gun, &c. The greatest part of the profits of the slave trade are raised on the sugar plantations. If by establishing factories, and encouraging civilisation on the coast of Africa, and returning some of our West-Indian slaves to their original country, we tried to make up for our past treachery to the natives, and instructed the inhabitants in the culture of tobacco, indigo, cotton, rice, &c. to barter with us for our manufactures, and supply us with those articles, our demand for which has been so advantageous to America, great would be our profits. Were Africa civilized, and could we procure the affection of the natives, and introduce gradually our religion, manners, and language among them, we should open a market that would fully employ our manufacturers and seamen, morally speaking, till the end of time. And while we enriched ourselves, we should contribute to their happiness. For Africa, in its highest probable state of culture, could not possibly interfere with the staple of Britain, so as to hinder an extensiv and mutually advantageous trade from being carried on between the countries. The great difference of climate and soil must always distinguish the supplies and wants of each."

This slave-trade indeed has been long considered as disgraceful to an enlightened age; and in this country a spirit is arisen which seems bent on annihilating it altogether, or so changing the nature of it as to blend humanity with policy. During the session of 1788, the philanthropy of parliament, supported by that of the nation, paid a very particular attention to this odious branch of traffic. It was, however, a subject of too comprehensive a nature, and too materially connected with our African commerce at large and our West-Indian colonies to come to an immediate decision upon it. Parliament, therefore, was obliged to content itself for that time with a temporary bill to regulate the shipping and carrying slaves in British vessels from those coasts. But the public attention has been since kept awake by a great variety of publications on both sides of the question; and the final arrangement of this important business, in which the honour of the British commerce and the British character, as well as the happiness of millions of our noble African brethren, is involved, is expected to take place during the present session 1791. — This traffic in human beings is not, however, without its advocates. But the most specious arguments of its ablest defenders reach no farther than political expediency, which can never alter the real nature of things. That in question would not remain less an unjust, cruel, and wicked trade, in its very nature eternally and unalterably wrong. Its abolition, therefore, not in a rash, but in a gentle and equitable way as circumstances will allow, is devoutly to be wished, and it is hoped may be accomplished."

New Guinea, a long and narrow island of the East-Indies, very imperfectly known. It was supposed to be connected with New-Holland, until Captain Cook discovered the strait which separates them. New Guinea, including Papua, its north-western part (which according to Bougainville's conjecture is separated from it by a strait), reaches from the equator to the 11th degree of south latitude, and from 130 to 150 degrees east longitude; in one part it does not appear to be above 50 miles broad. It was first visited by an European ship in 1599. Dampier, a Portuguese, who made the discovery of the north-west part of this country, called it Terra de Papaus or Papos. Van Schoten a Dutch discoverer, afterwards gave the name of New-Guinea to its south-western parts. Admiral Roggewein also touched here; and before him Dampier, 1st January 1700. Captain Cook made the coast of New-Guinea, in latitude 6 degrees 15 minutes, longitude 158 east, on the 3d of September, and landed in the pinnae, accompanied by Mr. Banks, Doctor Solander, nine of the ship's crew, and servants well armed, and leaving two seamen to take care of the boat, advanced some little way up the country; but coming to the skirts of a thick wood, they judged it prudent to proceed no further, lest they should fall into an ambuscade of the natives, and their retreat to the boat be cut off. Having advanced about a quarter of a mile from the boat, three Indians rushed out of the wood with a horrid shout; they drew their darts, and showed such a hostile disposition, that the party, to prevent the destruction of these people, returned to the boat, as they had no intention forcibly to invade their country, either to gratify their curiosity, and it was evident nothing could be done upon friendly terms. When they got on board the boat, they rowed along the shore, and the number of Indians assembled.
femed seemed to be between 60 and 100. They made much the same appearance as the New-Hollanders, being stark naked and their hair cropped short. All the while they were gaming defiance, and throwing something out of their hand which burnt exactly like gun-powder, but made no report; what these fires were, or for what purpose intended, could not be guessed at; those who discharged them had in their hands a short piece of flick, possibly a hollow cane, which they swung from their side, and immediately fire and smoke issued, exactly resembling the discharge of a musket, and of no longer duration. This wonderful phenomenon was observed from the ship; and the deception was so great, that the people on board thought they had fire-arms; and even in the boat if they had not been so near as that they must have heard the report, if there had been any, they would have thought they had been firing volleys. After looking at them attentively for some time, without taking any notice of their dancing and vociferation, the sailors fired some muskets over their heads. Upon hearing the balls rattling among the trees, they walked leisurely away, and the boat returned to the ship. Upon examining some weapons which the natives had thrown, they were found to be light darts, about four feet long, very ill made, of a reed or bamboo cane, and pointed with hard wood, in which there were many barbs. They were discharged with great force, for at 60 yards distance they went beyond the party; but in what manner they were thrown could not be exactly seen. But the general opinion was, that they were thrown with a flick in the manner practised by the New-Hollanders.

The land here is very low, as is every other part of the coast; but it is covered with a luxuriance of wood and herbage that can scarcely be conceived. Here the cocoa-nut, plan,ain, and bread-fruit, flourish in the highest perfection.

GUINEA, a gold coin, struck and current in Britain. The value or rate of guineas has varied: it was first struck on the footing of 20s. by the scarcity of gold was afterwards advanced to 21s. 6d. but it is now sunk to 2ts. The pound weight troy of gold is cut in zis. See GUINEA-Pig. See COMPANY. See Company (African.) See GUINEA-Hen. In ornithology. See Numida. See GUINEA-Wheat. See ZEA.

GUITUSCOA, the north-east division of the province of Biscay in Spain, situated on the confines of Navarre.

GUISE, a small town of France in Picardy, and in Tierache, with a very strong castle, and the title of a duchy. It is seated on the River Guise, in E. Long. 1. 42. N. Lat. 49. 44.

GUISE (Henry) of Lorraine, duke of Guise (eldest son of Francis of Lorraine duke of Guise), memorable in the history of France as a gallant officer; but an imperious, turbulent, fidelious subject, who placed himself at the head of an armed force, and called his rebel hand, The League. The plan was formed by the cardinal, his younger brother; and under the pretext of defending the Roman Catholic religion, the king Henry III, and the freedom of the state, against the design of the Huguenots, or French Protestants, they carried on a civil war, massacred the Huguenots, and governed the king, who forbid his appearance at Paris; but Guise now became an open rebel, entered the city against the king's express order, and put to the sword all who opposed him; the streets being barricaded to prevent his progress, this fatal day is called in the French history, The day of the barricades. Masses of Paris, the policy of the Guises failed them: for they suffered the king to escape to Blois, though he was de­ferred in his palace at Paris by his very guards. At Blois, Henry convened an assembly of the states of France; the duke of Guise had the boldness to appear to a commoner sent to him for that purpose; a forced re­conciliation took place between him and the king, by the advice of this assembly; but it being accidentally discovered, that Guise had formed a design to de­throne the king, that weak monarch, instead of re­voluntely bringing him to justice, had him privately assassinated, December 23, 1568, in the 38th year of his age. His brother the cardinal shared the same fate the next day.

GUITTAR, GUITARRA, a musical instrument of the stringed kind, with five double rows of strings: of which those that are braids are in the middle, except it be for the burden, an octave lower than the fourth. —This instrument was first used in Spain and by the Italians. In the former country it is still greatly in vogue. There are few of that nation who cannot play on the guitar; and with this instrument they fer­enade their missresses at night. At Madrid, and other cities in that country, it is common to meet in the streets young men equipped with a guitar and a dark lanthorn, who, taking their station under the windows, sing, and accompany their voices with this instrument; and there is scarce an artificer or day-labourer in any of the cities or principal towns who does not entertain himself with his guitar.

GULDENSTAEDT (John Anthony), was born at Riga, April 26, 1745; received the rudiments of his education in that town; and in 1762 was admitted into the medical college of Berlin. He completed his studies at Frankfort upon the Oder, and in 1767 received the degree of M. D. in that university. On account of his knowledge of foreign languages, and the considerable progress he had made in natural his­tory, he was considered as a fit person to engage in the expeditions which were planned by the imperial aca­demy. Being invited to St. Petersburg, he arrived in that city in 1768, was created adjoint of the academy, and afterwards, in 1770, member of that society, and professor of natural history. In June 1761 he set out upon his travels, and was absent seven years. From Moscow, where he continued till March 1769, he pas­sed to Voronetz, Tzaritzin, Afracan, and Kiljar, a fortress upon the western shore of the Caffian, and close to the confines of Persia. In 1770 he had explored the districts watered by the river Terek, Sunha, and Aik­sa, in the eastern extremity of Caucasus; and in the course of the ensuing year penetrated into Ossetia, in the highest part of the same mountain; where he col­lected
GUL

GUL, or Gullet, is represented in engraving by perpendicular lines. It is a term of itself to denote martial prowess, boldness, and hardihood; for the ancients used this colour to make themselves terrible to their enemies, to flirt up magnanimity, and to prevent the seeing of blood, by the likeness of the colours; for which reason perhaps it is used by the English. But, according to G. Leigh, if this tincture is compounded with

| Or. | Delfire. |
| Arg. | Envy. |
| Azu. | Arduor. |
| Ver. | Strength. |
| Sab. | Wariness. |

This colour is by the generality of the English heralds ranked before azure; but French heralds, N. Upton and his followers, prefer azure to it.

GULL, in ichthyology. See Larus.

GULF, a broad and capacious bay comprehended between two promontories, and sometimes taking the name of a sea when it is very extensive; but particularly when it only communicates with the sea by means of a strait. Such are the Euxine or Black sea, otherwise called the Gulf of Constanza; the Adriatic Sea, called also the Gulf of Venice; the gulf of Sicily near Barbary; and the gulf of Lions near France. All these gulfs are in the Mediterranean.

There are, besides the gulf of Mexico, the gulf of St Lawrence, and the gulf of California, which are in North-America. There are also the gulf of Persia, otherwise called the Red Sea, between Persia and Arabia; the gulf of Bengal in India; and the gulfs of Cochinchina and Kamtchatka, near the countries of the same name.

The word comes from the French gulf, and that from the Italian gulfos, which signifies the same. Some deduce these further from the Greek γαλαγωγος, which signifies the same. Gullart again derives from the Hebrew גול, a gulf. Du Cange derives them from the barbarous Latin gulfam, or gulfus, which signifies the same thing.

GULLET. See Gula.

GUM (Gummi), is a concrete vegetable juice, of no particular smell or taste, becoming viscous and tenacious when moistened with water; totally dissolving in water into a liquid, more or less glutinous in proportion to the quantity of the gum; not dissolving in vicious spirits or in oils; burning in the fire to a black coal, without melting or catching flame; suffering no dissipation in the heat of boiling water.

The true gums are gum arabic, gum tragacanth, gum senega, the gum of cherry and plum trees, and such like. All else have more or less of resin in them.

Gum-Arabic is the produce of a species of Mimosarum; which see.

GUM. The medical character of gum arabic is its glutinous quality, in consequence of which it serves to incrustate and obtund thin acrid humour, to prove useful in tickling coughs, alvine fluxes, hoarseness, in fluxes of the belly with gripes, and where the mucus is abraded from the bowels or from the uina.

The true gum arabic is more cooling than the other simple gums, so should be preferred.

One ounce of gum arabic renders a pint of water considerably glutinous: four ounces gives it a thick syrupy

CON-
confidence: but for mucilage, one part gum to two parts water is required; and for some purgatives an equal proportion will be necessary.

In Dr. Percival's Essays we have the following curious account, by Mr. Henry, of the faculty which this gum bath of dissolving and keeping suspended in water not only resinous but also other substances, which should seem likely to be at all affected by it.

"One scruple of balsam of tolu, rubbed with half an ounce of distilled rain-water, added gradually to it for 15 minutes, formed a mixture, which on standing about a minute subsided, but re-united by shaking: being left by a few days, the balsam became a concrete mass, not again miscible by shaking up the bottle. The same quantity required more triturating to mix it with common pump-water. One scruple of the same, rubbed with 15 grains of gum arabic, was nearly as long in perfectly uniting with half an ounce of distilled water as that without the gum. This was perhaps owing to the latter piece being more resinous; however, though on long standing there was a small sediment, it immediately reunited a week after by agitation. Fifteen grains of balsam capivari united very smoothly with half an ounce of distilled water, by the medium of three grains of gum arabic. Five grains of the gum were not so effectual with pump-water. Balsam Peru ten drops, with gum arabic three grains, distilled water half an ounce, formed a neat white emulsion, but with common water a very unequal mixture. Gum myrrh (powdered that there might be no difference in the several quantities used), half a scruple, dissolved readily with gum arabic three grains, in both kinds of water, and even mixed with them by longer triturating without any medium, but more easily with distilled than common spring water. Olibanum, mastich, gum guaiacum, and galbanum, may likewise be mixed with water by rubbing, without any gum arabic or egg. The spring water made use of in these experiments was very alumineous.

"In the making of all the saline preparations, when any considerable quantities of water are used, distilled or pure rain or river water is greatly to be preferred; for the calcareous, alumineous, and felsinement matter, which so much abounds in most spring water, will render any salt dissolved in it very impure. The solution of crude mercury with mucilage of gum arabic being so easily accomplished, and it being very disagreeable to many patients, and to some almost impossible, to swallow pills, boluses, or electuaries, I was induced to try whether calomel, cinnabar, and the other heavy and metalline bodies commonly administered only under their forms, might not by the same means be rendered miscible with water, so as to be given more agreeably in a liquid form. I accordingly rubbed ten grains of cinnabar of antimony and a scruple of gum arabic, with a sufficient quantity of distilled water to form a mucilage, and added a drachm of simple fyrup and three drachms more of water. This makes an agreeable little draught; and having stood about half an hour without depositing any sediment, I added three drachms more of water to it; and notwithstanding the mucilage was rendered so much more dilute, very little of the cinnabar subsided even after it had stood some days.

Steel simply prepared, and prepared tin, were both mixed with water by their own weight of gum arabic, and remained suspended, except a very small portion of each, which was not reduced to a sufficiently fine powder.

"Five grains of calomel were mixed with two drachms of distilled water and half a drachm of simple fyrup by means of five grains of gum arabic, which kept it sufficiently suspended: a double quantity of the gum preferred the mixture uniform still longer. In this form it will be much more easily given to children than in fyrups, conserves, &c. as a great part of it is generally waisted, in forcing those viscid vehicles into them; and it may be joined with feammony and other resinous purgatives by the same method, and of these perhaps the gum arabic would be the best corrector.

"Gum arabic likewise greatly abates the disagreeable taste of the corrosive sublimate, mixed with water instead of brandy; and (from the few trials I have made) it's easier on the stomach, and will not be so apt to betray the patient by the smell of the brandy.

"Mr. Plenck, who first introduced us in the method of mixing quicksilver with mucilage, observes (and experience confirms the truth of it), that this preparation is not so apt to bring on a spitting as the argent. vis. mixed by any other medium, or as the saline and other mercurial preparations.—How far the theory by which he accounts for it may be just is not of much importance; but it may perhaps be worth while to inquire, whether it would not be equally effectual in preventing calomel, and the other preparations of mercury, from affecting the mouth,—if so, is it not improper, where a salivation is intended, to give emulsions with gum arabic and other mucilaginous liquors for the patient's common drink, as by that means the spitting may be retarded? And, on the contrary, may it not be a useful medicine to diminish the effu-charge when too copious?

"The following case may in some measure serve to confirm the above observation.—A gentleman, always easily affected by mercurials, having taken about 26 grains of calomel in doses from 1 to 3 grains, notwithstanding he was purged every third day, was suddenly seized with a salivation. He spat plentifully, his breath was very fetid, teeth loofe, and his gums, fauces, and the margin of his tongue, greatly ulcerated and inflamed. He was admitted to the following garle. B. Gum. arb. fesamum. folve in aqua fum. bullient, feli., &c. &c. et add. mel. rufii. unc. unam. M. 5. gargar. And to drink freely of a pitan prepared with ag. hard. lib. ij. gum. arabic unc. ij. nitr. pur. drachm. ij. fescar. alb. unc. j. His purgative was repeated the succeeding morning. The next day his gums were less inflamed, but the lothu on his tongue, &c. were still as foul: his spitting was much the same; he had drank about a pint of the pitan. Some f. vitrioli was added to the gargar. From this day to the fourth he was purged every day without effect, his salivation still continued, his mouth was no better, he had neglected the mucilaginous drink. This evening he was persuaded to drink about a pint of it which remained, and he had it repeated, and drank very freely of it that night. On the fifth morning the purgative was again repeated. Though it operated very little, yet the change was very surprizing: his mouth was nearly well, and his phytalism greatly decreased. The pitan was repeated;
GUM [193] GUN

...and on the fiftth day, being quite well, he was permitted to go abroad.

In Mr. Hesselqui's Travels we have an instance of the extraordinary nutritive virtues of this gum. The Abyssinians (says he) make a journey every year to Cairo, to sell the products of their country. They must travel over terrible deserts, and their journey depends as much on the weather as a voyage at sea; consequently they know as little as a seaman how long they must be on their journey; and the necessaries of life may chance to fall them when the journey lasts too long. This happened to the Abyssinian caravan in the year 1740, their provisions being consumed when they had still two months to travel. They were then obliged to search for something among their merchandise where with they might support nature; and found nothing more proper than gum arabie, of which they had carried a considerable quantity along with them. This served to support above 1000 persons for two months; and the caravan at last arrived at Cairo without any great loss of people either by hunger or diseases.

Gum Senega, is a gum extremely resembling gum arabic. It is brought to us from the country through which the river Senega runs, in loose or tingle drops; but these are much larger than those of the gum arabic usually are; sometimes it is of the bigness of an egg, and sometimes much larger: the surface is very round or wrinkled, and appears much lighter than the inner substance where the mafles are broken. It has no smell, and scarce any taste. It is probably produced from a tree of the same kind with the former. The virtues of it are the same with the gum arabic; but it is rarely used in medicine, unless as mixed with the gum arabic: the dyers and other artificers consume the great quantities of it that are annually imported hither. The negroes dissolve it in milk, and in that state it was sold at Cairo without any great loss of people either by hunger or diseases.

Gum Tragacanth, the gum of the tragacanth, a thorny bush growing in Crete, Aisa, and Greece. See Astragalus.

Other substances known by the name of gums are as follow:

Gum Ammoniac. See Ammoniac.
Gum Elmi. See Amyris.
Gum Keno. See Keno.
Gum Guaiacum. See Guaiacum.
Gum Lacco. See Cocusc and Lacco.

Gum, among gardeners, a kind of granate incident to fruit-trees of the fone kind, arising from a corruption of the sap, which, by its vividness, not being able to make its way through the fibres of the tree, is, by the protrusion of other juice, made to extravasate and ooze out upon the bark.

When the dissenter surrounds the branch, it admits of no remedy; but when only on one part of a bough, it should be taken off to the quick, and some cow dung clapped on the wound, covered over with a linen cloth, and tied down. M. Quinquinie directs to cut off the morbid branch two or three inches below the part affected.

Gumma, a folt of venereal excrecence on the periodontium of the bones.

GUMS, in anatomy, the hard fliehy substance in either jaw, through which the teeth spring from the jawbone. See Anatomy, vol. 102.

The gums are apt to become spongy, and to separate from the teeth; but the cause in frequently a flopy kind of cruit, which forms itself therein, which when separated, the gums soon return to their former state, especially if rubbed with a mixture of the infusion of rotes four parts, and the tincture of myrrh one part. The fcurvy is another disorder, which affects the gums. This disorder, when not manifeft in any other part, sometimes appears in this: indeed, when a scurvy disorder invades the whole habit its first symptom is a putrid flate of the gums.

GUN, in the military art, a fire-arm, or weapon of offence, which forcibly discharges a ball or other hard and solid matter through a cylindrical tube, by means of inflamed gun-powder. See Gun-powder.

The word gun now includes most of the species of fire-arms; pistols and mortars being almost the only ones excepted from this denomination. They are divided into great and small guns: the former including all that we also call cannon, ordnance, or artillery; the latter includes musquets, carabines, musqueions, blunderbusses, fowling-pieces, &c.

It is not known at what time these weapons were first invented. Though, comparatively speaking, the introduction of guns into the western part of the world is but of a modern date; yet it is certain that in some parts of Asia they have been used, though in a very rude and imperfect manner, for ages. Philostratos speaks of a city near the river Aphasia in the Indies, which was said to be impregnable, and that its inhabitants were relations of the gods, because they threw thunder and lightning upon their enemies. Hence some imagine that guns were used by the eastern nations even in the time of Alexander the Great; but however this may be, many of our modern travellers assert that they were used in China as far back as the year of Christ 85, and have continued in use ever since.

The first hint of the invention of guns in Europe is in the works of Roger Bacon, who flourished in the 13th century. In a treatise written by him about the year 1280, he proposes to apply the violent explosive force of gun-powder for the destruction of armies. In 1320, Bartholomew Schwartz, a German monk, is commonly said to have invented gun-powder, though it is certainly known that this composition is described by Bacon in some of his treatises long before the time of Schwartz. The following is said to have been the manner in which Schwartz invented gun-powder. Having pounded the materials for it in a mortar, which he afterwards covered with a fone, a spark of fire accidentally fell into the mortar and set the mixture on fire; upon which the explosion blew the fone to a considerable distance. Hence it is probable that Schwartz might be taught the simplest method of applying it in war; for Bacon seems rather to have conceived the manner of using it to be by the violent effect of the flame unconfined, and which is indeed capable of producing annihilating effects. The figure and name of mortars given to species of old artillery, and their employment (which was throwing great stone-bullets at an elevation), very much corroborates this conjecture.

Soon after the time of Schwartz, we find guns commonly made use of as instruments of war. Great A a guns
GUN

Guns were first used. They were originally made of iron bars folded together, and fortified with iron hoops; some of which are still to be seen, viz: one in the Tower of London, two at Woolwich, and one in the royal arsenal at Lisbon. Others were made of thin sheets of iron rolled up together and hooped; and in emergencies they were made of leather, with plates of iron or copper. These pieces were made in a rude and imperfect manner, like the first essays of many new inventions. Stone balls were thrown out of them, and a small quantity of powder used on account of their weakneſs. These pieces had no ornaments, were placed on their carriages by rings, and were of a cylindrical form. When or by whom they were made is uncertain; the Venetians, however, used cannon at the siege of Clandia Jeda, now called Chigga, in 1266, which were brought thither by two Germans, with some powder and leaden balls; as likewise in the wars with the Genoese in 1379. King Edward III. made use of the cannon at the siege of Creauté in 1346, and at the siege of Calais in 1347. Cannon were made use of by the Turks at the siege of Confitantinople, then in possession of the Christians, in 1394, and in that of 1452, when a weight of 100 lb. but they generally burst either the first, second, or third shot. Louis XII. had one cast at Tours, of the fame fize, which threw a ball from the Battille to Charenton. One of those famous cannon was taken at the siege of Dièu in 1545, by Don John de Castro; and is in the caftle of St. Julian da Barra, 10 miles from Lisbon: its length is 20 feet 7 inches, diameter at the centre 6 feet 3 inches, and it discharges a ball of 100 lb. It has neither dolphins, rings, nor button; is of a curious kind of metal; and has a large Indoran inscription upon it, which says it was cast in 1400.

Formerly the cannon were dignified with uncommon names; for, in 1505, Louis XII. had 12 brads cannon cast, of an extraordinary fize, called after the names of the 12 peers of France. The Spanish and Portuguese called them after their faints. The emperor Charles V. when he marched before Tunis, found before him the 23 apostles. At Milan there is a 70 pounder, called the Pimantelle; and one at Bovis-le-duc, called the Devil. A 60 pounder at Dover-calle, called Queen Elizabeth's pocket-pistol. An 80 pounder in the tower of London (formerly in Edinburgh-calle), called Mount-meg. An 80 pounder in the royal arsenal at Berlin, called the Thunderer. An 80 pounder at Malaga, called the Terrible. Two curious 60 pounders in the arsenal at Bremen, called the Messengers of bad news. And, lastly, an uncommon 70 pounder in the caftle of St. Angelo at Rome, made of the nails, that covered the copper-plates which covered the ancient Pantheon, with this inscription upon it: Ex clavis trahabilibus porticus Agrippae.

In the beginning of the 15th century these uncommon names were generally abolished, and the following more universal ones took place, viz:

<table>
<thead>
<tr>
<th>Pounders</th>
<th>Cwt.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cannon royal, or earthcach</td>
<td>=48</td>
</tr>
<tr>
<td>Bafliſte cannon, or 4 earthcach</td>
<td>=36</td>
</tr>
<tr>
<td>2 Carthou</td>
<td>=24</td>
</tr>
<tr>
<td>Whole culverins</td>
<td>=18</td>
</tr>
</tbody>
</table>

Demi culverins  = 9  = 90
Falcon  =6  = 60
Sacker  = 5  = 50
Sackr  = 6  = 60
Bafliſte  = 8  = 80
Serpentine  = 4  = 40
Afpie  = 2  = 20
Dragon  = 6  = 60
Syren  = 60
Falconet  = 3, 2, & 1  = 15, 10, 5.

Moyens, which carried a ball of 10 or 20 ounces, &c.

Robiner, which carried a ball of 16 ounces.

These curious names of beasts and birds of prey were adopted on account of their swiftness in motion or of their cruelty, as the falconet, falcon, sacker, and culverin, &c. for the swiftness in flying; the bafilſte, serpentine, afpie, dragon, syren, &c. for their cruelty. At present cannon take their names from the weight of the ball they discharge. Thus a piece that discharges a ball of 24 pounds is called a 24 pounder; one that carries a ball of 12 pounds, is called a 12 pounder; and so of the rest, divided into the following forts, viz:

Ship-guns, confiling in 42, 36, 22, 18, 12, 9, and 6 pounders.

Garrison-guns, in 42, 32, 24, 18, 12, 9, and 6 pounders.

Battering-guns, in 24, 18, and 12 pounders.

Field-pieces, in 12, 9, 6, 3, 2, 1, and ½ pounders.

Mortars are thought to have been fully as ancient as cannon. They were employed in the wars of Italy, to throw balls of red-hot iron, stones, &c. long before the invention of shells. These last are thought to be of German invention, and the use of them in war to have been taught by the following accident. A citizen of Venlo, at a certain festival celebrated in honour of the duke of Cleves, threw a number of shells, one of which fell on a house and set fire to it, by which misfortune the greatest part of the town was reduced to ashes. The first account of shells used for military purposes is in 1435, when Naples was besieged by Charles VIII. History informs us with more certainty, that shells were thrown out of mortars at the siege of Walthendomk, in Guelderland, in 1568, by the earl of Mansefield. Mr Maltar, an English engineer, first taught the French the art of throwing shells, which they practiced at the siege of Motte in 1634. The method of throwing red-hot balls out of the mortars was first certainly put in practice at the siege of Stralsund in 1675 by the elector of Brandenburgh, though some lay in 1653 at the siege of Bremen. For the proper dimensions of guns, their weight, the metal of which they are formed, &c. see the article GUNNERY.

Muskets were first used at the siege of Rhede in the year 1529. The Spaniards were the first who armed part of their foot with these weapons. At first they were very heavy, and could not be used without a rest. They had match-locks, and did execution at a great distance. On their march the soldiers carried only the rests and ammunition, and had boys to bear their muskets after them. They were very slow in loading, not only by reason of the unwieldiness of their pieces, and

and because they carried the powder and ball separate, but from the time it took to prepare and adjust the match; so that their fire was not near to brisk as ours is now. Afterwards a lighter matchlock musket came in use; and they carried their ammunition in bandoliers, to which were hung several little casks of wood covered with leather, each containing a charge of powder. The balls were carried loose in a pouch, and a priming-horn hanging by their side. The muskets with reits were used as late as the beginning of the civil wars in the time of Charles I. The lighter kind succeeded them, and continued till the beginning of the present century, when they also were diffused, and the troops throughout Europe armed with firelocks.

GUNDELIA, in botany: A genus of the polygamia segregata order, belonging to the syngentes class of plants; and in the natural method ranking under the 49th order, Compositae. There is scarce any calyx, but quincuncialis, with tubular hermaphrodite stamens, the receptacle briefly, with scarce any poppus.

GUNELLUS, in ichthyology. See Brennus.

GUNNER, an officer appointed for the service of the cannon, or one skilled to fire the guns.

GUNNER, an officer carries a field staff, and a large powder-horn in a firing over his left shoulder: he marches by the guns; and when there is any apprehension of danger, his field staff is armed with match. His business is to lay the gun to, and to help to load and traverse her.

Muster GUNNER, a patent-officer of the ordnance, who is appointed to teach all such as learn the art of gunnery, and to certify to the master-general the sufficiency of any person recommended to be one of the king’s gunners. To every scholar he administers an oath not to serve, without leave, any other prince or state; or teach any one the art of gunnery but such as have taken the said oath.

GUNNERA, in botany; a genus of the diandria order, belonging to the gymnosperms class of plants. The amentum consists of uniflorous scales there is neither calyx nor corolla; the germen is bidentate, with two styles and one seed.

GUNNERY,

The art of charging, directing, and exploding firearms, as cannons, mortars, muskets, &c. to the best advantage.—As this art depends greatly on having the guns and shot of a proper size and figure, and well adapted to each other, it hence follows that the proper dimensions, &c. of cannons and small arms come properly to be considered under the present article.

Sect. I. History of Gunnery.

The ancients, who knew not the use of gunpowder and fire-arms, had notwithstanding machines which were capable of discharging stones, darts, and arrows, with great force. These were actuated chiefly by the elastic force of ropes, or of strong springs, and required a great number of men to work them; for which reason, the explosion of gunpowder, as acting instantaneously, and seemingly with irresistible force, seemed to be a more proper succedaneum for all the powers by which the military engines in former times were actuated. It soon appeared, however, that this force was not very easily applied. Though the experiment of Bartholomew Schwartz, mentioned under the article Gun, had given a good hint towards this application in a successful manner, yet the violent reaction of the inflamed powder on the containing vessels rendered them very apt to burst, to the great danger of those who stood near them. The gunpowder in those days, therefore, was much weaker than it is now made; indeed this proved a very insufficient remedy for the inconvenience above-mentioned. It was also soon discovered, that iron bullets of much less weight than stone ones would be more efficacious if impelled by greater quantities of stronger powder. This occasioned an alteration in the manner and form of the cannon, which were now cast of brass. These were lighter and more manageable than the former, at the same time that they were stronger in proportion to their bore. Thus they were capable of enduring greater charges of a better powder than what had been formerly used.

and their iron-bullets (which were from 40 or 60 pounds weight), being impelled with greater velocities were more effectual than the heaviest stones could ever prove. This change took place about the latter end of the 15th century.

By this means powder compounded in the manner now practised over all Europe came first in use. But the change of the proportion of materials was not the only improvement it received. The method of granting it is undoubtedly a considerable advantage. At first the powder was always in the form of fine meal, such as it was reduced to by grinding the materials together. It is doubtful whether the first granting of powder was intended to increase its strength, or only to render it more convenient for filling into small charges and the charging of small arms, in which alone it was applied for many years, whilst meal-powder was still made use for cannon. But at last the additional strength which the granted powder was found to acquire from the free passage of the air between the grains, occasioned the meal powder to be entirely laid aside.

For the last two hundred years, the formation of cannon hath been very little improved: the best pieces of modern artillery differing little in their proportions from those used in the time of Charles V. Indeed lighter and shorter pieces have been often proposed and essayed; but though they have their advantages in particular cases, yet it seems now to be agreed that they are altogether insufficient for general service. But though the proportions of the pieces have not been much varied within that period, yet their use and application have undergone considerable alterations; the same ends being now accomplished by smaller pieces than what were formerly thought necessary. Thus the battering cannon now universally approved of are those formerly called demi-cannons, carrying a ball of 24 pounds weight; it being found by experience, that their stroke, though less violent than that
Theory of larger pieces, is yet sufficiently adapted to the strength of the usual profiles of fortification; and that the facility of their carriage and management, and the ammunition they spare, give them great advantages beyond the whole cannons formerly employed in making breaches. The method also of making a breach, by first cutting off the whole wall as low as possible before its upper part is attempted to be beat down, seems also to be a considerable modern improvement in the practical part of gunnery. But the most considerable improvement in the practice is the method of firing with small quantities of powder; and elevating the piece so that the bullet may just go clear of the parapet of the enemy, and drop into their works. By this means the bullet, coming to the ground at a small angle, and with a small velocity, does not bury itself, but bounds or rolls along in the direction in which it was fired: and therefore, if the piece be placed in the line with the battery it is intended to fince, or on the front: it is to sweep, each shot takes the whole length of that battery or front; and has thereby a much greater chance of disabling the defenders, and dismounting their cannon, than it would have if fired in the common manner. This method was invented by Vauban, and was by him styled Batterie a Ricochet. It was first put in practice in the year 1692 at the siege of Aeth.—Something similar to this was put in practice by the king of Prussia at the battle of Rofbach in 1757. He had several six-inch mortars, made with trunnions and mounted on travelling carriages, which fired obliquely on the enemy's lines, and amongst their horse. They were charged with eight ounces of powder, and elevated at an angle of one degree fifteen minutes, and did great execution; for the shells rolling along the lines with burning-fuses made the floutest of the enemy not wait for their barruling.

Sect. II. Theory of Gunnery.

The use of fire-arms had been known for a long time before any theory concerning them was attempted. The first author who wrote profeffedly on the flight of cannon-shot was Tartalea. In 1537 he published a book, at Venice, intitled Nova Scientia; and afterwards another, intitled Quasai et Inventions diversi, printed at the same place in 1546, in which he treats profeffedly on these motions. His discoveries were few, on account of the imperfect state of mechanical knowledge at that time. However, he determined that the greatest range of cannon was with an elevation of 45 degrees. He likewise determined, (contrary to the opinion of practitioners), that no part of the tract described by a bullet was a right line: although the curvature was in some cases so little, that it was not attended to. He compared it to the surface of the sea; which, though it appears to be a plane, is yet undoubtedly incurvated round the centre of the earth. He also assumes to himself the invention of the gunner's quadrant, and often gave shrewd guesses at the event of some untried methods. But as he had not opportunities of being conversant in the practice, and founded his opinions only on speculation, he was condemned by most of the succeeding writers, though often without any sufficient reason. The philosophers of those times also intermeddled in the questions hence arising, and many disputes on motion were set on foot (especially in Italy), which continued till the time of Galileo, and probably gave rise to his celebrated Dialogues on motion. These were published in the year 1638; but in this interval, and before Galileo's doctrine was thoroughly established, many theories of the motion of military projectiles, and many tables of their comparative ranges at different elevations, were published; all of them egregious fallacious, and utterly irreconcileable with the motions of these bodies. Very few of the ancients indeed refrained from indulging themselves in speculations concerning the difference between natural, violent, and mixed motions; although scarce any two of them could agree in their theories.

It is strange, however, that, during all these contests, so few of those who were intruded with the charge of artillery though it worth while to bring these theories to the test of experiment. Mr Robins informs us, in his Preface to the New Principles of artillery, that he had met with no more than four authors who had treated on this subject. The first of these is Collado, who has given the ranges of a falcon carrying a three-pound shot to each point of the gunner's quadrant. But from his numbers it is manifest, that the piece was not charged with its customary allowance of gun-powder. The results of his trials were, that the point-blank shot, or that in which the path of the ball did not sensibly deviate from a right line, extended 268 paces. At an elevation of one point (or 7½ of the gunner's quadrant) the range was 594 paces; at an elevation of two points, 794 paces; at three points, 954 paces; at four, 1010: at five, 1040; and at six, 1053 paces. At the seventh point, the range fell between those of the third and fourth; at the eighth point, it fell between the ranges of the second and third; at the ninth point, it fell between the ranges of the first and second; at the tenth point, it fell between the point-blank distance and that of the first point; and at the eleventh point, its fell very near the piece.—The spaces spoke of by this author are not geometrical ones, but common steps.

The year after Collado's treatise, another appeared on the same subject by one Bourne an Englishman. His elevations were not regulated by the points of the gunner's quadrant, but by degrees; and he ascertains the proportions between the ranges at different elevations and the extent of the point-blank shot. According to him, if the extent of the point-blank shot be represented by r, the range at 5° elevation will be 2r; at 10° it will be 3r, at 15° it will be 4r; at 20° it will be 4½, and the greatest random will be 5½. This last, he tells us, is in a calm day when the piece is elevated to 42°; but according to the strength of the wind, and as it favours or opposes the flight of the shot, it may be from 45° to 360°.—He hath not informed us with what piece he made his trials; though by his proportions it seems to have been a small one. This however ought to have been attended to, as the relation between the extent of different ranges varies extremely according to the velocity and density of the bullet.

After him Eldred and Anderson, both Englishmen, published treatises on this subject. The first published...

Sect. II.

Theory.

Galileo's theory.  

In 1638, Galileo, printed his dialogue on motion. In these he pointed out the general laws observed by nature in the production and composition of motion; and he was the first who described the action and effects of gravity on falling bodies. On these principles he determined, that the flight of a cannon shot, or any other projectile, would be in the curve of a parabola, except in as far as it was diverted from that track by the resistance of the air. He has also proposed the means of examining the inequalities which arise from thence, and of discovering what sensible effects that resistance would produce in the motion of a bullet at some given distance from the piece.

Though Galileo had thus shown, that independent of the resistance of the air, all projectiles would, in their flight describe the curve of a parabola; yet those who came after him, seem never to have imagined that it was necessary to consider how far the operations of gunnery were affected by this resistance. The subsequent writers indeed boldly asserted, without making the experiment, that no considerable variation could arise from the resistance of the air in the flight of shells or cannon shot. In this persuasion they supported themselves chiefly by considering the extreme rarity of the air, compared with those dense and ponderous bodies; and at last it became an almost generally established maxim, that the flight of these bodies was nearly in the curve of a parabola.

In 1674, Mr Anderon, abovementioned published his tracts on the nature and effects of the gun, in which he proceeds on the principles of Galileo, and firemoufly afferts, that the flight of all bullets is in the curve of a parabola; undertaking to answer all objections that could be brought to the contrary. The same thing was also undertaken by Mr Blondel, in a tracts published at Paris in 1683; where, after long discussion, the author concludes, that the variations from the air's resistance are so slight as scarcely merit notice. The same subject is treated of in the Philosophical Transactions, No. 216, p. 68, by Dr Halley; and he also, sway'd by the very great disproportion between the density of the air and that of iron or lead, thinks it reasonable to believe, that the opposition of the air to large metal-shot is scarcely discernible; although in small and light shot he owns that it must be accounted for.

But though this hypothesis went on smoothly in speculation; yet Anderon, who made a great number of trials, found it impossible to support it without some new modification. For though it does not appear that he ever examined the comparative ranges of either cannon or musket shot when fired with their usual velocities, yet his experiments on the ranges of shells thrown with small velocities (in comparison of those abovementioned), convinced him that their whole track was not parabolical. But instead of making the proper inferences from hence, and concluding the resistance of the air to be of considerable efficacy, he framed a new hypothesis; which was, that the shell or bullet, at its first discharge, flew to a certain distance in a right line, from the end of which line only it began to describe a parabola. And this right line, which he calls the line of the impulse of the fire, he supposed to be the same in all elevations. Thus, by assigning a proper length to this line of impulse, it was always in his power to reconcile any two shots made at different angles, let them differ as widely as we please to suppose. But this he could not have done with three shots; nor indeed doth he ever tell us the event of his experiments when three ranges were tried at one time.

When Sir Isaac Newton's Principia was published, Laws of he particularly considered the resistance of the air to the air's re-projectiles which moved with small velocities; but as resistance laid; he never had an opportunity of making experiments down by on those which move with such prodigious velocities, he did not imagine that a difference in velocity could make such differences in the resistance as are now found to take place. Sir Isaac found, that, in small velocities, the resistance was increased in the duplicate proportion of the velocities with which the body moved; that is, a body moving with twice the velocity of another of equal magnitude, would meet with four times as much resistance as the first, with thrice the velocity it would meet with nine times the resistance, &c. This principle itself is now found to be erroneous, with regard to military projectiles, though, if it had been properly attended to, the resistance of the air might even from thence have been reckoned much more considerable than was commonly done. So far, however, were those who treated this subject scientifically, from giving a proper allowance for the resistance of the atmosphere, that their theories differed most egregiously from the truth. Huygens alone seems to have attended to this principle; for, in the year 1699, he published a treatise on Gravity, in which he gave an account of some experiments tending to prove, that the track of all projectiles moving with very swift motions was widely different from that of a parabola. The rest of the learned acquiesced in the justness of Galileo's doctrine, and very erroneous calculations concerning the ranges of cannon were accordingly given. Nor was any notice taken of these errors till the year 1716. At that time Mr Reffons, a French officer of artillery, distinguished by the number of sieges at which he had served, by his high military rank, and by his abilities in his profession, gave a memoir to the Royal Academy, of which he was a member, importing, that, although it was agreed, that theory joined with practice did constitute the perfection of every art; yet experience had taught him, that theory was of very little service in the use of mortars: That the works of M. Blondel had jolly enough described the several parabolic lines, according to the different degrees of the elevation of the piece; but that practice had convinced him, there was no theory in the effect of gunpowder; for having endeavoured, with the greatest precision, to point a mortar according to these calculations, he had never been able to establish any solid foundation upon them.

From the history of the academy, it doth not appear that the sentiments of Mr Reffons were at any time controverted, or any reason offered for the failure of the
The theory of projectiles when applied to use. Nothing farther, however, was done till the time of Benjamin Robins, who in 1742 published a treatise, intitled, New Principles of Gunningry, in which he hath treated particularly not only of the resistance of the atmosphere, but almost every thing else relating to the flight of military projectiles, and indeed advanced the theory of gunnery much nearer perfection than ever it was before.

The first thing considered by Mr Robins, and which is indeed the foundation of all other particulars relative to gunnery, is the explosive force of gunpowder. This he determined to be owing to an elastic fluid similar to our atmosphere, having its elastic force greatly increased by the heat. “If a red-hot iron (says he) be included in a receiver, and the receiver be exhausted, and gunpowder be then let fall on the iron, the powder will take fire, and the mercurial gage will suddenly descend upon the explosion; and though it immediately ascends again, it will never rise to the height it first fell to, but will continue depressed by a space proportioned to the quantity of powder which was let fall on the iron. The same proportion likewise takes place when gunpowder is fired in the air: first a small quantity of powder is placed in the upper part of a glass tube, the lower part of which is immersed in water, and the fluid be made to rise near to the top, that only a small portion of air is left in that part where the gunpowder is placed; if in this situation the communication of the upper part of the tube with the external air is closed, and the gunpowder fired, which may be easily done by means of a burning-glass, the water will in this experiment descend upon the explosion, as the quicksilver did in the last; and will always continue depressed below the place at which it flooded before the explosion. The quantity of this depression will be greater if the quantity of powder be increased, or the diameter of the tube be diminished.

When any considerable quantity of gunpowder is fired in an exhausted receiver, by being let fall on a red-hot iron, the mercurial gage instantly descends upon the explosion, and as suddenly ascends again. After a few vibrations, none of which except the first are of any great extent, it seemingly fixes at a point lower than where it flood before the explosion. But even when the gage has acquired this point of apparent rest, it still continues rising for a considerable time, although by such imperceptible degrees, that it can only be discovered by comparing its place at distant intervals: however, it will not always continue to ascend, but will rise and flow, till at last it will be absolutely fixed at a point lower than where the mercury flooded before the explosion. The same circumstances nearly happen, when powder is fired in the upper part of an unexhausted tube, whose lower part is immersed in water.

That the elasticity or preffure of the fluid produced by the firing of gunpowder is, ceteris paribus, directly as its density, may be proved from hence, that if in the same receiver a double quantity of powder be let fall, the mercury will subside twice as much as in the firing of a single quantity. Also the descents of the mercury, when equal quantities of powder are fired in different receivers, are reciprocally as the capacities of those receivers, and consequently as the density of produced fluid in each. But as, in the usual method of trying this experiment, the quantities of powder are so very small that it is difficult to ascertain these proportions with the requisite degree of exactness, I took a large receiver containing about 520 inches, and letting fall at once on the red-hot iron one drachm or the sixteenth part of an ounce avoirdupois of powder, the receiver being first nearly exhausted; the mercury, after the explosion, was subducted two inches exactly, and all the powder had taken fire. Then heating the iron a second time, and exhausting the receiver as before, two drachms were let down at once, which sunk the mercury three inches and three quarters; and a small part of the powder had fallen beside the iron, which (the bottom of the receiver being well) did not fire, and the quantity which thus escaped did appear to be nearly sufficient, had it fallen on the iron, to have sunk the mercury a quarter of an inch more; in which case the two descents, viz. two inches and four inches, would have been accurately in the proportion of the respective quantities of powder; from which proportion, as it was, they very little varied.

As different kinds of powder produce different quantities of this fluid, in proportion to their different degrees of goodness, before any definite determination of this kind can take place, it is necessary to ascertain the particular species of powder that is proposed to be used. (Here Mr Robins determines in all his experiments to make use of government-powder, as consisting of a certain and invariable proportion of materials, and therefore preferable to such kinds as are made according to the fancy of private persons.)

"This being settled, we must further premise the two principles: 1. That the elasticity of this fluid increases by heat and diminishes by cold, in the same manner as that of the air; 2. That the density of this fluid, and consequently its weight, is the same with the weight of an equal bulk of air, having the same elasticity and the same temperature. Now, from the last experiment it appears, that \( \frac{7}{4} \) of an ounce avoirdupois or about 27 grains Troy of powder, sunk the gage, on its explosion, two inches; and the mercury in the barometer standing at near 30 inches, \( \frac{7}{4} \) ths of an ounce avoirdupois, or 410 grains Troy, would have filled the receiver with a fluid whose elasticity would have been equal to the whole preffure of the atmosphere, or the same with the elasticity of the air we breathe; and the content of the receiver being about 520 cubic inches, it follows, that \( \frac{7}{4} \) ths of an ounce of powder will produce 520 cubic inches of a fluid possessing the same degree of elasticity with the common air; whereas an ounce of powder will produce near 575 cubic inches of such a fluid.

"But in order to ascertain the density of this fluid, we must consider what part of its elasticity, at the time of this determination, was owing to the heat it received from the included hot-iron and the warm receiver. Now the general heat of the receiver being manifestly less than that of boiling water, which is known to create the elasticity of the air to somewhat more than \( \frac{1}{4} \) of its augmented quantity; I collect from hence and other circumstances, that the augmentation of elasticity from this cause was about \( \frac{1}{4} \) of the whole: that is, if the fluid arising from the explosion had been reduced to the temperature of the external air, the defect of the
the mercurial gauge, instead of two inches, would have been only 1 1/2 inch; whence 575, reduced in the proportion of five to four, become 460; and this last number represents the cubic inches of an elastic fluid equal in density and elasticity with common air, which are produced from the explosion of 1 ounce avoidupolfe of gun-powder; the weight of which quantity of fluid, according to the usual estimation of the weight of air, is 131 grains; whence the weight of this fluid is 132 or 133, this nearly of the weight of the generating powder.

The ratio of the bulk of gunpowder to the bulk of this fluid may be determined from considering that 17 drams avoided so of powder fill two cubic inches, if the powder be well shook together; therefore augmenting the number last found in the proportion of 16 to 17, the resulting term 488 is the number of cubic inches of an elastic fluid, equal in density with the air produced from two cubic inches of powder; whence the ratio of the respective bulk of the powder, and of the fluid produced from it, is in round numbers as 1 to 244.

This calculation was afterwards justified by experiments.

If this fluid, instead of expanding when the powder was fired, had been confined in the same space which the powder filled before the explosion then it would have had, in that confined state, a degree of elasticity 244 times greater than that of common air; and this independent of the great augmentation this elasticity would receive from the action of the fire in that instant.

Hence, then, we are certain, that any quantity of powder, fired in a confined space, which it adequately fills, exerts, at the instant of its explosion, against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of the common air, or, which is the same thing than the pressure of the atmosphere; and this without conferring the great addition which this force will receive from the violent degree of heat with which it is affected at that time.

To determine how far the elasticity of air is augmented when heated to the extremity of red-hot iron, I took a piece of a musket-barrel about six inches in length, and ordered one end to be closed up entirely; but the other end was drawn out conically, and finished in an aperture of about ½ of an inch in diameter. The tube thus fitted, was heated to the extremity of a red heat in a smith's forge; and was then immersed with its aperture downwards in a bucket of water, and kept there till it was cool: after which it was taken out carefully, and the water which had entered it in cooling was exactly weighed. The heat given to the tube at each time, was the beginning of what workmen call a white heat; and to prevent the rushing in of the aqueous vapour at the immersion, which would otherwise drive out great part of the air, and render the experiment fallacious, I had an iron wire filed tapering, so as to fit the aperture of the tube, and with this I always stopped it up before it was taken from the fire, letting the wire remain in till the whole was cool, when, removing it, the due quantity of water would enter. The weight of the water thus taken in at three different trials was 610 grains, 595 grains, and 600 grains, respectively. The content of the whole cavity of the tube was 796 grains of water; whence the spaces remaining unfilled in these three experiments were 186, 201, and 196 grains respectively. These spaces undoubtedly contained all the air which, when the tube was red-hot, extended through its whole length, and that the elasitic force by which the air contained in this tube, when heated to the extreme heat of red-hot iron, was to the elasiticity of the same air, when reduced to the temperature of the ambient atmosphere, as the whole capacity of the tube to the respective spaces taken up by the cooled air; that is, as 796 to 186, 201, 196: or taking the medium of these three trials, as 796 to 194.

As air and this fluid appear to be equally affected by heat and cold, and consequently have their elasitcites equally augmented by the addition of equal degrees of heat to each; if we suppose the heat with which the flame of fired powder is endowed to be the same with that of the extreme heat of red-hot iron, then the elasiticity of the fluid generated by the explosion, being augmented in the extremity of this heat in the ratio of 194: to 796, it follows, that as 244 be augmented in this ratio, the resulting number, which is 999, will determine how many times the elasiticity of the flame of fired powder exceeds the elasiticity of common air, supposing it to be confined in the same space which the powder filled before it was fired. Hence then the absolute quantity of the pressure exerted by gunpowder at the moment of its explosion may be ascertained; for, since the fluid then generated has an elasiticity of 999, or in round numbers 1000 times greater than that of the atmospheric, and since common air by its elasiticity exerts a pressure on any given surface equal to the weight of the incumbent atmosphere with which it is in equilibrium, the pressure exerted by fired powder before it dilates itself is 1000 times greater than the pressure of the atmosphere; and consequently the quantity of this force, on a surface of an inch square, amounts to above six ton weight; which force, however, in the proportion of the state of the fire, ever, diminishes as the fluid dilates itself. But though we have here supposed that the heat of gunpowder when fired in any considerable quantity, is the same with iron heated to the extremity of red heat, or to the beginning of a white heat, yet it cannot be doubted but that the fire produced in the explosion is somewhat varied (like all other fires) by a greater or lesser quantity of fuel; and it may be presumed, that, according to the quantity of powder fired together, the flame may have all the different degrees, from a languid red heat to that sufficient for the vitrification of metals. But as the quantity of powder requisite for the production of this last mentioned heat, is certainly greater than what is ever fired together for any military purpose, we cannot be far from our scope, if we suppose the heat of such quantities as are usually fired to be nearly the same with that of red-hot iron; allowing a gradual augmentation to this heat in larger quantities and diminishing it when the quantities are very small."

Havmg.
Having thus determined the force of the gunpowder, Mr. Robins next proceeds to determine the velocity with which the ball is discharged. The solution of this problem depends on the two following principles. 1. That the action of the powder on the bullet ceases as soon as the bullet is got out of the piece. 2. That all the powder of the charge is fired and converted into elastic fluid before the bullet is sensibly moved from its place.

"The first of these (says Mr. Robins) will appear manifest, when it is considered how suddenly the flame will extend itself on every side, by its own elaticity, when it is once got out of the mouth of the piece; for by this means its force will then be dissipated, and the bullet no longer sensibly affected by it."

"The second principle is indeed less obvious, being contrary to the general opinion of almost all writers on this subject. It might however be sufficient for the proof of this position, to observe the prodigious compression of the flame in the chamber of the piece. Tho' who attend to this circumstance, and to the easy passage of the flame through the intervals of the grains, may soon satisfy themselves, that no one grain contained in that chamber can continue for any time uninfamed, when thus surrounded and pressed by such an active fire. However, not to rely on mere speculation in a matter of so much consequence, I confidered, that if part only of the powder is fired, and that successively; then by laying a greater weight before the charge (suppose two or three bullets instead of one), a greater quantity of powder would necessarily be fired, since a heavier weight would be a longer time in passing through the barrel. Whence it should follow, that two or three bullets would be impelled by a much greater force than one only. But the contrary to this appears by experiment; for firing one, two, and three bullets laid contiguous to each other with the same charge respectively, I have found that their velocities were not much different from the reciprocal of their subduplicate quantities of matter; that is, if a given charge would communicate to one bullet a velocity of 1700 feet in a second, the same charge would communicate to two bullets a velocity from 1230 to 1300 feet in a second, and to three bullets a velocity from 1050 to 1110 feet in the same time. From hence it appears, that, whether a piece is loaded with a greater or less weight of bullet, the action is nearly the same; since all mathematicians know, that if bodies containing different quantities of matter are successively impelled through the same space by the same power acting with a determined force at each point of that space; then the velocities given to these different bodies will be reciprocally in the subduplicate ratio of their quantities of matter. The excess of the velocities of the two and three bullets above what they ought to have been by this rule (which are that of 1200 and 980 feet in a second), undoubtedly arises from the flame, which, escaping by the side of the first bullet, acts on the surface of the second and third.

"Now, this excess has in many experiments been imperceptible, and the velocities have been reciprocally in the subduplicate ratios of the number of bullets, to sufficient exactness; and where this error has been greater, it has never arisen to an eighth part of the whole; but if the common opinion was true, that a small part only of the powder fires at first, and other parts of it successively as the bullet passes through the barrel, and that a considerable part of it is often blown out of the piece without firing at all; then the velocity which three bullets received from the explosion ought to have been much greater than we have found it to be.—But the truth of this second postulate more fully appears from those experiments, by which it is shown, that the velocities of bullets may be ascertained to the same exactness when they are acted on through a barrel of four inches in length only, as when they are discharged from one of four feet.

"With respect to the grains of powder which are often blown out unfired, and which are always urged as a proof of the gradual firing of the charge, I believe Diego Uffano, a person of great experience in the art of gunnery, has given the true reason for this accident; which is, that some small part of the charge is often not ramm'd up with the rest, but is left in the piece before the wad, and is by this means expelled by the blast of air before the fire can reach it."

13. Instantaneous firing of powder.

14. Why some powder is blown out of the mouth of a cannon without being fired.
consequently the line LP will determine a line proportion- 
al to the uniform force of gravity in every point; 
whilst the hyperbola FHQB determines in like manner 
such lines as are proportional to the impelling 
force of the powder in every point; whence by the 
39th Prop. of lib. 1. of Sir Isaac Newton’s Principia, 
the areas FLPB and FHQB are in the duplicate 
proportion of the velocities which the ball would acquire 
when aed upon by its own gravity through the space 
FB, and when impelled through the same space by the 
force of the powder. But since the ratio of AF to 
AB and the ratio of FH to FL are known, the ratio 
of the area FLPB to the area FHQB is known; and 
therefore its subduplicate. And since the line FB is gi- 
gen in magnitude, the velocity which a heavy body 
would acquire when impelled through this line by its 
own gravity is known; being no other than the velo- 
city it would acquire by falling through a space equal 
to that line: find then another velocity to which this 
latter mentioned velocity bears the given ratio of the sub-
duplicate of the area FLPB to the area FHQB; and 
this velocity thus found is the velocity the ban will ac­ 
quire when impelled through the space FB by the ac­ 
tion of the inflated powder.

Now to give an example of this: Let us suppose 
AB, the length of the cylinder, to be 45 inches, its di- 
ameter DC, or rather the diameter of the ball, to be 
4ths of an inch; and AF, the extent of the powder, 
to be 21 inches; to determine the velocity which 
will be communicated to a leaden ball by the explo- 
sion, supposing the bullet to be laid at first with its 
surface contiguous to the powder.

By the theory we have laid down, it appears, 
that at the first instant of the explosion the flame will 
exert, on the bullet lying close to it, a force 1000 
times greater than the pressure of the atmosphere. 
The medium pressure of the atmosphere is reckoned equal 
to a column of water 33 feet in height; whence, lead 
being to water as 11.245 to 1, this pressure will be 
equal to that of a column of lead 349 inches in height. 
Multiplying this by 1000, therefore, a column of lead 
34900 inches (upwards of half a mile) in height, 
would produce a pressure on the bullet equal to what 
is exerted by the powder in the first instant of the ex- 
plosion; and the leaden ball being 4ths of an inch in 
diameter, and consequently equal to a cylinder of lead 
of the same base half an inch in height, the pressure at 
first acting on it will be equal to 34900x2, or 69800 
times its weight: whence FL to FH as 1 to 69800; 
and FB to FA as 45—21; or 42 21; that is, 
as 339 to 21; whence the rectangle FLPB is to the re- 
cangle AFHS as 339 to 21x69800, that is, as 1 to 4324. —And from the known application of the loge-
theories to the mensuration of the hyperbolic spaces it 
follows, that the rectangle AFHS is to the area FHQB 
as 43,429, &c. is to the tabular logarithm of AB.

In order to compare the velocities communicated 
to bullets by the explosion, with the velocities result- 
ing from the theory by computation, it is necessary 
that the actual velocities with which bullets move 
should be discovered. The only methods hitherto prac- 
ticed for this purpose, have been either by observing 
the time of the flight of a shot through a given space, 
or by measuring the range of a shot at a given elevation 
and thence computing, on the parabolic hypo- 
thesis,
Theory. What degree of velocity would produce this range.—The first method labours under this insurmountable difficulty, that the velocities of these bodies are often so swift, and consequently the time observed is so short that an imperceptible error in that time may occasion an error in the velocity thus found of 2, 3, 4, 5, or 600 feet, in a second. The other method is so fallacious, by reason of the resistance of the atmosphere (to which inequality the first is also liable), that the velocities thus assigned may not perhaps be the part of the actual velocities sought.

The simplest method of determining this velocity is by means of the instrument represented fig. 1, where ABCD represents the body of the machine composed of the three poles B, C, D, spreading at bottom, and joining together at the top A; being the same with what is vulgarly used in lifting and weighing very heavy bodies, and is called by workmen the triangles. On two of these poles, towards their tops, are screwed on the fockets RS; and on these fockets the pendulum EFGHK is hung by means of its cross-piece EF, which becomes its axis of suspension, and on which it must be made to vibrate with great freedom. The body of this pendulum is made of iron, having a broad part at bottom, and its lower part is covered with a thick piece of wood GKI, which is fastened to the iron by screws. Something lower than the bottom of the pendulum there is a brace OP, joining the two poles to which the pendulum is suspended; and to this brace there is fastened a contrivance MNU, made with two edges of steel, bearing on each other in the line UN, something in the manner of a drawing-pen; the strength with which these edges press on each other being diminished or increased at pleasure by means of a screw Z going through the upper piece. There is fastened at the bottom of the pendulum a narrow ribbon LN, which passes between these steel edges, and which afterwards, by means of an opening cut in the lower piece of steel, hangs loosely down, as at W.

This instrument thus fitted, if the weight of the pendulum be known, and likewise the respective distances of its centre of gravity, and of its centre of oscillation from its axis of suspension, it will thence be known what motion will be communicated to this pendulum by the percussion of a body of a known weight moving with a known degree of celerity, and striking it in a given point; that is, if the pendulum be supposed at rest before the percussion, it will be known what vibration it ought to make in consequence of such a determined blow; and, on the contrary, if the pendulum, being at rest, is struck by a body of a known weight, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may from thence be determined.

Hence then if a bullet of a known weight strikes the pendulum, and the vibration which the pendulum makes after the blow is known, the velocity of the striking body may thence be determined.

Now the extent of the vibration made by the pendulum after the blow, may be measured to great accuracy by the ribbon LN. But let the pendulum be so regulated by the screw Z, that the motion of the ribbon between them may be free and easy, though with some minute resistance; then setting the pendulum at rest, let the part LN between the pendulum and its edges be drawn straight, but not strained, and fix a pin in that part of the ribbon which is then contiguous to the edges: let now a ball impinge on the pendulum; then the pendulum swinging back will draw out the ribbon to the just extent of its vibration, which will consequently be determined by the interval on the ribbon between the edges LN and the place of the pin.

The weight of the whole pendulum, wood and all, was 651, 3 oz. its centre of gravity was 32 inches distant from its axis of suspension, and 200 of its small weights were performed in the time of 253 seconds; whence its centre of oscillation (determined from hence) is 62; inches distant from that axis. The centre of the piece of wood GKI is distant from the same axis 66 inches.

In the compound ratio of 65 to 62, and 66 to 62, take the quantity of matter of the pendulum to a 4th quantity, which will be 42 lb. 2 oz. Now geometers will know, that if the blow be struck on the centre of the piece of wood GKI, the pendulum will resist to the stroke in the manner as if this last quantity of matter only (42 lb. 2 oz.) was concentrated in that point, and the rest of the pendulum was taken away: whence, supposing the weight of the bullet impinging in that point to be the 4th of a pound, or the 4th of this quantity of matter nearly, the velocity of the point of oscillation after the stroke will, by the laws observed in the congress of such bodies as rebound not from each other, be the 4th of the velocity the bullet moved with before the stroke; whence the velocity of this point of oscillation after the stroke being ascertained, that multiplied by 305 will give the velocity with which the ball impinged.

But the velocity of the point of oscillation after the stroke is easily deduced from the chord of the arch, through which it ascends by the blow; for it is a well known proposition, that all pendulous bodies ascend to the same height by their vibratory motion as they would do, if they were projected directly upwards from their lowest point, with the same velocity they have in that point: wherefore, if the verfed line of the ascending arch be found (which is easily determined from the chord and radius being given), this verfed line is the perpendicular height to which a body projected upwards with the velocity of the point of oscillation would arrive; and consequently what that velocity is, can be easily computed by the common theory of falling bodies.

For instance the chord of the arch, described by the ascent of the pendulum after the stroke measured on the ribbon, has been sometimes 17½ inches; the distance of the ribbon from the axis of suspension is 7½ inches; whence reducing 17½ in the ratio of 7½ to 66, the resuling number, which is nearly 16 inches, will be the chord of the arch through which the centre of the board GKI ascended after the stroke; now the verfed line of the arch, whose chord is 16 inches, and its radius 66, is 3,93929; and the velocity which would carry a body to this height, or, which is the same thing, the velocity which a body would acquire by descending through this space, is nearly that of 3½ feet in 1/14.
GUNNERY.

Section II.

Theory.

"To determine then the velocity with which the bullet impinging on the centre of the wood, when the chord of the arch described by the ascent of the pendulum, in consequence of the blow, was 17½ inches measured on the ribbon, no more is necessary than to multiply 3½ by 505, and the resulting number 1641 will be the feet which the bullet would describe in 10, if it moved with the velocity it had at the moment of its percussion: for the velocity of the point of the pendulum, on which the bullet struck, we have just now determined to be that of 3½ feet in 10; and we have before shown, that this is the 17th of the velocity of the bullet. If then a bullet weighing ½th of a pound strikes the pendulum in the centre of the wood GKH, and the relation drawn out 17½ inches by the blow; the velocity of the bullet is that of 1641 feet in 10. And since the length the ribbon is drawn is always nearly the chord of the arch described by the ascent, (it being placed so as to differ insensibly from those chords which most frequently occur), and these chords are known to be in the proportion of the velocities of the pendulum acquired from the stroke; it follows, that the proportion between the lengths of ribbon drawn out at different times, will be the same with that of the velocities of the impinging bullets; and consequently, by the proportion of these lengths of ribbon to 17½, the proportion of the velocity with which the bullets impinge, to the known velocity of 1641 feet in 10, will be determined.

"Hence then is shown in general how the velocities of all kinds may be found out by means of this instrument; but that those who may be disposed to try these experiments may not have unforeseen difficulties to struggle with, we shall here subjoin a few observations, which it will be necessary for them to attend to, both to secure success to their trials and safety to their persons.

"And first, that they may not conceive the piece of wood GKH to be an unnecessary part of the machine, we must inform them, that if a bullet impelled by a full charge of powder should strike directly on the iron, the bullet would be beaten into shivers by the stroke, and these shivers will rebound back with such violence, as to bury themselves in any wood they chance to light on, as I have found by hazardous experience; and besides the danger, the pendulum will not in this instance ascertain the velocity of the bullet, because the velocity with which the parts of it rebound is unknown.

"The weight of the pendulum, and the thickness of the wood, must be in some measure proportioned to the size of the bullets which are used. A pendulum of the weight here described will do very well for all bullets under three or four ounces, if the thickness of the board be increased to seven or eight inches for the heaviest bullets; beech is the toughest and properest wood for this purpose.

"It is hazardous standing on the side of the pendulum, unless the board be so thick, that the greatest part of the bullet's force is lost before it comes at the iron; for if it strikes the iron with violence, the shivers of lead, which cannot return back through the wood, will force themselves out between the wood and iron, and will fly to a considerable distance.

"As there is no effectual way of hardening the wood to the iron but by fowings, the heads of which must come through the board; the bullets will sometimes light on those fowings, from whence the shivers will differ from themselves on every side.

"When in these experiments so small a quantity of powder is used, as will not give to the bullet a velocity of more than 400 or 500 feet in 10; the bullet will not stick in the wood, but will rebound from it entire, and (if the wood be of a very hard texture) with a very considerable velocity. Indeed I have never examined any of the bullets which have thus rebounded, but I have found them indented by the bodies they have struck against in their rebound.

"To avoid then these dangers, to the braving of which in philosophical researches no honour is annexed; it will be convenient to fix whatsoever barrel is used, on a strong heavy carriage, and to fire it with a little slow match. Let the barrel too be very well fortified in all its length; for no barrel (I speak of musket barrels) forged with the usual dimensions will bear many of the experiments without bursting. The barrel I have most relied on, and which I procured to be made on purpose, is nearly as thick at the muzzle as at the breech; that is, it has in each place nearly the diameter of its bore in thickness of metal.

"The powder used in these experiments should be exactly weighed: and that no part of it be scattered in the barrel, the piece must be charged with a ladle in the same manner as is practised with cannon; the wad should be of tow of the same weight each time, and no more than is just necessary to confine the powder in its proper place: the length of the cavity left behind the ball should be determined each time with exactness; for the increasing or diminishing that space will vary the velocity of the shot, although the bullet and quantity of powder be not changed. The distance of the mouth of the piece from the pendulum ought to be such, that the impulse of the flame may not act on the pendulum; this will be prevented in a common barrel charged with a pound of powder, if it be at the distance of 16 or 18 feet: in larger charges the impulse is sensible farther off; I have found it to extend to above 25 feet; however, between 25 and 18 feet is the distance I have usually chosen.

"With this instrument, or others similar to it, Mr. Account of Robins made a great number of experiments on bar Mr. Roberts of different lengths, and with different charges of gun powder. He hath given us the results of 61 of these, with many others, and having compared the actual velocities with the computed ones, his theory appears to have come as near the truth as could well be expected. In seven of the experiments there was a perfect coincidence; the charges of powder being fix or twelve pennyweights; the barrels 4½, 24, 32, and 7½ inches in length. The diameter of the first (marked A) was ½th of an inch; of the second (B) was the same; and of D, 83 of an inch. In the rest of the experiments, another barrel (C) was used, whole length was 12.575 inches, and the diameter of its bore 3½ inches. In 14 more of the experiments, the difference between the length of the chord of the pendulum's arch shown by the theory and the actual experiment was ½th of an inch over or under. This showed an error in the theory varying according to the different lengths of the chord from ½ to ⅞ of the whole; the charges of powder were..."
GUNNERY.

Sect. II.

The error was

From these experiments Mr. Robins deduces the following conclusions: "The variety of these experiments, and the accuracy with which they correspond to the theory, leave us no room to doubt of its certainty. This theory, as here established, supposes that, in the firing of gunpowder, about $\frac{1}{4}$ of its substance is converted by the sudden inflammation into a permanently elastic fluid, whose elasticity, in proportion to its heat and density, is the same with that of common air in the like circumstances; it farther supposes, that all the force exerted by gunpowder in its most violent operations, is no more than the action of the elasticity of the fluid thus generated; and these principles enable us to determine the velocities of bullets impelled from fire-arms of all kinds; and are fully sufficient for all purposes where the force of gunpowder is to be estimated.

"From this theory many deductions may be made of the greatest consequence to the practical part of gunnery. From hence the thickness of a piece, which will enable it to confine, without bursting, any given charge of powder, is easily determined, since the effort of the powder is known. From hence appears the inconclusiveness of what some modern authors have advanced, relating to the advantages of particular forms of chambers for mortars and cannon; for all their laboured speculations on this head are evidently founded on very erroneous opinions about the action of fired powder. From this theory we are taught the necessity of leaving the same space behind the bullet when we would, by the same quantity of powder, communicate to it an equal degree of velocity; since, on the principles already laid down, it follows, that the same powder has a greater or less degree of elasticity, according to the different spaces it occupies. The method which I have always practised for this purpose has been by marking the rammer; and this is a maxim which ought not to be dispensed with when cannon are fired at an elevation, particularly in those called by the French batteries à ricochet.

"From the continued action of the powder, and its manner of expanding described in this theory, and the length and weight of the piece, one of the most essential circumstances in the well directing of artillery may be easily ascertained. All practitioners are agreed, that no shot can be depended on, unless the piece be placed on a solid platform; for if the platform shakes with the first impulse of the powder, it is impossible but the piece must also shake which will alter its direction, and render the shot uncertain. To prevent this accident, the platform is usually made extremely firm to a considerable depth backwards; so that the piece is not only well supported in the beginning of its motion, but likewise through a great part of its recoil. However, it is sufficiently obvious, that when the bullet is separated from the piece, it can be no longer affected by the trembling of the piece or platform; and, by a very easy computation, it will be found, that the bullet will be out of the piece before the latter hath recoiled half; whereas, if the platform be sufficiently solid at the beginning of the recoil, the remaining part of it may be much lighter; and hence a more compendious method of constructing platforms may be found out.

"From this theory also it appears how greatly these authors have been mistaken, who have attributed the force of gunpowder, or at least a considerable part of it, to the action of the air contained either in the powder or between the intervals of the grains; for they have supposed that air to exist in its natural elastic state, and to receive all its addition of force from the heat of the explosion. But from what hath been already delivered concerning the increase of the air's elasticity by heat, we may conclude that the heat of the explosion cannot augment this elasticity to five times its common quantity; consequently the force arising from this cause only cannot amount to more than the 200th part of the real force exerted on the occasion.

"If the whole substance of the powder was converted into an elastic fluid at the instant of the explosion, then from the known elasticity of this fluid affixed by our theory, and its known density, we could easily determine the velocity with which it would begin to expand, and could thence trace out its future augmentations in its progress through the barrel; but as we have shown that the elastic fluid, in which the activity of gunpowder consists, is only $\frac{1}{4}$ of the substance of the powder, the remaining $\frac{3}{4}$ is, in the explosion, be mixed with the elastic part, and will by its weight retard the activity of the explosion; and yet they will not be so completely united as to move with one common motion; but the unelastic part will be more accelerated than the rest, and some will not even be carried out of the barrel, as appears by the considerable quantity of unelastic matter which adheres to the inside of all fire-arms after they have been used.---These inequalities in the expansive motion of the flame oblige us to recur to experiments for its accurate determination.

"The experiments made use of for this purpose were of two kinds. The first was made by charging the barrel A with 19 pennyweights of powder, and a small
small wad of tow only: and then placing its mouth 19 inches from the centre of the pendulum. On firing it in this situation, the impulse of the flame made it pass through an arch whose chord was 13.3 inches, whence, if the whole substance of the powder was supposed to strike against the pendulum, and each part to strike with the same velocity, that common velocity must have been at the rate of about 2650 feet in a second.—But as some part of the velocity of the flame was lost in passing through 19 inches of air: I made the remaining experiments in a manner not liable to this inconvenience.

I fixed the barrel A on the pendulum, so that its axis might be both horizontal and also perpendicular to the plane HK; or, which is the same thing, that it might be in the plane of the pendulum's vibration: the height of the axis of the piece above the centre of the pendulum was six inches; and the weight of the piece, and of the iron that fastened it, was 12 lb. The barrel in this situation being charged with 12 penny-weights of powder, without either ball or wad, only put together with the rammer; on the discharge the pendulum ascended through an arch whose chord was 10 inches, or reduced to an equivalent blow in the centre of the pendulum, supposing the barrel away, it would be 14.4 inches nearly.—The same experiment being repeated, the chord of the ascending arch was 10.1 inches, which reduced to the centre, is 14.6 inches.

To determine what difference of velocity there was in the different parts of the vapour, I loaded the piece again with 12 penny-weights and rammed it down with a wad of tow, weighing one penny-weight. Now, I conceived that this wad being very light, would presently acquire that velocity with which the elastic part of the fluid would expand itself when uncomprised; and I accordingly found, that the chord of the ascending arch was by this means increased to 12 inches, or at the centre to 17.2; whence, as the medium of the other two experiments is 14.5, the pendulum ascended through an arch 2.8 inches longer, by the additional motion of one penny-weight of matter, moving with the velocity of the swiftest part of the vapour; and consequently the velocity with which this penny-weight of matter moved, was that of about 7000 feet in a second.

It will perhaps be objected to this determination, that the augmentation of the arch through which the pendulum vibrated in this case was not all of it owing to the quantity of motion given to the wad, but part of it was produced by the confinement of the powder, and the greater quantity thereby fired. But if it were true that a part only of the powder fired when there was no wad, it would not happen that in firing different quantities of powder without a wad the chord would increase and decrease nearly in the ratio of these quantities; which yet I have found it to do: for with nine pennyweights that chord was 7.3 inches, which with 12 pennyweights we have seen was only 10, and 10.1 inches; and even with three pennyweights the chord was two inches; deficient from this proportion by 5 only; for which defect too other valid reasons are to be ascribed.

And there is still a more convincing proof that all the powder is fired, although no wad be placed before the charge, which is, that the part of the recoil arising from the expansion of powder alone is found to be no greater when it impuls a leaden bullet before it than when the same quantity is fired without any wad to confine it. We have seen that the chord of the arch through which the pendulum rose from the expansive force of the powder alone is 10, or 10.1; and the chord of that arch, when the piece was charged in the customary manner with a bullet and wad, I found to be the first time 22.1, and the second 22.4, or at a medium 22.36. Now the impulse of the ball and wad, if they were supposed to strike the pendulum in the same place in which the barrel was suspended, with the velocity they had acquired at the mouth of the piece, would drive it through an arch whose chord would be about 12.3; as is known from the weight of the pendulum, the weight and position of the barrel, and the velocity of the bullet determined by our former experiments: whence, subtracting this number 12.3 from 22.36, the remainder 10.26 is nearly the chord of the arch which the pendulum would have ascended through from the expansion of the powder alone with a bullet laid before it. And this number, 10.26, differs but little from 10.1, which we above found to the chord of the ascending arch, when the same quantity of powder expanded itself freely without either bullet or wad before it.

Again, that this velocity of 7000 feet in a second is not much beyond that most active part of the flame acquires in expanding, is evinced from hence, that in some experiments a ball has been found to be discharged with a velocity of 2400 feet in a second: and yet it appeared not that the action of the powder was at all diminished on account of this immense celerity: consequently the degree of swiftness with which in this instance, the powder followed the ball without losing any part of its pressure, must have been much more of what the powder alone would have expanded with, had not the ball been there.

From these determinations may be deduced the force of retardation; since their action depends entirely on the impulse of the flame: and it appears that a quantity of powder properly dispersed in such a machine, may produce as violent an effect as a bullet of twice its weight, moving with a velocity of 1400 or 1500 feet in a second.

In many of the experiments already recited, the ball was not laid immediately contiguous to the powder, but at a small distance, amounting, at the utmost, only to an inch and a half. In these cases the greatest velocity when laid at a distance from the powder, being as 12.18. or 24 inches, we cannot then apply to this ball the same principles which may be applied to those laid in contact, or nearly so, with the powder: for when the surface of the fired powder is not confined by a heavy body, the flame dilates itself with a velocity far exceeding that which it can communicate to a bullet by its continued pressure: consequently, as at the distance of 12, 18, or 24 inches, the powder will have acquired a considerable degree of this velocity of expansion, the first motion of the ball will not be produced by the continual pressure of the powder, but by the actual percussion of the flame.
flame; and it will therefore begin to move with a quantity of motion proportioned to the quantity of this flame, and the velocities of its respective parts.

From hence then it follows, that the velocity of the ball, laid at a considerable distance before the charge ought to be greater than what would be communicated to it by the pressure of the powder acting in the manner already mentioned; and this deduction from our theory we have confirmed by manifold experience; by which we have found, that a ball laid in the barrel $A$, with its hinder part 17 inches from its breech, and impelled by 12 pennyweights of powder, has acquired a velocity of about 1400 feet in a second; when, if it had been acted on by the pressure of the flame only, it would not have acquired a velocity of 1200 feet in a second. The same we have found to hold true in all other greater distances (and also in lesser, though not in the same degree), and in all quantities of powder: and we have likewise found, that these effects nearly correspond with what has been already laid down about the velocity of expansion and the elastic and unelastic parts of the flame.

From hence too arises another consideration of great consequence in the practice of gunnery; which is, that no bullet should at any time be placed at a considerable distance before the charge, unless the piece is extremely well fortified; for a moderate charge of powder, when it has expanded itself through the vacant space, and reaches the ball, will, by the velocity each part has acquired, accumulate itself behind the ball, and thereby be condensed prodigiously; whence if the barrel be not extremely firm in that part, it must by means of this reinforced elasticity, infalubly burst. The truth of this reasoning I have experienced in an exceeding good Tower-musket, forged of very tough iron; for charging it with 12 pennyweights of powder, and placing the ball 16 inches from the breech, on firing it, the part of the barrel just behind the barrel was swelled out to double its diameter like a blown bladder, and two large pieces of two inches long were burst out of it.

Having seen that the entire motion of a bullet laid at a considerable distance from the charge, is acquired by two different methods in which the powder acts on it: the first being the percussion of the parts of the flame with the velocity they had respectively acquired by expanding, the second the continued pressure of the flame through the remaining part of the barrel; I endeavoured to separate these different actions, and retain that only which arose from the continued pressure of the flame. For this purpose I no longer placed the powder at the breech, from whence it would have full scope for its expansion; but I scattered it as uniformly as I could through the whole cavity left behind the bullet; imagining that by this means the progressive velocity of the flame in each part would be prevented by the expansion of the neighboring parts; and I found, that the ball being laid 11 inches from the breech, its velocity, instead of 1400 feet in a second, which it acquired in the last experiments, was now no more than 1150 feet in the second, which is 100 feet short of what according to the theory should arise from the continued pressure of the powder only.

The reason of this deficiency, was doubtless, the intense motion of the flame; for the ascent of the powder thus distributed through so much larger a space than it could fill, must have produced many reverberations and pulsations of the flame; and from these internal agitations of the fluid, its pressure on the containing surface will (as is the cause of all other fluids) be considerably diminished; and in order to avoid this irregularity, in all other experiments I took care to have the powder closely confined in so small a space as possible, even when the bullet lay at some little distance from it.

With regard to the resistance of the air, which so remarkably affects all military projectiles, it is necessary to premise, that the greatest part of authors have established it as a certain rule, that while the body moves in the flame medium, it is always resisted in the duplicate proportion of its velocity; and, if the resisted body move in one part of its track with three times the velocity with which it moved in some other part, then its resistance to the greater velocity will be nine times the resistance to the lesser. If the velocity in one place be four times greater than in another, the resistance of the fluid will be 16 times greater in the first than in the second, &c. This rule, however, though pretty near the truth when the velocities are confined within certain limits, is excessively erroneous when applied to military projectiles, where such resistances often occur as could scarcely be effected, on the commonly received principles, even by a treble augmentation of its density.

By means of the machine already described, I have it in my power to determine the velocity with which a ball moves in any part of its track, provided I can direct the piece in such a manner as to cause the bullet to impinge on a pendulum placed in that part: and therefore charging a musket-barrel three times successively with a leaden ball ⅓ of an inch in diameter, and about half its weight of powder; and taking such precaution in weighing of the powder and placing it, that I was assured by many previous trials, that the velocity of the ball could not differ by 20 feet in a second from its medium quantity; I fired it against the pendulum placed at 25, 75, and 125 feet distance from the mouth of the piece respectively; and I found that it impinged against the pendulum, in the first case, with a velocity of 1670 feet in a second; in the second case, with a velocity of 1550 feet in a second; and in the third case, with a velocity of 1425 feet in a second; fo that, in passing through 50 feet of air, the bullet lost a velocity of 120 or 125 feet in a second; and the time of its passing through that space being about $\frac{5}{4}$ or $\frac{7}{8}$ of a second, the medium quantity of resistance must, in these instances, have been about 120 times the weight of the ball; which (as the ball was nearly $\frac{1}{4}$ of a pound) amounts to about 10 lb. avoirdupois.

Now, if a computation be made according to the method laid down for compressed fluids in the 38th proposition of Newton's "Principia," supposing the weight of water to that of air as 850 to 1, it will be found that the resistance to a globe of ⅞ of an inch diameter, moving with a velocity of about 1600 feet in a second, will not, on these principles amount to any more than 4½ lb. avoirdupois; whence, as we know that the rules contained in that proposition are very
Sec. II.

G U N N E R Y.

Theory. very accurate with regard to flow motions, we may hence conclude, that the resistance of the air in flow motions is less than in that of swift motions, in the ratio of 4: to 1; a proportion between that of 1 to 2, and 1 to 3.

“Again, I charged the same piece a number of times with equal quantities of powder, and balls of the same weight; taking all possible care to give to every shot an equal velocity; and, firing three times against the pendulum placed only 25 feet from the month of the piece, the medium of the velocities with which the ball impinged was nearly that of 1690 feet in a second: then removing the piece 175 feet from the pendulum, I found, taking the medium of five shots, that the velocity with which the ball impinged at this distance was 1500 feet in a second; whence the ball, in passing through 150 feet of air, lost a velocity of about 350 feet in a second; and the resistance computed from these numbers comes out something more than in the preceding instance; it amounting here to between 11 and 12 pounds avoidujoife; whence, according to these experiments, the resisting power of the air to swift motions is greater than to flow ones, in a ratio which approaches nearer to that of 3 to 1 than in the preceding experiments.

“Having thus examined the resistance to a velocity of 1700 feet in a second, I next examined the resistance to smaller velocities: and for this purpose, I charged the same barrel with balls of the same diameter, but, with less powder, and placing the pendulum at 25 feet distance from the piece, I fired against it five times with an equal charge each time; the medium velocity with which the ball impinged, was that of 1180 feet in a second; then removing the pendulum to the distance of 250 feet, the medium velocity of five shots, made at this distance, was that of 950 feet in a second; whence the ball, in passing through 255 feet of air, lost a velocity of 230 feet in a second; and as it passed through that interval in about \( \frac{1}{6} \) of a second, the resistance to the middle velocity will come out to be near \( \frac{1}{3} \) times the gravity of the ball, or 2lb. 1oz. avoidujoife. Now, the resistance to the same velocity, according to the laws observed in flowery motions, amounts to \( \frac{1}{6} \) of the same quantity; whence, in a velocity of 1065 feet in a second, the resisting power of the air is augmented in no greater a proportion than that of 7 to 11; whereas we have seen in the former experiments, that to fill greater degrees of velocity the augmentation approached very near the ratio of one to three.

“But farther, I fired three shot, of the same size and weight with those already mentioned, over a large piece of water; so that their dropping into the water being very discernible, both the distance and time of their flight might be accurately ascertained. Each shot was discharged with a velocity of 400 feet in a second; and I had satisfied myself by many previous trials of the same charge with the pendulum, that I could rely on this velocity to tent feet in a second. The first shot flew 313 yards in four seconds and a quarter, the second flew 319 yards in four seconds, and the third 373 yards in five seconds and a half. According to the theory of resistance established for flow motions, the first shot ought to have spent no more than 3.2 seconds in its flight, the second 3.28, and the the third 4 seconds: whence it is evident, that every shot was retarded considerably more than it ought to have been had that theory taken place in its motion: consequently the resistance of the air is very sensibly increased, even in such a small velocity as that of 400 feet in a second.

“As no large shot are ever projected in practice Plate with velocities exceeding that of 1700 feet in a second, it will be sufficient for the purposes of a practical gun, Fig. 3, to determine the resistance to all lesser velocities: which may thus be exhibited. Let AB be taken to AC, in the ratio of 1700 to 1 in the second to the given velocity to which the resisting power of the air is required. Continue the line AB to D, so that BD may be to AD, as the resisting power of the air to flow motions is to its resisting power to a velocity of 1700 feet in a second; then shall CD be to AD as the resisting power of the air to flow motions is to its resisting power to the given velocity represented by AC.

“From the computations and experiments already mentioned, it plainly appears, that a leaden ball of one inch diameter, and weighing nearly 2 oz. avoidujoife, if it be fired from a barrel of 45 inches in length, with half its weight of powder, will issue from that piece with a velocity which, if it were uniformly continued, would carry it near 1700 feet in a second. If, instead of a leaden ball, an iron one, of an equal diameter, was placed in the same situation in the same piece, and was impelled by an equal quantity of powder, the velocity of such an iron-bullet would be greater than that of the leaden one in the subduplicate ratio of the specific gravities of lead and iron; and supposing that ratio to be as three to two, and computing on the principles already laid down, it will appear, that an iron bullet of 24 lb. weight, shot from a piece of 10 feet in length, with 16 lb. of powder, will acquire from the explosion a velocity which, if uniformly continued, would carry it nearly 1650 feet in a second.

“This is the velocity which, according to our theory, a cannon-ball of 24 lb. weight is discharged with when it is impelled by a full charge of powder; but if, instead of a quantity of powder weighing two-thirds of the ball, we suppose the charge to be only half the weight of it, then its velocity will on the same principles be no more than 1490 feet in a second. The fame would be the velocities of every lighter bullet fired with the same proportions of powder, if the lengths of all pieces were constantly in the same ratio with the diameters of their bore; and although according to the usual dimensions of the smaller pieces of artillery, this proportion does not always hold, yet the difference is not great enough to occasion a very great variation from the velocities here assigned; as will be obvious to any one who shall make a computation thereon. But in these determinations we suppose the windage to be no more than is just sufficient for putting down the bullet easily; whereas in real service, either through negligence or unskilfulness, it often happens, that the diameter of the bore of a musket exceeds the diameter of the bullet; that great part of the inflamed fluid escapes by its side; whence the velocity of the shot in this case may be considerably less than what we have assigned. However, this perhaps may be compensated by the greater heat which in all probability attends the firing of these large quantities of powder.

“From
From this great velocity of cannon-shot we may clear up the difficulty concerning the point-blank shot which on diameter the invention of Anderson's strange hypothesis. 

Having our author deceived by not knowing how greatly the primitive velocity of the heaviest shot is diminished in the course of its flight by the resistance of the air. And the received opinion of practical gunners is more difficult to account for; since, when they agree that every shot flies in a straight line to a certain distance from the piece, which imaginary distance they have called the extent of the point-blank shot, we need only suppose, that, within that distance they thus determine, the deviation of the path of the shot from a straight line is not very perceptible in their method of pointing. Now, as a shot of 241b. fired with two-thirds of its weight of powder, will, at the distance of 500 yards from the piece, be separated from the line of its original direction by an angle of little more than half a degree; those who are acquainted with the inaccurate methods often used in the directing of cannon will easily allow, that so small an aberration may not be attended to by the generality of practitioners, and the path of the shot may consequently be deemed a straight line; especially as other causes of error will often intervene much greater than what arises from the incurvation of this line by gravity.

We have now determined the velocity of the shot both when fired with two-thirds of its weight and with half its weight of powder respectively; and on this occasion I must remark, that on the principles of our theory, the increasing the charge of powder will increase the velocity of the shot, till the powder arrives at a certain quantity; after which, if the powder be increased the velocity of the shot will diminish. The quantity producing the greatest velocity, and the proportion between that greatest velocity and the velocity communicated by greater and lesser charges, may be thus asigned. Let AB represent the axis of the piece; draw AC perpendicular to it, and to the asymptotes AC and AB draw any hyperbola LF, and draw BF parallel to AC; and now the point D, where the rectangle ADEG is equal to the hyperbolic area AD; will represent that height of the charge which communicates the greatest velocity to the shot: whence AD being to AB as 1 to 2.71828, as appears from the table of logarithms, from the length of the line AD thus determined, and the diameter of the bore, the quantity of powder contained in this charge is easily known. If, instead of this charge, any other filling the cylinder to the height AI be used, draw IH parallel to AC, and through the point H to the same asymptotes AC and AB describe the hyperbola HK; then the greatest velocity will be the velocity communicated by the charge AI, in the subduplic part of the rectangle AB to the same rectangle diminished by the trilinear space KKK.

It hath been already shown, that the resistance of the air on the surface of a bullet of 2 of an inch diameter, moving with a velocity of 1670 feet in a second, amounted to about 101b. It hath also been shown that an iron-bullet weighing 241b, if fired with 161b of powder (which is usually esteemed its proper bultering charge), acquires a velocity of about 1650 feet in a second, scarcely differing from the other: whence as the surface of this last bullet is more than 54 times greater than the surface of a bullet of 2 of an inch diameter, and their velocities are nearly the same, it follows, that the resistance on the larger bullet will amount to more than 5401b, which is near 25 times its own weight.

The two last propositions are principally aimed against those theorists who have generally agreed in supposing the flight of shot and shells to be nearly in the curve of a parabola. The reason given by those authors for their opinion is the supposed inconsiderable resistance of the air; since, as it is agreed on all sides that the tract of projectiles would be a perfect parabola if there was no resistance, it has from thence been too rashly concluded, that the interruption which the ponderous bodies of shells and bullets would receive from such a rare medium as air would be scarcely sensible, and consequently that their parabolic flight would be hereby scarcely affected.

Now the prodigious resistance of the air to a bullet of 241b, weight, such as we have here established it, sufficiently confutes this reasoning; for how erroneous must that hypothesis be, which neglects as inconsiderable a force amounting to more than 20 times the weight of the moving body! But here it is necessary to assume a few particulars, the demonstrations of which, on the commonly received principles may be seen under the article PROJECTILES.

1. If the resistance of the air be so small that the motion of a projected body is in the curve of a parabola, then the axis of that parabola will be perpendicular to the horizon, and consequently the part of the curve in which the body ascends will be equal and similar to that in which it descends.

2. If the parabola in which the body moves is terminated on a horizontal plane, then the vertex of the parabola will be equally distant from its two extremities.

3. Also the moving body will fall on that horizontal plane in the same angle, and with the same velocity with which it was first projected.

4. If a body be projected in different angles but with the same velocity, then its greatest horizontal range will be when it is projected in an angle of 45° with the horizon.

5. If the velocity with which the body is projected is known, then this greatest horizontal range may be thus found. Compute, according to the common theory of gravity, what space the projected body ought to fall through to acquire the velocity with which it is projected: then twice that space will be the greatest horizontal range, or the horizontal range when the body is projected in an angle of 45° with the horizon.

6. The horizontal ranges of a body, when projected with the same velocity at different angles, will be between themselves as the sines of twice the angle in which the line of projection is inclined to the horizon.

7. If a body is projected in the same angle with the horizon but with different velocities, the horizontal ranges will be in the duplicate proportion of those velocities.

These postulates which contain the principles of the modern art of gunnery are all of them falre, for,
To put a musket-ball \( \frac{1}{2} \) of an inch in diameter, fired with half its weight of powder, from a piece 45 inches long, moves with a velocity of near 700 feet in a second. Now, if this ball flew in the curve of a parabola, its horizontal range at 45° would be found by the fifth postulate to be about 17 miles. But all the practical writers assure us, that this range is equally short of half a mile. Diego Ufano assigns to an arquebus, four feet in length, and carrying a leaden ball of \( \frac{1}{4} \) oz. weight (which is very near our dimensions), an horizontal range of 797 common paces, when it is elevated between 40 and 50 degrees, and charged with a quantity of fine powder equal in weight to the ball. Merianus also tells us, that he found the horizontal range of an arquebus at 45° to be less than 400 fathom, or 800 yards; whence, as either of these ranges are short of half an English mile, it follows, that a musket-shot, when fired with a reasonable charge of powder at the elevation of 45°, flies not \( \frac{1}{2} \) part of the distance it ought to do if it moved in a parabola. Nor is this great contradiction of the horizontal range to be wondered at, when it is considered that the resistance of this bullet when it first issues from the piece amounts to 120 times its gravity, as hath been experimentally demonstrated, in \( \text{no. 23} \).

To prevent objections, our next instance shall be in an iron bullet of 24 lb. weight, which is the heaviest in common use for land service. Such a bullet fired from a piece of the common dimensions with its greatest allotment of powder hath a velocity of 1650 feet in a second, as already shown. Now, if the horizontal range of this shot, at 45°, be computed on the parabolic hypothesis by the fifth postulate, it will come out to be about 16 miles, which is between five and six times its real quantity; for the practical writers all agree in making it less than three miles.

But farther, it is not only when projectiles more with these very great velocities that their flight sensibly varies from the curve of a parabola; the same aberration often takes place in such as move slow enough to have their motion traced out by the eye: for there are few projectiles that can be thus examined, which do not visibly disagree with the first, second, and third postulate; obviously descending thro' a curve, which is shorter and less inclined to the horizon than that in which they ascended. Alto the highest point of their flight, or the vertex of the curve, is much nearer the place where they fall to the ground than to that from whence they were at first discharged.

I have found too by experience, that the fifth, sixth, and seventh postulates are excessively erroneous when applied to the motions of bullets moving with small velocities. A leaden bullet \( \frac{1}{2} \) of an inch in diameter, discharged with a velocity of about 400 feet in a second, and in an angle of 10° 5' with the horizon, ranged on the horizontal plane no more than 448 yards; whereas its greatest horizontal range found by the fifth postulate to be at least 1700 yards, the range at 10° 5' ought by the fifth postulate to have been 1050 yards; whence, in this experiment, the range was about \( \frac{1}{2} \) of what it must have had if the commonly received theory been true.

From this and other experiments, it is clearly proved, that the track described by the flight even of the heaviest shot, is neither a parabola, nor approaching to a parabola, except when they are projected with very small velocities. The nature of the curve really described by them is explained under the article Projects. But as a specimen of the great complication of that subject, we shall here infer an account of a very extraordinary circumstance which frequently takes place therein.

"As gravity acts perpendicularly to the horizon, it is evident, that if no other power but gravity deflected a projected body from its course, its motion would be constantly performed in a plane perpendicular to the horizon, pulling through the line of its original direction; but we have found, that the body in its motion often deviates from this plane, sometimes to the right hand, and at other times to the left; and this in an incurvated line which is convex towards the plane: so that the motion of a bullet is frequently in a line having a double curvature, it being bent towards the horizon by the force of gravity, and again bent out of its original direction to the right or left by some other force: in such case no part of the motion of the bullet is performed in the same plane, but its track will lie in the surface of a kind of cylinder, whose axis is perpendicular to the horizon.

This proposition may be indisputably proved by the experience of every one in the least conversant with the practice of gunnery. The same piece which will carry its bullet within an inch of the intended mark at 10 yards distance, cannot be relied on to 10 inches in 100 yards, much less to 30 inches in 300 yards. Now this inequality can only arise from the track of the bullet being incurvated sideways as well as downwards: for by this means the distance between that incurvated line and the line of direction will increase in a much greater ratio than that of the distance; these lines being coincident at the mouth of the piece, and afterwards separating in the manner of a curve and its tangent, if the mouth of the piece be considered as the point of contact.—To put this matter out of all doubt, however, I took a barrel carrying a ball \( \frac{1}{2} \) of an inch diameter, and fixing it on a heavy carriage, I satisfied myself of theeadines and truth of its direction, by firing at a board 1\( \frac{1}{2} \) feet square, which was placed at 180 feet distance; for I found, that in 16 successive shots I missed the mark but once. Now, the same barrel being fixed on the same carriage, and fired with a small quantity of powder, so that the shock on the discharge would be much less, and consequently the direction less changed, I found, that at 750 yards distance the ball flew sometimes 100 yards to the right of the line it was pointed on, and sometimes as much on the left. I found too, that its direction in the perpendicular line was not less uncertain, it falling one time above 200 yards short of what it did at another; although by the nicest examination of the piece after the discharge, it did not appear to have flared in the least from the position it was placed in.

The reality of this double curvated track being thus demonstrated, it may perhaps be asked, what can be the cause of a motion so different from what has been heretofore supposed? And to this I answer, That the deflection in question must be owing to some power acting obliquely to the progressive motion of the body;
Theory.

body; which power can be no other than the resistence of the air. If it be farther asked, how the resistence of the air can ever come to be oblique to the progressive motion of the body! I farther reply, that it may sometimes arise from inequalities in the refuse surface; but that its general cause is doublets a whirling motion acquired by the bullet about its axis: for by this motion of rotation, combined with the progressive motion, each part of the bullet's surface will strike the air very differently from what it would do if there was no such whirl; and the obliquity of the action of the air arising from this cause will be greater as the motion of the bullet is greater in proportion to its progressive one.

"This whirling motion undoubtedly arises from the friction of the bullet against the side of the piece; and as the rotatory motion will in some part of its resolution confpire with the progressive one, and another part be equally opposed to it; the resistence of the air on the fore part of the bullet will be hereby affected, and will be increased in that part where the whirling motion confpires with the progressive one, and diminished where it is opposed to it means the whole effort of the resistence, instead of being opposed to the direction of the body, will become oblique thereto, and will produce those effects already mentioned. If it was possible to predict the position of the axis round which the bullet should whirl, and that axis was unchangeable during the whole flight of the bullet, then the aberration of the bullet by this oblique force would be in a given direction; and the incurvation produced thereby would regularly extend the same way from one end of its track to the other. For instance, if the axis of the whirl was perpendicular to the horizon, then the incurvation would be to the right or left. If that axis was horizontal, and perpendicular to the direction of the bullet, then the incurvation would be upwards or downwards. But as the first position of this axis is uncertain, and as it may perpetually shift in the course of the bullet's flight; the deviation of the bullet is not necessarily either in one certain direction, or tending to the same side in one part of its track that it does in another, but more usually is continually changing the tendency of its deflection, as the axis round which it whirls must frequently shift its posision to the progressive motion by many inevitable accidents.

"That a bullet generally acquires such a rotatory motion, as here describ'd, is, I think demonstrable: however, to leave no room for doubt or dispute, I confirmed it, as well as some other parts of my theory, by the following experiments.

"I caused the machine to be made represented in Plate CCXXV. fig. 4. BCDE is a brafs barrel, movable on its axis, and so adjusted by means of frictions wheels, not represented in the figure, as to have no friction worth attending to. The frame in which this barrel is fixed is so placed that its axis may be perpendicular to the horizon. The axis itself is continued above the upper plate of the frame, and has fastened on it a light hollow cone, AFG. From the lower part of this cone there is extended a long arm of wood, GH, which is very thin, and cut feather-edged. At its extremity there is a contrivance for fixing on the body, whose resistence is to be investigat'd (as here the globe P); and to prevent the arm GH from swaying out of its horizontal position by the weight of the annexed body P, there is a brace, AH, of fine wire, fastened to the top of the cone which supports the end of the arm.

"Round the barrel BCDE, there is wound a fine silk line, the turns of which appear in the figure; and after this line hath taken a sufficient number of turns, it is conducted nearly in a horizontal direction to the pully L over which it is passed, and then a proper weight M is hung to its extremity. If this weight be left at liberty, it is obvious that it will defend by its own gravity, and will, by its decent, turn round the barrel BCDE, together with the arm GH, and the body P fastened to it. And whilst the resistence on the arm GH and on the body P is less than the weight M, that weight will accelerate its motion; and thereby the motion of GH and P will increase, and consequently their resistence will increase, till at last this resistence and the weight M become nearly equal to each other. The motion with which M descends, and with which P revolves, will not then be very different. When resistance is not difficult to conceive, that, by proper observations made with this machine, the resistence of the body P may be determined. The most natural method of proceeding in this investigation is as follows: Let the machine first have acquired its eqluable motion, which it will usually do in about five or six turns from the beginning; and then let it be observed, by counting a number of turns, what time is taken up by one revolution of the body P: then taking off the body P and the weight M, let it be examined what smaller weight will make the arm GH revolve in the same time as when P was fixed to it; this smaller weight being taken from M, the remainder is obviously equal in effort to the resistence of the revolving body P; and this remainder being reduced in the ratio of the length of the arm to the semi-diameter of the barrel, will then become equal to the absolute quantity of the resistence. And as the time of one revolution is known, and consequently the velocity of the revolving body, there is hereby discovered the absolute quantity of the resistence to the given body P moving with a given degree of celerity.

"Here, to avoid all objections, I have generally chose when the body P was removed, to fix in its stead a thin piece of lead of the same weight, placed horizontally; so that the weight which was to turn round the arm GH, without the body P, did also carry round this piece of lead. But the mathematicians will easily allow that there was no necessity for this precaution.—The diameter of the barrel BCDE, and of the silk string wound round it, was 2.06 inches. The length of the arm GH, measured from the axis to the surface of the globe P, was 49.5 inches. The body P, the globe made of wood, was placed on the flat top of the board; its surface very neatly coated with marbled paper. It was not much different from the size of a 12lb. shot, being in diameter 4.5 inches, so that the radius of the circle described by the centre of the globe was 51.75 inches. When this globe was fixed at the end of the arm, and a weight of half a pound was hung at the end of the string at M, it was examined how soon the motion of the defending weight M, and of the revolving body P, would become equal as to force. With this view, three
Sect. II.

Theory.

three revolutions being suffered to elapse, it was found that the next 10 were performed in 27½, in less than 3½, and 82/3; so that the first 10 were performed in 27½, the second in 27½, and the third in 27½.

These experiments sufficiently evince, that even with half a pound, the smallest weight made use of, of the motion of the machine was sufficiently equable after the first three revolutions.

"The globe abovementioned being now fixed at the end of the arm, there was hung on it a weight of 3½ lb.; and 10 revolutions being suffered to elapse, the succeeding 20 were performed in 27½. Then the globe being taken off, and a thin plate of lead, equal to it in weight, placed in its room; it was found, that instead of 3½ lb. a weight of one pound would make it revolve in less time than it did before; performing now 20 revolutions after 10 were elapsed in the space of 27½.

"Hence then it follows, that from the 3½ lb. first hung on, there is less than 1 lb. to be deduced for the resistance on the arm; and consequently the resistance on the globe itself is not less than the effort of 3½ lb. in the situation M; and it appearing from the former measures, that the radius of the barrel is nearly 1/8 of the radius of the circle, described by the centre of the globe; it follows, that the absolute resistance of the globe, when it revolves 20 times in 27½, (about 25 feet in a second,) is not less than the 50th part of two pounds and a quarter, or of 36 ounces; and this being considerably more than half an ounce, and the globe nearly the size of a twelve-pound shot, it irrefragably confirms a proposition I had formerly laid down from theory, that the resistance of the air to a 12 lb. iron shot, moving with a velocity of 25 feet in a second, is not less than half an ounce.

"The rest of the experiments were made in order to confirm another proposition, namely, that the resistance of the air within certain limits is nearly in the duplicate proportion of the velocity of the resisted body. To investigate this point, there were successively hung on at M, weights in the proportion of the numbers 1, 4, 9, 16; and letting 10 revolutions first elapse, the following observations were made on the rest.—With 1 lb. the globe went 20 turns in 54/4, with 2 lb. it went 20 turns in 27½, with 4 lb. it went 30 turns in 27½, and with 8 lb. it went 40 turns in 27½. Hence it appears, that no resistances proportioned to the numbers 1, 4, 9, 16, have correspondent velocities of the resisted body in the proportion of the numbers 1, 2, 3, 4: which proves, with great nicety, the proposition abovementioned.

With regard to the rotatory motion, the first experiment was to evince, that the whirlings motion of a ball combining with its progressive motion would produce such an oblique resistance and defective power as had already mentioned. For this purpose a wooden ball of 4½ inches diameter was suspended by a double string, about eight or nine feet long. Now, by turning round the ball and twisting the double string, the ball when left to itself would have a revolving motion given it from the untwisting of the string again. And if, when the string was twisted, the ball was drawn to a considerable distance from the perpendicular, and there let go, it would at first, before it had acquired its revolving motion, vibrate stealthily enough in the same vertical plane, vibrate stealthily enough in the same vertical plane; but when, by the untwisting of the string, it had acquired a sufficient degree of its whirling motion, it constantly deviated to the right or left of its first tract; and sometimes proceeded so far as to have its direction at right angles to that in which it began its motion; and this deviation was not produced by the string itself, but appeared to be entirely owing to the resistance being greater on the one part of the leading surface of the globe than the other. For the deviation continued when the string was totally untwisted; and even during the time that the string, by the motion the globe had received, was twisting the contrary way. And it was always easy to predict, before the ball was let go, which way it would deviate, only by considering on what side the whirl would be combined with the progressive motion, for on that side always the deflection was greater than on the side where the whirl and progressive motion were opposed to one another.

Though Mr. Robinson considered this experiment as an incontestable proof of the truth of his theory, he undertook to give ocular demonstration of this deflection of musket-bullets even in the short space of 100 yards.

"As all projectiles," says he, "in their flight, are acted upon by the power of gravity, the deflection of a bullet from its primary direction, supposes that deflection to be upwards or downwards in a vertical plane; because, in the vertical plane, the action of gravity is compounded and entangled with the defetcive force. And for this reason my experiments have been principally directed to the examination of that deflection which carries the bullet to the right or left of that plane in which it began to move. For it appears at any time that the bullet has shifted from that vertical plane in which the motion began; this will be an incontestable proof of what we have advanced. Now, by means of screens of exceeding thin paper, placed parallel to each other at proper distances, this deflection in question may be many ways investigated. For by firing bullets which shall traverse the screens, the flight of the bullet may be traced; and it may easily appear whether they do or do not keep invariably to one vertical plane. This examination may proceed on three different principles, which I shall here separately explain.

"For first, an exactly vertical plane may be traced out upon all these screens, by which the deviation of any single bullet may be more readily investigated, only by measuring the horizontal distance of its trace from the vertical plane thus delineated; and by this means the absolute quantity of its aberration may be known. Or if the description of such a vertical plane should be estimated a matter of difficulty and nicety, a second method may be followed; which is that of resting the piece in some fixed notch or socket, so that though the piece may have some little play to the right and left, yet all the lines in which the bullet can be directed shall intersect each other in the centre of that fixed socket: by this means, if two different shots are fired from the piece thus fixed, the horizontal distances made by the two bullets on any two screens ought to be in the same proportion to each other as—C e 2 the
the respective distances of the screens from the socket in which the piece was laid. And if the horizontal distances differ from that proportion, then it is certain that one of the shots at least hath deviated from a vertical plane, although the absolute quantities of deviation cannot hence be assigned; because it cannot be known what part of it is to be imputed to one bullet, and what to the other.

But if the constant and invariable position of the notch or socket in which the piece was placed, be thought too hard an hypothesis in this very nice affair; the third method, and which is the simplest of all, requires no more than that two shot be fired through three screens without any regard to the position of the piece each time; for in this case, if the shots diverge from each other, and both keep to a vertical plane, then if the horizontal distances of their traces on the first screen be taken from the like horizontal distances on the second and third, the two quantities will differ in the same proportion with the distances of the second and third screen from the first. And if they are not in this proportion, then it will be certain that one of them at least hath been deflected from the vertical plane; though here, as in the last case, the quantity of that deflection in each will not be known.

All these three methods I have myself made use of at different times, and have ever found the success agreeable to my expectation. But the most eligible method seemed to be a compound of the two last. The apparatus was as follows.—Two screens were set up in the larger walk in the charter-house garden; the first of them at 25 feet distance from the wall, which was to serve for a third screen; and the second 200 feet from the same wall. At 50 feet before the first screen, or at 300 feet from the wall, there was placed a large block weighing about 200 lb. weight, and having fixed into it an iron bar with a socket at its extremity, in which the piece was to be laid. The piece itself was of a common length, and bored for an ounce ball. It was each time loaded with a ball of 17 to the pound, so that the windage was extremely small, and with a quarter of an ounce of good powder. The screens were made of the thinnest flax paper; and the resistence they gave to the bullet (and consequently their probability of deflecting it) was so small, that a bullet lighting on the third near the extremity of one of the screens, left a fine thin fragment of it towards the edge entire, which was so very weak that it was difficult to handle it without breaking. These things thus prepared, five shots were made with the piece refted in the notch above mentioned; and the horizontal distances between the first shot, which was taken as a standard, and the four succeeding ones, both on the first and second screen and on the wall, and measured in inches, were as follows:

<table>
<thead>
<tr>
<th>First Screen</th>
<th>Second Screen</th>
<th>Wall</th>
</tr>
</thead>
<tbody>
<tr>
<td>10 to 2</td>
<td>1.75 R.</td>
<td>16.7 R.</td>
</tr>
<tr>
<td>3</td>
<td>3.15 L.</td>
<td>15.6 L.</td>
</tr>
<tr>
<td>4</td>
<td>4.25 L.</td>
<td>15.0 L.</td>
</tr>
</tbody>
</table>

Here the letters R and L, denote that the shot in question went either to the right or left of the first.

If the position of the socket in which the piece was placed be supposed fixed, then the horizontal distances measured above on the first and second screen, and on the wall, ought to be in proportion to the distances of the first screen, the second screen, and the wall from the socket. But by only looking over these numbers, it appears, that none of them are in that proportion; the horizontal distance of the first and third, for instance, on the wall being above nine inches more than it should be by this analogy.

If, without supposing the invariable position of the socket, we examine the comparative horizontal distances according to the third method described above, we shall in this case discover diversifications still more extraordinary; for, by the numbers set down, it appears, that the horizontal distances of the second and third shot on the two screens, and on the wall, are as under:

<table>
<thead>
<tr>
<th>First Screen</th>
<th>Second Screen</th>
<th>Wall</th>
</tr>
</thead>
<tbody>
<tr>
<td>1 to 2</td>
<td>1.6 R.</td>
<td>9.4 R.</td>
</tr>
<tr>
<td>3</td>
<td>6.4 L.</td>
<td>2.3 R.</td>
</tr>
<tr>
<td>4</td>
<td>4.7 R.</td>
<td>8.5 R.</td>
</tr>
<tr>
<td>5</td>
<td>12.6 R.</td>
<td>6.5 R.</td>
</tr>
</tbody>
</table>

Here, again, on the supposed fixed position of the piece, the horizontal distance on the wall between the first and third will be found above 16 inches less than it should be if each kept to a vertical plane; and like irregularities, though smaller, occur in every other experiment. And if they are examined according to the third method set down above, and the horizontal distances of the third and fourth, for instance, are compared, those on the first and second screen, and on the wall, appear to be thus:

<table>
<thead>
<tr>
<th>First Screen</th>
<th>Second Screen</th>
<th>Wall</th>
</tr>
</thead>
<tbody>
<tr>
<td>1.1</td>
<td>21.25</td>
<td>38.5</td>
</tr>
</tbody>
</table>

And if the horizontal distance on the first screen be taken from the other two, the remainders will be 15 and 27.4; where the least of them, instead of being five times the first, as it ought to be, is 23.35 short of it; so that here is a deviation of 35 inches.

From these experiments it is evident that the question seems to be incontestably evinced. But to give some further light to this subject, I took a barrel of the same bore with that hitherto used; and bent it at about three or four inches from its muzzle to the left, the bend making an angle of three or four degrees with
with the axis of the piece. This piece, thus bent was fired with a loo[...]

Strange anomaly in the resistance of the air.
must render the event of each shot very precarious. The resistance of the atmosphere simply considered without any of those anomalies arising from its density at different times, is a problem which, notwithstanding the labours of Mr. Robins and others, hath not been completely solved; and, indeed, if we consider the matter in a physical light, we shall find, that without some other data than those which are yet obtained, an exact solution of it is impossible.

It is an objection that hath been made to the mathematical philosophy, and to which in many cases it is most certainly liable, that it considers the resistance of matter more than its capacity of giving motion to other matter. Hence, if in any case matter acts both as a resisting and moving power, and the mathematician overlooks its effort towards motion, founding his demonstrations only upon its property of resisting, these demonstrations will certainly be false, though they should be supported by all the powers of geometry. It is to an error of this kind we are to attribute the great differences already taken notice of between the calculations of Sir Isaac Newton, with regard to the resisting force of fluids, and what actually takes place upon trial. These calculations were made upon the supposition that the fluid through which a body moved could do nothing else but resist it; yet it is certain, that the air (the fluid with which we have to do at present) proves a source of motion, as well as resistance, to all bodies which move in it.

To understand this matter fully, let ABC represent a crooked tube made of any solid matter, and $a, b, c$ two pistons which exactly fill the cavity. If the space between these pistons is full of air, it is plain they cannot come into contact with each other on account of the elasticity of the included air, but will remain at some certain distance as represented in the figure. If the piston $b$ is drawn up, the air which presses in the direction $Cb$ acts as a resisting power, and the piston will not be drawn up with such ease as if the whole was in vacuo. But though the column of air pressing in the direction $Cb$ acts as a resisting power on the piston $b$, the column pressing in the direction $Ab$ will act as a moving power upon the piston $a$. It is therefore plain, that if $b$ is moved upwards till it comes to the place marked $d$, the other will descend to that marked $c$. Now, if we suppose the piston $a$ to be removed, it is plain, that when $b$ is pulled upwards to $d$, the air descending through the leg $Ab$ will press on the under side of the piston $b$, as strongly as it would have done upon the upper side of the piston $a$, had it been present. Therefore, though the air falling down through the leg $CB$ resists the motion of the piston $b$ when drawn upwards, the air pressing down through the leg $AB$ forwards it as much: and accordingly the piston $b$ may be drawn up or pulled down at pleasure, and with very little trouble. But if the orifice at $A$ is stopped, so that the air can only exert its resisting power on the piston $b$, it will require a considerable degree of strength to move the piston from $b$ to $d$.

If now we suppose the tube to be entirely removed (which indeed answers no other purpose than to render the action of the air more evident), it is plain, that if the piston is moved either up or down, or in any other direction we can imagine, the air presses as much upon the back part of it as it resists it on the fore part; and of consequence, a ball moving through the air with any degree of velocity, ought to be as much accelerated by the action of the air behind, as it is retarded by the action of that before. Here then it is natural to ask, If the air accelerates a moving body as much as it retards it, how comes it to make any resistance at all? Yet certain it is, that this fluid doth resist, and that very considerably. To this it may be answered, that the air is always kept in some certain state or constitution by another power which rules all its motions, and it is this power undoubtedly which gives the resistance. It is not to our purpose at present to inquire what that power is; but we see that the air is often in very different states: one day, for instance, its parts are violently agitated by a storm; and another, perhaps, they are comparatively at rest in a calm. In the first case, nobody hesitates to own, that the storm is occasioned by some cause or other, which violently resists any other power that would prevent the agitation of the air.

In a calm, the case is the same; for it would require the same exertion of power to excite a tempest in a calm day, as to allay a tempest in a stormy one. Now it is evident, that all projectiles, by their motion, agitate the atmosphere in an unnatural manner; and consequently are resisted by that power, whatever it is, which tends to restore the equilibrium, or bring back the atmosphere to its former state.

If no other power besides that above-mentioned acted upon projectiles, it is probable that all resistance to their motion would be in the duplicate proportion of their velocities; and accordingly, as long as the velocity is small, we find it generally is so. But when the velocity comes to be exceedingly great, other sources of resistance arise. One of these is a subduction of part of the moving power; which though not properly a resistance, opposing another power to it, is an equivalent thereto. This subduction arises from the following cause. The air, as we have already observed, presses on the hinder part of the moving body by its gravity, as much as it resists the forepart of it by the same property. Nevertheless, the velocity with which the air presses upon any body by means of its gravity, is limited; and it is possible that a body may change its place with great velocity that the air hath not time to rush in upon the back part of it, in order to afflict its progressive motion. When this happens to be the case, there is in the first place a deficiency of the moving power equivalent to 15 pounds on every square inch of surface; at the same time that there is a positive resistance of as much more on the forepart, owing to the gravity of the atmosphere, which must be overcome before the body can move forward.

This deficiency of moving power, and increase of resistance, do not only take place when the body moves with a very great degree of velocity, but in all motions whatever. It is not in all cases perceptible, because the velocity with which the body moves, frequently bears but a very small proportion to the velocity with which the air presses in behind it. Thus, supposing the velocity with which the air rushes into a vacuum to be 1200 feet in a second, if a body moves with a velocity of 20, 40, or 50 feet in a second, the force with which the air presses on the back part is but $\frac{1}{2}$ at the utmost less than that which resists on the forepart, which
G U N N E R Y.

Sect. II.

Theory. which will not be perceptible; but if, as in the case of bullets, the velocity of the projectile comes to have a considerable proportion to the velocity wherewith the air rushes in behind it; then a very perceptible and otherwise unaccountable resistance is observed, as we have seen in the experiments already related by Mr Robins. Thus, if the air presses in with a velocity of 1200 feet in a second, if the body changes its place with a velocity of 600 feet in the same time, there is a resistance of 15 pounds on the fore part, and a pressure of only 7½ on the back part. The resistance therefore not only overcomes the moving power of the air by 7½ pounds, but there is a deficiency of other 7½ pounds owing to the want of half the pressure of the atmosphere on the back part, and thus the whole loss of the moving power is equivalent to 15 pounds; and hence the exceeding great increase of resistance observed by Mr Robins beyond what it ought to be according to the common computations. — The velocity with which the air rushes into a vacuum is therefore a defeudating in gunnery. Mr Robins supposes that it is the same with the velocity of sound; and that when a bullet moves with a velocity greater than that of 1200 feet in a second, it leaves a perfect vacuum behind it. Hence he accounts for the great increase of resistance to bullets moving with such velocities; but as he does not take notice of the loss of the air’s moving power, the anomalies of all lesser velocities are inexplicable on his principles. Nay, he even tells us, that Sir Isaac Newton’s rule for computing resistances may be applied in all velocities less than 1100 or 1200 feet in a second, though this is expressly contradicted by his own experiments mentioned in the last.

Though for these reasons it is evident how great difficulties must occur in attempting to calculate the resistance of the air to military projectiles, we have not even yet discovered all the sources of resistance to these bodies when moving with immense velocities. Another power by which they are opposed (and which at last becomes greater than any of those hitherto mentioned), is the air’s elasticity. This, however, will not begin to show itself in the way of resistance till the velocity of the moving body becomes considerably greater than that by which the air presses into a vacuum. Having therefore first ascertained this velocity, which we shall suppose be 1200 feet in a second, it is plain, that if a body moves with a velocity of 1800 feet in a second, it must compress the air before it; because the fluid hath neither time to expand itself in order to fill the vacuum left behind the moving body, nor to rush in by its gravity. This compression will be resisted by its elastic power, which thus becomes a new source of resistance, increasing without any limit, in proportion to the velocity of the moving body. If now we suppose the moving body to set out with a velocity of 2400 feet in a second, it is plain that there is not only a vacuum left behind the body, but the air before it is compressed into half its natural space. The loss of motion in the projectile therefore is now very considerable. It first looses 15 pounds on every square inch of deficiency on account of the moving power of the air behind it; then it looses 15 pounds more on account of the resistance of the air before it; again it looses 15 pounds on account of the elasticity of the compressed air; and lastly another 15 pounds on account of the vacuum behind which takes off the weight of the atmosphere, that would have been equivalent to one half of the elasticity of the air before it. The whole resistance therefore upon every square inch of surface moving with this velocity is 60 pounds, besides that which arises from the power tending to preserve the general state of the atmosphere, and which increases in the duplicate proportion of the velocity as already mentioned. If the body is supposed to move with a velocity of 4800 feet in a second, the resistance from the air’s elasticity will then be quadrupled, or amount to 60 pounds on the square inch of surface; which, added to the other causes, produces a resistance of 105 pounds upon the square inch; and thus would the resistance from the elasticity of the air go on continually increasing, till at last the motion of the projectile would be as effectually stopped as if it was fired against a wall. This obstacle therefore we are to consider as really insuperable by any art whatever, and therefore it is not advisable to use larger charges of powder than what will project the shot with a velocity of 1200 feet in a second. To this velocity the elasticity of the air will not make great resistance, if indeed it do make any at all; for though Mr Robins hath conjectured that air rushes into a vacuum with the velocity of sound, or between 11 and 1200 feet in a second; yet we have no decisive proof of the truth of this supposition. At this velocity indeed, according to Mr Robins a very sudden increase of resistance takes place; but this is denied by Mr Glenie, who supposes that the resistance proceeds gradually; and indeed it seems to be pretty obvious, that the resistance cannot very suddenly increase, p. 48, 50, if the velocity is only increased in a small degree. Yet it is certain, that the swiftest motions with which cannon-balls can be projected are very soon reduced to this standard; for Mr Robins acquaints us, that “a 24-pound shot, when discharged with a velocity of 2000 feet in a second, will be reduced to that of 1200 feet in a second in a flight of little more than 500 yards.”

In the 71st volume of the Philosophical Transactions, Mr Thomson has proposed a new method of determining the velocities of bullets, by measuring the force of the recoil of the piece. As in all cases action and reaction are supposed to be equal to one another, it appears that the momentum of a gun, or the force of its recoil backwards, must always be equivalent to the force of its charge; that is, the velocity with which the gun recoils, multiplied into its weight, is equal to the velocity of the bullet multiplied into its weight; for every particle of matter, whether solid or fluid, that flies out of the mouth of a piece must be impelled by the action of some power, which power must re-act with equal force against the bottom of the bore. — Even the fine invisible elastic fluid that is generated from the powder in its inflammation, cannot put itself in motion without reacting against the gun at the same time. Thus we see pieces, when they are fired with powder alone, recoil as well as when their charges are made to impel a weight of shot, though the recoil is not in the same degree in both cases. It is easy to determine the velocity of the recoil in any given case, by suspending the gun in an horizontal position by two pendulous rods, and measuring the arc of its ascent by means of a ribbon, as mentioned under the
Thus, if \( W \) is put equal to \( c \), and the charge is made to impel one or more bullets, as has been determined by a great variety of experiments.

If therefore a gun, supplied according to the method preferred, is fired with any given charge of powder, but without any bullet or wad, and the recoil is observed, and if the same piece is afterwards fired with the same quantity of powder, and a bullet of a known weight, the excess of the velocity of the recoil in the latter case, over that in the former, will be proportional to the velocity of the bullet; for the difference of these velocities, multiplied into the weight of the gun, will be equal to the weight of the bullet multiplied into its velocity. — Thus, if \( W \) is put equal to the weight of the gun, \( U \) the velocity of the bullet when fired with a given charge of powder without any bullet; \( V \) the velocity of the recoil, when the same charge is made to impel a bullet; \( B \) the weight of the bullet, and \( v \) its velocity; it will be 
\[
\frac{V - U + W}{B} \]

To determine how far this theory agreed with practice, an experiment was made with a charge of 1865 grains of powder without any bullet, which produced a recoil of 5.5 inches; and in another, with a bullet, the recoil was 5.6 inches; the mean of which is 5.55 inches; answering to a velocity of 1.1358 feet in a second. In five experiments with the same charge of powder, and a bullet weighing 380 grains, the mean was 14.6 inches; and the velocity of the recoil answering to the length just mentioned, is 2.0880 feet in a second; consequently \( V - U \), or 2.9880, is equal to 1.8322 feet in a second. But as the velocities of recoil are known to be as the cords of the arcs through which the barrel ascends, it is not necessary, in order to determine the velocity of the bullet, to compute the velocities \( V \) and \( U \); but the quantity \( V - U \), or the difference of the velocities of the recoil when the given charge is fired with and without a bullet, may be computed from the value of the difference of the chords by one operation. — Thus the velocity answering to the chord 9.05, is that of 1.8322 feet in a second, is just equal to \( V - U \), as was before found.

In this experiment the weight of the barrel with its carriage was just 474 pounds, to which \( \frac{1}{2} \) of a pound were to be added on account of the weight of the rods by which it was suspended; which makes \( W = 48 \) pounds, or 336,000 grains. The weight of the bullet was 380 grains; whence \( B \) is to \( W \) as 380 to 336,000; that is, as \( 1 \) to \( 7 \frac{799}{100} \) very nearly. The value of \( V - U \), answering to the experiments before mentioned, was found to be 1.8322, consequently the velocity of the bullet \( = \frac{1.8322 \times 5.55}{336,000} \) feet per second. This method, after being suspended by a string, was fired with a given charge of powder without any bullet, the recoil was 4.5, 4.9, or 4.4; \( C - c \) therefore was 13.24, 13.28, or 13.32 inches; and the velocity of the bullet = 8.84 + 13.35 = 1045 feet in a second; the velocities by the pendulum coming out 10.40 feet in the same space of time.

In the far greatest number of experiments to determine the comparative accuracy of the two methods, a surprizing agreement was found between the last mentioned and that by the pendulum; but in some few the differences were very remarkable. Thus, in two where the recoil was 12.92, and 13.28 the velocity, by computation from the chords is 1050 feet per second; but in computing by the pendulum it amounted only to 903; but in their some inaccuracy was suspected in the experiment with the pendulum, and that the computation from the recoil was most to be depended upon. In another experiment, the velocity by the recoil exceeded that by the pendulum by no less than 346 feet; the former showing 2109, and the latter only 1763 feet in a second. In two others the pendulum was also deficient, though not in such a degree. In all these it is remarkable, that where the difference was considerable, it was still in favour of the recoil. The deficiency in these experiments appears to have been somewhat embarrassing to our author. "It cannot be supposed, says he, that it arose from any imperfection in Mr Robin's method of determining the velocities of bullets; for that method is founded upon such principles as leave no room to doubt of its accuracy; and the practical errors that occur in making the experiments, and which cannot be entirely prevented, or exactly
GUNNERY.

Theory. exactly compensated, are in general so small, that the difference in the velocities cannot be attributed to them. It is true the effect of those errors is more likely to appear in experiments made under such circumstances as the present; for the bullet being very light \( A \), the arc of the pendulum was but small; and a small mistake in measuring the chord upon the ribbon would have produced a very considerable error in computing the velocity of the bullet: Thus a difference of one-tenth of an inch, more or less, upon the ribbon, in that experiment where the difference was greatest, would have made a difference in the velocity of more than 120 feet in a second. But, independent of the pains that were taken to prevent mistakes, the striking agreement of the velocities in so many other experiments, affords abundant reason to conclude, that the errors arising from those causes were in no case very considerable.—But if both methods of determining the velocities of bullets are to be relied on, then the difference of the velocities, as determined by them in these experiments, can only be accounted for by supposing that it arose from their having been determined by the resistance of the air in the passage of the bullets from the mouth of the piece to the pendulum: and this supposition will be much strengthened when we consider how great the resistance of the air is to bodies that move very swiftly in it; and that the bullets in these experiments were not only projected with great velocities, but were also very light, and consequently more liable to be retarded by the resistance on that account.

"To put the matter beyond all doubt, let us see what the resistance was that these bullets met with, and how much their velocities were diminished by it. The weight of the bullet in the most erroneous experiment was 90 grains; its diameter 0.78 of an inch; and it was projected with a velocity of 2109 feet in a second. If now a computation be made according to the law laid down by Sir Isaac Newton for compressed fluids, it will be found that the resistance to this bullet was not less than 87 pounds avoirdupois, which is something more than 600 times its own weight. But Mr. Robins has shown by experiment, that the resistance of the air to bodies moving in it with very great velocity, is near three times greater than Sir Isaac has determined it; and as the velocity with which this bullet was impelled is considerably greater than any in Mr. Robins's experiments, it is highly probable, that the resistance in this instance was at least 2000 times greater than the weight of the bullet.

"The distance from the mouth of the piece to the pendulum was 12 feet; but, as there is reason to think that the blast of the powder, which always follows the bullet, continues to act upon it for some tolerable space of time after it is out of the bore, and, by urging it on, counterbalances, or at least counteracts in a great measure, the resistance of the air, we will suppose that the resistance does not begin, or rather that the motion of the bullet does not begin to be retarded, till it has got to the distance of two feet from the muzzle. The distance, therefore, between the barrel and the pendulum, instead of 12 feet, is to be estimated at 10 feet; and as the bullet took up about \( \frac{1}{4} \) part of a second in running over the space, it must in that time have lost a velocity of about 335 feet in a second, as will appear upon making the computation; and this will very exactly account for the apparent diminution of the velocity in the experiment: for the difference of the velocities, as determined by the recoil and the pendulum = 2109—1763 = 346 feet in a second, is extremely near 335 feet in a second, the diminution of the velocity by the resistance as here determined.

"If the diminution of the velocities of the bullets in the two subsequent experiments be computed in like manner, it will turn out in one 65, and in the other 23, feet in a second; and, making these corrections, the comparison of the two methods of ascertaining the velocities will stand thus:

Difference after correction | +11 | +48 | +119 |

"It appears therefore, that notwithstanding these corrections, the velocities as determined by the pendulum, particularly in the last, were considerably deficient. But the manifest irregularity of the velocities, in those instances, affords abundant reason to conclude, that it must have arisen from some accidental cause; and therefore that little dependence is to be put upon the result of those experiments. I cannot take upon me to determine positively what the cause was which produced this irregularity, but I strongly suspect that it arose from the breaking of the bullets in the barrel by the force of the explosion: for these bullets as has already been mentioned, were formed of lead, including lesser bullets of plaster of Paris; and I well remember to have observed at that time several small fragments of the plaster which had fallen down by the side of the pendulum. I confess I did not then pay much attention to this circumstance, as I naturally concluded that it arose from the breaking of the bullet in penetrating the target of the pendulum; and that the small pieces of plaster I saw upon the ground, had fallen out of the hole by which the bullet entered. But if the bullets were not absolutely broken in pieces in firing, yet if they were considerably bruised, and the platter, or a part of it, were separated from the lead, such a change in the form might produce a great increase in the resistance, and even their initial velocities might be affected by it; for their form being changed from that of a globe to some other figure, they might not fit the bore; and a part of the force of the charge might be lost by the windage.—That this actually happened in the experiment last mentioned, seems very probable; as the velocity with which the bullet was projected, as it was determined by the recoil, was considerably less in proportion in that experiment than in many others which preceded and followed it in the same fet.

"As allowance has been made for the resistance of the air in these cases, it may be expected that the same

\[ D \]

\[ d \]

GUNNERY.  

Sect. III.

Theory.  It may happen that the augmentation of the force, on account of one of these circumstances, may be infuficient to counterbalance the diminution of it arising from the other, and if it should be found upon trial, that this is the case in general, in pieces as they are now constructed, and with all the variety of shot that are made use of in practice, it would be of great use to know the fact: but when, with Mr Robins, concluding too hastily from the result of a partial experiment, we suppose, that because the sum total of the prejudice of the elastic fluid upon the bullet, during the time of its passage through the bore, happens to be the same when bullets of different weights are made use of, that therefore it is always so, our reasonings may prove very inconclusive, and lead to very dangerous errors."

In the prosecution of this subject Mr Thomson proves mathematically, as well as by actual experiment, that the theory laid down by Mr Robins in this respect is erroneous. The excess is in favour of heavy bullets, which acquire a velocity greater than they ought to do according to Mr Robins's rule; and so considerable are the errors, that in one of Mr Thomson's experiments, the difference was no more than 20 inches in a second. When the weight of the bullet was increased four times, the action of the powder was found to be nearly doubled; for in one experiment, when four bullets were discharged at once, the collective pressure was as 1; but when only a single bullet was made use of, it was no more than 0,5825; and on the whole he concludes, that the velocity of bullets is in the reciprocal sub-triplicate ratio of their weights. Our author observes also, that Mr Robins is not only mistaken in the particular just mentioned, but in his conclusion with regard to the absolute force of gunpowder compared with the pressure of the atmosphere; the latter being to the force of gunpowder as 1 to 1000 according to Mr Robins; but as 1 to 1308 according to Mr Thomson.

Sect. III. Practice of Gunnery.

With regard to the practical part of gunnery, which ought to consist in directing the piece in such a manner, as always to hit the object against which it is pointed, there can be no certain rules given. The following maxims are laid down by Mr Robins as of use in practice.

1. In any piece of artillery whatever, the greater the quantity of powder it is charged with, the greater will be the velocity of the bullet.

2. If two pieces of the same bore, but of different lengths, are fired with the same charge of powder, the longer will impel the bullet with a greater celerity than the shorter.

3. If two pieces of artillery different in weight, and formed of different metals, have yet their cylinders of equal bores and equal lengths; then with like charges of powder and like bullets they will each of them discharge their shot with nearly the same degree of celerity.

4. The ranges of pieces at a given elevation are no just measures of the velocity of the shot; for the same piece fired successively at an invariable elevation, with the powder, bullet, and every other circumstance as nearly
Section III. GUNNERY.

Practice. nearly the same as possible, will yet range to very different distances.

5. The greatest part of that uncertainty in the ranges of pieces which is described in the preceding maxim, can only arise from the resistance of the air.

6. The resistance of the air acts upon projectiles in a twofold manner: for it opposes their motion, and by that means continually diminishes their celerity; and it besides diverts them from the regular track they would otherwise follow; whence arise those deviations and indentions already treated of.

7. That action of the air by which it retards the motion of projectiles, though much neglected by writers in artillery, is yet in many instances, of an immense force; and hence the motion of these refitted bodies is totally different from what it would otherwise be.

8. This retarding force of the air acts with different degrees of violence, according as the projectile moves with a greater or lesser velocity; and the resistances observe this law. That to a velocity which is double another, the resistance within certain limits is fourfold; to a treble velocity, ninefold; and so on.

9. But this proportion between the resistances to two greater velocities, does not hold if one of the velocities be less than that of 1200 feet in a second, and the other greater. For in this case the resistance to the greater velocity is near three times as much as it would come out by a comparison with the smaller, according to the law explained in the last maxim.

10. To the extraordinary power exerted by the resistance of the air it is owing, that when two pieces of different bores are discharged at the same elevation, the piece of the largest bore usually ranges farthest, provided they are both fired with fit bullets, and the culmatory allotment of powder.

11. The greatest part of military projectiles will at the time of their discharge acquire a whirling motion round their axis by rubbing against the inside of their respective pieces; and this whirling motion will cause them to strike the air very differently from what they would do had they no other than a perpendicular motion. By this means it will happen, that the resistance of the air will not always be directly opposed to their flight; but will frequently act in a line oblique to their course, and will thereby force them to deviate from the regular track they would otherwise describe. And this is the true cause of the irregularities described in maxim 4.

12. From the sudden trebling the quantity of the air's resistance, when the projectile moves swifter than at the rate of 1200 feet in a second (as has been explained in maxim 9), it follows that whatever be the regular range of a bullet discharget with this last mentioned velocity, that range will be but little increased how much soever the velocity of the bullet may be still farther augmented by greater charges of powder.

13. If the same piece of cannon be successively fired at an invariable elevation, but with various charges of powder, the greatest charge being the whole weight of the bullet in powder, and the least not less than the fifth part of that weight; then if the elevation be not less than eight or ten degrees, it will be found, that some of the ranges with the least charge will exceed some of those with the greatest.

14. If two pieces of cannon of the same bore, but of different lengths, are successively fired at the same elevation with the same charge of powder; then it will frequently happen that some of the ranges with the shorter piece will exceed some of those with the longer.

15. In distant cannonadings, the advantages arising from long pieces and large charges of powder are but of little moment.

16. In firing against troops with grape-shot, it will be found, that charges of powder much less than those generally used are the most advantageous.

17. The principal operations in which large charges of powder appear to be more efficacious than small ones, are the running of parapets, the dismounting of batteries covered by float merlons, or battering in breach; for, in all cases, if the object be but little removed from the piece, every increase of velocity will increase the penetration of the bullet.

18. Whatever operations are to be performed by artillery, the least charges of powder with which they can be effected are always to be preferred.

19. Hence, then, the proper charge of any piece of artillery is not that allotment of powder which will communicate the greatest velocity to the bullet (as most practicioners formerly maintained); nor is it to be determined by an invariable proportion of its weight to the weight of the ball: but, on the contrary, it is such a quantity of powder as will produce the least velocity for the purpose in hand; and, instead of bearing always a fixed ratio to the weight of the ball, it must be different according to the different business which is to be performed.

20. No field-piece ought at any time to be loaded with more than of, or at the utmost of, the weight of its bullet in powder; nor should the charge of any battering piece exceed of the weight of its bullet.

21. Although precepts very different from those we have here given have been often advanced by artillerists, and have been paid to be derived from experience; yet is that pretended experience altogether fallacious: since from our doctrine of resistance established above, it follows, that every speculation on the subject of artillery, which is only founded on the experimental ranges of bullets discharged with considerable velocities, is liable to great uncertainty.

The greatest irregularities in the motion of the bullets described as we have seen, owing to the whirling motion on their axis, acquired by the friction against the sides of rifed barrels. These pieces have the insides of their cylinders cut with a number of spiral channels; so that it is in reality a female screw, varying from the common screws only in this, that its threads, or ribs, are less delected, and approach more to a right line; it being usual for the threads with which the rifed barrel is indented, to take little more than one turn in its whole length. The numbers of these threads are different in each barrel, according to the size of the piece and the fancy of the workman; and in like manner the depth to which they are cut is not regulated by any invariable rule.

The usual method of charging these pieces is this: When the proper quantity of powder is put down; a

D d 2 cor

leaden
杖. A leaden bullet is taken, a small matter larger than the
bore of the piece was before the rifle were cut: and this bullet
when laid on the mouth of the piece, and con¬
sequently too large to go down of itself, it is forced
by a strong rammer impelled by a mallet, and by re¬
peated blows is driven home to the powder; and the
fronts of the lead giving way to the violence with
which the bullet is impelled, that zone of the bullet
which is contiguous to the piece varies its areolar
form, and takes the shape of the inside of the barrel;
so that it becomes part of a male screw exactly an¬
swering to the indents of the rifle.

In some parts of Germany and Switzerland, how¬
ever, an improvement is added to this practice; espe¬
cially in the larger pieces which are used for shooting
at great distances. This is done by cutting a piece
of very thin leather, or of thin feltian, in a circular
shape, somewhat larger than the bore of the barrel.
This circle being greased one side, is laid upon the
muzzle with its areolar side downwards; and the bullet
being then placed upon it, is forced down the barrel
with it: by which means the leather or feltian incloses
the lower half of the bullet, and by its interposition
between the bullet and the rifles, prevents the lead
from being cut by them. But it must be remembered,
that in the barrels where this is practised, the rifles
are generally shallow, and the bullet ought not to be
too large. But as both these methods of charging at
the mouth take up a good deal of time; the rifled
barrels which have been made in Britain, are con¬
trived to be charged at the breech, where the piece is
for this purpose made larger than in any other part.
The powder and bullet are put in through the side of
the barrel by an opening, which, when the piece is
loaded, is then filled up with a screw. By this means,
when the piece is fired, the bullet is forced through
the rifles, and acquires the spiral motion already de¬
scribed: and perhaps somewhat of this kind, says
Mr. Robins, though not in the manner now practised,
would be of all others the most perfect method for the
construction of these kinds of barrels.

From the whirling motion communicated by the
rifles, it happens, that when the piece is fired, that
indentation of the bullet follows the sweep of the
rifles: and thereby, besides its progressive motion, ac¬
cquires a circular motion round the axis of the
barrel, which circular motion will be continued to the bullet
after its separation from the piece; and thus a bullet
discharged from a rifled barrel is constantly made to
whirl round an axis which is coincident with the line
of its flight. By this whirling on its axis, the aber¬
rations of the bullet which proves so prejudicial to all
operations on gunnery, is almost totally prevented.

The reason of this may be easily understood from con¬
sidering the flow motion of an arrow through the air.
For example, if a bent arrow, with its wings not placed
in some degree in a spiral position, so as to make it
revolve round its axis as it flies through the air, were
shot at a mark with a true direction, it would con¬
stantly deviate from it, in consequence of being pre¬
ferred to one side by the convex part opposing the
air obliquely. Let us now suppose this deviation in a
flight of 1000 yards to be equal to 10 yards. Now,
if the same bent arrow were made to revolve round its
axis once every two yards of its flight, its greatest de¬
viation would take place when it had proceeded only
one yard, or made half a revolution; since at the end
of the next half revolution it would again return to
the same direction it had at first; the convex side of
the arrow having been once in opposite positions.
In this manner it would proceed during the whole course
of its flight, constantly returning to the true path at
the end of every two yards; and when it reached the
mark, the greatest deflection to either side that could
happen would be equal to what it makes in proceeding
one yard, equal to one part of the former, or
3.6 inches, a very small deflection when compared with
the former one. In the same manner, a cannon-
ball which turns not round its axis, deviates greatly
from the true path, on account of the inequalities on
its surface; which, although small, cause great devia¬
tions by reason of the resistance of the air, at the same
time that the ball acquires a motion round its axis
in uncertain direction occasioned by the friction
against its sides. But by the motion acquired from
the rifles, the error is perpetually corrected in the
manner just now described; and accordingly such
pieces are much more to be depended on, and will
do execution at a much greater distance, than the
other.

The reasons commonly alleged for the superiority
of rifled pieces over common ones, are, either that the
inflammation of the powder is greater, by the resist¬
ance which the bullet makes by being thus forced into
the barrel, and that hereby it receives a much greater
impulse; or that the bullet by the compounding
of its circular and revolving motions, did as it were bore
the air, and thereby flew to a much greater distance
than it would otherwise have done; or that by the
same boring motion it made its way through all solid
substances, and penetrated into them much deeper
than when fired in the common manner. But Mr.
Robins hath proved these reasons to be altogether
erroneous, by a great number of experiments made
with rifled-barrelled pieces. "In these experiments," says
he, "I have found that the velocity of the bullet fired
from a rifled barrel was usually less than that of the
bullet fired from a common piece with the same pro-
portion of powder. Indeed it is but reasonable to
expect that this should be the case; for if the rifles
are very deep, and the bullet is large enough to fill
them up, the friction bears a very considerable pro-
portion to the effort of the powder. And that in this
case the friction is of consequence enough to have its
effects observed, I have discovered by the continued
use of the same barrel. For the metal of the barrel
being soft, and wearing away space, its bore by half
a year's use was considerably enlarged, and consequen-
tly the depth of its rifles diminished; and then I found
that the same quantity of powder would give to the
bullet a velocity near a tenth part greater than what
it had done at first. And as the velocity of the bul-
et is not increased by the use of rifled barrels, so nei-
ther is the distance to which it flies, nor the depth of
its penetration into solid substances. Indeed these two
facts suppress us not at the first sight too chimerical to
deferve a formal confutation. But I cannot help ob-
serving, that those who have been habituated to the
use of rifled pieces are very excusable in giving way to
these prepossessions. For they constantly found, that
with
with them they could fire at a mark with tolerable success, though it were placed at three or four times the distance to which the ordinary pieces were suppos’d to reach. And therefore, as they were ignorant of the true cause of this variety, and did not know that it arose only from preventing the deflection of the ball; it was not natural for them to imagine that the superiority of effect in the rifled piece was owing either to a more violent impulse at first, or to a more easy passage through the air.

In order to confirm the foregoing theory of rifled-barrelled pieces, I made some experiments by which it might be seen whether one side of the ball discharged from them uniformly keeps foremost during the whole course. To examine this particular, I took a rifled barrel carrying a bullet of six to the pound; but instead of its leaden bullet used a wooden one of the same fize, made of a soft springy wood, which bent itself easily into the rifles without breaking. And firing the piece thus loaded against a wall at such a distance as the bullet might not be shivered by the blow, I always found, that the same surface which lay foremost in the piece continued foremost without any sensible deflection during the time of its flight. And this was easily to be observed, by examining the bullet; as both the marks of the rifles, and the part that impinged on the wall, were sufficiently apparent. Now, as these wooden bullets were but the 16th part of the weight of the leaden ones; I conclude, that if there had been any unequal resistance or deflective power; its effects must have been extremely sensible upon this light body, and consequently in some of the trials I made the surface which came foremost from the piece must have been turned round in another situation.

But again, I took the same piece, and loading it now with a leaden ball, I let it nearly upright, sloping it only three or four degrees from the perpendicular in the direction of the wind; and firing it in this situation, the bullet generally continued about half a minute in the air, it rising by computation to near three quarters of a mile perpendicular height. In these trials I found that the bullet commonly came to the ground to the leeward of the piece, and at such a distance from it, as nearly corresponded to the angle of its inclination, and to the effort of the wind; it usually falling not nearer to the piece than 100, nor farther from it than 350 yards. And this is a strong confirmation of the almost steady flight of this barrel for about a mile and a half; for were the same trial made with a common piece, I doubt not but the deviation would often amount to half a mile, or perhaps considerably more; though this experiment would be a very difficult one to examine, on account of the little chance there would be of discovering where the ball fell.

It must be observed, however, that though the bullet impelled from a rifed-barrelled piece keeps for a time to its regular track with sufficient nicety; yet if its flights be so far extended that the track becomes considerably incurvated, it will then undergo considerable deflections. This, according to my experiments, arises from the angle at last made by the axis on which the bullet turns, and the direction in which it flies; for that axis continuing nearly parallel to itself, it must necessarily diverge from the line of the flight of the bullet, when that line is bent from its original direction; and when it once happens that the bullet whirls on an axis which no longer coincides with the line of its flight, then the unequal resistance formerly described will take place, and the deflecting power hence arising will perpetually increase as the track of the bullet, by having its range extended, becomes more and more incurvated.—This matter I have experienced in a small rifle-barrelled piece, carrying a leaden ball of near an ounce weight. For this piece, charged with one drachm of powder, ranged about 350 yards at an angle of 12 degrees with sufficient regularity; but being afterwards elevated to an angle of 24 degrees, it then ranged very irregularly, generally deviating from the line of its direction to the left, and in one case not less than 100 yards. This apparently arose from the cause above-mentioned, as was confirmed from the constant deviation of the bullet to the left; for by considering how the revolving motion was continued with the progressive one, it appeared that a deviation that way was to be expected.

The next remedy I can think of for this defect is the making use of bullets of an egg-like form instead of spherical ones. For if such a bullet hath its shorter axis made to fit the piece, and it be placed in the barrel with its smaller end downwards, then it will acquire by the rifles a rotation round its larger axis; and its centre of gravity lying nearer to its base than its hinder part, its longer axis will be constantly forced by the resistance of the air into the line of its flight; as we see, that by the same means arrows constantly lie in the line of their direction, however that line be incurvated.

But besides this, there is another circumstance in the use of these pieces, which renders the flight of their bullets uncertain when fired at a considerable elevation. For I find by my experiments, that the velocity of a bullet fired with the same quantity of powder from a rifled barrel, varies much more from itself in different trials than when fired from a common piece.—This, as I conceive, is owing to the great quantity of friction, and the impossibility of rendering it equal in each experiment. Indeed, if the rifles are not deeply cut, and if the bullet is nicely fitted to the piece, so as not to require a great force to drive it down, and if feather or feltian well greased is made use of between the bullet and barrel, perhaps, by a careful attention to all these particulars, great part of the inequality in the velocity of the bullet may be prevented, and the difficulty in question be in some measure obviated: but, till this be done, it cannot be doubted, that the range of the same piece, at an elevation, will vary considerably in every trial, although the charge be each time the same. And this I have myself experienced, in a number of diversified trials, with a rifed-barrelled piece loaded at the breech in the English manner. For here the rifles being indented very deep, and the bullet too large as to fill them up completely, I found, that though it flew with sufficient exactness to the distance of 400 or 500 yards; yet when it was raised to an angle of about 12 degrees at which angle, being fired with one-fifth of its weight in powder, its medium range is nearly 1000 yards; in this case, I say, I found that its range was variable, although the greatest care was taken to prevent any inequalities.
in equalities in the quantity of powder, or in the manner of charging. And as, in this case, the angle was too small for the first mentioned irregularity to produce the observed effects; they can only be imputed to the different velocities which the bullets each time received by the unequal action of the friction.

Thus we see, that it is in a manner impossible entirely to correct the aberrations arising from the resistance of the atmosphere; as even the rifle-barrelled pieces cannot be depended upon for more than one-half of their actual range at any considerable elevation. It becomes therefore a problem very difficult of solution to know, even within a very considerable range, how far a piece will carry its ball with any probability of hitting its mark, or doing any execution. The best rules hitherto laid down on this subject are those of Mr. Robins. The foundation of all his calculations is the velocity with which the bullet flies off from the mouth of the piece. Mr. Robins himself had not opportunities of making many experiments on the velocities of cannon-balls, and the calculations from smaller ones cannot always be depended upon. In the 68th volume of the Phil. Trans. Mr. Hutton hath recited a number of experiments made on cannon carrying balls from one to three pounds weight. His machine for discovering the velocities of these balls was the same with that of Mr. Robins, only of a larger size. His charges of powder were two, four, and eight ounces; and the results of 15 experiments which seem to have been the most accurate, are as follow.

Mean velo. 708 993 1397

In another course, the mean velocities, with the same charges of powder, were 673, 873, 1162. The mean velocities of the balls in the first course of experiments (says Mr. Hutton) with two, four, and eight ounces of powder, are as the numbers 1, 1.414, and 1.993: but the subduplicate ratio of the weights (two, four, and eight) give the numbers 1, 1.414, and 1, to which the others are sufficiently near. It is obvious, however, that the greatest difference lies in the last number, which answers to the greatest velocity. It will still be a little more in defect if we make allowance for the weights of the balls; for the mean weights of the balls with the two and four ounces in 183 ounces, but of the eight ounces it is 183: diminishing therefore the number 1.993 in the reciprocal subduplicate ratio of 183 to 183, it becomes 1.095, which falls short of the number 2 by 0.015, or the 133d part of itself. A similar defect was observed in the other course of experiments; and both are owing to three evident causes, viz. 1. The less length of cylinder through which the ball was impelled; for with the eight-ounce charge it lay three or four inches nearer to the muzzle of the piece than with the others. 2. The greater quantity of elastic fluid which escaped in this case than in the others by the windage. This happens from its moving with a greater velocity; in consequence of which, a greater quantity escapes by the vent and windage than in smaller velocities. 3. The greater quantity of powder blown out unfired in this case than in that of the lighter velocities; for the ball which was impelled with the greater velocity, would be sooner out of the piece than the others, and the more so as it had a less length of the bore to move through; and so powder fire in time, which cannot be denied, though indeed that time is manifestly very short, a great quantity of it must remain unfired when the ball with the greater velocity leaves from the piece, than when that which has the less velocity goes out, and still the more so as the bulk of powder which was at first to be inflamed in the one case so much exceeded that in the others.

Let us now compare the corresponding velocities in both cases. In the one they are 701, 993, 1397; in the other, 673, 873, 1162. Now the ratio of the first two numbers, or the velocities with two ounces of powder, is that of 1 to 1.1436, the ratio of the next two is that of 1 to 1.1375, and the ratio of the last is that of 1 to 1.2022. But the mean weight of the shot for two and four ounces of powder, was 28½ ounces in the first course and 18½ in this; and for eight ounces of powder, it was 28½ in the first and 18¾ in this. Taking therefore the reciprocal subduplicate ratios of these weights of shot, we obtain the ratio of 1 to 1.224 for that of the balls which were fired with two ounces and four ounces of powder, and the ratio of 1 to 1.241 for the balls which were fired with eight ounces. But the real ratios above found are not greatly different from these: and the variation of the actual velocities from this law of the weights of shot inclines the same way in both courses of experiments. We may now collect into one view the principal inferences that have resulted from these experiments.

1. It is evident from them, that powder fires almost instantaneously.

2. The velocities communicated to balls or shot of the same weights with different quantities of powder, are nearly in the subduplicate ratio of these quantities; a very small variation in defect taking place when the quantities of powder become great.

3. When shot of different weights are fired with the same quantity of powder, the velocities communicated to them are nearly in the reciprocal subduplicate ratio of their weights.

4. Shot which are of different weights, and impelled by different quantities of powder, acquire velocities which are directly as the square roots of the quantities of powder, and inversely as the square roots of the weights of the shot nearly.

The velocities of the bullets being thus found as Mr. Robins nearly as possible, the ranges may be found by the following rules laid down by Mr. Hutton, and by Mr. Robins of 1 to 1.224: nearly as possible, the ranges may be found by the following rules laid down by Mr. Hutton, and by Mr. Robins of 1 to 1.224.

1. Till the velocity of the projectile surpasses that of 1100 feet in a second, the resistance may be reckoned to be in the duplicate proportion of the velocity, and its mean quantity may be reckoned about half an ounceavoirdupois on a 12-pound shot, moving with a velocity of about 25 or 26 feet in a second.

2. If the velocity be greater than that of 1200 or 1700 feet in a second, then the absolute quantity of the resistance in these greater velocities will be nearly three times as great as it should be by a comparison with
Sect. III.

G U N N E R Y.

With the smaller velocities.—Hence then it appears, that if a projectile begins to move with a velocity less than that of 1100 feet in 1", its whole motion may be supposed to be considered on the hypothesis of a resistance in the duplicate ratio of the velocity. And if it begins to move with a velocity greater than this last mentioned, yet if the first part of its motion, till its velocity be reduced to near 1100 feet in 1", be considered separately from the remaining part in which the velocity is less than 1100 feet in 1"; it is evident, that both parts may be truly aligned on the same hypothesis; only the absolute quantity of the resistance is three times greater in the first part than in the last. Wherefore, if the motion of a projectile on the hypothesis of a resistance in the duplicate ratio of the velocity be truly and generally aligned, the actual motions of resisted bodies may be thereby determined, notwithstanding the increased resistances in the great velocities. And, to avoid the division of the motion into two, I shall show how to compute the whole at one operation with little more trouble than if no such increased resistance took place.

To avoid frequent circumscriptions, the distance to which any projectile would range in a vacuum on the horizontal plane at 45° of elevation, I shall call the potential random of that projectile; the distance to which the projectile would range in vacuo on the horizontal plane at any angle different from 45°, I shall call the potential range of the projectile at that angle; and the distance to which a projectile really ranges, I shall call its actual range.

If the velocity with which a projectile begins to move is known, its potential random and its potential range at any given angle are easily determined from the common theory of projectiles: or more generally, if either its original velocity, its potential random, or its potential range, at a given angle, are known, the other two are easily found out.

To facilitate the computation of resisted bodies, it is necessary, in the consideration of each resisted body, to align a certain quantity, which I shall denominate F', adapted to the resistance of that particular projectile. To find this quantity F to any projectile given, we may proceed thus: First find, from the principles already delivered, with what velocity the projectile must move, so that its resistance may be equal to its gravity. Then the height from whence a body must descend in a vacuum to acquire this velocity is the magnitude of F sought. But the concise way of finding this quantity F to any shell or bullet is this: If it be of solid iron, multiply its diameter measured in inches by 300, the product will be the magnitude of F expressed in yards. If, instead of a solid iron-bullet, it is a shell or a bullet of some other substance; then, as the specific gravity of iron is to the specific gravity of the shell or bullet given, so is the F corresponding to an iron-bullet of the same diameter to the proper F for the shell or bullet given. The quantity F being thus aligned, the necessary computations of these resisted motions may be dispatched by the three following propositions, always remembering that these propositions proceed on the hypothesis of the resistance being in the duplicate proportion of the velocity of the resisted body.

How to apply this principle, when the velocity is so great as to have its resistance augmented beyond this rate,

shall be shown in the corollary to be annexed to the first proposition.

"PROP. I. Given the actual range of a given shell or bullet at any small angle not exceeding 8° or 10°, to determine its potential range, and consequently its potential random and original velocity.

"Sol. Let the actual range given be divided by F corresponding to the given projectile, and find the quote in the first column of the preceding table; then the corresponding number in the second column multiplied into F will be the potential range sought: and thence by the methods already explained, the potential random and the original velocity of the projectile is given.

Exam. An 18 pounder, the diameter of whose shot is about 5 inches, when loaded with 2 lb. of powder, ranged at an elevation 3° 50' to the distance of 975 yards.

"The F corresponding to this bullet is 1500 yards, and the quote of the actual range by this number is 65; corresponding to which, in the second column, is .871; whence 871 F, or 1225 yards, is the potential range sought; and this, augmented in the ratio of the sine of twice the angle of elevation to the radius, gives.
gives 10050 yards for the potential random; whence it will be found, that the velocity of the projectile was that of 98 4 feet in a second.

"Cor. 1st. If the converse of this proposition be desired; that is, if the potential range in a small angle be given, and thence the actual range be fought; this may be solved with the same facility by the same table: for if the given potential range be divided by its correspondent $F$, then opposite to the quote found in the second column, there will be found in the first column a number which multiplied into $F$ will give the actual range required. And from hence it follows, that if the actual range be given at one angle, it may be found at every other angle not exceeding 5° or 10°.

"Cor. 2d. If the actual range at a given small angle be given, and another actual range be given, to which the angle is fought; this will be determined by finding the potential range corresponding to the two given actual ranges; then the angle corresponding to one of these potential ranges being known, the angle corresponding to the other will be found by the common theory of projectiles.

"Cor. 3d. If the potential range deduced from the actual range by this proposition exceeds 13000 yards; then the original velocity of the projectile was so great as to be affected by the treble resistance described above; and consequently the real potential range will be greater than that which is here determined. However, in this case, the true potential range may be thus nearly assigned. Take a 4th continued proportional to 13000 yards, and the potential range found by this proposition, and the 4th proportional thus found may be assumed for the true potential range sought. In like manner, when the true potential range is given greater than 13000 yards, we must take two mean proportional between 13000 and this range*; and the frif of these mean proportional must be assumed instead of the random given, in every operation described in these propositions and their corollaries. And this method will nearly allow for the increased resistance in large velocities, the difference only amounting to a few minutes in the angle of direction of the projected body, which provided that angle exceeds two or three degrees is usually scarce worth attending to.

"Of this process take the following example.

"A 24 pounder fired with 12 pounds of powder, when elevated at 70° 15', ranged about 2500 yards. Here the $F$ being near 1700 yards, the quote to be sought in the first column is 147, to which the number corresponding in the second column is 2.256; whence the potential range is near 4350 yards, and the potential random thence resulting 17400. But this being more than 13000, we must, to get the true potential range, take a 4th continued proportional to 13000 and 17400; and this 4th proportional, which is about 21000 yards, is to be esteemed the true potential range sought; whence the velocity is nearly that of 1730 feet in a second.

"Scholium. This proposition is confined to small angles, not exceeding 8° or 10°. In all possible cases of practice, this approximation, thus limited, will not differ from the most rigorous solution by so much as what will often intervene from the variation of the density of the atmosphere in a few hours time; so that the errors of the approximation are much short of other inevitable errors, which arise from the nature of this subject.

"PROP. II. Given the actual range of a given shell or bullet, at any angle not exceeding 45°, to determine its potential range at the same angle; and thence its potential random and original velocity.

"Sol. Diminish the $F$ corresponding to the shell or bullet given in the proportion of the radius to the cosine of $\frac{1}{2}$ of the angle of elevation. Then, by means of the preceding table, operate with this reduced $F$ in the same manner as is prescribed in the solution of the last proposition, and the result will be the potential range fought; whence the potential random, and the original velocity, are easily determined.

"Exam. A mortar for sea-service, charged with 30lb. of powder, has sometimes thrown its shell, of 12 inches diameter, and of 237 lb. weight, to the distance of 2 miles, or 5450 yards. This at an elevation of 45°. The $F$ to this shell, if it were solid, is 3825 yards; but as the shell is only $\frac{1}{2}$ of a solid globe, the true $F$ is no more than 3060 yards. This, diminished in the ratio of the radius to the cosine of $\frac{1}{2}$ of the angle of elevation, becomes 2544. The quote of the potential range by this diminished $F$ is 1384; which fought in the first column of the preceding table gives 2280 for the corresponding number in the second column; and this multiplied into the reduced $F$, produces 5800 yards for the potential range fought, which, as the angle of elevation was 45°, is also the potential random: and hence the original velocity of this shell appears to be that of about 748 feet in a second.

"Cor. The converse of this proposition, that is, the determination of the actual range from the potential range given, is easily deduced from hence by means of the quote of the potential range divided by the reduced $F$; for this quote searched out in the second column will give a corresponding number in the first column, which multiplied into the reduced $F$, will be the actual range fought.

"Also, if the potential range of a projectile be given, or its actual range at a given angle of elevation; its actual range at any other angle of elevation, not greater than 45°, may hence be known. For the potential range will assign the potential range at any given angle; and thence, by the method of this corollary, the actual range may be found.

"Exam. A fit musquet-bullet fired from a piece of the standard dimensions, with $\frac{1}{2}$ of its weight in good powder, acquires a velocity of near 900 feet in a second; that is, it has a potential random of near 8400 yards. If now the actual range of this bullet at 15° was fought, we must proceed thus: From the given potential random it follows, that the potential range at 15° is 4200 yards; the diameter of the bullet is $\frac{1}{2}$ of an inch; and thence, as it is of lead, its proper $F$ is 337.5 yards, which, reduced in the ratio of the radius to the cosine of $\frac{1}{2}$ of 15°, becomes 321 yards. The quote of 4200 by this number is 12.7 nearly; which, being fought in the second column, gives 3.2 nearly for the corresponding number in the first column; and this multiplied into 321 yards (the reduced $F$) makes 1039 yards for the actual range fought.

"Exam. II. The same bullet, fired with its whole weight in powder, acquires a velocity of about 2100 feet.
GUNNERY.

Sec. III. Practice.

A foot in a second, to which there corresponds a potential random of about 45700 yards. But this number greatly exceeding 13000 yards, it must be reduced by the method described in the third corollary of the first proposition, when it becomes 19700 yards. If now the actual range of this bullet at 15° was required, we shall from hence find, that the potential range at 15° is 9850 yards, which divided by the reduced F of the last example, gives for a quote 2975: and hence following the steps prescribed above, the actual range of this bullet comes out 1396 yards, exceeding the former range by no more than 337 yards; whereas the difference between the two potential ranges is above ten miles. Of such prodigious efficacy is the resistance of the air, which hath been hitherto treated as too insignificant a power to be attended to in laying down the theory of projectiles!

SCHOL. I must here observe, that as the density of the atmosphere perpetually varies, increasing and diminishing often by 1/20 part, and sometimes more, in a few hours, for that reason I have not been over rigorous in forming these rules, but have considered them as sufficiently exact when the errors of the approximation do not exceed the inequalities which would take place by a change of 1/20 part in the density of the atmosphere. With this restriction, the rules of this proposition may be safely applied in all possible cases of practice. That is to say, they will exhibit the true motions of all kinds of shells and cannon-balls, so far as 45° of elevation, and of all musket bullets fired with their largest customary charges, if not elevated more than 30°. Indeed, if experiments are made with extraordinary quantities of powder, producing potential randoms greatly surpassing the usual rate; then in large angles some further modifications may be necessary. And though, as these cases are beyond the limits of all practice, it may be thought unnecessary to consider them; yet to enable those who are disposed to examine these uncommon cases, I shall here insert a proposition, which will determine the actual motion of a projectile at 45°, how enormous forever its original velocity may be. But as this proposition, will rather relate to speculative than practical cases, instead of supposing the actual range known, thence to align the potential random, I shall now suppose the potential random given, and the actual range to be thence investigated.

PROP. III. Given the potential random of a given shell or bullet, to determine its actual range at 45°.

SOL. Divide the given potential random by the F corresponding to the shell or bullet given, and call the quotient q, and let 1 be the difference between the tabular logarithms of 25 and of q, the logarithm of 10 being supposed unity; then the actual range sought is 34 F-2F - 10 F, where the double sine of 2F is to be thus understood; that if q be less than 25, it must be -2F; if it be greater, then it must be +2F. In this solution, q may be any number not less than 3, nor more than 2500.

Cor. Computing in the manner here laid down, we shall find the relation between the potential randoms, and the actual range at 45°, within the limits of this proposition, to be expressed in the following table.

<table>
<thead>
<tr>
<th>Potential Randoms</th>
<th>Actual Range at 45°</th>
</tr>
</thead>
<tbody>
<tr>
<td>3 F</td>
<td>1,5 F</td>
</tr>
<tr>
<td>6 F</td>
<td>2,1 F</td>
</tr>
<tr>

</tr>
<tr>
<td>1000 F</td>
<td>6,4 F</td>
</tr>
<tr>
<td>2500 F</td>
<td>7,0 F</td>
</tr>
</tbody>
</table>

Whence it appears that, when the potential random is increased from 3 F to 2500 F, the actual range is only increased from 1,5 F to 7,0 F, so that an increase of 2497 F in the potential random produces no greater an increase in the actual range than 5 F, which is not its 7/20 part; and this will again be greatly diminished on account of the increased resistance, which takes place in great velocities. So extraordinary are the effects of this resistance; which we have hitherto taught to regard as inconsiderable.

That the justness of the approximations laid down in the 2d and 3d propositions may be easier examined; I shall conclude these computations by inferring a table of the actual ranges at 45° of a projectile, which is refilled in the duplicate proportion of its velocity. This table is computed by methods different from those hitherto described, and is sufficiently exact to serve as a standard with which the result of our other rules may be compared. And since whatever errors occur in the application of the preceding propositions, they will be most sensible at 45° of elevation, it follows, that hereby the utmost limits of those errors may be ascertained.

We have now only to consider that part of practical gunnery which relates to the proportions of the different parts of cannon, the metal of which they are made, &c.

Formerly the guns were made of a very great length, and were on that account extremely troublesome and unmanageable. The error here was first discovered by accident; for some cannon, having been cast by mistake two feet and a half shorter than the common standard, were found to be equally efficacious in service with the common ones, and much more manageable. This soon produced very considerable alterations in the form of the artillery throughout Europe; but in no country have greater improvements in this respect been made than in Britain. For a long time brass, or rather a kind of bell-metal, was thought preferable to cast iron for making of cannon. The composition of this metal is generally kept a secret by each particular founder. The author of the Military Dictionary gives the following proportion as the most common, viz. "To 240 lb. of metal fit for calling they put 68 lb. of copper, 50 lb. of brass, and 12 lb. of tin. To 420 lb. of metal fit for calling the Germans put 368 lb. of copper, 203 lb. of brass, and 307 lb. of tin. Others use 100 lb. of copper, 6 lb. of brass, and 9 lb. of tin; while some make use of 100 lb. of copper, 10 lb. of brass, and 15 lb. of tin. This composition was both found to be very expensive, and also liable to great inconveniences in the using. A few years ago, therefore, a proposal was made by Mr. Muller for using iron guns of a lighter construction than the brass ones, by which he supposed that a very great saving would be made in the expense; and likewise that the guns of the new construction would be more manageable, and even efficacious, than the old ones. "The reduction of the expense (says Mr. Muller) of the very large artillery necessary for sea and land service, is to be considered under two heads; the one, To diminish the weight; and the other, Not to use any brass field-artillery, but only iron, to lessen the great burthen of our ships of war, and to carry larger calibers than those of other nations of the same rate. If the weights of our guns are diminished, they will require fewer hands to manage them, and of consequence a smaller number will be exposed to danger at a time: and if we carry larger calibers, our rates will be a match for larger ships.

"The advantage of using iron guns in the field instead of brass, will be that the expences are lessened in proportion to the calib of brass to that of iron, which is as 8 to 1.

"The only objection against iron is, its pretended brittleness: but as we abound in iron that is stronger and tougher than any brass, this objection is invalid. This I can affirm; having seen some that cannot be broken by any force, and will flatten like hammered iron; if then we use such iron, there can be no danger of the guns burfting in the most severe action.

"Though brass guns are not liable to burft, yet they are sooner rendered un serviceable in action than iron. For by the softnes of the metal, the vent widens so fast, and they are so liable to bend at the muzzle, that it would be dangerous to fire them; as we found by experience at Belleisle, and where we were obliged to take guns from the ships to finish the siege.

"These being undeniable facts, no possible reason can be assigned against using iron guns in both sea and land service, and thereby lessen the expences of artillery so considerably as will appear by the following tables.

GUNNERY.

Sect. III.

Fig. 8. shows Mr. Galcoigne's newly-invented or rather improved gun called a carronade; and which, in June 1779, was by the king and council instituted a standard navy-gun, and to of them appointed to be added to each ship of war, from a first-rate to a sloop. Of this gun the Carron company have published the following account.

"The carronade is made fo short, that it is worked with its carriage in the ship's port; the trunnions lying immediately over the sill of the port: it is correctly bored; and the shot being perfectly round, fills the barrel with such exactness, that the least possible of the impulse of the powder escapes, upon explosion, between the cylinder and the shot; which last is thereby more truly directed in its flight. The bottom of the cylinder is a hemisphere, to which the end of the carriage is not liable to stick, and in which the smallest charge of powder envelopes the shot, exhausting nearly the whole of its impelling force upon it; the trunnions are placed so as to lessen the recoil, and that the gun cannot rest against the sides of the carriage, and is balanced with the utmost facility. There are views cast upon the vent and muzzle, to point the gun quickly to an object at 250 and 500 yards distance. There is an handle A fixed upon the pommel-end of the gun, by which it is horizontally ranged and pointed; and there is a ring cast upon the cap-cable, through which the breech-pin is received, the only rope used about these guns.

"The carronade is mounted upon a carriage B, with a perfectly smooth bottom of strong plank, without tracks; instead of which there is fixed on the bottom of the carriage, perpendicular from the trunnions, a gudgeon C of proper length, with an iron washer D and pin E at the lower end thereof. This gudgeon is let into a corresponding groove F, cut in a second carriage G, called a slide-carriage; the washer supported by the pin over-reaching the under-edges of the groove H. This slide-carriage is made with a smooth upper surface, upon which the gun-carriage is moved, and by the gudgeon always kept in its right station to the port; the groove in the slide-carriage being of a sufficient length to allow the gun to recoil and be loaded within board. The slide-carriage, the groove included, is equally broad with the fore-part of the gun-carriage, and about four times the length; the fore-part of the slide-carriage is fixed by hinged-bolts I, to the quick-work of the ship below the port, the end lying over the fill, close to the outside plank, and the groove reaching to the fore end; the gudgeon of the gun-carriage, and consequently the trunnions of the gun, are over the fill of the port when the gun is run out; and the port is made of such breadth, with its sides bevelled off within board, that the gun and carriage may range from bow to quarter. The slide-carriage is supported from the deck at the hinder end, by a wedge K, or rep-flood; which being altered at pleasure, and the fore-end turning upon the hinge-bolts, the carriage can be constantly kept upon a horizontal plane, for the more easy and quick working of the gun when the ship lies along.

"The gun on carriages being in their places, the breech-pin, which must be strong and limber, is received through the ring on the breech, then led th'o' an eye-bolt drove downwards, the eye standing up-right upon the upper edge of each check of the gun-carriage; from th'o' eye-bolts the ends of the breech-pin rope are feized down as usual to an eye bolt driven into the quick-work on each side, in a line with the lower surface of the slide-carriage.

"The gun being mounted and ready for action, is loaded with 1/9th part of the weight of its ball in service charge of powder put into a waddon-carriage, and the end tied up with worsted yarn, and placed next to the slot; and with a single ball, well rammed home upon and without a wadding between them; the gun being then run out in the port, is ranged and elevated with great facility, by means of the handle on the pommel; and, by the views, very quickly pointed. Upon discharge, the gun attempts to kick upwards, which being prevented by the washer of the gudgeon bearing hard against the under part of the slide-carriage, the recoil takes place; and the gudgeon sliding backwards in the groove (the washer still bearing against an iron plate on the under edge of the groove), till the gun is brought up by the breeching rope, as much re-action succeeds as slackens the rope, so that the gun and carriage may be instantly turned fore and aft by the handle, and loaded again.

"This gun has many singular advantages over the others of light construction. It is so extremely light, that the smallest ships can carry almost any weight of shot (the 12-pounder weighing under 500 wt. and the other calibers in proportion), and that without being attended with the inconveniences imputed generally to light guns, since it cannot injure its carriage, or jump out of its station in the port upon recoil; and it will never heat.

"It can be easily managed and worked of all calibers, from the 12 pounders downwards with two hands, and the 18 and 24-pounders with three hands. It may be readily ranged, pointed, and discharged, twice in three minutes, which doubles the strength of the ship against an enemy of equal force. It is wont upon a horizontal plane to windward or to leeward how much sooner the ship lies along under a press of sail; and therefore, besides being hampered with no tackles or other ropes, except the breech-pin rope, it may be worked with as much ease and expedition in chase or in a gale of wind as in lying to for action. —It can be ranged from bow to quarter, so as to bring a broadside to bear in a circuit of above 10 points of the compass on each side. —It is no more expensive in ammunition than the old guns of two thirds less weight of shot; and it requires very few hands above the complement necessary for navigating merchant-ships, and increases the strength of privateers crews, by exposing few hands at the guns, and augmenting the number at small arms.

"Though the carronade cannot, strictly speaking, throw its shot to an equal distance with a longer gun; yet, from the finics of the shot to its cylinder, the powers of this gun will greatly surpass the expectations of such as are not intimately acquainted with the effects of the elastic force of fired powder, since, with 1/9th part of the weight of its ball, at very small elevations, it will range its shot to triple the distance at which ships generally engage, with sufficient velocity for the greatest execution, and with all the accuracy in
G U N N E R Y.

Sec. III.

Practice.

There have been two seeming disadvantages imputed to this gun, which it does not merit, viz. the
nicety of fitting the shot to the bore of the gun, and its incapacity to hold more than two shot at one
close; for, however just it may be the cylinder, and however perfect and smooth may be the bore of
its corresponding shot, and admitting that the impulse of the shot acts through the centre of gravity
of the shot, and also that the shot consequently leaves the piece in a direction parallel to the axis of its
cylinder; yet, if the shot is less powdered charged, but it becomes more or less infected by its gravity, and
deflected, according to its velocity, by the resistance of the air and wind.

These irregularities are of little importance in close sea-fights, and, being the effect of natural causes, are
common to all. Besides these, the deviation of a shot from its true direction, is further augmented by the
windage between the cylinder and its shot; but the greatest uncertainty in the flight of a shot, making
allowance for the action of its gravity, and the air's resistance, springs from the defects of the shot itself.
Round-shot for ship-guns are seldom nicely examined; and, unless they are cast solid and truly globular, and free
of all hollows, roughness, and other outside blemishes, and well fitted to the gun, cannot even be discharged in
the direction of the axis of the piece; to the disapprobation of those that use such, and to the discredit of the
gun-founder, however justly the piece is viewed, or dispaired; but, being impelled against the surface of the
cylinder, bounds and rebounds from side to side, acquires a rotatory motion, and when cast hollow withal,
and breaking within the cylinder before discharge, (which sometimes happens, especially with double charges),
ever fails to injure; and, when often repeated, may at last burst the very best guns. Round-shot should not be taken on board a ship, without being examined as to its shape and surface; gauged for its
and weighed that it be not above or below the standard more than half an ounce in the pound of its respective caliber. Good shot
then, being of the same importance to all guns, removes the first objection.

If the direction of the flight of a shot to its object is affected by so many seeming trivial causes, how much
more uncertain must it be, when two or more shot are discharged together from one gun? for the shot next
the powder being impelled with more celerity than that immediately before it, strikes against it after discharge,
and sometimes shivers itself to pieces, and never fails to change obliquely the direction of both; and this
happens with round and double-headed, &c. and all double charges; and which, from their various figures,
cannot reach an object at the same elevations with the round-shot; especially when these other shots are of
greater weight than the round, which is often the case. However frightful a broadside with double charges
may appear at sea, more confusion is created by them, and more time lost within board, by the strain and ex-
ceeding recoil, than real damage done without board by the additional charge: for upon a trial on shore,
where the effect can be traced, it will be found, that, at 100 yards distance, more shot will take place within
in a small compass by single than by double charges; and the charges will be oftener repeated in a given
time, without heating the gun; and these facts being established, remove also the second objection.

The following account of the proof of one of these guns will perhaps serve to give a more adequate idea of
the great usefulness of them, than any description:

On Monday, Oct. 4. 1779, there was an experiment made at Carron, before the earl of Dunmore, &c. &c. with a 68-pounder carronade, nearly of the
weight of a British navy 74-pounder gun, and charged with the same quantity (viz. 6 lb. of powder.—The
carronade was mounted, on its proper carriages, into a port of the dimensions of a 74 gun ship's lower-deck
dort; was pointed without elevation, at a centre of eight inches diameter, marked on a bulk's head of the
thickness of two feet five inches solid wood, at 163 yards distance; behind which, at 168 yards, there
was another bulk's head of two feet four inches thick; and behind that again, at 170 yards distance, a bank of
earth. The shot pierced the bulk's head each time, and was buried from three to four feet into the bank,
and the splinters were thrown about to a considerable distance on all sides.

1st shot struck 1 foot 7 inches below the horizontal line, and 5 feet from the mark. 1st shot struck 1 foot 7 inches below the horizontal line, and 5 feet from the mark.
2d do. ditto 2 feet ditto, 2d do. ditto 2 feet ditto, 3d do. do. through the horizontal line 3d do. do. through the horizontal line
4th do. do. ditto 4th do. do. ditto
5th do. do. ditto 5th do. do. ditto
6th do. do. 2 inches below 6th do. do. 2 inches below
7th do. do. touched the lower part of ditto 7th do. do. touched the lower part of ditto
8th do. do. 2 inches below 8th do. do. 2 inches below
9th do. do. 2 feet below 9th do. do. 2 feet below
10th do. do. 3 inches below 10th do. do. 3 inches below

The carronade was laid each time by the views without an instrument; and the shot were all to the
left of the mark, owing to a small error in disparting the views; the third, fourth, and fifth shot, made one
fracture, as did also sixth, seventh, and eighth, and
the sixth and eighth struck the same porte.

The Carronade was easily worked with four men, and may be readily worked and discharged on board a
The above dimensions are taken from some elegant 4 pound guns, which were made for the prince of Aufturias by the Carron company.

The rifles make one spiral turn in the length of the bore; but go no nearer to the breech, in their full size, than two calibers; and then terminate with a gentle flop in half a caliber more, so as not to prevent the cartridge with the powder from being easily lented home to the bottom of the gun, which would otherwise constantly happen with the flannel cartridges, and even sometimes with paper ones, if not made to enter very loofly. The shape of the rifles is semicircular, their breadth being equal to the diameter, which is $\frac{3}{4}$ of a caliber, and their depth equal to the semidiameter, or $\frac{3}{4}$ of a caliber.

The bullets, fig. 10, are of lead, having six knobs cast on them to fit the rifles of the gun. Being thus made of soft metal, they do not injure the rifles; and may also save an army the trouble of carrying a great quantity of shot about with them, since a supply of lead
GUNNERY.

Sect. III.

Practice.

lead may be had in most countries from roofs, &c.,
which can be cast into balls as occasion requires. Lead
likewise being of greater specific gravity than calib-
iron, flies to a much greater distance.

Rifled ordnance of any caliber might be made to
carry iron shot for battering or for other purposes;
provided holes, that are a little wider at their bottom
than at their upper parts, be cast in a zone round
the ball, for receiving afterwards leaden knobs to fit
the rifles of the cannon; by which means, the iron shot
will have its intended line of direction preferred, with-
out injuring the rifles more than if the whole line of
lead, the rotatory motion round its axis, in the line of
its direction (which corrects the aberration) being com-
mmunicated to it by the leaden knobs, following the
spiral turn of the rifles in its progress out of the gun.
It is particularly to be observed, that the balls must be
made to glide down into the piece, so that the car-
tridge with the powder and the bullet may be both fit
home together, with a single pull of the hand, without
any wadding above either powder or ball; by which
means, the gun is quickly loaded, and the ball flies
farther than when it is forcibly driven into the gun, as
was found from many experiments. The only reason
why, in common rifled muskets, the bullets are ram-
med in forcibly, is this, that the zone of the ball which
is contiguous to the inside of the bore may have the
figure of the rifles imprinted upon it, in such a manner
as to become part of a male screw, exactly fitting the
indents of the rifle, which is not at all necessary in the
present case, the figure of the rifles being originally
cast upon the ball. These knobs retard the flight of
the ball in some degree: but this small disadvantage
is fully made up by the ease with which the gun is
loaded, its service being nearly as quick as that of a
common field-piece; and the retardation and quantity
of the whirling motion which is communicated to the
bullet being constantly the same, it will not in the
least affect the experiments made with them, in order to
determine the resistence of the air.

In order to hit the mark with greater certainty than
can be done in the common random method, these
guns are furnished with a sector, the principal parts of
which are,
1. The limb, which is divided in such a
manner as to show elevations to 15 or 20 degrees.
The length of the radius is five inches and an half, and its
nominal is 3 divided as to show minutes of a degree.
2. The telescope, AB, fig. 11. an achromatic refrac-
tor, is seven inches in length (such as is used in Had-
ley's quadrants, that are fitted for taking distances of
the moon from the sun, or stars, in order to obtain the
longitude at sea), having crofs hairs in it.
3. The parallel cylindric bar, CD, is $\frac{1}{2}$ of an inch in di-
meter, having two rectangular ends EF, each half an inch
square and an inch long. On one end of the eye next
the limb of the sector, is a mark corresponding to a
similar one in the hinder cock of the gun with which it
must always coincide when placed on the gun. The
length of the parallel bar, together with its ends, is
seven inches. This bar is fixed to the sector by means
of two hollow cylinders, G, H, which allow the sector
a motion round the bar. There is a finger-screw, a, up-
on the hollow cylinder, G, which is fitted, in order to
tighten it at pleasure upon the bar.
4. The circular level, fig. 11. and 12, for setting the plane of the
sector always perpendicular when placed upon the gun, is
$\frac{1}{2}$ of an inch in diameter. There is a small screw, $b$, to
adjust the level at right angles to the plane of the
sector.
5. The finger-screw $c$, for fixing the index
of the sector at any particular degree of elevation
proped.

The line of collimation (that is, the line of vision
cut by the intersecting point of the two crofs-hairs in
the telescope (must be adjusted truly parallel to the bar
of the sector when at 0 degrees. This is done by
placing the sector so that the vertical hair may exactly
cover some very distant perpendicular line. If it again
covers it when the sector is moved, by turning it half
round upon the bar, which has all the while been kept
steady and firm, that hair is correct: if not, correct
half the error by means of the small screws, c d e,
fig. 11. and 12, at the eye-end of the telescope, and
the other half by moving the bar; place it again to
cover the perpendicular line, and repeat the above oper-
tion till the hair covers it in both positions of the
sector.

Then turn the sector, till the horizontal hair cov-
er the same perpendicular line, and turning the sector
half round on its bar, correct it, if wrong, in the same
manner as you did the vertical hair.

N. B. Of the four small screws at the eye-end of
the telescope, those at the right and left hand move
whatever hair is vertical, and those at top or underneath
move whatever hair is horizontal.

On the side of the gun, upon the first reinforce, are
cast two knobs, F, fig. 9. and 14. having their middle
part distant from each other six inches, for fixing
on the brass cocks, A, fig. 14. and 15. which receive
the rectangular ends of the parallel cylindric bar of
the sector, when placed on the gun.

The next adjustment is to make the parallel bar, and
line of collimation of the telescope, when set at 0 de-
gress, parallel to the bore of the gun, and consequently
to the direction of the shot. The gun being loaded,
the cartridge picked, and the gun primed, place the
sector in the cocks of the gun, and having first set the
sector to what elevation you think necessary, bring the
intersecting of the crofs-hairs in the telescope upon the
centre of the mark, the limb of the sector being set
vertically, from the least elevation, to make the parallel
line, falling through the centre of the mark, the line
of collimation of the telescope and direction of the shot
agree. But if it hit to the right of the mark, so much
do they differ. In order to correct which, bring the
gun into the same position it was before firing, and
secure it there. Then file away as much of the fore-
cock, on the side next the gun, as will let the inter-
section of the crofs-hairs fall somewhere on the line pass-
ing perpendicularly through the point where the shot
fell; and it is then adjusted in that position, so much
being filed off the side of the cock at a, fig. 14. and
18., as will allow the side b to be screwed closer, that
the ends of the parallel bar may have no shake in the
cocks. To correct it in the other position, and so to
find the true 0 degrees of the gun, that is, to bring the
line of collimation of the telescope, parallel bar, and
bar of the gun, truly parallel to each other, repeat
the above with the trunnions perpendicular to the ho-
rizon, the sector being turned a quarter round upon its
bar.
GUNNERY

Sect. III.

Practice.

bar, so as to bring its plane vertical. The deviation of the shot found in this way is corrected by deepening one of the cocks, so that the vertical hair of the telescope may be brought to cover the line passing perpendicularly through the point where the bullet hits; the gun being placed in the same position it was in before it was fired. This adjustment being repeated two or three times, and any error that remains being corrected, the gun is fit to be mounted on its carriage for service. It is to be observed, that this cock will fit any gun, if the cocks and rectangular ends, &c. of the parallel bar be of the above dimensions, and will be equally applicable to all such pieces whose cocks have been adjusted, as if it had been adjusted separately with each of them. And if the cock be set at any degree of elevation, and the gun moved so as to bring the intersection of the cross hairs on the object to be fired at (the limb of the sector being vertical), the bore of the gun will have the same elevation above it, in the true direction of the shot, whatever position the carriage of the gun is standing in. A telescope with cross hairs, fixed to a common rifled mufket, and adjusted to the direction of the shot, will make any person, with a very little practice, hit an object with more precision than the most experienced markman.

For garrison-service, or for batteries, the ship or garrison carriage, with two iron staples on each side to put through a couple of poles to carry these guns from place to place with more dispatch, are as proper as any. But, for the field, a carriage like that at fig. 16, where the shafts pull in upon taking out the iron pins a b, and moving the cross bar a, upon which the breach of the gun rests, as far down as the shafts were pushed in, is the properest; since the whole can then be carried like a hand-barrow, over ditches, walls, or rough ground, all which may be easily understood from the figure.

The principal advantage that will accrue from the use of rifled ordnance, is the great certainty with which any object may be hit when fired at with them, since the shot deviates but little from its intended line of direction, and the gun is capable of being brought to bear upon the object with great exactness, by means of the telescope of cross hairs.

The other pieces of artillery commonly made use of are mortars, howitzes, and royals. The mortars are a kind of short cannon of a large bore, with chambers for the powder, and are made of brass or iron. Their use is to throw hollow shells filled with powder, which falling on any building, or into the works of a fortification, burn, and with their fragments destroy everything near them. Cascales are also thrown out of them; which are a sort of shells with five holes, filled with pitch and other materials, in order to set buildings on fire; and sometimes baskets full of stones, of the size of a man's fist, are thrown out of them upon an enemy placed in the covert-way in the time of a siege. Of late the ingenious General Defaguliers has contrived to throw bags filled with grape-shot, containing in each bag from 400 to 600 shot of different dimensions, out of mortars. The effect of these is tremendous to troops forming the line of battle, passing a desfile, or landing, &c. the shot pouring down like a shower of hail on a circumference of above 300 feet.

Mortars are chiefly distinguished by the dimensions of their bore; for example, a 13th-inch mortar is one the diameter of whose bore is 13 inches, &c.—The land-mortars are those used in sieges, and of late in battles. They are mounted on beds, and both mortar and bed are transported on block carriages. There is likewise a kind of land-mortars mounted on travelling carriages, invented by Count Bayeburg, which may be elevated to any degree; whereas all the English mortars are fixed to an angle of 45°. This suffices, however, does no appear to have any foundation in reason. In a siege, shells should never be thrown with an angle of 45 degrees, excepting one case only; that is, when the battery is so far off, that they cannot otherwise reach the works; for when shells are thrown out of the trenches into the works of a fortification, or from the town into the trenches, they should have as little elevation as possible, in order not to bury themselves, but to roll along the ground, whereby they do much more damage, and occasion a much greater consolation among the troops, than if they sink into the ground. On the contrary, when shells are thrown upon magazines, or any other buildings, the mortars should be elevated as high as possible, that the shells may acquire a greater force in their fall, and consequently do more execution.

There are other kinds of mortars, called partridge-mortars, hand-mortars, and firelock-mortars; which last are also called bombards. The partridge-mortar is a common one, surrounded with 12 other little mortars bored round its circumference, in the body of the metal; the middle one is loaded with a shell, and the others with grenades. The vent of the large mortar being fired, communicates its fire to the rest; so that both the shell and grenades go off at once. Hand-mortars were frequently used before the invention of cohorns. They were fixed at the end of a staff four feet and a half long, the other end being fixed with iron to stick in the ground; and while the bombardier with one hand elevated it at pleasure, he fired it with the other. The firelock mortars, or bombards, are small mortars fixed to the end of a firelock. They are loaded as all common firelocks are; and the grenade, placed in the mortar at the end of the barrel, is discharged by a flint-lock. To prevent the recoil hurting the bombardier, the bombards rest on a kind of halberd made for that purpose.

The chamber in mortars is the place where the powder is lodged. They are of different forms, and made variously by different nations; but the cylindric seems to be preferable to any other form.

The howitzer is a kind of mortar mounted on a field carriage like a gun; it differs from the common mortars in having the trunnions in the middle, whereas those of the mortar are at the end. The construction of howitzers is as various and uncertain as that of mortars, excepting that the chambers are all cylindric. They are distinguished by the diameter of their bore; for instance, a 10-inch howitzer is that which has a bore of 10 inches diameter, and so of others. They were much more lately invented than mortars, and indeed are plainly derived from them.
GUNNERY.

Section III.

Practice.

53. Instruments used in loading cannon.

55. Parts of a mortar.

Practice.

Royals are a kind of small mortars, which carry a shell whose diameter is 5.5 inches. They are mounted on beds in the same way as other mortars.

Fig. 17, represents a mortar; and the names of its parts are as follow:

- AB, the whole length of the mortar.
- AC, the muzzle.
- CD, chace.
- DE, reinforce.
- EF, breech.
- GA, trunnions.
- a, vent.
- b, dolphin.
- cc, vent-aftragal and fillets.
- dd, breech-ring and ogee.
- ff, reinforce-ring and ogee.
- gg, reinforce-aftragal and fillets.
- hh, muzzle-aftragal and fillets.
- Jl, muzzle-ring and ogee.
- ll, interior part.
- m, shoulders.
- n, breech.
- oo, chamber.
- p, bore.
- qr, vent.

The mortar-beds are formed of very solid timber, and placed upon very strong wooden frames, fixed in such a manner that the bed may turn round. The forepart of these beds is an arc of a circle described from the centre on which the whole turns.

There are several instruments employed in the loading of cannon. The names of these are as follow:

1. The lantern or ladle, which serves to carry the powder into the piece, and which consists of two parts, viz. of a wooden box, appropriated to the caliber of the piece for which it is intended, and of a caliper and a half in length with its vent; and of a piece of copper nailed to the box, at the height of a half caliper.—This lantern must have three calibers and a half in length, and two calibers in breadth, being rounded at the end to load the ordinary pieces.

2. The rammer is a round piece of wood, commonly called a box, fastened to a stock 12 feet long, for the pieces from 12 to 33 pounds; and to the 8 and 4 pounders, which serve to drive home the powder and ball to the breech.

3. The sponge is a long flaff or rammer, with a piece of sheep or lamb-skin wound about its end, to serve for scouring the cannon when discharged, before it be charged with fresh powder; to prevent any spark of fire from remaining in her, which would endanger the life of him that should load her again.

4. Wad-screw consists of two points of iron turned serpent-wife, to extract the wad out the pieces when one wants to unload them, or the dirt which had chanced to enter into it.

5. The boteaux are flacks two or three feet long, and an inch thick, split at one end, to hold an end of the match twisted round it, to fire the cannon.

6. The priming-iron is a pointed iron-rod, to clear the touch-hole of the pieces of powder or dirt; and also to pierce the cartridge, that it may sooner take fire.

Vol. VIII.

7. The primer, which must contain a pound of powder at least, to prime the pieces.

8. The quoin of mire, which are pieces of wood with a notch on the side to put the fingers on, to draw them back or push them forward when the gunner points his piece. They are placed on the sole of the carriage.

9. Lead-plates, which are used to cover the touch-hole, when the piece is charged, lest some dirt should enter it and spoil it.

Before charging the piece, it is well fponged, to clean it of all filth and dirt within it; then the proper managing weight of gunpowder is put in and rammed down; care being taken that the powder be not bruised in ramming, which weakens its effect; it is then run over by a little quantity of paper, hay, or the like; and lastly, the ball is thrown in.

To point, level, or direct the piece, so as to play against any certain point, is done by the help of a quadrant with a plummet; which quadrant consists of two branches made of brass or wood; one about a foot long, eight lines broad, and one line in thickness; the other four inches long, and the same thickness and breadth as the former. Between these branches is a quadrant, divided into 90 degrees, beginning from the shorter branch, and furnished with thread and plummet.

The longest branch of this instrument is placed in the cannon's mouth, and elevated or lowered till the thread cuts the degree necessary to hit the proposed object. Which done, the cannon is primed, and then set fire to. The method by the fecor, however, proposed by Dr. Lind, is certainly in all cases to be preferred.

A 24 pounder may very well fire 90 or 100 shots every day in summer, and 60 or 75 in winter. In case of necessity it may fire more; and some French officers of artillery assure, that they have caused such a piece to fire every day 150 shots in a siege. A 16 and a 12 pounder fire a little more, because they are easier served. There have even been some occasions where 200 shots have been fired from these pieces in the space of nine hours, and 138 in the space of five. In quick firing, tubes are made use of. They are made of tin; and their diameter is two-tenths of an inch, being just sufficient to enter into the vent of the piece. They are about six inches long, with a cap above, and cut flaring below, in the form of a pen; the point is strengthened with some folder, that it may pierce the cartridge without bending. Through this tube is drawn a quick-match, the cap being fitted with mealed powder moistened with spirits of wine. To prevent the mealed powder from falling out by carriage, a cap of paper or flannel fleeced in spirits of wine is tied over it. To range pieces in a battery, care must be taken to reconnoitre well the ground where it is to be placed, and the avenues to it. The pieces must be armed each with two lanterns or ladies, a rammer, a sponge, and two priming-irons. The battery must also be provided with carriages, and other implements, necessary to removal the pieces which the enemy should chance to dismount.

To serve expeditiously and safely a piece in a battery, it is necessary to have to each a sack of leather,
234

G U N N E R Y.

Sect. III.

Practice.

large enough to contain about 20 pounds of powder to charge the lantern or ladies, without carrying them to the magazine; and to avoid thereby making those trains of powder in bringing back the lantern from the magazine, and the accidents which frequently happen thereby.

A battery of three pieces must have 50 gabions, because six are employed on each of the two sides or epaulements, which make 12, and nine for each of the two merlons.

There ought to be two gunners and six soldiers to each piece, and an officer of artillery.

The gunner posted on the right of the piece must take care to have always a pouch full of powder and two priming irons; his office is to prime the piece, and load it with powder. The gunner on the left fetches the powder from the little magazine, and fills the lantern or ladle which his comrade holds; after which, he takes care that the match be very well lighted, and ready to set fire to the piece at the first command of the officer.

There are three soldiers on the right and three on the left of the piece. The two first take care to ram and sponge the piece, each on his side. The rammer and sponge are placed on the left, and the lantern or ladle on the right. After having rammed well the wad put over the powder and that put over the bullet, they then take each a handspike, which they pass between the forewheels of the wheel, the ends whereof will pass under the head of the carriage, to make the wheel turn round, leaning on the other end of the handspike, towards the embrasure.

It is the office of the second soldier on the right to provide wad, and to put it into the piece, as well over the powder as over the bullet; and that of his comrade on the left to provide 50 bullets, and every time the piece is to be charged, to fetch one of them and put it into the piece after the powder has been rammed. Then they both take each a handspike, which they pass under the hind part of the wheel, to pull it in battery.

The officer of artillery must take care to have the piece diligently served.

In the night he must employ the gunners and soldiers, who shall relieve those who have served 24 hours to repair the embrasures.

If there be no water near the battery, care must be taken to have a cask filled with it, in which to dip the sponges and cool the pieces every 10 or 12 rounds.

The carriage for a mortar of 12 inches of diameter must be 6 feet long, the flasks 12 inches long and 10 thick. The trunnions are placed in the middle of the carriage.

The carriage of an 18 inch mortar must be 4 feet long, and the flasks 11 inches high and 6 thick.

To mount the mortars of new invention, they use carriages of cast iron.

In Germany, to mount mortars from 8 to 9 inches, and carry them into the field, and execute them horizontally as a piece of cannon, they make use of a piece of wood 8 feet 3 inches long, with a hole in the middle to lodge the body of the mortar and its trunnions as far as their half diameter, and mounted on two wheels four feet high, to which they join a van train proportioned to it, and made like those which serve to the carriages of cannons.

Having mounted the mortar on its carriage, the next thing is to caliber the bomb by means of a great calibcr, the two branches whereof embrace the whole circumference of the bomb; these two branches are brought on a rule where the different calibers are marked, among which that of the bomb is found.

If no defect be found in the bomb, its cavity is filled, by means of a funnel, with whole gunpowder; a little space or liberty is left, that when a fusee or wooden tube, of the figure of a truncated cone, is driven thro' the aperture (with a wooden mallet, not an iron one for fear of accident), and fastened with a cement made of quicklime, ashes, brick-dust, and steel filings, worked together in a glutinous water, or of four parts of pitch, two of colophony, one of turpentine, and one of wax, the powder may not be bruised. This tube is filled with a combustible matter made of two ounces of nitre, one of sulphur, and three or more of gunpowder dust well rammed. See FUZEE.

This fusee set on fire burns slowly till it reaches the gunpowder; which goes off at once, bursting the shell to pieces with incredible violence. Special care, however, must be taken that the fusee be so proportioned as that the gunpowder do not take fire ere the shell arrives at the defined place; to prevent which, the fusee is frequently wound round with a wet clammy thread.

Batteries consist.—1. Of an epaulement to shelter the mortars from the fire of the enemy. 2. Of platforms on which the mortars are placed. 3. Of small magazines of powder. 4. Of a boyan, which leads to the great magazine. 5. Of ways which lead from the battery to the magazine of bombs. 6. Of a great ditch before the epaulement. 7. Of a berm or retraite.

The platforms for mortars of 12 inches must have 9 feet in length and 6 in breadth. 1. The lambourds for common mortars must be four inches thick; those of a concave chamber of 8 lb. of powder, 5 inches; those of 12 lb. 6 inches; those of 18 lb. 7 inches or thereabouts. Their length is at discretion, provided there be enough to make the platforms 9 feet long. The forepart of the platform will be situated at two feet distance from the epaulement of the battery. The bombadiers, to shelter themselves in their battery, and not be seen from the town besieged, raise an epaulement of 7 feet or more high, which epaulement has no embrasures.

To serve expeditiously a mortar in battery, there are required,—five strong handspikes; a dame or rammer, of the caliber of the conic chamber, to ram the wad and the earth; a wooden knife a foot long, to place the earth round the bomb; an iron scraper two feet long, one end whereof must be four inches broad and roundwise, to clean the bore and the chamber of the mortar, and the other end made in form of a spoon to clean the little chamber; a kind of brandard to carry the bomb, a shovel, and pick-axe.

The officer who is to mind the service of the mortar must have a quadrant to give the degrees of elevation.

Five bombardiers, or others, are employed in that service: the first must take care to fetch the powder to charge the chamber of the mortar, putting his priming-iron in the touch-hole before he charges the chamber; and
The mortar, in order to
Of tables to discover the different distances from the principles already laid down,
he takes an handspike in the same place to put himself behind the carriage of the mortar, in order to help to push it into battery: having laid down his handspike, he takes out his priming-iron, and primes the touch-hole with fine powder.

The second follower on the right and left will have by that time brought the bomb ready loaded, which must be received into the mortar by the first follower, and placed very strait in the bore or chafe of the mortar.

The first on the right will furnish him with earth to put round the bomb, which he must take care to ram close with the knife given him by the second on the left.

This done, each shall take a handspike, which the two first on the right and left shall put under the pegs of retreat on the forepart, and the two behind under those of the hindpart, and they together push the mortar in battery.

Afterwards the officer points or directs the mortar.

During that time, the first follower takes care to prime the touch-hole of the mortar, without ramming the powder; and the left on the right must have the match ready to set fire to the fusee of the bomb on the right, while the first is ready with his on the left to set fire to the touch-hole of the mortar, which he ought not to do till he sees the fusee well lighted.

The foremost followers will have their handspikes ready to raise the mortar upright as soon as it has discharged, while the hindmost on the left shall with the scraper clean the bore and chamber of the mortar.

The magazine of powder for the service of the battery shall be situated 15 or 20 pieces behind, and covered with boards and earth over it.—The loaded bombs are on the side of the laden magazine, at five or six pieces distance.

The officer who commands the service of the mortar must take care to discover as much as possible with the eye the distance of the place where he intends to throw his bomb, giving the mortar the degree of elevation according to the judgment he has formed of the distance. Having thrown the first bomb, he must diminish or increase the degrees of elevation according to the place on which it shall fall. Several make use of tables to discover the different distances according to the differences of the elevations of the mortar, especially the degrees of the quadrant from 1 to 45: but these, from the principles already laid down, must be fallacious.

The petard is the next piece of artillery which deserves our attention; and is a kind of engine of metal, somewhat in shape of a high-crowned hat, serving to break down gates, barricades, draw bridges, or the like works, which are intended to be surprized. It is very short, narrow at the beech and wide at the muzzle, made of copper mixed with a little brass, or lead with tin.

The petards are not always of the same height and bigness: they are commonly 10 inches high, 7 inches of diameter at top, and 10 inches at bottom. They weigh commonly 40, 45, and 50 pounds.

The madrier, on which the petard is placed, and where it is tied with iron circles, is of two feet for its greatest width, and of 18 inches on the sides, and no thicker than a common madrier. Under the madrier are two iron-bars paffed crosswise, with a book, which serves to fix the petard.

To charge a petard 15 inches high, and 6 or 7 inches of caliber or diameter at the bore, the inside must be first very well cleaned and heated, so that the hand may bear the heat; then take the left powder that may be found, throw over it some spirit of wine, and expose it to the sun, or put it in a frying-pan; and when it is well dried, 5 lb. or 6 lb. of this powder is put into the petard, which reaches within three fingers of the mouth: the vacancies are filled with tow, and flopped with a wooden-tampion; the mouth being strongly bound up with cloth tied very tight with ropes; then it is fixed on the madrier, that has a cavity cut in it to receive the mouth of the petard, and fastened down with ropes.

Some, instead of gunpowder for the charge, use one of the following composition, viz. gunpowder seven pounds, mercury sublimate one ounce, camphor eight ounces; or gunpowder six pounds, mercury sublimate three ounces, and sulphur three; or gunpowder six, beaten glass half an ounce, and camphor three quarters.

Before any of these pieces are appropriated for service, it is necessary to have each undergo a particular trial of its soundness, which is called a proof, to be made by or before one authorized for the purpose, called the proof-master.

To make a proof of the piece, a proper place is chosen, which is to be terminated by a mound of earth very thick to receive the bullets fired against it, that none of them can run through it. The piece is laid on the ground, supported only in the middle by a block of wood. It is fired three times; the first with powder of the weight of the bullet, and the two others with; of the weight; after which a little more powder is put in to finge the piece, and after this, water, which is impressed with a spunge, putting the finger on the touch-hole to discover if there be any cracks; which done, they are examined with the car, which is a piece of iron with three grafts, dipped in the form of a triangle, and of the caliber of the piece; then it is visited with a wax-candle, but if of very little service in the small pieces, because if they be a little long the smoke extinguishes it immediately. See Plate CCXXIV.

Besides the large pieces already mentioned, invented for the destruction of mankind, there are others arms called small guns; viz. muskets of rammers, common muskets, fults, carabiners, musketons, and pithole.

A musket, or musquet, is a fire-arm borne on the shoulder, and used in war, formerly fired by the application of a lighted match, but as present with a flint and lock. The common musket is of the caliber of 20 leaden balls to the pound, and receives balls from 22 to 24: its length is fixed to 3 feet 8 inches from the muzzle to the touch-pan.
GUNNERY.

GUNPOWDER, a composition of saltpetre, sulphur, and charcoal, mixed together and usually granulated; which easily takes fire, and, when fired, rarifies or expands with great vehemence, by means of its elastic force.

It is to this powder we owe all the action and effect of guns, ordnance, &c. so that the modern military art, fortification, &c. in a great measure depend thereon.

Invention of Gunpowder. See Gun.

Method of making Gunpowder. Dr Shaw's receipt for this purpose is as follows: Take four ounces of refined saltpetre, an ounce of brimstone, and six drams of small coal; reduce these to a fine powder, and continue beating them for some time in a stone mortar with a wooden pestle, wetting the mixture between whiles with water, so as to form the whole into an uniform paste, which is reduced to grains, by passing it through a wire-sieve fit for the purpose; and in this form being carefully dried, it becomes the common gunpowder.

For greater quantities mills are usually provided, by means of which more work may be performed in one day than a man can do in a hundred.

The nitre or saltpetre is refined thus: Dissolve four pounds of rough nitre as it comes to us from the Indies, by boiling it in as much water as will commodiously suffice for that purpose: then let it flow for two or three days in a covered vessel of earth, with sticks laid across for the crystals to adhere to. These crystals being taken out, are drained and dried in the open air.

In order to reduce this salt to powder, they dissolve a large quantity of it in as small a proportion of water as possible; then keep it constantly filtering over the fire till the water exhales and a white dry powder is left behind.

In order to purify the brimstone employed, they dissolve it with a very gentle heat; then strain and pass it through a double strainer. If the brimstone should happen to take fire in the melting, they have an iron cover that fits on close to the melting-vessel, and damps the flame. The brimstone is judged to be sufficiently refined if it melts, without yielding any fetid odour, between two hot iron-plates, into a kind of red sub stance.

The coal for the making of gunpowder is either that of willow or hazel, well charred in the usual manner, and reduced to powder. And thus the ingredients are prepared for making this commodity; but as these ingredients require to be intimately mixed, and as there would be danger of their firing if heat in a dry form, the method is to keep them continually moist, either with water, urine, or a solution of sal ammoniac: they continue thus stamping them together for 24 hours; after which the mass is fit for coming and drying in the sun, or otherwise, so as sedulously to prevent its firing.

Different kinds of Gunpowder. The three ingredients of gunpowder are mixed in various proportions according as the powder is intended for muskets, great guns, or mortars; though these proportions seem not to be perfectly adjusted or settled by competent experience.

Semicnowitz, for mortars, directs an hundred pounds of saltpetre, twenty-five of sulphur, and as many of charcoal; for great guns, an hundred pounds of saltpetre, fifteen pounds of sulphur, and eighteen pounds of charcoal; for muskets and pistols, an hundred pounds of saltpetre, eight pounds of sulphur, and ten pounds of charcoal. Mithiész extols the proportion of one pound of saltpetre to three ounces of charcoal, and two or two and a quarter of sulphur; than which, he affirms, no gunpowder can possibly be stronger. He adds, that the usual practice of making the gunpowder weaker for mortars than guns, is without any foundation, and renders the expense needlessly much greater: for whereas to load a large mortar, twenty-four pound of common powder is required, and consequently, to load it ten times, two hundred and forty pound, he shows, by calculation, that the same effect would be had by one hundred and fifty pound of the strong powder.

On this subject Mr Thomson observes, that almost all those who have written upon gunpowder, particularly those of the last century, have given different receipts for its composition; and he proposes it as a query, Whether these differences have not arisen from observing that some kinds of powder were better adapted to particular purposes than others, or from experiments made on purpose to ascertain the fact? "There is one circumstance (he says) that would lead us to suppose that this was the case. That kind of powder designed for mortars and great guns was weaker than that intended for small arms: for if there is any foundation for these conjectures, it is certain, that the weakest powder, or the heaviest in proportion to its elastic force, ought to be used to impel the heaviest bullets; and particularly in guns that are imperfectly formed, where the vent is large, and the windage very great. I am perfectly aware (adds he), that an objection may here be made, viz. that the elastic fluid generated from gunpowder must be supposed to have the same properties very nearly, whatever may be the proportion of its several ingredients: and that therefore the only difference there can be in powder is, that..."
one kind may generate more of this fluid, and another
les; and that when it is generated it acts in the same
manner, and will alike cleave, and with the same ve-
locity, by any passage it can find. But to this an-
swer, that though the fluid may be the same, as it un-
doubtedly is, and though its density and elasticity
may be the same in all cases, at this instant of its ge-
eration; yet in the explosion, the elastic and unelastic
parts are so mixed together, that I imagine the fluid
cannot expand without taking the grous matter along
with it; and the velocity with which the flame issue
at the vent is to be computed from the elacticity of
the fluid, and the density or weight of the fluid and
grois matter taken together, and not simply from the
density and elacticity of the fluid."

To increase the strength of powder, Dr Shaw thinks
it proper to make the grains considerably large, and to
have it well lifted from the small dust. We see that
gunpowder is capable of being burnt, even in its present
state; but when the grains are large, the flame of one grain
has a ready passage to another, so that the whole par-
cel may thus take fire nearly at the same time, other-
wise much force may be lost, or many of the grains
may go away as shot unburst.

In the 71st volume of the Phil. Trans. Mr Thomfon
gives an account of several attempts to augment the
force of gunpowder by the addition of different ingre-
dients. The power of steam has by many been over-
rated to such a degree, as to be supposed capable of
answering the purposes of gunpowder; but no at-
tempts to accomplish this have ever succeeded in any
degree. Mr Thomfon attempted to combine the forces
of steam and gunpowder together in the following man-
ner. Having procured a number of air bladders of
very small siphons, he put different quantities of water
into them from the size of a small pea to that of a
pistol bullet, and tying them up with some very fine
thread, hung them up to dry on the outside. He then
provided a number of cartridges made of fine paper,
and filled them with a quantity of gunpowder equal
to the usual charge for a common horfeman's pistol.
A small board was used for the propelling body, a bullet, fired in
an oaken plank about six feet from the muzzle, and observed the recoil and penetration of the bullet. He
next tried the effect of one of these small bladders of
water when put among the gunpowder, but always
found the force of the powder very much diminished,
and the larger the quantity of water the greater was
the diminution; the report of the explosion was also
diminishing in a still greater proportion than the force
of the bullet or recoil. It being supposed that the
bladder had burst, and thus by wetting the gunpowder
preventing fire from taking fire, the experiment was re-
peated with highly rectified spirit of wine, but the
diminution of the force was very little inferior to what
it had been by water. Etherial oil of turpentine,
and small quantities of quicksilver were also tried, but
with no better success than before. Thinking, how-
ever, that the failure of the quicksilver might be owing
to its having been too much in a body, the experiment
was repeated with the metal dispersed in small particles
through the powder. To accomplish this dispersion
the more completely, 30 grains of Ethiopis mineral were
mixed very intimately with 145 grains of powder;
but still the force of the bullet was much less than if
the powder had been used without any addition.

The explosion of pulvis fulminans appears vastly supe-
rior to that of gunpowder; some salt of tartar in its
pure state, was mixed in the proportion of 20 grains
to 145 of powder; but on firing the gun the force
was still found that the force of the explosion was heightened.
Sal ammoniac was next tried; which, under certain
circumstances, is found to produce a great quantity of
air or elastic vapour; but on mixing 20 grains of it
with 145 of gunpowder, the force of the explosion
was still found to be diminished. As most of the me-
tals, when dissolved in acids, particularly brafs in
spirit of nitre, are found to produce much elastic vapour, it
was thought worth while to try whether the force of
powder could be augmented by this means. Twenty
grains of brafs dust were therefore mixed with 145
grains of powder; but still the force of the explosion
was not augmented. In our author's opinion, how-
soever, neither brafs dust nor Ethiopis mineral diminish
the force of the explosion otherwise than by filling up
the interspaces between the grains, obstructing the pas-
sage of the flame, and thus impeding the progress of
the inflammation. Thus it appears, that little hope
remains of augmenting the force of gunpowder by
any addition either of liquid or inflammablebodies; the
reason is obvious, viz. because all of them, the liquids
especially, absorb great quantities of heat before they
then over vaporized; and this vapour, after
it is formed, requires more heat to make it expand
more forcibly than air; hence, as the effects of
powder depend entirely upon the emission of a quan-
tity of air, and its rarefaction by vehement heat, the
power must be greatly diminished by the aborption
of this heat, which ought to be spent in rarefying the
air. Even solid bodies cannot be set on fire without
a previous absorption of heat to convert them into va-
pour; but liquids have this property still more than
solids, as is explained under the article CHEMISTRY,
EVAPORATION, &c. and must therefore diminish the
explosive force still more. Lime added to gunpowder,
however, is said to augment the power of the explo-
sion by one third.

In his experiments on gunpowder, Mr Thomfon had
the curiosity to compare the strength of aurum fulmi-
nans, when enclosed in a gun barrel, with that of com-
mon gunpowder; but his experiment only verified
what has been found by others, viz. that this powder,
which in the open air makes such a violent report,
has in close vessels scarce any power, comparati-
vely speaking, either of explosion or projecting a
bullet. Mr Thomfon, however, taking it for granted
that the power of aurum fulminans would be much
greater than that of gunpowder, took care to have a barrel of uncommon strength prepared for the
experiment. The weight of it was 71l. 5 oz.; the
length 13,25 inches, and the width of the bore
0.45 inches. This barrel, being charged with 27,44
grains of aurum fulminans and two leaden bullets,
which, together with the leather put about them
were made fit the bore without wincage, weighed
427 grains: it was laid upon a charging-dish of live
coals at the distance of about ten feet from the pen-
dulum, and the piece was directed against the centre
of the pendulum. Some minutes elapsed before the
powder exploded; but when it did so, the explosion
In order to determine the goodness of powder by Mr. Thomfon's method, it is necessary to have a barrel suspended by two iron rods in such a manner that it can easily move backward or forward by the vibration of the rods; and the space it moves through ascertained by marking it on a piece of ribbon. The barrel being then charged with powder, and fitted with a proper bullet, is to be fired, and the recoil marked upon the ribbon. The experiment is to be repeated three or four times, or oftener, if there is any difference in the recoil; the extremes of which may be marked with black lines on the ribbon, and the word proof written upon the middle line between the two. But if the experiments are made with sufficient accuracy, there will commonly be very little difference in the length to which the ribbon is drawn out. Thus the comparative goodness of powder may easily be ascertained; for the stronger the powder is, the greater will be the recoil, and consequently the greater length to which the ribbon will be drawn out; and if care is taken in proportioning the charge to the weight of the bullet, to come as near as possible to the medium proportion that obtains in practice, the determination of the goodness of gunpowder from the result of this experiment cannot fail to hold good in actual service. The bullets should be made to fit the bore with very little windage; and it would be better if they were all cast in one mould, and in the same parcel of lead, as in that case their weights and dimensions would be more accurately the same; and the experiments would of course be more conclusive. The flated charge of powder might be half an ounce, and it should always be put in a cartridge; and after the piece is loaded, it should be primed with other powder, first taking care to prick the cartridge by thrusting a priming wire down the vent.

From several experiments it appears, that the effect of the charge is considerably augmented or diminished, according to the greater or less force employed in ramming it down. To prevent this inconvenience, Mr. Thomfon advises the use of a cylindrical ramrod of wood, fitted with a metal ring about an inch or an inch and a half in diameter; which being placed in that part of the bore which goes up into the bore, will prevent the powder from being too much compressed. In making experiments of this kind, however, it is necessary to pay attention to the heat of the barrel as well as to the temperature of the atmosphere; for heat and cold, dryness and moisture, have a very sensible effect upon gunpowder to augment or diminish its force. When a very great degree of accuracy therefore happens to be requisite, it will be proper to begin by firing the piece two or three times, merely to warm it; after which three or four experiments may be made with standard powder, to determine the proof; mark a second time, for the strength of powder is different at different times, and at different places of the atmosphere. After this the experiments may be made with the powder that is to be proved, taking care to preserve the same interval of time between the discharges, that the heat of the piece may be the same in each trial.

Having thus determined the comparative degrees of strength of two different kinds of powder, their comparative value may be ascertained by augmenting the quantity of the weaker powder till the velocity of the bullets
bullets in both cases becomes the same. The strong powder is therefore precisely as much more valuable than the weak, as it produces the same effect with a smaller quantity. Thus if a quarter of an ounce of one kind of powder discharges a bullet with the same velocity that half an ounce of another kind does, it is plain that the former is twice as valuable as the latter, and ought to be sold at double the price.—By comparisons of this kind, Mr Thompion found that the best battle powder (so called from its being made at the village of Battle in Kent) is stronger than government powder, in the proportion of 4 to 3; and from a comparison of the prices, it appears that the former is no less than 4i per cent. dearer than it ought to be; and consequently, that whoever uses it in preference to government powder, does it at a certain loss of 4i per cent. of the money it costs him.

There has been much talk of a white powder, which, if it answered the character given it, might be a dangerous composition; for they pretend that this white powder will throw a ball as far as the black, yet without making a report; but none of the white powder we have seen, answers to this description. I was convinced that I could not be more surprised (says he), upon taking hold of the barrel immediately after an experiment when it was fired with 330 grains of powder without any bullet, to find it so very hot that I could scarce bear it in my hand, evidently much hotter than I had ever found it before, notwithstanding the flame charge of powder had been made use of in the two preceding experiments; and in both these experiments the piece was loaded with a bullet, which one would naturally imagine, by confining the flame, and prolonging the time of its action, would heat the barrel much more than when it was fired with powder alone. I was convinced that I could not be mistaken in the fact: for it had been my constant practice to take hold of the piece to wipe it out as soon as an experiment was finished, and I never before had found any inconvenience from the heat in holding it. But in order to put the matter beyond all doubt, after letting the barrel cool down to the proper temperature, I repeated the experiment twice with the same charge of powder and a bullet; and in both these trials the heat of the piece was evidently much less than what it was in the experiment above mentioned. Being much struck with this accidental discovery of the great degree of heat that pieces acquire when they are fired with powder, without any bullet, and being desirous of finding out whether it is a circumstance that obtains universally, I was very attentive to the heat of the barrel after each of the succeeding experiments: and I confinately found the heat sensibly greater when the piece was fired with powder only, than when the flame charge was made to impel one or more bullets.”

To account for this, our author supposes that very little of the heat acquired in firing a piece of ordnance comes from the powder; for the time that it continues in the piece, perhaps not exceeding the four hundred times of a second, is so small, that were the flame of the bulk of the heat, instead of four times, as Mr Hobson supposes, hotter than red hot iron, it is by far too short to communicate a sensible degree of heat to one of our large pieces of cannon. Besides, if the heat of the flame was sufficient to communicate such a degree of heat to the gun, it must undoubtedly be capable of burning up all combustible bodies that come in its way, and of melting lead shot when such were used: but instead of this, we frequently see the finest paper discharges from the mouth of a gun without being inflamed, after it has fulfilled the action of the fire through the whole length of the bore; and the smallest lead-shot is discharged without being melted. The objection drawn from the heat of bullets taken up immediately after being discharged from fire-arms does not hold; for bullets discharged from air-guns and even cross bows are likewise found hot, especially when they happen to strike...
GUN

Strike any hard body, and are much flattened. If a musket ball be discharged into water, or against any very soft body, it will not be sensibly heated; but if it hits a plate of iron or any other body which it cannot penetrate, it will be broken in pieces by the blow, and the disfigured parts will be found in a fine little shott of actual fusion. Hence our author concludes, that bullets are not heated by the flame but by percussion. Another objection is, that the vents of brass guns are frequently enlarged to such a degree by repeatedly firing them, that the piece becomes useless. But this proves only that brass is easily corroded by the flame of the gunpowder; which indeed is the case with iron also. We cannot suppose that in either case any real solution takes place: on the contrary, it is very evident that it does not; for when the vents of firearms are lined with gold, they will remain without enlargement for any length of time, though it is well known that gold is much more easily melted than iron. As the heat communicated to bullets, therefore is not of the action. The heat acquired by bullets is to be attributed, in our author's opinion, to the motion and friction of the internal parts of the metal among themselves by the violent action of the flame upon the inside of the bore. To generate heat, the action of the powder must be not only sufficient to strain the metal, and produce a motion in its parts, but this effect must be extremely rapid; and the effect will be much augmented if the exertion of the force and the duration of its action are momentaneous; for in this case the fibres of the metal that are violently fretched will return with their full force and velocity, and the swift vibratory motion and attrition abovementioned will be produced. Now the effort of any given charge of powder upon the gun is very nearly the same whether it be fired with a bullet or without; but the velocity with which the generated elastic fluid makes its escape, is much greater when the powder is fired alone than when it is made to impel one or more bullets; the heat ought therefore to be much greater in the former than in the latter case as has been found by experiment. “But to make this matter still plainer, (says our author), we will suppose any given quantity of powder to be confined in a space that is just capable of containing it, and that in this situation it is set on fire. Let us suppose this space to be the chamber of a piece of ordnance, and that a bullet or any other solid body is so firmly fixed in the bore, immediately upon the charge that the whole effort of the powder shall not be able to remove it as the powder goes on to be inflamed, and the elastic fluid to be generated, the preassure upon the inside of the chamber will be increased, till at length all the powder being burnt, the strain upon the metal will be at its greatest height, and in this situation things will remain; the cohesion or elasticity of the particles of metal counterbalancing the preassure of the fluid.—Under these circumstances very little heat would be generated; for the continued effort of the elastic fluid would approach to the nature of the preassure of a weight; and that concussion, vibration, and friction among the particles of the metal, which in the collision of elastic bodies is the cause of the heat produced, would fearfully take effect. But instead of being firmly fixed in its place, let the bullet now be moveable, but let it give way with great difficulty and by slow degrees. In this case the elastic fluid will be generated as before, and will exert its whole force upon the chamber of the piece; but as the bullet gives way to the preassure, and moves on in the bore, the fluid will expand itself and grow weaker, the particles of the metal will gradually return to their former situations; but the velocity with which the metal resists itself being but small, the vibration that remains in the metal after the elastic fluid has made its escape will be very languid, as will the heat be which is generated by it. But if instead of giving way with so much difficulty, the bullet is made lighter, so as to afford but little resistance to the elastic fluid in making its escape, or if it is fired without any bullet at all; then, there being little or nothing to oppose the passage of the flame through the bore, it will expand itself with an amazing velocity, and its action upon the gun will cease almost in an instant; the strained metal will restore itself with a very rapid motion, and a sharp vibration will ensue, by which the piece will be much heated.”

This reasoning of Mr Thomson’s, however, seems not to be very well founded. In the first place, we are by no means certain that heat is produced by the motion or vibration of the particles of a solid body among each other. On the contrary, even in the hottest bodies we cannot be made sensible of vibration existing among their particles, while certain sounds will cause the most solid substances vibrate perceptibly, and yet without producing any heat.—From this as well as innumerable other experiments, it is probable, that heat consists in the emission of a certain subtile fluid from the heated body, which is every moment replaced from the atmosphere, or from some other source. Hence the more air that has access to any burning body, the hotter it will become, and the more will any other that is in its vicinity be heated. This is evident from the contrivance of Argand’s lamp, which is neither more nor less than the admission of a larger quantity of air to the same quantity of flame. The case is the same with the firing of gunpowder, when a bullet is put into the piece, the access of the air is much more effectually prevented than when only a simple wadding is made use of. In consequence of this, no sooner is the powder fired without a bullet, than the external air rushes down the bore, mingleth with the flame, and vehemently augments the heat, as well as the absolute force of the explosion. It is true, that without the external air, the nitre in the gunpowder itself produces as much air as to inflame it very violently; but this does not prove that it could not be inflamed still more by the admission of more air. Besides, when the external air is thus admitted, the flame itself is agitated by its admission, and driven against the sides of the piece with a force superior to what it has by the mere expansive preassure; whence the heat must also be considerably augmented, in the same manner that the heat of any other body will be by the having flame blown against it instead of being blown away from it, or suffered to burn quietly by its side. Thus, without any recourse to an unknown and conjectural vibration among the particles of a solid metal, we may account for the augmented head of a piece charged only with powder, and likewise in some measure for the prodigious
gunpowder.

The force of gunpowder is manifestly augmented in close vessels, as has been already laid, by being rammed down or compressed together: but this arises from another cause, namely, that a greater quantity of flame is comprized into the same space than when the powder is not rammed; and this is comprehended when the flame is in proportion to the compression of the powder in the chamber of the piece. But in this case the flame is probably less powerful than in the former, though the quantity inclosed in a small space may probably make up for the quality. Mr. Thomson’s experiments on the increased force of gunpowder by compression are as follow:—Having put a charge of 218 grains of powder, inclosed in a cartridge of very fine paper, gently into the bore of the piece, the velocity of the bullets, at a mean of four experiments, was at the rate of 1235 feet in a second; but in a medium of three experiments, when the same quantity of powder was rammed down by five or six strokes of the ramrod, the velocity was 1329 feet in a second. "Now (says he) the total force or pressure exerted by the charge upon the bullet, is as the square of its velocity; and 1235 is to 1329 as 1,776 is to 1; or nearly as 6 is to 5; and in that proportion was the force of the given charge of powder increased by being rammed.—When, instead of ramming the powder, or prefling it gently together in the bore, it is put into a space larger than it is capable of filling, the force of the charge is thereby very feibly leffened, as Mr. Robins and others have found by repeated trials. In my 30th experiment, the charge, confisting of no more than 165 grains of powder, was made to occupy 3.2 inches of the bore, instead of 1.45 inches, which space it just filled. When it was gently pulied into its place without being rammed, the consequence was, that the velocity of the bullet, instead of being 1100 feet or upwards in a second, was only at the rate of 914 feet, and the recoil was leffened in proportion. Hence we may draw this practical inference, that the powder with which a piece of ordnance or a fire-arm is charged, ought always to be prefled together in the bore; and if it is rammed to a certain degree, the velocity of the bullet will be full farther increased. It is well known that the recoil of a musket is greater when its charge is rammed than when it is not; and there cannot be a stronger proof that ramming increases the force of powder."

To recover damaged Gunpowder. The method of the powder-merchants is, to put part of the powder on a flat cloth, to which they add an equal weight of what is really good; and with a knife mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place. Others again, if it be very bad, restore it by moflening it with vinegar, water, urine, or brandy: then they beat it fine, leare it, and to every pound of powder add an ounce, a half, or two ounces, according as it is decayed, of melted saltpetre. Afterwards, these ingredients are to be moflened and mixed well, so that nothing can be discerned in the composition, which may be known by cutting the mass; and then they granulate it as aforesaid. In case the powder be in

G - length

manner quite spoiled, the only way is to extract the saltpetre with water according to the usual manner, by boiling, filtering, evaporating, and crystallizing; and then with fresh sulphur and charcoal to make it up anew again.

In regard to the medical virtues of gunpowder, Boerhaave informs us, that the flame of it affords a very healthy flame in the height of the plague, because the explosive acid vapour of nitre and sulphur corrects the air, and that the same vapour, if received in a small close pent-up place, kills infects.

It is enabled by 5 and 10 of Geo. I. and 5 Gee. II. c. 20, that gunpowder be carried to any place in a covered carriage; the barrels being close-jointed; or in cases and bags of leather, &c. And persons keeping more than 200 pounds weight of gunpowder at one time, within the cities of London and Westminster, &c. are liable to forfeitures if it be not removed; and justices of peace may issue warrants to search for, seize, and remove the same.

Gun-Smither, a maker of small fire-arms, as muskets, fowling-pieces, pistols, &c.

Gun-Smithery, the business of a gun-smith, or the art of making fire-arms of the smaller forts, as muskets, fowling-pieces, pistols, &c.

The principal part of these instruments is the barrel, which ought to have the following properties.

1. Lightness, that it may accommodate the person who carries it as little as possible. 2. Sufficient strength and other properties requisite to prevent its bursting by a discharge. 3. It ought to be constructed in such a manner as not to recoil with violence. And, 4. It ought to be of sufficient length to carry the shot to at great a distance as the force of the powder employed is capable of doing.

The manufacture of fire-arms is now carried to such a degree of perfection by different European nations, that it may perhaps be justly doubted whether any farther improvement in the qualities just mentioned can be made. For the materials, the finest iron that can be procured is to be made use of. The belt in Britain are formed of flubs as they are called, or old horse-shoe nails, which are gathered and wrought over by gun-smiths from farriers, and from poor people who subsist by picking them up on the great roads leading to London. These are sold at about 1s. per cwt. and 28 pounds are requisite to form a single musket barrel. The method of manufacturing them from this material is as follows: A hoop of about an inch broad, and six or seven inches diameter, is placed in a perpendicular situation, and the flubs, previously well cleaned, piled up in it with their heads outward on each side, till the hoop is quite filled and wedged tight with them. The whole then resembles a rough circular cake of iron which being heated to a white heat, and then strongly hammered, coalesces into one solid lump. The hoop is now removed, and the hearings and hammerings repeated till the iron is rendered very tough and close in the grain; when it is drawn out into pieces of about 24 inches in length, half an inch or more in breadth, and an half an inch in thickness.

Four of these pieces are employed for one barrel; but in the ordinary way a single bar of the best soft iron is employed. The workmen begin with hammering out this into the form of a flat ruler having its
length and breadth proportioned to the dimensions of the intended barrel. By repeated heating and hammering, this plate is turned round a tempered iron rod called a mandril, the diameter of which is considerably smaller than the intended bore of the barrel. One of the edges of the plate being laid over the other, about half an inch and a half wide, is placed in a hole in the anvil, and driven into it, with a mandril being then introduced for three inches at a time, hammering it briskly, but with moderate strokes, upon an anvil which has a number of semicircular furrows in it, adapted to barrels of different sizes. Every time the barrel is withdrawn from the fire, the workman strikes it gently against the anvil once or twice in an horizontal direction. By this operation the particles of the metal are more perfectly consolidated, and every appearance of a seam in the barrel is obliterated. The mandril being then again introduced into the cavity of the barrel, the latter is very strongly hammered upon it in one of the semicircular hollows of the anvil, by small portions at a time; the heastings and hammerings being repeated until the whole barrel has undergone the operation, and its parts rendered as perfectly continuous as if they had been formed out of a solid piece. To effect this completely, three welding heats are necessary when the very best iron is made use of, and a greater number for the coarser kinds. The French workmen imagine, that by giving the barrel, while in the fire, slight horizontal strokes with the hammer, so as to communicate a vibratory motion to the iron, those particles are thrown off which are in a state of fusion and cannot easily be converted into malleable iron; but considering the great number of operations already described which the metal has undergone, we can scarce suppose this to be of much consequence.

The next operation in forming the barrels is the boring of them, which is done in the following manner: Two beams of oak, each about six inches in diameter, and six or seven feet long, are placed horizontally and parallel to one another; having each of their extremities mortised upon a strong upright piece about three feet high, and firmly fixed. A space of three or four inches is left between the horizontal pieces, in which a piece of wood is made to slide by having at either end a tenon let into a groove which runs on the inside of each beam throughout its whole length. Through this sliding piece a strong pin or bolt of iron is driven or screwed in a perpendicular direction, having at its upper end a round hole large enough to admit the breech of the barrel, which is secured in it by means of a piece of iron that serves as a wedge, and a vertical ferret passing through the upper part of the hole. A chain is fastened to a staple in one side of the sliding piece which runs between the two horizontal beams; and passing over a pulley at one end of the machine, has a weight hooked on to it. An upright piece of timber is fixed above this pulley and between the ends of the beams, having its upper end perforated by the axis of an iron crank furnished with a square socket; the other axis being supported by the wall, or by a strong post, and loaded with a heavy wheel of cast iron to give it force. The axes of this crank are in line with the hole in the bolt already mentioned. The borer being then fixed into the socket of the crank, has its other end, previously well oiled, introduced into the barrel, whose breech part is made fast in the hole of the bolt; the chain is then carried over the pulley, and the weight hooked on the crank being then turned with the hand, the barrel advances as the borer cuts its way, till it has passed through the whole length. The boring bit consists of an iron rod somewhat longer than the barrel, one end of which fits the socket of the mandril, the other being adapted to a cylinder of tempered steel about an inch and a half in length, having its surface cut after the manner of a perpetual screw, with five or six threads, the obliquity of which is very small. The breadth of the furrows is the same with that of the threads, and their depth sufficient to let the metal cut by the threads pass through them easily. Thus the bit gets a very strong hold of the metal; and the threads, being sharp at the edges, soon out and remove all the inequalities and roughness from the inside of the barrel, and render the cavity smooth and equal throughout. A number of bits, each a little larger than the former, are afterwards successively passed through the barrel in the same way, until the bore has acquired the magnitude intended. By this operation the barrel is very much heated, especially the first time the borer is passed through it, by which means it is apt to warp. To prevent this in some measure, the barrel is covered with a cloth kept constantly wetted, which not only preserves the barrel from an excess of heat, but likewise prevents the temper of the bit from being destroyed. The borer itself must also be withdrawn from time to time; both to clean it from the shavings of the metal and to oil it, or repair any damages it may have undergone. Every time a fresh bit has been passed through the barrel, the latter must be carefully examined, to see if it has warped; and likewise if there are any spots, by the workmen called black, on its inside. When warped, it must be straightened on the anvil; for which a few slight strokes on the convex parts will be sufficient; and this is termed fitting up the barrel. When black spots are perceived on the corresponding part on the outside must be marked, and driven in by gentle strokes with the hammer, when they will be completely removed by passing the borer another time through the piece.

The equality of the bore is of the utmost consequence to the perfection of a barrel; inform the greatest possible accuracy in every other respect will not make amends for any deficiency in this respect. The method used by gunsmiths to ascertain this is by a cylindrical plug of tempered steel highly polished, about an inch in length, and fitting the bore exactly. This is screwed upon the end of an iron rod, and introduced into the cavity of the barrel, where it is moved backwards and forwards; and the places where it passes with difficulty being marked, the boring bit is repeatedly passed until it moves with equal ease through every part. Any person who wishes to know the merit of his piece in this respect, may do it with tolerable accuracy by means of a plug of lead cast on a rod of iron; or even by a musket ball filed exactly to the bore, and pulled through the barrel by a cord; taking care, however, not to use much force lest the ball be flattened, and its passage thus rendered difficult.

The last step towards the perfection of the inside of the barrel is termed fine boring, by which is meant the smoothing it in such a manner as to remove all marks and inequalities left by the borer. The fine borer resembles
fembles the other in its general construction: but instead of the piece of steel cut in form of a screw which belongs to that, it is furnished with a square breech 10 or 12 inches long, highly polished, and very sharp, by which means it cuts the metal very smoothly. It is found to answer the purpose best when only two of its edges are allowed to work, the other two are covered with slips of oiled paper, one or more additional slips being put on each time that the instrument is passed through the barrel. The fine-borer is frequently passed through from the muzzle to the breech, and from the breech to the muzzle, until the whole inside presents a perfectly equal and polished surface; the barrel being likewise examined and set up, if requisite, after each time. It is absolutely necessary that this instrument should be perfectly true, and not in the least cait or warped in the tempering.

Besides the operations above described, another, called polishing, is usually performed in gun-barrels, though it is doubtful whether this last be attended with any good effect or not. It is performed by a cylinder of lead, five or six inches long, cast upon a rod of iron, and filed exactly to the bore. The lead being then covered with very fine emery and oil, is wrought backwards and forwards through the whole length of the barrel until the inside has acquired the requisite degree of polish. The disadvantages of this operation are that it is scarce possible to perform it without precluding more upon one part than another, and thus producing some degree of inequality on the inside, which is of very great consequence to fire-arms. The polish thus given is likewise very perishable, so that the fine-boring may justly be considered as the last operation necessary for the inside of a barrel; and it is then proper to give the external form and proportions by means of a file. For this purpose, four faces are first formed upon it, then eight, then 16; and so on till it be quite round, excepting the part next the breech, called the reinforced part, which is always left of an octagonal form. It being absolutely necessary that the barrel should be equally thick on every side, gunsmiths employ, for accomplishing this purpose, a particular tool named a file-diffuser. This consists of an iron rod bent in such a manner as to form two parallel branches about an inch distant from one another. One of these branches is introduced into the barrel, and kept closely applied to the side, by means of one or more springs with which it is furnished: the other defends parallel to this on the outside, and has several screws passing through it with their points directed to the barrel. By screwing these until their points touch the surface of the barrel, and then turning the instrument round within the bore, we perceive where the metal is too thick, and how much it must be reduced, in order to render every part perfectly equal through its circumference. It may be made long enough to reach the whole length of the barrel, though it will be more convenient to have it only half as much, and to introduce it first at one end and then at the other. Instead of rounding the barrel by means of a file and compasses, however, some people do so by turning it in a lathe; which is no doubt more expedients, though neither so certain nor exact. A file as long as a gun barrel cannot without great difficulty, be prevented from springing considerably under the tool employed to reduce or smooth it in turning; whence it is found, that by this operation barrels are more frequently warped than by all the borings they undergo; and there is now this farther inconvenience, that they cannot be set up as formerly, without danger of destroying them entirely.

The barrels being thus bored and formed externally, it is customary for the gunsmiths in France to folder the loops and aim before they breech the barrel. The English, however, do not restrict themselves in this manner: for as soft folder is sufficient for fastening on these, they never use any other; while the French, who use hard folder, must of confluence employ a great heat. Thus the inside is roughened sometimes to considerably, that it is necessary to repeat the fine-boring; which could not be done without injuring the threads of the ferew formed for the breech, if the barrel were prepared for the latter without foldering on the former.

The first tool employed in forming the breech-screw is a plug of tempered steel, somewhat conical, with the threads of a male screw upon its surface, and by the workmen termed a screw tap. This being introduced into the barrel, and worked from left to right and back again, until it has marked out the four first threads of the screw, another left conical tap is introduced; and when this has carried the impression of the screw as far as it is intended to go, a third one, nearly cylindrical, is made use of, scarcely differing from the plug of the breech intended to fill the screw thus formed in the barrel. The plug itself has its screw formed by means of a screw-plate of tempered steel, with several female screws, corresponding with the taps employed for forming that in the barrel. Seven or eight threads are a sufficient length for a plug; they ought to be neat and sharp, so as completely to fill the turns made in the barrel by the tap. The breech-plug is then to be case-hardened, or to have its surface converted into steel, by covering it with thavings of horn, or the parings of the hoofs of horses, and keeping it for some time red hot; after which it is plunged in cold water.

The only thing now requisite for completing the barrels is to give them a proper colour; as a preparation for which their outside ought to be evenly polished with oil and emery. This being done, it was the custom to give such a degree of heat as would make them blue throughout; but as this cannot be effected without a partial calcination of the surface, which of consequence affects the inside also, the blue colour has been for some time disfavored, and a brown one substituted in its place. To give this colour, the pieces are first rubbed over with aquafortis or spirit of salt diluted with water; after which they are laid by till a complete coat of rost is formed upon them: a little oil is then applied; and the surface, being rubbed dry, is polished by means of a hard brush and bees-wax.

Thus the common musket-barrels for the purposes especially of sportmanship are made: but there are some other methods of manufacture, by which the barrels are made to differ in some respects from those just described, and are thought to be considerably improved. One kind of these are called twisted barrels, and by the English workmen are formed out of the plates made of steel formerly described. Four of these, of the size already mentioned, are requisite to make one barrel. One of them heated red hot for five or six inches is turned
GUN

GUN

[ 244 ]

GUN

turned like a cork-screw by means of the hammer and anvil; the remaining parts being treated successively in the same manner until the whole is turned into a spiral, forming a tube the diameter of which corresponds with the bore of the intended barrel. There are generally sufficient to form a barrel of the ordinary length, i.e. from 32 to 38 inches; and the two which form the breech or strongest part, called the reinforced part, are considerably thicker than those which form the muzzle or fore part of the barrel. One of these tubes is then welded to a part of an old barrel, to serve as an handle, after which the turns of the spiral are united by heating the tube two or three inches at a time to a bright white heat, and striking the end of it several times against the anvil in a horizontal direction with considerable strength, which is called jumping the barrel, and the heats given for this purpose are called jumping heats. The next step is to introduce a mandrel into the cavity, and to hammer the heated portion lightly in order to flatten the ridges or hurs raised by the jumping at the place where the spirals are joined. As soon as one piece is jumped throughout its whole length, another is welded to it, and treated in the same manner, until the four pieces are united, when the part of the old barrel is cut off, as being no longer of any use. The welding is repeated three times at least, and is performed exactly in the same manner as directed for plain barrels; and the piece may afterwards be finished accordingly to the directions already given.

The operation for the French twisted barrels is very different from that just mentioned, and much more exceptionable. It consists in heating the barrel by a few inches at a time to a strong red heat; one end is then screwed into a vice, and a square piece of iron with an handle like an auger is introduced into the other. By means of the fibre the fibres of the heated portion are twirled into a spiral direction, which is supposed to re-ful the effort of the inflamed powder better than the other. To render this operation complete, however, it must be observed, that when once the several portions of the barrel have been twisted, the subsequent heats ought not to be very great, or the grain of the metal will regain its former state, and the barrel be no better for the twisting than before. To twist a barrel in this manner, also, it will be necessary to forge it at least half a foot longer than it is intended to be, that a sufficient length may be kept cold at each end to give a sufficient purchase to the vice and twisting instrument; and these portions must afterwards be cut off before the barrel is bored, or two pieces of an old barrel may be welded to the muzzle and breech of that which is to be twisted, and cut off when the operation is over. These pieces may also be made stronger than usual to resist the force of the vice and twisting instrument; and in order to give the latter a firmer hold, the cavity of the muzzle may be made of a square form. The English workmanship are unanimously of opinion that this method of twisting is really injurious to the barrel, by straining the fibres of the metal. At any rate, from the injudicious methods followed by the French artists, the greatest part of their barrels, felt to be twisted, are not so in reality; there being at least six or seven inches at the muzzle, and seven or eight at the breech, which are not affected by the operation.

The French ribbon barrels have a great resemblance to the English twisted ones; but the process for making them is much more operose, though it seems not to posses any real advantage over that used by the English artists. A plate of iron, about the twelfth part of an inch in thickness, is turned round a mandril, and welded its whole length in the same manner as a plain barrel. Upon this slight barrel, which is called the lining, a plate of iron about an inch in breadth, and bevelled off at the edges, is by means of successive heats rolled in a spiral direction; after which it is termed the ribbon, and must have a thickness corresponding with that part of the barrel which it is to form. As it would, however, be difficult to form a ribbon of sufficient length for the whole barrel, it is made in several pieces; and when one piece is rolled on, another is welded to its end, and the operation continued until the lining is entirely covered. The edges are so much bevelled, that the one folds over the other about a quarter of an inch. After the ribbon is all rolled on, the barrel must be heated by two or three inches at a time, and the turns of the spiral united to each other and to the lining by being welded in the same manner as the twisted barrel; though, from what has been said of the construction of these barrels, it is plain that the operation of jumping cannot be admitted in them. The barrel is afterwards bored in such a manner that almost the whole of the lining is cut out, and scarce anything left but the ribbon with which the lining was covered.

The superiority of twisted and ribbon barrels over the plain kind gave occasion to a third sort named wired barrels. These were invented by an ingenious workman at Paris named Barrois; whose method was as follows: Upon a thin barrel, filed and dressed as usual, he rolled, as close as possible, and in a spiral direction, a tempered iron wire about the thickness of a crow-quill, the first layer covering only the reinforced part. The turns of the wire were folded to each other and to the barrel with a composition which he kept a secret. The wired part was then filed smooth and bright, but not so much as to weaken it; a second layer of wire was applied over the first, extending two-thirds of the length of the barrel; and this being smoothed and brightened like the first, a third layer was applied, which covered the two former and reached quite to the muzzle.

The barrels made after this manner are supposed to be much superior to others, though the supposition seems not to be well founded. It is certain that wire is not preferable to other iron as a material for gun-barrels; and the folder used by M. Barrois in a quantity nearly equal to the wire itself, must be accounted a defect as far as it was used; for no metal has yet been found equal to iron for the purposes of gunsmiths: so that by the use of so much of this folder in the composition of the barrel, it must be undoubtedly weaker than if it had been all made of iron. We are not to suppose the wire absolutely free from flaws; and even though it were, there will always be small cavities between its turns, which the folder cannot fill completely. Besides, as the operation of wiring was performed by M. Barrois upon a barrel that had been previously bored and dressed within, the repeated heats to which it was afterwards subjected in folding, if they did not cause it warp, at least rendered it fo rough
rough that it was necessary to fine-bore it afterwards. The only advantage therefore which these barrels were found to possess was their beautiful appearance; which was greatly overbalanced by the circumstances just mentioned, as well as by the extravagant prices at which they were sold; a single barrel being sold at 51. and a double one at twice that sum; whence the fate of them never answered the expectation of the inventor, and after his death nobody thought of making them.

The Spanish barrels have long been held in great estimation, both on account of their being formed of better iron than those of other countries, and likewise from an opinion of their being more perfectly forged and bored. Thofe made at Madrid are the best, and even of those thus as have been made by former gunsmiths are in the greatest estimation. The most celebrated Spanish gunsmiths were Nicholas Bizz, who lived in the beginning of the present century, and died in 1724; and the barrels fabricated by him in the former part of his life are held in the greatest estimation. Thofe of his contemporaries, Juan Belan and Juan Fernandez, are not less valued; all of their barrels selling in France at 1000 livers, or 451. 152. sterl. The successors of these great artists were Diego Elquiabal, Alonso Martinez, Agonin Ortiz, Matthias Viera, Luis Santos, Juan Santos, Francisco Garcia, Francisco Targarone, Joseph Cano, and N. Zelaya. The most celebrated now in life are Francisco Loper, Salvador Cenarro, Miguel Zeguarras, Iñuroro Soler, and Juan de Soto. The three first are gunsmiths to the king; and the barrels made by all of them sold for 451. 152. sterl. Altogether all the Madrid barrels are composed of the old shoes of horsfes and mules, which are collected for the purpose. They are manufactured first by welding longitudinally, and then being joined together in four or five pieces like the English barrels made from flue, as already mentioned. In this, and indeed all other operations for making gun barrels, an immense waste of the iron takes place; but that of the Spanish iron is by far the greatest, a mass of 40 or 45 pounds being required to make one barrel, which when rough from the forge weighs only six or seven pounds; so that from 30 to 38 pounds are lost in the hammerings. It may perhaps, however, be doubted, whether the iron be really purified by this waste; for it is certain, that by long continued working in the fire it may be rendered totally useless and destroyed; neither can we be assured that the other advantages pretended to result from their mode of manufacture are of any consequence. The Spanish artificers likewise value themselves on giving the inside of their barrels a very high polish; but the advantage of this, as has already been observed, is extremely dubious. The only thing requisite in a gun-barrel is that it do not leak; that is, that the mark of the bullet be not perceived on the inside after it has been discharged, by some of the lead rubbed off as it passes through. In the opinion of very good judges, therefore, it is better to take a barrel immediately after it has undergone the operation of fine-boring than to give it any higher polish; and in support of this opinion, M. de Marolles, an author of great reputation, informs us, that he has seen a barrel rough from the borner throw a charge of shot deeper into a quire of paper than one which was highly polished within, though the length, bore, and charge were the same in both.

As the Spanish iron is universally allowed to be excellent, it has not been unreasonably supposed that the superiority of the barrels manufactured in that kingdom is owing more to the goodness of the material than to the skill of the workmen. It must be observed, however, that instead of making the plates overlap a little in the place where they join, they give one of them a complete turn; so that every Spanish barrel may be said to be double throughout its whole length. The different portions of the iron are also forged in such a manner, that the grain of the iron is diffipated in a spiral manner; whence it has the same effect with a ribbon or twisted barrel. The outside is finished by turning them in a lathe; whence probably they are always less elegantly wrought than the French and English pieces. The great value put upon them is also thought to be more owing to fancy than to any real good qualities they possess. Formerly they were made from three to three feet and a half long; their bore being such as to admit a bullet from 22 to 24 in the pound; and their weight from three to three pounds and an half. The reinforced part extends two-fifths of the length; and at 10 or 12 inches from the breech there is placed a sight, such as is usually put upon rifle-barrels or those intended only for ball. According to Espinas, arquebus-bearer to Philip IV, the weight of a Spanish barrel ought to be four pounds and an half when their length is 42 inches; but both weight and length are now much reduced, they seldom exceeding the dimension already mentioned. Next to the barrels made at Madrid, the most esteemed are those of Biscay; and of these, those of Bispindul and St. Olabe at Placentia in Biscay; and of Jenn and Clement Padwettu, Eudal Pous, and Martin Marechal, at Barcelona; the usual price of them being about 31. 10s. sterl.

Having now described the method of forging barrels, we shall next proceed to give an account of those imperfections to which they are sometimes liable, and which render them apt to burst or recoil with violence. The principal of these are the chink, crack, and flaw. The first is a small rent in the direction of the length of the barrel; the second across it; and the third is a kind of scale or small plate adhering to the barrel by a narrow base from which it spreads out like the head of a nail from its shaft, and when separated leaves a pit or hollow in the metal. The chink or flaw are of much worse consequence than the crack in fire-arms, the force of the powder being exerted more upon the circumference than the length of the barrel. The flaw is much more frequent than the chink, the latter scarce ever occurring in plain barrels formed out of a single plate of iron, and then only when the metal is deficient in quality. When flaws happen on the outside, they are of no great consequence; but in the inside they are apt to lodge moisture and foulnefs which corrode the iron, and thus the cavity enlarges continually till the piece bursts. This accident, however, may arise from many other causes besides the defect of the barrel itself. The best pieces will burst when the ball is not sufficiently ramm'd home, by which is meant that there is left between it and the powder. A very small windage or passage for the inflamed powder between the sides of the barrel and ball will be sufficient to prevent the
The truth of this I have experienced in a very good Tower musket forged of very tough iron: for charging it with 12 pennyweight of powder, and placing the ball 16 inches from the breach, on the firing of it the part of the barrel just behind the bullet was swelled out to double its diameter like a blown bladder, and two large pieces of two inches in length were bursting out of it. A piece will frequently burst from having its mouth flapped up with earth or snow; which accident forms an obstacle to the expansion of the flame in leaping a ditch in which they have affixed themselves with their fouling-piece, putting the mouth of it to the ground; and when this does not happen, it is only to be accounted for from the flapping being extremely slight. For the same reason a musket will certainly burst if it be fired with the muzzle immersed nearly a very little way in water. It will also burst from an overcharge; but when such an accident happens in other circumstances, it is most probably to be attributed to a defect in the workmanship, or in the iron itself. These defects are principally an imperfection in the welding, a deep flaw having taken place, or an inequality in the bore; which last is the most common of any, especially in the low-priced barrels.

The reason of a barrel's bursting from an inequality in the bore is, that the elastic fluid, set free by the inflammation of the powder, and endeavouring to expand itself in every direction, being repelled by the stronger parts, acts with additional force against the weaker ones, and frequently bursts through them. Which would not have done had the tubes been equally thick and strong throughout. With regard to defects arising from bad quality of the iron, it is impossible to say any thing certain. As the choice of the materials depends entirely on the gunsmith, the only way to be assured of having a barrel made of proper metal is to purchase it from an artist of known reputation, and to give a considerable price for the piece.

The recoil of a piece becomes an object of importance only when it is very great; for every piece recoils in some degree when it is discharged, the most frequent cause of an excessive recoil is an inequality in the bore of the barrel; and by this it will be occasioned even when the inequality is too small to be perceived by the eye. The explanation of this upon mechanical principles indeed is not very easy; for as it is there an irremovable law, that action and reaction are equal to one another, we should be apt to suppose that every time a piece is discharged it should recoil with the whole difference between the velocity of the bullet and that of the inflamed powder. But were this the case, no man could fire a musket without being destroyed; for the bullet flies out only with a velocity of 1700 feet in a second, or not much more, while that of the powder, as calculated by Mr. Robins, is not less than 7000 feet in the same space. But was the recoil to be made with the difference of these velocities, or with one half of it, it is plain that no man could bear it. The same thing therefore must take place in the recoil of a musket which Dr. Prieley observed in his experiments on the explosion of inflammable and dephlogisticated air, viz. that the force is exerted much more upon the part farthest from that where the inflammation begins than upon that next to it. At any rate, however, the strength of the recoil will always be found proportional to the weight of the piece; that is, the lighter the piece is, the greater the recoil, and vice versa. The recoil may be increased by any thing which retards the passage of the shot; whence it is also augmented by the fouling of the barrel by repeated firing. M. de Marolles informs us also, that a piece will recoil, if, from the breech-plug being made too short, some turns of the screw remain empty; as in these a part of the powder is lodged which forms a ditch in which the powder is blown; though in what manner this explosion takes place is not very apparent, as, though the powder lodged there might contribute little or nothing to the force of the explosion, it can scarce be shown to stand in the way of it. The fame author likewise informs us that a barrel mounted upon a very straight block will recoil more than one that is considerably bent. Sometimes also a fouling-piece will recoil from the sportsman applying it improperly to his shoulder; though this last circumstance seems likewise inexplicable. It is most probable therefore that the supposed greater recoil taken notice of in this case, arises only from the usual recoil being more feebly felt in one position than another.

The cause to which too great a recoil in muskets has been usually attributed, is the placing of the touch-hole at some distance from the breech-plug; so that the powder is fired about the middle, or towards its fore-part, rather than at its base. To avoid this, some artists form a groove or channel in the breech-plug, as deep as the second or third turn of the screw; the touch-hole opening into this channel, and thus firing the powder at its very lowest part. It appears, however, from a number of experiments made upon this subject by M. le Clerc gunsmith to the king of France, that it made very little difference with regard to the recoil, whether the touch-hole was close to the breech: or an inch distant from it. The only circumstance to be attended to with respect to its situation therefore is, that it be not quite close to the breech-plug: as in such a case it is found to be more apt to be choked up than when placed about a quarter of an inch from it.

The only other circumstance now to be determined with regard to musket-barrels is their proper length. Formerly it was supposed that the longer they were made, the greater would be the distance to which they carried the shot, and that without any limitation. This opinion continued to prevail till about half a century ago, when it was first propounded as a doubt whether long barrels carried farther than short ones. With regard to cannon, indeed, it had long before this time been
...been known that they might be made too long; and Balhazar Killar, a celebrated cannon-founder in the reign of Louis XIV. was able to account for it. When asked by Mons. Suriry de St Remy, why the culverin of Nancy, which is 22 feet long, did not carry a ball equally far with a shorter piece? he replied, that 'the powder, when inflamed, ought to quit the cavity of the piece in a certain time, in order to exert its whole force upon the bullet; by a longer stay, part of the force is lost; and the same cause may produce an inequality in the shots, by giving a variation to the bullet, so as to destroy its rectilinear course, and throw it to one side or other of the mark.' Mr. Robins, who on this as well as every other question in gunnery has almost exhausted the subject, informs us, that 'if a musket-barrel, of the common length and bore be fired with a leaden bullet and half its weight of powder, and if the same barrel be afterwards shortened one half and fired with the same charge, the velocity of the bullet in this shortened barrel will be about one-sixth less than what it was when the barrel was entire; and if instead of shortening the barrel, it be increased to twice its usual length, when it will be near eight feet long, the velocity of the bullet will not hereby be augmented more than one-eighth part. And the greater the length of the barrel is in proportion to the diameter of the bullet, and the smaller the quantity of powder, the more considerable will these alterations of velocity be.' From these considerations it appears, that the advantages gained by long barrels are by no means equivalent to the disadvantages arising from the weight and incumbrance of carrying them; and from a multitude of experiments it is now apparent, that every one may choose what length be pleases, without any sensible detriment to the range of his piece. The most approved lengths are from 32 to 38 inches.

An opinion has generally prevailed among sportsmen, that by some unknown manoeuvre the gunsmith is able to make a piece, loaded with small shot, throw the contents fo close together that even at the distance of 40 or 50 paces the whole will be confined within the breadth of a hat. From such experiments as have been made in this subject, however, it appears, that the closefens or wideness with which a piece throws its shot is liable to innumerable variations from causes which no skill in the gunsmith can possibly reach. So variable are these causes, that there is no possibility of making the same piece throw its shot equally close twice successively. In general, however, the closer the wadding is, the better disposed the shot seems to be to fall within a small compass. 'The closefens of the shot therefore would seem to depend in a great measure on preventing the flame of the powder from inflaming itself among its particles; whence the following method is said to be practised with success by those who shoot for a wager at a mark with small shot; viz. to put in the shot by small quantities at a time, ramming down a little tow or thin paper over each; so as to fill the interfaces of the grains, and thus prevent the flame from getting in amongst the grains and scattering them. In firing with small shot, a curious circumstance sometimes occurs, viz. that the grains, instead of being equally distributed over the space they strike, are thrown in clusters of 10, 12, 15, or more; whilst several considerable spaces are left without a grain in them. Sometimes one-third or one half of the charge will be collected into a cluster of this kind; nay, sometimes, though much more rarely, the whole charge will be collected into one mass, so as to pierce a board near an inch thick at the distance of 40 or 45 paces. Small barrels are said to be more liable to this clustering than large ones; and M. de Marolles informs us, that this is especially the case when the barrels are new, and likewise when they are fresh-warmed; though he acknowledges that it did not always happen with the barrels he employed even after they were warmed. It is probable, therefore, that the closefens of the shot depends on some circumstance relative to the wadding rather than to the mechanism of the barrel.

Some pieces are composed of two or more barrels joined together; in which case the thickness of each of the barrels is somewhat less than in single-barrelled pieces. After being properly dressed each of them is fixed flat on the side where they are to join each other, so that they may fit more closely together. The corresponding notches are then made at the muzzle and breech of each barrel; and into these are fitted two small pieces of iron to hold them more strongly together. Being then united by turning the contiguous parts, a triangular piece of iron called the rib is inserted on in like manner, running the whole length on the upper side; which serves to hold them more strongly together. After this they are to be polished and polished in the manner described for single barrels. Great care should be taken that the barrels joined in this manner should be quite equal in strength to one another, and that both should be quite upright, or of an equal thickness throughout. If any inequality takes place in the strength of the barrels, the weaker will be warped by the action of the stronger, and the warping from this cause has sometimes been so considerable as to render one of the barrels useless. To bring every part of the circumference of each barrel to an equal strength as nearly as possible, so that no part may be strained by the explosion, that side where they touch each other must be so reduced, that the partition between the two cylinders may be no thicker than either barrel was at the same place before it was filed to join in this manner. Formerly the double-barrelled pieces were made with one barrel lying over the other, each barrel having a separate pan, hammer, and hammer-spring, but only one cock for both. The barrels were therefore made to turn round at the place where the breeches joined with the fock, so that as soon as one was fired off, the other could be brought into its place by pulling a spring moved by the guard with the right hand, while with the left the barrels were turned upon their common axis; and as soon as the charged-barrel was thus brought into its proper situation, the spring defended into a notch and kept it firm. But this method was found to be too complicated and embarrased, though upon the same plan three and four barrels were sometimes mounted upon one fock; but these pieces were intolerably heavy, and have no real superiority over the double-barrelled pieces which do not turn round, and which of consequence are now only made use of.

In forging barrels of all kinds, it is of considerable importance to have them made at first as near as possible...
ble to the weight intended when they are finished, so
that very little be taken away by the boring and filing:
for as the outer surface, by having undergone the ac-
tion of the hammer more immediately than any other
part, is then on that side more compressed and pure, we should
carefully to remove as little of it as possible; and the
same holds, though in a less degree, with the inside,
which is to be cut with the borer. Pit-rolls are
forged in one piece, two at a time, joined by their
muzzles, and are bored before they are cut smaller;
by which means there is not only a saving of time and
labour, but a greater certainty of the bore being the
same in both.

GUNTER (Edmund), an excellent English mathe-
matician and astronomer, was born in Hertfordshire in
1581, and studied at Westminster-school; from whence
he removed to Oxford, where he took the degree of
master of arts in 1605, and afterwards entered into holy
orders. In 1615 he took the degree of bachelor of
divinity: but being peculiarly eminent for his know-
ledge in the mathematics, he had two years before been
chosen professor of astronomy in Gresham-college, Lon-
don; where he distinguished himself by his lectures
and writings. He invented a small portable quadrant;
and also the famous line of proportions, which, after
the inventor, is called Gunter's scale. He likewise
published Canon Triangulorum; and a work intitled
Of the Sectors, Cross-staff, and other instruments. This
last was published, with an English translation of his
Canon Triangulorum, in 1640, by Samuel Fuller profes-
or of Gresham-college. Mr Gunter died at that col-
lege in 1626.

Gunter's Line, a logarithmic line, usually graduated
upon scales, sectors, &c.

It is also called the line of lines and line of number:
being only the logarithms graduated upon a ruler,
which therefore serves to solve problems instrumentally
in the same manner as logarithms do arithmetically.
It is usually divided into 100 parts, every tenth where-
of is numbered, beginning with 1 and ending with 10:
so that if the first great division, marked 1, stand for
one tenth of any integer, the next division marked 2,
will stand for two tenths, 3, three-tenths, and so on;
and the intermediate divisions will in like manner be
marked the most compact and pure: if each of the
great divisions represent integers, then will the
lessor divisions stand for integers; and if the greater
divisions be supposed each 100, the subdivisions will be
each 10.

Use of Gunter's Line. 1. To find the product of two
numbers. From 1 extend the compasses to the multi-
plier; and the same extent, applied the same way from
the multiplicand, will reach to the product. Thus if
the product of 4 and 8 be required, extend the compas-
ses from 1 to 4, and that extent laid from 8 the
same way will reach to 32, their product. 2. To di-
vide one number by another. The extent from the divi-
sor to unity will reach from the dividend to the quo-
tient: thus, to divide 36 by 4, extend the compasses
from 4 to 1, and the same extent will reach from 36
to 9, the quotient sought. 3. To three given numbers
to find a fourth proportional. Suppose the numbers 6,
8, 9: extend the compasses from 6 to 8; and this ex-
tent, laid from 9 the same way, will reach to 12, the
fourth proportional required. 4. To find a mean pro-
portional between the two given numbers. Suppose 8
and 52; extend the compasses from 8, in the left-hand par-
t of the line, to 52 in the right; then bisecting this
distance, its half will reach from 8 forward, or from
52 backward, to 16, the mean proportional sought.
5. To extract the square root of any number. Suppose 25
bisect the distance between 1 on the scale and the point
representing 25; then of this distance, set off from
1, will give the point representing the root 5.

In the same manner the cube root, or that of any
higher power, may be found by dividing the distance
on the line between 1 and the given number into as
many equal parts as the index of the power expresses;
then one of those parts, set from 1, will find the point
representing the root required.

Gunter's Quadrant, one made of wood, brass, &c.,
containing a kind of stereographic projection of the
sphere, on the plane of the equinoctial; the eye being
supposed placed in one of the poles.

Gunter's Quadrant, called by navigators simply the
gunter, is a large plain scale, generally two feet long,
and about an inch and a half broad, with artificial
lines delineated on it, of great use in solving questions
in trigonometry, navigation, &c.

GUNWALE, or GUNNEL, is the uppermost wale
of a ship, or that piece of timber which reaches on ei-
ther side from the quarter-deck to the forecastle, being
the uppermost bend which finishes the upper works of
the hull, in that part in which are put the flancheons
which support the wale-trees.

GURK, an episcopal town of Carinthia in Germany,
47. 10.

GURNARD, in ichthyology. See Trigla.

GUST, a sudden and violent squall of wind, bur-
ftling from the hills upon the sea so as to endanger the
shipping near the shore. These are peculiar to some
coasts, as those of South Barbary and Guinea.

GUSTAVIA, in botany; a genus of the poly-
andria order, belonging to the monadelphous class
of plants. There is no caulix: the petals very numerous;
the berry multilocular; the seeds appendaged.

Gustavus I. king of Sweden, son of Eric de
Vasa duke of Gripsholm. Christian II. king of Den-
mark having made himself master of the kingdom of
Sweden, confined Gustavus at Copenhagen; but he
making his escape wandered a long time in the forests,
till the cruelties of the tyrant having occasioned a re-
revolution, he was first declared governor of Sweden,
and in 1513 elected king. This prince introduced
Lutheranism into his dominions, which in a little time
spread itself all over the kingdom. He died in 1560;
having made his kingdom hereditary, which was before
elective. See SWEDEN.

Gustavus Adolphus, surnamed the Great, king
of Sweden, was born at Sockholm in 1594, and succe-
eded his father Charles in 1611. He espoused the caufe
of the Protestants in Germany, who were opprified
and almost entirely ruined by the emperor Ferdinand.
He was a great warrior, and gained many victories,
whereof an account is given under the article SWEDEN.
He was at last killed in the battle of Lutzen, where
his troops got the victory, and defeated two of the
empire's armies.

GUTHALUS, or Gunnalus (anc. geogr.), is thought
GUY [ 249 ]

Guy, thought to be the Videutus of Ptolemy. Now the Oder; which rising in Moravia, runs through Sileia, Brandenburg, and Pomerania, into the Baltic.

GUTTA, a Latin term for what in English we call drops.

Gutta Rojava, in medicine, denotes a red or pimpled face; a distemper which, though not always owing its original to hard drinking, is nevertheless most incident to tipplers of strong beer, wines, spirits, &c.

Gutta Serena, a disease in which the patient, without any apparent fault in the eye, is deprived of sight. See (Index subjoined to) Medicine.

GUTTA, in architecture, are ornaments in the form of little cones used in the Doric cornice, or on the architrave underneath the triglyphs, representing a ffort or drops of bells.

GUTTURAL, a term applied to letters or sounds pronounced or formed as it were in the throat.

GUTTY, in heraldry, a term used when any thing is charged or sprinkled with drops. In blazoning, the colour of the drops is to be named; as goutty of table, of gules, &c.

GUY (Thomas), an eminent bookseller, founder of the hospital for old and lame in Southwark bearing his name, was the son of Thomas Guy lighterman and coad-dealer in Horley-down, Southwark. He was put apprentice, in 1660, to a bookseller in the porch of Mercer's-chapel; and set up trade with a flock of about 200 l. in the house that forms the angle between Cornhill and Lombard-street. The English Bibles being at that time very badly printed, Mr Guy engaged with others in a scheme for printing them in Holland and importing them; but this being put a stop to, he contrived with the university of Oxford for their privilege of printing them, and carried on a great bible-trade for many years to a considerable advantage. Thus he began to accumulate money, and his gains refted in his hands; for being a single man, and very penurious, his expences could not be great when it was his custom to dine on his shop-counter which no other table covering than an old newspaper; he was moreover as little scrupulous about the style of his apparel. The bulk of his fortune, however, was acquired by purchasing fennat tickets during queen Anne's wars, and by Southsea flock in the memorable year 1720. To show what great events spring from trivial causes, it may be obferved, that the foundation of the Hospital, was the greatest part of his innumerable fortune to charitable purposes, to the indigent officiousness of his maid-servant in interfering with the mending of the pavement before the door. Guy had agreed to marry her; and, preparatory to his nuptials, had ordered the pavement before his door, which was in a neglected state, to be mended, as far as to a particular flone which he pointed out. The maid, while her matter was out, inculcantly looking on the paviers at work, faw a broken place that they had not repaired, and mentioned it to them; but they told her that Mr Guy had directed them not to go to far. Well, says she, do you mend it? tell him I bade you, and I know he will not be angry. It happened, however, that the poor girl presumed too much on her influence over her careful lover, which a few extraordinary flhillings expence turned the scale totally against her: the men obeyed; Guy was enraged to find his orders exceeded, his matrimonial scheme was renounced, and he built hospitals in his old age. In the year 1707 he built and furnished three wards on the north side of the outer court of St Thomas's Hospital in Southwark, and gave 100 l. to it annually for eleven years preceding the erection of his own hospital: and, some time before his death, erected the slated iron-gate, with the large house on each side, at the expense of about 5000 l. He was 76 years of age when he formed the design of building the hospital contiguous to that of St Thomas's, which bears his name, and lived to see it rooted in; dying in the year 1744. The charge of erecting this vast pile amounted to 18,793 l. and he left 219,499 l. to endow it; a much larger sum than had ever been dedicated to charitable uses in Britain by any one man. He erected an alms-house with a library at Tanworth in Staffordshire (the place of his mother's nativity, and for which he was representative in parliament) for 14 poor men and women; and for their pensions, as well as for the putting out poor children apprentices, bequeathed 125 l. a-year. Lastly he bequeathed 1000 l. to every one who could prove themselves in any degree related to him.

GUY, a rope used to keep steady any weighty body, whilst it is hoisting or lowering, particularly when the ship is shaken by a tempestuous sea.

Guy is likewise a large thick rope, extending from the head of the main-mast to the head of the fore-mast, and having two or three large blocks fastened to the middle of it. This is chiefly employed to sustain the tackle used to haul in and out the cargo of a merchant ship, and is accordingly removed from the main-head as soon as the vessel is laden or delivered.

Guy's Cliff, in Warwickshire, a great cliff on the west side of the Avon and the north side of Warwick, where in the Britons time was an oratory, and in that of the Saxons a hermitage, where Guy earl of Warwick, who is said to have retired to it after his fatigues by the toils and pleasures of the world, built the chapel, and habited with the hermit; and that from thence it had the name. This hermitage was kept up to the reign of Henry VI. when Rich. Beauchamp earl of Warwick established a chantry here, and in memory of the famous Guy erected a large statue of him in the chapel eight feet in height, and raised a roof over the adjacent springs. The chapel is in the parish of St Nicholas, in the suburbs of Warwick.

GUYON (Johanna Mary Bourdiers de la Mothe), a French lady, memorable for her writings, and for her sufferings in the cause of Quietism, was descended from a noble family, and born at Montargis in 1648. She gave some extraordinary symptoms of illumination from her earliest infancy; and tried to take the veil before she was of age to dispose of herself; but her parents obliged her to marry a gentleman to whom they had promised her. She was a widow at the age of 28; when diturbing herself in, and making many convictions, the way of contemplation and prayer known by the name of Quietism, complaints were made of her spiritualism, and she was confined by order of the king, and severely examined for eight months. She was discharged; but was afterwards involved in the persecution of the archbishop of Cambrai, and thrown into the Bastille, where the underwent many examinations: but nothing being made out against her, she once more obtained
obtained her liberty, and lived private to her death in 1717. She spent her latter years in mystical reveries; covering her tables, ceilings, and every thing that would receive them, with the failies of a visionary imagination. Her pious verses were collected after her death in 5 vols. intitled Cantiques spirituels, ou d’Emblemes sur l’Amour Divin. Her publications were, Le moyen court et tres facile de faire Oraisons; and Le Cantiques des Cantiques de Salomon interprete felon le sens mystique; which were condemned by the archbishop of Paris.

GWINIAD, in ichthyology. See SALMUS.

GYARUS (anc. geog.), one of the Cyclades, 12 miles in compass, lying to the east of Delos. It was a defart island, and allotted for a place of banishment by the Romans.

GYBING, the art of shifting any boom-fail from one side of the mast to the other. In order to understand this operation more clearly, it is necessary to remark, that by a boom-fail is meant any sail whose whole bottom is extended by a boom, the fore-end of which is hooked on its respective mast; so as to swing occasionally on either side of the vessel, describing an arch, of which the mast will be the centre. As the wind or the course changes, it also becomes frequently necessary to change the position of the boom, together with its sail, which is accordingly shifted to the other side of the vessel as a door turns upon its hinges. The boom is pulled out by the effort of the wind upon the sail, and is refrained in a proper situation by a strong tackle communicating with the vessel’s stern, and called the back. It is also confined on the fore-part by another tackle called the guy.

GYGUS (anc. geog.), called also Colours; a lake of Lydia, distant 40 stadia, or 5 miles, from Sardes.

GYGES (fab. hist.), a Lydian, to whom Candaules, king of the country, showed his wife naked. The queen was so incensed at this instance of impiety and infamy of her husband, that she ordered Gyges either to prepare for death himself, or to put Candaules to death. He chose the latter; and marrying the queen, ascended the vacant throne about 718 years before the Christian era. He was the first of the Mermnads who reigned in Lydia. He reigned 38 years, and distinguished himself by the regularity with which he made the oracle of Delphi (Herod. i. c. 8.)—According to Plato, Gyges defended into a chain of the earth, where he found a brazen horse, whose sides he opened, and saw within the body of the carcase a man of uncommon size, from whose finger he took a brazen ring. This ring, when he put it on his finger, rendered him invisible; and by means of its virtue he introduced himself to the queen, murdered her husband, and married her and usurped the crown of Lydia. (Gic. Off. iii. c. 9.)

GYNASIARCH, in antiquity, the director of the gymnasion. He had two deputies under him; the one called xyflarch, who presided over the athletes, and had the oversight of wrestling; the other was gymnaster, who had the direction of all other exercises.

GYNASIUM, in Grecian antiquity, a place fitted for performing exercises of the body, &c.—The word is Greek, formed of γυμνός, “naked”; by reason they anciently put off their clothes, to practise with the more freedom. Gymnasia, according to Potter, were first used at Lacedemon, but were afterwards very common in all parts of Greece; and imitated, very much augmented, and improved, at Rome. There were three principal gymnasia at Athens; the academy where Plato taught; the Lyceum, noted for Aristotle’s lectures; and the Cynoarges, allotted for the populace.

Vitruvius describes the structure and form of the ancient gymnasia, lib. v. cap. 11. They were called gymnasia, because several of the exercises were performed naked; and palæstre, from wrestling, which was one of the most usual exercises there: the Romans some times also called them thermae, because the baths and gymnasia were made a principal part of the building.—It appears that they did not perform their exercises quite naked so early as the time of Homer, but always in drawers; which they did not lay aside before the 72d Olympiad. One Orppus is said to have been the first who introduced the practice; for having been wrosted by means of his drawers undoing and entangling him, he threw them quite aside, and the rest afterwards imitated him. They were not single edifices, but a knot of buildings united, being sufficiently capacious to hold many thousands of people at once; and having room enough for philosophers, rhetoricians, and the professors of all other sciences to read their lectures, and wrestlers, dancers, and all others who had a mind to exercise, at the same time without the least disturbance or interruption. They consisted of a great many parts. Vitruvius recites no less than 12, viz. 1. The exterior portico, where the philosophers, rhetoricians, mathematicians, physicians, and other virtuosos, read public lectures, and where they also disputed and rehearsed their performances. 2. The ephebeum, where the youth assembled very early, to learn their exercises in private, without any spectators. 3. The coryceum, apodyterion, or gymnasterion, a kind of wardrobe, where they stripped, either to bathe, or exercise. 4. The elaeothemum, alipiterion, or unctarium, appointed for the unctions, which either preceded or followed the use of the bath, wrestling, pancratias, &c. 5. The con.jfaceium or consilium, in which they covered themselves with sand or dust, to dry up the oil or sweat. 6. The palaestra, properly called, where they practised wrestling, the pancratias, gymnastics, and divers other exercises. 7. The palaestriarium or tennis-court, reserved for exercises wherein they used balls. 8. Large unpaired avenues, which comprehended the space between the porticos and the walls wherein the edifice was surrounded. 9. The xystis, which were porticoes for the wrestlers in winter or bad weather. 10. Other xystis or open avenues, allotted for summer and fine weather, some of which were quite open, and others planted with trees. 11. The baths, consisting of several different apartments. 12. The stadium, a large space of a semicircular form, covered with sand, and surrounded with seats for the spectators.

For the administration of the gymnasia, there were different officers: the principal were, 1. The gymnarch, who was the director and superintendant of the whole. 2. The xyflarch, who presided in the xystis or stadium. 3. The gymnasiarch, or master of the exercises, who undertook their different effects, and could accommodate them to the different complections of the athlete. 4. The pedotribus, whose business was mechanically to teach the exercises, without understanding their
GYMNASIUM.

Gymnastics, or gymnastic art, denotes the art of performing exercises of the body, whether for defence health, or diversion. See Gymnasium.

Several modern writers have treated of this art. M. Buret has given the history of gymnastics in the Memoirs of the Royal Academy of Inscriptions.

On the first establishment of society, men, being apprised of the necessity of military exercises, for repelling the insults of the neighbours, invented games and proposed prizes to animate their youth to combat divers kinds. And as running, leaping, strength and dexterity of arm in throwing the javelin, driving a ball, or rolling a quoit, together with wrestling, &c. were exercises suited to the manner of fighting in those days; so the youth vied to excel in them, in the presence of the aged, who sat as their judges, and dispensed prizes to the conquerors; till what was originally only amusement, became at length a matter of such importance, as to interest great cities and entire nations in its practice. Hence arose an emulation and eagerness to excel, in hopes, one day, of being proclaimed and crowned conquerors in the public games, which was the highest honour a mortal could arrive at; nay, they went so far as to imagine, that even gods and demigods were not intemible of what men were so captivated with; and, in consequence hereof, to introduce the greatest part of these exercises into their religious ceremonies, the worship of their gods, and the funeral honours done to the manes of the dead. Though it be hard to determine the precise epocha of the gymnastic art, yet it appears from several passages in Homer, and particularly the 23d book of the Iliad, where he describes the games celebrated at the funeral of Patroclus, that it was not unknown at the time of the Trojan war. From that description, which is the earliest monument now extant of the Grecian gymnastics, it appears, that they had chariot-races, boxing, wrestling, foot-races, gladiators, throwing the discus, drawing the bow, and hurling the javelin; and it should seem, from the particular account Homer gives of these exercises, that even then the gymnastic art wanted little of perfection: so that when Galen says there was no gymnastic art in Homer's days, and that it began to appear no earlier than Plato, he is to be understood of the medicinal gymnastics only. This lat indeed had its rise later; because while men continued sober and laborious, they had no occasion for it; but when luxury and idleness had reduced them to the sad necessity of applying to physicians, these, who had found that nothing contributed so much to the preservation and re-establishment of health as exercises, proportioned to the different complexities, ages, and sexes, did not fail to refer them to the practice of gymnastics.

According to Plato, one Herodicus, prior a little time to Hippocrates, was the first who introduced this art into physic; and his successors, convinced by experience of its usefulness, applied themselves in earnest to improve it. Hippocrates, in his book of Regimen, has given instances of it, where he treats of exercise in general, and of the particular effects of walking, with regard to health. Also of the different sorts of races, either on foot or horseback; leaping, wrestling, the exercise of the suspended ball, called eurryces, chronometry, unctions, frictions, rolling in the sand, &c. But as physicians did not adopt all the exercises of the gymnastic art in their practice, it came to be divided between them and the masters of martial and athletic exercises, who kept schools, the number of which was greatly increased in Greece. At length the Romans also caught the fame taste; and, adopting the military and athletic exercises of the Greeks, they improved and advanced them to the utmost pitch of magnificence, not to say extravagance. But the declension of the empire involved the arts in its ruin, and, among others, gymnastics and medicine; which left unhappily then relinquished the title it had to the former, and has neglected to resume it ever since.

GYMNOPIRIS, in natural history, a name given by Dr. Hill to the pyrite of a simple internal structure, and not covered with a crust. See Pyrites.

Of these are only two species. 1. A green variously shaped kind. 2. A botryoid kind.

The first species is the most common of all the pyrites, and appears under a great diversity of shapes, it is very hard and heavy, very readily gives fire with steel, but will not at all burn with aquafortis. The second species is very elegant and beautiful, and its usual colour is very agreeable pale green; but what most distinguishes it from all other pyrites, is, that its surface is always beautifully elevated into tubercles of various sizes, resembling a cluster of grapes.

GYMNOSEPHISTS, a set of Indian philosophers, famous in antiquity; so denominated from their going barefoot. The word is formed of the Greek γυμνοσθέφω, q. d. a fophit or philospher who goes naked.

This name was given to the Indian philosophers, whom the excessive heat of the country obliged to go naked; as that of Peripatetics was given to those who philosophized walking. The Gymnosophists, however, did not go absolutely naked; but only clothed themselves in natural raiment.
Gymnosomia [ 252 ]

Gymnosomia

Gymnosomia, belonging to the order of apodes. They have two tentacula at the upper lip; the eyes are covered with the common skin; there are five rays in the membrane of the gills; the body is compressed, and carinated on the belly with a fin. There are five species, the most remarkable of which is the electricus, or electric eel, called by the French anguille tremblante. This species is peculiar to Surinam; and is found in the rocky parts of the river, at a great distance from the sea. The most_plate accurate description we have of this fish is in the Philoso-

Phical Transactions for 1775, where Alex. Garden, M. D. gives an account of three of them brought to Charleston in South Carolina. The largest was about three feet eight inches in length, and might have been from 10 to 14 inches in circumference about the thickest part of its body. The head was large, broad, flat, and smooth, impressed here and there with holes, as if perforated with a blunt needle, especially towards the sides, where they were more regularly ranged in a line on each side. There were two nostrils on each side; the first large, tubular, and elevated above the surface; the others small, and level with the skin. The eyes were small, flatish, and of a bluish colour, placed about three quarters of an inch behind the nostrils. The whole body, from about four inches below the head was clearly distinguished into four longitudinal parts or divisions. The upper part or back was of a dark colour, and separated from the other parts on each side by the internal lines. These lines took their rise at the base of the head, just above the pectoral fins, and run down the sides, gradually converging as the fish grew smaller to the tail. The second division was of a lighter and clearer colour than the first, inclining to blue. It seemed to swell out on each side; but towards the under part of it is again contracted and sharpened into the third part or carina. This part is easily distinguished from the other two by its thinness, its apparent laxness, and by the reticulated skin of a more grey and light colour, with which it is covered. The carina begins about six or seven inches below the base of the head; and gradually deepening or widening as it goes along, reaches down to the tail, where it is thinnest. The fourth part is a long, deep, soft, and heavy one, which takes its rise about three or four inches, and is moat below the head; and thus runs down the sharp edge of the carina to the extremity of the tail. The situation of the anus was very singular; being an inch more forward than the pectoral fins. Externally it seemed to be a pretty large rima, but the formed excrements were only the size of a quill of a common dung-hill-fowl. There were two pectoral fins situated just behind the head, scarcely an inch in length; of a very thin, delicate consistence, and orbicular shape. They seemed to be chiefly useful in supporting and raising the head of the fish when he came up to breathe; which he was obliged to do every four or five minutes. Across the body were a number of fine bony or circular divisions, or rather rings of the skin. By means of these the fish seemed to partake of the vermicular nature, had the power of lengthening or shortening its body like a worm, and could swim backwards as well as forwards, which is another property of the vermicular tribe. Every now and then it laid itself on one side in the water as if to rest.—For an account of the singular properties of this fish, see ELECTRICITY, p. 355.

Gymnotus in ichthyology, a genus of fishes belonging to the order of apodes. They have two tentacula at the upper lip; the eyes are covered with the common skin; there are five rays in the membrane of the gills; the body is compressed, and carinated on the belly with a fin. There are five species, the most remarkable of which is the electricus, or electric eel, called by the French anguille tremblante. This species is peculiar to Surinam; and is found in the rocky parts of the river, at a great distance from the sea. The most_plate accurate description we have of this fish is in the Philoso-

Phical Transactions for 1775, where Alex. Garden, M. D. gives an account of three of them brought to Charleston in South Carolina. GYNECUM, among the ancients, the apartment of the women, a separate room in the inner part of the house, in which they employed themselves in spinning, weaving, and needle-work.

GYNACOCRACY, denotes the government of women, or a state where women are capable of the supreme command. Such are Britain and Spains.

GYNACOCRATUMENI, an ancient people of Sarmatia Europæa, inhabiting the eastern banks of the river Tanais, near its opening into the Pallas Moesias; thus called, as authors relate, because they had no women among them; or, rather, because they were under the dominion of women. The word is formed of γυναῖκα, and ἀρχήν, signifying, of women I overcome, q. d. overcome by women.

F. Hardouin, in his notes on Phinys, says, they were thus called, because after a battle which they lost against the Amazons, on the banks of the Themrodon, they were obliged to have their commerce with them, in order to get them children: Et quod victrix ad procurandam subobtem. Hardouin calls them the husbands of the Amazons, Amazoneon cunhassa; for, as the author observes, the word unde must be retrenched from Phinys, having been falsified into the text by people who were not masters of the author's meaning, unde Amazoneon cunhassa. See Amazons. They who take the Amazons for a fabulous people, will conclude the fame of the Gynacocratumeni.

GYNANDRIA, (from γυναῖκα a woman; and ἄνδρα a man.) The name of the 20th clade in Linnaeus's sexual system, consisting of plants with hermaphrodite flowers, in which the stamens are placed upon the style, or, to speak more properly, upon a pillar-shaped receptacle, resembling a style, which sits in the middle of the flower, and bears both the stamens and pistil; that is, both the supposed organs of generation. See Botany. p. 430.

The flowers of this clade, says Linnaeus, have a monstrous appearance, arising, as he imagines, from the singular and unusual situation of the parts of fructification.

GYPSES, or EGYPTIANS, an outlandish tribe of vagrants, who disguising themselves in uncouth habits, finear their faces and bodies, and framing to themselves a canting language, wander up and down, and, under pretence of telling fortunes, curing diseases, &c., abuse the common people, trick them of their money, and steal all that they can come at.

They are a strange kind of commonwealth among themselves of wandering impostors and jugglers, who made their first appearance in Germany about the beginning of the 16th century. Munster, it is true, who is followed and relied upon by Spelman, fixes the time of their first appearance to the year 1417: but as he owns that the first whom he ever saw were in 1529, it is probably an error of the press for 1517; especially as other historians inform us, that when Sultan Selim conquered Egypt in the year 1517, several of the natives refused to submit to the Turkish yoke, and revolted under one Zinganeus; whence the Turks call them Zinganees; but being at length surrounded and banished, they agreed to differ from small parties all over the world, where their supposed skill in the black art gave them an universal reception in that age of perfidy and credulity. In the compass of a very few years they gained such a number of idle proteluses (who imitated their language and complexion, and beat themselves to the face with chains, being, and pilfering), that they became troublesome, and even formidable to most of the states of Europe. Hence they were expelled from France in the year 1569, and from Spain in 1591. And the government of England took the alarm much earlier: for in 1530 they are described by Stat. 22. Hen. VIII. c. 10, as "an outlandish people calling themselves Egyptians, using no craft nor fear of merchandize, who have come into this realm, and gone from house to house, and place to place, in great companies, and did great, subtle, and crafty means to deceive the people; hearing them in hand that they by palmistry could tell mens and women fortunes; and so many times by craft and subtilety have deceived the people of their money, and also have committed many heinous felonies and robberies." Whereas they are directed to avoid the realm, and not to return under pain of imprisonment, and forfeiture of their goods and chattels; and upon their trials for any felony which they may have committed, they shall not be entitled to a jury of moditated. And afterwards it is enacted, by statutes 33 and 24 Eliz., and Mary, c. 4, and 5th Eliz. c. 20, that if any such persons shall be imported into the kingdom, the importer shall forfeit 40l. And if the Egyptians themselves remain one month in the kingdom, or any person being 14 years old, whether natural born subject or stranger which hath been seen or found in the fellowship of such Egyptians, or which hath disguised himself or herself like them, shall remain in the same one month at one or several times, it is felony without benefit of clergy. And Sir M. Hale informs us, that at one Sudfolk aijxe no less than 13 persons were executed upon these statutes a few years before the restoration.

But, to the honour of the national humanity, there are no instances more modern than this of carrying these laws into practice; and the last singular act is itself now repealed by 23 Geo. III. c. 54.

In Scotland they seem to have enjoyed some share of indulgence; for a writ of privy seal, dated 1594, supports John Faw, lord and earl of Little Egypt, in the execution of justice on his company and folk, conform to the laws of Egypt, and in punishing certain persons who there named who rebelled against him, left him, robbed him, and refused to return home with him. James's subjects are commanded to assist in apprehending them, and in afflicting Faw and his adherents to return home. There is a like writ in his favour from Mary Q. of Scots 1553, and in 1554 he obtained a pardon for the murder of Nunan Small. So that it appears he had lived long in Scotland, and perhaps some of the time in England; and from him this kind of flattering people might receive the name of Faw Gang, which they still retain.

A very circumstantial account of this singular race of vagrants has been lately given in an express Inqury concerning them, written in German by H. M. D. Grummel, and translated by Mr. Rapin. It is incredible to think how this regular swarm of bandits has spread itself over the face of the earth. They wander about in Asia, in the interior parts of Africa, and, like locusts, have over-run most of the European nations.
In Italy Gypies. In the reigns of Henry VIII. and queen Elizabeth, as we have seen, they were set up as a mark of general persecution in England; yet their numbers do not appear to have much diminished. Spain is supplied by Mr Twiss to contain 40,000 of these vagrants; but by others 60,000; and by some even double that number. They are left numerous in France in consequence of the strictness of the police. In Italy they abound, especially in the dominions of the church, on account of the bad police and the prevalence of superstition, which permit and entice them to deceive the ignorant. They are scattered, thought not in great numbers, through Germany, Denmark, Sweden, and Russia; but their chief population is in the south-east parts of Europe, which seem to be the general rendezvous of the gypsy nation. At a moderate computation Europe contains more than seven hundred thousand of these vagabonds. For near four centuries they have wandered through the world; and in every region, and among every people, whether barbarous or civilized, they have continued equally unchanged by the lapse of time, the variation of climate, and the force of example. Their singular physiognomy and particular manners are the same in every country. Their fair complexion receives no darker shade from the wearing of old laced coat, while the rest of the garment is dirty and ragged. In Hungary, Transylvania, their summer habitations are tents; in Spain, nor acquire any new industry in England: in Turkey they behold the mosque and the crescent with equal indifference. The only science which they have attained is a childish way of thinking; and their wild fancies are derived from a former wayward; for they are executed by criminals, flayers of mankind, and executioners of criminals, slayers of men, and horse-dealing; and in Hungary and Transylvania, the fort of regular government, rather nominal than real or effective. They have their leaders or chiefs, whom they dignify by the Slavonian title, Waywode. To this dignity every person is eligible who is of a family descended from a former waywode; but the preference is generally given to those who have the best clothes and the most wealth; who are of a large stature, and not past the meridian of life. Of religion, however, they have no sense; though, with their usual cunning and hypocrisy, they profess the established faith of every country in which they live. They also speak the languages of the respective countries, yet have a language of their own; from whence derived, authors differ. The only science which they have attained is music. Their poetry is ungrammatical and indifferent rhyme.

Their general character and capacities are thus described: Imagine a people of a childish way of thinking; their minds filled with raw, undigested conceptions; guided more by sense than reason; using underhand affection, and reflection for only as they promote the gratification of any particular appetite; and you have a perfect sketch of the gypsy character. They are lively, unconcerned, loquacious, and chattering; fickle in the extreme, consequently inconstant in their pursuits; faithless to every body, even their own sect; void of the least emotion of gratitude, frequently rewarding benefactors with the most infectious malignity. Fears makes them flavishly compliant when under suspicion; but having nothing to apprehend, like other timorous people, they are cruel. Desire of revenge often causes them to take the most desperate resolutions. To such a degree of violence is their fury sometimes excited, that a mother has been known in the excess of passion, to take her infant by the feet, and therewith strike the object of her anger, when no other instrument has readily prefented itself. They are so addicted to drinking, as to sacrifice what is most necessary to them, that they may feast their palate with spirits. They have, too,
nothing (continues our author) can exceed the unreasoned depravity of manners existing among these people, I allude particularly to the other sex.Unchecked by any idea of shame, they give way to every desire. The mother endeavours, by the most scandalous arts, to train up her daughter for an offering to sensuality; and this is scarcely grown up before she becomes the seducer of others. Laziness is so prevalent among them, that were they to subsist by their own labour only, they would hardly have bread for two of the seven days in the week. This indolence increases their propensity to idleness and lolling; the common attendants on idleness. They seek to avoid themselves of every opportunity to satisfy their lawless desires. Their universal bad character therefore for fickleness, indecency, ingratitude, revenge, malice, rage, depravity, laziness, knavery, thieves, and cunning, though not deficient in capacity and cleverness, render these people of no use in society, except as soldiers to form marrowing parties. Persons in their company, and under their disfigure, have formed dangerous designs against cities and countries. They have been banished from almost all civilized states, in their turn, except Hungary and Transylvania, and to little purpose. Our author is of opinion, that as Turkey would allow them toleration, it would be better for the European states to take some steps for cultivating and civilizing them, and making them useful. But while they are insensible of religion and strongly attached to their own manners, it is to be feared the attempt will be impracticable. This appears from a very intelligent Hungarian lady's experience on the subject, communicated in a letter as follows: 'There are a great number of them on my estates, but I have permitted two families in particular to establish themselves at the place of my own residence, under the express condition that no others shall come here and join them. I took all possible pains to make them reparable creatures. I got the elder ones to work; the younger ones tend the cattle. I observed that they were more fond of horses than any thing else; for which reason I placed a gypsey under each groom. I had their children clothed, that none of them might be running about naked, according to their usual practice. It appeared, however, that custom was become nature with them. The old ones worked diligently so long as any body flood over them; the moment their back was turned, they all got together in a circle, their legs across, facing the sun, and chattered. Thus they cannot possibly earn more, indeed hardly so much, as would find them bread, although very cheap with us; for the bread I give them does not stand me in half a krenzter the pound. Even in winter they cannot bear a hat on their head nor shoes on their feet. The boys run like wild things wherever they are sent, either on foot or on horstback; but they spoil horses unmercifully; so as to make them run down with blood. They cannot be brought by any means whatever to dress horses. Cloath them as you will, they always fell or lose their cloaths. In a word, one cannot but consider them as void of reason; it is really shocking to see even well grown children put whatever they find into their mouths, like infants before they can speak; wherefore they eat every think, even carrion, let it think never so much. Where a mortality happens among the cattle, there these wretched beings are to be found in the greatest number.'

The origin of this people, as we have seen, has been generally believed to be Egyptian; and that belief is as old as their existence in Europe. Thomaeus, Salmon the English geographer, and lately Signior Grifelini, have endeavoured to prove it by satisfactory evidence. This theory, however, according to our author, is without foundation. The Egyptian descent of these people, he thinks, is not only delusive of proofs, but the most positive evidence is found to contradict it. Their language differs entirely from the Coptic; and their customs are very different from those of the Egyptians. They are indeed to be found in Egypt; but they wander about there as strangers, and form a differentiated people, as in other countries. The expressions of Bellonius are strong and decisive: 'No part of the world, I believe is free from those banditti, wandering about in troops; whom we by mistake call Egyptians and Bohemians. When we were at Cairo, and in the villages bordering on the Nile, we found troops of these throstle thieves sitting under palm trees; and they are esteemed foreigners in Egypt as well as among us.'

The Egyptian descent of the gypseys being rejected, our author next endeavours to show that they come from Hindoostan. The chief basis of his theory, however, is no other than that very dubious one, a similarity of language. He adds a long vocabulary of the gipsy and the Hindoostanic languages; in which, it must be confessed, many words are the same; but many are different. A principal proof which he adduces on this head is from the relation of Captain Szekely von Doba, to whom a printer in 1763 related, that a preacher of the Reformed church, when a student at Leyden, being intimately acquainted with three young Malabar students, took down 1000 of their words, which he fancied corresponded with the gipsy language; and they added, that a tract of land in their island was named Osigania. He repeated these words to the Raber gypseys, who explained them without trouble or hesitation. This account was published in the Vienna Gazette. Supposing these three young men to be sons of Bramins, who use the Sanscrit, the common language of Hindoostan comes as near to that as modern Italian to pure Latin. The comparison of
the two languages takes up above 30 pages; and Mr. Grellman thinks it establishes his system. The same opinion is maintained by Mr. Marfden, in a paper upon this subject in the 7th volume of the Archæologia. The numerals, however, both in Hindostanic and gipsy, differ greatly as stated by the two authors. And here, as in other such comparisons, one is astonished at the credulity of the comparers of orthoepy and orthography (as a periodical critic observes), which can have no connection in languages with which we are not perfectly familiar, even were both languages reduced to writing by their respective people; how much less, then, where one of the two languages is never reduced to writing, as is the case of the gipsy, but is blended with the language of the country where the clan resides? This appears from the correspondence of several words in all languages with the gipsy. Mr. Grellman acknowledges the two gipsy versions of the Lord's Prayer, at different periods, differ so widely, that one would almost be inclined to doubt whether they were really the same language. We think we can discern a few words differently indeed written, but probably pronounced alike. Nor can we, in all the parts, in which Chamberlayne gives the Lord's Prayer, perceive the least resemblance to the gipsy name of father, Dade and Daid, except in the Welsh, Taad. In prosecuting his argument, Mr. Grellman does not intimate the similarity of colour between the two peoples, nor on the cowardice common to both, nor on the attachment of the Indians to tents, or letting their children go naked; all these being traits to be met with in other nations; but he dwells on the word Prager, the name of one of the first gipsy leaders, and of the Indo-fanian god of marriage; also on the correspondence between the travelling smiths in the two peoples, who carry two pairs of bellows; the Indian's boy blows them in India, the Traveller's in Europe; as if every travelling tinker, in every nation where tinkers travel, had not the same journeymen. In lascivious dances and chiroantry the two people agree; nor are they uncommon in other parts of the globe. The excessive loquacity of the two people is produced as similar; as if no other nations in the world were loquacious. Paiser remembrance are, a fondness for farron, and the intermarrying only with their own people. The last postulatum is that the gipsies are of the lowest class of Indians, namely, Parisa, or, as they are called in Hindostan, Suders. He compares the manners of this class with those of the gipsies, and enumerates many circumstances in which they agree: some of the comparisons are frivolous, and prove nothing. As an instance of which we may take the following: 'Gipsies are fond of being about horses; the Suders in India like-wisely, for which reason they are commonly employed as horse-keepers by the Europeans resident in that county.' This reasoning does not prove that the gipsies are Suders, any more than they are Arabians or Yorkshire farmers.

The objections, however, to which this learned and ingenious work of the author's theory is liable, are such as only show it to be by no means satisfactory; but do not prove that it is wrong. It may possibly be right; and upon this supposition the cause of their emigration from their country, he conjectures, not without probability, to be the war of Timur Beg in India. In the years 1408 and 1409 this conqueror ravaged India; and the progress of his arms was attended with devastation and cruelty. All who made resistance were destroyed; those who fell into the enemy's hands were made slaves; of these, very, very, very, very, very many were put to death. Ason is an occasion an universal panic took place, what could be more natural than that a great number of terrified inhabitants should endeavour to save themselves by flight? In the last place, the author endeavours to trace the route by which the gipsies came from Hindostan to Europe: but here he justly acknowledges that all that can be said on the subject is mere far-fetched; and, upon the whole, after perusing all the preceding details, the reader will probably be of opinion that there still hangs a cloud over the origin of this extraordinary race.

GYPSOPHILA, in botany: A genus of the diasy order, belonging to the decandria class of plants; and in the natural method ranking under the 22d order, Caryophylla. The calyx is monophyllous, campanulated, and angulated; the petals are five in number, ovate, and fiddle; the capsule globose and unilocular.

GYPSUM, PLASTER-STONE, or Alabaster; a natural combination of the calcareous earth with vitriolic acid. See ALABASTER.

The properties of gypsum, according to Cronstedt, are. 1. It is looser and more friable than a calcareous earth. 2. It does not effervesce with acids either in its crude or calcined state; or at all in a very slight degree, in proportion to what it wants of the vitriolic acid for the complete saturation of its base. 3. It falls into powder in the fire very readily. 4. When burnt without being made red-hot, its powder readily concretes with water into a mass which soon hardens; but without any sensible heat being excited in the operation. 6. According to our author, it is nearly as difficult of fusion as limestone; and shows almost the same effect upon other bodies with limestone, though the acid of vitriol seems to promote the vitrification. M. Magellan, however, informs us, that he has found most of the gypseous kind, particularly the fibrous, to melt in the fire pretty easily by themselves. 7. When melted in the fire with borax, it puffs and bubbles very much, and for a long time during the fusion. According to M. Magellan, when a small quantity of any gypsum is melted together with borax, the galls becomes colourless and transparent; but some sorts of alabaster and sparre gypse, when melted in quantity with borax, yield a fine yellow transparent coloured glas, resembling that of the best topazes; but if too much of the gypsum is used in proportion to the borax, the galls becomes opaque, just as it happens with the pure lime-stone. 8. When burnt with any inflammable matter it emits a sulphurous smell, and may thus be decomposed, as well as by either of the fixed alkaline salts; but if this last method is followed, there ought to be five or six times as much salt as there is of gypsum. 9. On being decomposed in this manner the residuum commonly shows some signs of iron. The species are.

1. Friable gypseous earth of a white colour, found in Saxony.

2. Indurated gypsum of a solid texture, the particles of which are not visible, commonly called Alabaster. This is sometimes found unsaturated with vitriol acid;
GYP [ 257 ]

GYP

Gypseum, in which case only it will effervesce with aquafortis, as it is said to do under the Article Alabaster. It is very easily fawed or cut, and takes a dull polish. It is of several kinds; as, white; clear transparent from Periba, opaque from Italy and Trapans in Sicily; of a yellow colour, of which there are likewise two kinds, transparent and opaque; the former being met with in the mountain countries, the latter in Spain. Brunnet informs us, that in this country there are a great many kinds, varieties, viz: with coarse or with fine fibres. This is found composed of capillary cryllals, sometimes white and sometimes with great celerity in circles on the surface of the water. It is soluble in 300 times its weight of warm water, or 450 times its weight of boiling water. It is well known by its property of forming an hard mass with water after being highly burned; and during this condensation a flight degree of heat is produced, though less than that when line is flaked. It is often employed in building, and may be taken off and used again for the same purpose.

4. Fibrous gypsum, or plaster stone, has likewise two varieties, viz: with coarse or with fine fibres. It is of a white colour.

5. Selenites, or spar-like gypsum, by some also called glacies mace, and confounded with the clear and transparent mica. It is found of two kinds, clear and transparent, or yellowish and opaque.

6. Crystalized gypsum, or gypseous drusen. This is found composed of wedge-shaped and sometimes of capillary cryllals, sometimes white and sometimes yellowish.

7. Sphaleritic gypsum is found of a great many different forms and colours. When found in large pieces it commonly varies between white and yellow, and likewise in its transparency in different parts of the same mass. It is used as alabaster in several works.

Before the countries already mentioned, England abounds with subfances of a gypseous nature. There are plenty in Derbyshire and Nottinghamshire, so fine as to be used like alabaster, that is, to take a fine polish. In the countries just mentioned there are large pits of this kind, also in most of the cliffs of the Severn, especially at the Old Passage at Somerfethire. A very fine semiopaque gypseous drusen is found in Derbyshire. Very fine fibrous sides are also found in the above-mentioned pits of stone, and many other places. Selenites everywhere abound, so that it is impossible to enumerate the different places. Very fine gypseous drusen are found in Sheppy Isle, and some exceedingly beautiful, large and clear as crystal, have been dug from the sail-rocks at Nantwich in Chester. The selenites rhomboïdales is found in plenty in England. There are very rare in other countries. Shotover hill in Oxfordshire is remarkable for them. The slate of Sheppy affords a kind of spar-like gypsum, of a fibrous nature, and always accreting like the radiations of a star on the sepiaria, and thence called stella septaria.

The principal use of gypsum is as a material for small statues and figures of various kinds, also for moulds for casting wax-works, &c. It has lately been introduced as a manure in France and America, though its success in this respect has not yet been sufficiently experienced.

GYR-FALCO, in zoology, the name of a large and fierce species of falcons, called in English the jer falcon. See Falcon.

It is a very bold and daring bird, attacking all other fowl without revenge, particularly the hen and fow kinds. The other falcons are all afraid of this.

GYRINUS, in zoology, a genus of insects of the coleoptera order. The generic characters are: The plate antennae are cylindrical, stiff, and shorter than the cæs upsetting head; and the eyes are four, two on the upper and two on the under part of the head. Mr Barbut, however, says that the eyes only appear on the upper and under parts of the head, but that they are not four. The nubit, or common water-flea, is of a bright black color; the feet are yellow, flat, and large; the insect is in length one-third of an inch. It feeds with great celerity in circles on the surface of the waters and is very difficult to catch, plunging down instantaneously when attempted to be taken. There are eight other species, which frequent the waters in different parts of the globe.

GYSHORN, a town of Germany, in the duchy of Lunenburgh, situated on the river Aller, in E. Long. 10. 45. N. Lat. 52. 30.

H.

The eighth letter and sixth consonant in our alphabet; though some grammarians will have it to be only an aspiration, or breathing. But nothing can be more ridiculous than to dispute its being a distinct sound, and formed in a particular manner by Vol. VIII.

HAB

Habda].

The family of the Phoenicians, the most ancient Greeks, and Romans, used the same figure with our $H$, which is used as a numeral, denotes 200; and with a dath over it, $HF$, 200,000.

As an abbreviation, $H$ was used by the ancients to denote homo, hares, hara, &c. Thus H. B. flood for hares bonus; and H. S. corrupted for LLS. fierce; and H. A. for Hadrianus.

HABAG, or HAAG, a town of the duchy of Bavaria in Germany, seated on a hill on the west side of the river Inn, in E. Long. 12. 23. N. Lat. 48. 16.

HABBKUK, one of the twelve leffer prophets, whose prophecies are taken into the cannon of the Old Testament. The name is written in the Hebrew with $n$ $bbet$; and signifies "a wrestler." There is no precise time mentioned in Scripture when this Habakkuk lived; but from his predicting the ruin of the Jews by the Chaldeans, it may be concluded that he prophesied before Zedekiah, or about the time of Manasseh. He is reported to have been the author of several prophecies which are not extant; but those that are indubitably his, are contained in three chapters. In these the prophet complains very pathetically of the disorders in the kingdom of Judaea. God reveals to him, that he would shortly punish them in a very terrible manner by the arms of the Chaldeans. He foretells the conquests of Nebuchadnezzar, his metamorphosis, and death. He foretells, that the vast designs of Jehoiakim would be frustrated. He speaks against a prince (probably the king of Tyre) who built with blood and iniquity; and he accuses another king (perhaps the king of Egypt) of having intoxicated his friend, in order to unloose his nakedness. The third chapter is a song or prayer to God, whose majesty he describes with the utmost grandeur and splendour of expression.

HABET, a province of Africa, in Barbary, and in the kingdom of Fez. It is surrounded by the Mediterranean, the Straits of Gibraltar, and the Atlantic Ocean. The principal towns are Arelaa, Tetuan, and Ceuta; which last is in possession of the Spaniards.

HABDALA, a ceremony of the Jews observed on the evening of the sabbath, when every one of the family is come home. At that time they light a taper or lamp, with two wicks at least. The master of the family then takes a cup, with some wine, mixed with fragrant spices, and having repeated a psalm or two of scripture, as for example, "I will take the cup of salvation," &c. Psal. cxxi. and "The Jews had light and gladness," &c. Ezech. viii. he blest the wine and spices. Afterwards he blest the light of the fire, and then ca's his eyes on his hands and nails, as remembering that he is going to work. The whole is intended to signify, that the sabbath is over, and is from that moment divided from the day of labour which follows. For this reason the ceremony is called Habdala, which signifies "distinction." After the ceremony is over, and the company breaks up, they with one another, not "a good night," but "a good week."

HABEAS CORPUS, in law, is the great remedy in cases of False Imprisonment. The incapacity of the three other remedies referred to under that article, to give complete relief in every case, hath almost entirely antiquated them, and hath caused a general recourse to be had, in behalf of persons aggrieved by illegal imprisonments to the present writ, the most celebrated in the English law. Of this there are various kinds made use of by the courts at Westminster, for removing prisoners from one court into another for the more easy administration of justice. Such is the habeas corpus ad respondendum, when a man hath a cause of action against one who is confined by the process of some inferior court; in order to remove the prisoner, and charge him with this new action in the court above. Such is that ad satisfaciendum, when a prisoner hath had judgment against him in an action, and the plaintiff is desirous to bring him up to some superior court to charge him with proceeds of execution. Such also are those ad profitendum, tesiicandum, de liberandum, &c.; which issue when it is necessary to remove a prisoner, in order to prosecute or bear testimony in any court, or to be tried in the proper jurisdiction wherein the fact was committed. Such is, lastly, the common writ ad factandum et recipiendum, which issues out of any of the courts of Westminster, when a person is sued in some inferior jurisdiction, and is desirous to remove the action into the superior court; commanding the inferior judges to produce the body of the defendant, together with the day and cause of his caption and detainer (whence the writ is frequently denominated an habeas corpus cum causa), to do and receive whatsoever the king's court shall consider in that behalf. This is a writ granter of common right, without any motion in court, and it instantly supersedes all proceedings in the court below. But, in order to prevent the surreptitious discharge of prisoners, it is ordered by statute 1 & 2 P. & M. c. 13, that no habeas corpus shall issue to remove any prisoner out of any goal, unless signed by some judge of the court of which it is awarded. And, to avoid vexatious delays by removal of frivolous causes, it is enacted by statute 21 Jac. 1. c. 22, that, where the judge of an inferior court of record is a barrister of three years standing, no cause shall be removed from thence by habeas corpus or other writ, after issue or demurrer deliberately joined: that no cause, if once remanded to the inferior court by writ of procedendo or otherwise, shall ever afterwards be again removed; and that no cause shall be removed at all, if the debt or damages laid in the declaration do not amount to the sum of five pounds. But an expediunt having been found out to elude the latter branch of the statute, by procuring a nominal plaintiff to bring another action for five pounds or upwards (and then by the course of the court the habeas corpus removed both actions together), it is therefore enacted by statute 12 Geo. I. c. 29, that the inferior court may proceed in such actions as are under the value of five pounds, notwithstanding other actions may be brought against the same defendant to a greater amount.

Habas

*own account of the matter, whose remonstrance was not cooled at the distance of forty and twenty years.*

These pitiful evasions gave rise to the statute 16 Car. I. c. 10. § 8, whereby it is *enacted*, that if any person be committed by the king himself in person, or by his privy council, or by any of the members thereof, he shall have granted unto him, without any delay upon any pretence whatsoever, a writ of *habeas corpus*, upon demand or motion made to the court of king's bench or common pleas; who shall thereupon, within three court-days after the return is made, examine and determine the legality of such commitment, and do what to justice shall appertain, in delivering, bailing, or remanding such prisoner. Yet still in the case of Jenks, before alluded to, who in 1676 was committed by the king in council for a turbulent speech at Guildhall, new shifts and devices were made side of to prevent his enlargement by law; the chief justice, (as well as the chancellor) declining to award a writ of *habeas corpus ad subjiciendum* in vacation, too late, for he thought proper to award the usual writs *ad deliberationem*, &c. whereby the prisoner was discharged at the Old Bailey. Other abuses had also crept into daily practice, which had in some measure defeated the benefit of this great constitutional remedy. The party imprisoned was at liberty to delay his obedience to the first writ, and might wait till a second and a third, called *alias* and *pluribus*, were inflicted before he produced the party; and any other vexatious shifts were practiced to detain state-prisoners in custody. But whoever will attentively consider the English history, may observe, that the flagrant abuse of any power, by the crown or its ministers, has always been productive of a struggle which either discovers the exercise of that power to be contrary to law, or (if legal) restrains it for the future. This was the case in the present instance. The oppression of an obscure individual gave birth to the famous *habeas corpus* act, 31 Car. II. c. 2, which is frequently confidered as another *modus charta* of the kingdom; and by consequence has also in the course of time reduced the method of proceeding on these writs (though not within the reach of that statute, but existing merely at the common law) to the true standard of law and liberty.

The statute itself *enacts*, 1. That the writ shall be returned and the prisoner brought up, within a limited time according to the distance, not exceeding in any case twenty days. 2. That such writs shall be endorsed, as granted in pursuance of this act, and signed by the person awarding them. 3. That on complaint and request in writing by or on behalf of any person committed and charged with any crime (unless committed for treason or felony expressed in the warrant, or for satisfaction of the fine, or as necessary thereon before the fact, or convicted or charged in execution by legal process), the lord chancellor, or any of the twelve judges in vacation, upon viewing a copy of the warrant, or affidavit that a copy is denied, shall (unless the party has neglected for two terms to apply to any court for his enlargement) award a *habeas corpus* for such prisoner, returnable immediately before himself or any other of the judges; and upon the return made shall discharge the party, if bailable, upon giving security to appear and answer to the accusation in the proper court of judicature. 4. That officers and keepers neglecting to make due returns, or not delivering to the prisoner on his warrant within six hours after demand a copy of the warrant of commitment, or shifting the custody of a prisoner from one to another without sufficient reason or authority (specified in the act), shall for the first offence forfeit 100l. and for the second offence 200l. to the party grievances, and be disabled to hold his office. 5. That no person, once delivered by *habeas corpus*, shall be committed for the same offence, on penalty of 500l. 6. That every person committed for treason or felony, shall, if he requires it the first week of the next term, or the first day of the next session of *eye* and *termine*, be indicted in that term or session, or else admitted to bail; unless the king's writs cannot be produced at that time; and if acquitted, or if not indicted and tried in the second term or session, he shall be discharged from his imprisonment for such impromptu offence: but that no person, after the assizes shall be opened for the county in which he is detained, shall be removed by *habeas corpus*, till after the assizes are ended; but shall be left to the justice of the judges of assize. 7. That any such prisoner may move for and obtain his *habeas corpus* as well out of the chancery or exchequer as out of the king's bench or common pleas; and the lord chancellor or judges denying the same, or (if legal) restraining the party grievously the same, shall be discharged from his imprisonment for such impromptu offence. 8. That the writ of *habeas corpus* shall run into the counties palatine, five ports, and other privileged places, and the islands of Jersey and Guernsey. 9. That no inhabitant of England (except persons contriving, or consorts praying to be transported; or having committed some capital offence in the place to which they are sent) shall be sent prisoner to Scotland, Ireland, Jersey, Guernsey or any places beyond the seas, within or without the king's dominions: on pain that the party committing the advice, aiders, and abettors, shall forfeit to the party grievances a fine not exceeding than 500l. to be recovered with treble costs; shall be disabled to bear any office of trust or profit; shall incur the penalties of *præmunitio*; and shall be incapable of the king's pardon. This is the substance of that great and important statute: which extends (we may observe) only to the case of commitments for such criminal charge as can produce no inconvenience to public justice by a temporary enlargement of the prisoner; all other cases of unjust imprisonment being left to the *habeas corpus* at common law. But even upon writs at the common law it is now expected by the court, agreeable to ancient precedents and the spirit of the act of parliament, that the writ should be immediately obeyed, without waiting for any *alias* or *pluribus*; otherwise an attachment will issue. By which admirable regulations, judicial as well as parliamentary, the remedy is now complete for removing the injury of unjust and illegal confinement. A remedy the more necessary, because the oppression does not always arise from the ill-nature, but sometimes from the mere inattention, of government. For it frequently happens in foreign countries (and has happened in England during the temporary suspensions of the statute), that persons
HAB

HABEDASH, in commerce, a seller of hats and other small wares. The master and wardens of the company of haberdashers in London, calling to their assistance one of the company of cappers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all haters who work hats with foreign wool, and who have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woof and madder; in which cases they are liable to penalties by flat, 8. Eliz. cap. 7. and 9 Geo. II. cap. 22.

For the etymology of this denomination, see Ber-

DASH.

HABERGION, or HAUSERGEON, HABERGETUM, a coat of mail; an ancient piece of defensive armour, in form of a coat, defending from the neck to the middle, and formed of little iron rings or mailles, linked into each other. — The word is also written haberge, hauger, hauere, hauerto, hauert, and hauerk. Spelman takes it to have been from the ancient French hâtre, " high," and hârge, " armour, covering;" as serving to defend the upper part of the body. Du Cange and Skinner choose to derive it from the French hâtre, " hat," and hârge, " to cover;" as if it were a peculiar defence for the neck. Others will have it formed of al, alla, q. d. all, and berge, " to cover;" as importing it a cover for the whole body.

HABAICOT (Nicholas), a celebrated surgeoan, born at Bonny in Gainsbols, acquired great reputation by his skill in his profession; and by his writings; and died in 1624. He wrote a treatise on the plague, and left several manuscripts in the hands of his son. His printed works are: 1. Poems under the title of Cassbura. 2. The Queen of Arragon, a tragico-comedy. 3. Observations upon History. 4. The history of Edward IV. king of England, written and published at the desire of Charles I. This work is composed in a very droll manner.

HABIT, in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act. See Custom and Habit.

Habit is also used for dres or garb, or the composition of garments, wherewith a person is covered. The principal part of the drapery worn by the Jews and Greeks was the muirica and the χειριστή. The μυηζης was an upper garment, consisting of a loose square piece of cloth wrapped round the body; the χειριστή was an under garment, or tunic, which was fastened round the body and embraced it closely, falling down to the mid-thigh. It is proper in this place to observe that a person divested of this upper garment or φασμα, in the easter{e}n language, is styled naked, and in this sense David danced naked before the ark.

The several sorts of garments in use with both sexes, amongst the Romans, were the toga, tunica, peluna, laceria, chlamys, paludamentum, lana, floa, pallium or pallae. See Toga, &c.

For the habits of the priests amongst the Jews, Greeks, and Romans, see the article PRIESTS.

HABIT is particularly used for uniform garments of the religious, conformable to the rules and order whereof they make profession; as the habit of St Benedict, St Augustine, &c.

In this sense we say absolutely, such a person has taken the habit; meaning he has entered upon a noviciate in a certain order. So he is said to quit the habit, when he renounces the order. See vow.

The habits of the several religious are not supposed to have been calculated for singularity or novelty; the founders of the orders, who were at first chiefly inhabitants of deferts and solitudes, gave their monks the habit usual among the country people. Accordingly, the primitive habits of St Anthony, St Hilary, St Benedict, &c. are described by the ancient writers as consisting chiefly of thick skins, the common dress of the peasants, shepherds, and mountaineers, of that time; and the same they gave to their disciples.

The orders established in and about cities and inhabited places took the habit worn by other ecclesiastics at the time of their institution. Thus, St Dominic gave his disciples the habit of regular canons, which he himself had always worn to that time. And the like may be said of the Jesuits, Barnabites, Theatins, Oratians, &c. who took the common habit of the ecclesiastics at the time of their foundation. And what makes them differ so much from each other, as well as from the ecclesiastical habit of the present times, is, that they have always kept invariably to the same form; whereas the ecclesiastics and laity have been changing their mode on every occasion.

HABITE and REPUTE, in Scots law, the common opinion of the people; among whom a person lives, with respect to any circumstance relating to him.

HABITUDE, among schoolmen, the respect or relation one thing bears to another. See Relation.

HABSBURGH, or HABSBURG, an ancient castle of Swisserland, in the canton of Bern. It is the place where the ancient counts of Hapsburg resided, and is seated near the lake of Lucern, and to the south of the town of that name. E. Long. 8. fol. N. Lat. 47. 22.

HACHA, a sea-port town of South America, in Terra Firma, seated at the mouth of a river of the same name. Here the Spanish galleons touch at their arrival in South America, from whence express are sent to all the settlements to give them notice of it. W. Long. 72. 8. N. Lat. 11. 30.

HACKET (John), bishop of Litchfield and Coventry, was born in 1592. In 1623, he was made chaplain to James I. and prebendary of Lincoln: and soon after obtained the rectory of St Andrew's Holborn, with that of Cheam in Surrey; his patron telling him, he intended Holborn for wealth, and Cheam for health. In 1642 he was presented to a prebendary and refidentiary; but was deprived of the enjoyment of them, as well as of St Andrew's, by the ensuing troubles. He then lived retired at Cheam with little disturbance, until he recovered his preferment by the restoration of Charles II. by whom he was preferred to the see of Litchfield and Coventry in 1661. Finding the beautiful cathedral of Litchfield almost battered to the ground,
HACKNEY, a parish of Middlesex, on the north-east side of London, containing no less than 12 hamlets. At the bottom of Hackney-Marsh, through which the river Lea runs, between Old-Ford and the Wyck, there have been discovered the remains of a great stone causeway, by which, the Roman coins, &c. found there, was no doubt one of the famous highways made by the Romans. The church here is of a very ancient foundation, so old as Edward II. and the number of its bells near 80. That part of London called Mare Street; the middle Church Street; and the north part: Clapton Dorleston and Shacklewell are of the west, and Hummerton, which leads to the Marsh, on the east. Here are three meeting-houses and several boarding-schools, besides the free schools in the church-yard, a charity-school, and 17 almshouses. It was from this place that the coaches let to the people in London first received their name; for in the last century, many people having gone on visit to see their friends at Hackney, it occasioned them often to hire hores or carriages, so that in time it became a common name for such horses, coaches, and chairs as were let to the people of London; and the name has now diffused itself not only throughout Britain, but likewise Ireland.

Hackney Coaches, those exposed to hire in the streets of London; and some other great cities, at rates fixed by authority. See Coach.—These first began to ply in the streets of London, or rather waited at inns, in the year 1625, and were only 20 in number; but in 1635 they were so much increased, that king Charles issued an order of council for restraining them. In 1637, he allowed 50 hackney-coachmen, each of whom might keep 12 horses. In 1652, their number was limited to 200; and in 1654, it was extended to 300. In 1661, 400 were licenced, at £1. annually for each. In 1694, 300 were allowed, and taxed by the 2 and 6 of W. & M. at 41. per annum each. By 9 Anne cap. 23. 800 coaches were allowed in London and Westminster; but by 8 Geo. III. cap. 24, the number is increased to 1000, which are to be licenced by commissioners, and to pay a duty of 5 l. per week to the king. On Sundays there were formerly only 175 hackney-coaches to ply, which were to be appointed by commissioners; but their number is now unlimited.

The fare of hackney coachmen in London, or within ten miles of the city, is 12 shillings and sixpence per day, allowing 12 hours per day. By the hour it is 1s. 6d. for the first, and 1s. for every hour afterwards; none are obliged to pay above 1s. for any distance not exceeding a mile and a half; or above 1s. 6d. for any distance not exceeding two miles. Where hackney coachmen refuse to go at, or exact more than, their limited hire, they are subject to a forfeit not under 10s. nor exceeding 3 l. and which the commissioners have power to determine. Every hackney-coach must be provided with check strings, and every coachman plying without them incurs a penalty of 3s.—Drivers of hackney coaches are to give way to perfons of quality and gentlemen's coaches, under the penalty of 3s. The duty arising from licences to hackney-coaches and chairs in London, forms a branch of the king's extraordinary and perpeetual revenue *. This revenue is governed by commissioners of its own, and is in truth a benefit to the subject; as the expense of it is felt by no individual, and its necessary regulations have established a competent jurisdiction, whereby a very refractory race of men may be kept in some tolerable order.

HADDON, the English name of a species of Gadus.

Haddersleben, a sea-port town of Denmark, in the duchy of Slewich, with a strong citadel, built upon a small island. It is seated on a bay of the Baltic Sea, and has a well-frequented harbour. E. Long. 9° 55'. N. Lat. 57° 24'.

Hades, in the Scriptures is used in various senses. Sometimes it signifies the invisible regions of the dead, sometimes the place of the damned, and sometimes the grave. In Greek authors it is used to signify in general the regions of the dead. See HELL.

HADLEY, a town of Suffolk, seated in a bottom on the river Preffon. It consists of about 600 houes; with a very handsome church, a chapel of ease, and a Presbyterian meeting-houe. The streets are pretty broad, but not paved. Large quantities of yarn are spun here for the Norwich manufacture; and this town had once a considerable woollen manufacture, which is now decayed. E. Long. 1° 0'. N. Lat. 52° 7'.

HADRIAN. See Adrian.

Hæmagogos, among physicians, a compound
Hæmatites, or Blood Stone, a hard mineral substance, red, black, or purple, but the powder of which is always red. It is found in mafes sometimes spherical, semi-spherical, pyramidal, or cellular, that is like a honeycomb. It contains a large quantity of iron. Forty pounds of this metal have been extracted from a quintal of stone; but the iron is of such a bad quality, that this ore is not commonly smelted. The great hardness of hematites renders it fit for furnishing and polishing metals.

Hæmatopus, the Sea-pigeon, in ornithology, a genus belonging to the order of Grallæ. The beak is compressed, with an equal wedge shaped point; the nostrils are linear; and the feet have three toes without nails. There is but one species, viz. The ostroleucus, or oyster-catcher, a native of Europe and America. It feeds upon shell-fish near the sea-shore, particularly oysters and limpets. In observing an oyster which gapes wide enough for the insertion of its bill, it thrusts it in, and takes out the inhabitant; it will also force the limpets from their adhesion to the rocks with sufficient ease. In turn it feeds on marine insects and worms. With these birds are often seen in considerable flocks in winter; in the summer they are met with only in pairs, though chiefly in the neighbourhood of the sea or salt rivers. The female lays four or five eggs, on the bare ground, on the floor, above a high-water mark; they are of a greenish grey, bloched with black. The young are said to be hatch'd in about three weeks. These birds are very wild when in flocks; yet are easily brought up tame, if taken young.

Hæmatoxylum, logwood, or Campeachy wood; a genus of the monogynia order, belonging to the decandria class of plants; and in the natural method ranking under the 3rd order, Lonontaceæ. The calyx is quiquinpartite; the petals five; the capsule lanceolated; unilocular, and bivalved; the valves navicular or keeled like a boat.

Of this genus there is only one species, viz. the campechianum, which grows naturally in the bay of Campeachy at Honduras, and other parts of the Spanish West-Indies, where it rises from 16 to 24 feet high. The stems are generally crooked, and very deformed; and seldomed thicker than a man's thigh. The branches, which come out on each side, are crooked, irregular, and armed with strong thorns, garnished with winged leaves, composed of three pair of obtuse lobes indent'd at the top. The flowers come in a racemus from the wings of the leaves, standing erect, and are of a pale yellowish colour, with a purple empanelment. They are succeeded by berries, which are of a beautiful red colour when ripe.

Culture. All these plants are natives of the Cape of Good Hope, and do not propagate very fast in Europe; their roots seldom putting forth many off-sets. The best method of managing them is to have a bed of good earth in a bricked pit, where they may be covered with a cluster of bright and tubulous flowers. It hath a large bulbous root, from which in the autumn come out two broad flat leaves of a fleshy consistence, shaped like a tongue, which turn backward on each side, and spread on the ground, so that they have a strange appearance all the winter. In the spring thehe decay; so that from May to the beginning of August they are deftitute of leaves. The flowers are produced in the autumn just before the leaves come out. 2. The carinatus, with keel shaped leaves, has a taller stalk and paler flowers than the former; its leaves are nodous, but hollowed like the keel of a boat. 3. The puniceus, with large spear-shaped waved leaves, grows about a foot high, and hath flowers of a yellowish red colour. These are succeeded by berries, which are of a beautiful red colour when ripe.
HAEMOPTYSIS, HEMOPTYSIS, or Hemoptoe, a spitting of blood. See (Index subjoined) to Medicine.

HÆMORRHAGY, (compound of αἷμα "blood," and μείζον "I burst forth,")) in medicine, a flux of blood at any part of the body; arising either from a rupture of the vessels, as when they are too full or too much pressed; or from an erosion of the same, as when the blood is too sharp and corrosive.—The haemorrhagy, properly speaking, as underflow by the Greeks, was only a flux of blood at the nose; but the moderns extend the name to any kind of flux of blood, whether by the nose, mouth, lungs, stomach, intestines, fundament, matrix, or whatever part. See Medicine and Surgery.

HÆMORRHOIDAL, an appellation given by anatomists to the arteries and veins going to the intineum rectum.

HÆMORRHoids, or Piles, an haemorrhage or issue of blood from the haemorrhoidal vessels. See (Index subjoined) to Medicine.

HÆMUS, (anc. "geg.,") a vast ridge, running from Illyricum towards the Euxine, (Pliny;) so high as to afford a prospect both of the Euxine and Adriatic.

Here, in after ages, was constituted a province called Haemimontis, or Haimontus.

HÆRETICO COMBURENDO, a writ which anciently lay against an heretic, who, having once been convicted of heresy by his bishop, and having abjured it, afterwads falling into it again, or into some other, is therupon committed to the secular power. This writ is thought by some to be as ancient as the common law itself; however, the conviction of hereby by the common law was not in a pagan ecclesiastical court, but before the archbishop himself in a provincial synod, and the delinquent was delivered up to the king to do with him as he pleased: so that the crown had a control over the spiritual power. But by 2 Hen. IV. cap. 15, the diocesan alone, without the intervention of a synod, might convict of heretical tenets; and unless the convict abjured his opinions, or if after abjuration he relapsed, the sheriff was bound to execute, if required by the bishop, to commit the unhappy victim to the flames, without waiting for the content of the crown. This writ remained in force, and was actually executed on two Anabaptists in the seventh of Elizabeth, and on two Arians in the ninth of James I. Sir Edward Coke was of opinion, that this writ did not lie in his time; but it is now formally taken away by statute 29 Car. II. cap. 9. But this statute does not extend to take away or abridge the jurisdiction of Protestant archbishops or bishops, or any other judges of any ecclesiastical courts, in cases of atheism, blasphemy, heresy, or schism, and other damnable doctrines and opinions; but they may prove and punish the same according to his majesty's ecclesiastical laws, by excommunication, deprivation, degradation, and other ecclesiastical censures, not extending to death, in such sort and no other, as they might have done before the making of Haelem this act. Sec. 2. See Heresy.

HAERLEM. See Harlem.

HAG, in zoology. See Myxine.

HAGARENS, the descendants of Ishmael. They are called also Ishmaelites and Saracens; and lastly, by the general name of Arabians.

As to the Hagarans, they dwelt in Arabia the Happy, according to Pliny. Strabo joins them with the Nabathæans, and Charlotæans, whose habitation was rather in Arabia Deserta. Others think their capital was Petra, otherwise Agra, and consequently they should be placed in Arabia Petraea. The author of the Lxxviii. Psalm, ver. 6, joins them with the Moabites; and in the Chronicles it is said (1 Chr. v. 10.), that the sons of Reuben, in the time of Saul, made war against the Hagarans, and became masters of their country eastward of the mountains of Gilead. This therefore was the true and ancient country of the Hagarans. When Trajan came into Arabia, he besieged the capital of the Hagarans, but could not take it. The sons of Hagar valued themselves of old upon their wisdom as appears by Baruch iii. 23.

HAGEDORN (Frederick,) a celebrated German poet, was born at Hainburgh, where his father was resident for the king of Denmark, in 1708. He finished his studies at Jena; and, in 1718, published a number of poetical pieces in Germany, which were well received. He afterwards came to England, where he obtained the friendship of many of the learned; and, at his return, was made secretary to the English Hamburgh company, a lucrative employment that left him sufficient time for cultivating the muse. In 1738, he published his Fables and Tales, the first collection of the kind which Germany can boast. He afterwards published other pieces of poetry of different kinds, as Moral Poems, Epigrams, and five books of Songs; which of all his poetical pieces are most esteemed. He died in 1754.

HAGENAU, a town of Germany, and capital of a bailiwick of the same name, which was formerly imperial, but now belongs to the French. It was taken by them in 1673; the Imperialists retook it in 1702; after which it was several times taken and retaken by both parties; but at last the French got possession of it in 1706. It is divided by the river Motter into two parts; and is seated near a forest of its own name, in E. Long. 7. 53. N. Lat. 48. 49.

HAGGI, the tenth of the small prophets, was born, in all probability, at Babylon, in the year of the world 3457, from whence he returned to Zerbhabel. It was this prophet who by command from God (Ezra, v. 1, 2, &c.) exhorted the Jews, after their return from the captivity, to finish the rebuilding of the temple, which they had intermitted for 14 years. His remonstrances had their effect; and to encourage them to proceed in the work, he assurred them from God, that the glory of this latter house should be greater than the glory of the former house; which was accordingly fulfilled, when Christ honoured it with his presence: for with respect to the building, this latter temple was nothing in comparison of the former.

We know nothing certain of Haggai's death. The Jews pretend, that he died in the last year of the
HAG [265]

Hague.

Hagiography, a name given to part of the books of scripture, called by the Jews Cetuvim. The word is compounded of σαββαν, "holy;" and γενεαν, "I write." The name is very ancient: St. Jerom makes frequent mention of it; before him, St. Epiphanius called these books simply Πανοιρια.

The Jews divide the sacred writings into three classes: The Law, which comprehends the five books of Moses: The Prophets, which they call Neviim: And the Cetuvim דתובים, called by the Greeks, &c. Hagiography; comprehending the book of Psalms, Proverbs, Job, Daniel, Ezra, including also the book of Nehemiah, Chronicles, Canticles, Ruth, the Lamentations, Ecclesiastes, and Esther.

The Jews sometimes call these books the Writings, by way of eminence, as being written by immediate inspiration of the Holy Spirit. Thus says Kimchi, in his preface to the Psalms, Maimonides in More Neioch, and Elias Levita in his Thesebi, under the word הָנָקַע.

They distinguish the hagiographers, however, from the prophets; in that the authors of the former did not receive the matters contained in them by the way called Prophecy, which consists in dreams, visions, whispers, ecstasies, &c. but by mere inspiration and direction of the Spirit.

HAGUE, a town of the United Provinces, in Holland, situated in E. Long. 4° 10. N. Lat. 58° 49'.—In Latin it is called Haga Comititi; in French, La Haye; in Dutch, der Haag, or "S Graaenhage, i.e. the Earl's Grove or Wood, from the wood near which it is built, and in which the earls of Holland had a country-house. Though it sends no deputies to the states, it is one of the most considerable towns in Holland, pleasantly situated, and exceedingly beautiful. It may indeed compare with almost any city in Europe, though geographers account it but a village. The inhabitants also breathe a better air than those of the other cities, as it stands on a dry soil, somewhat higher than the rest of the country. It has no gates or walls, but is surrounded by a moat over which there are many draw-bridges. Two hours are required to walk round it, and it contains about 40,000 or 50,000 souls. It is a place of much splendor and business, being the seat of the high courts of the republic and province of Holland, and the residence of the stadtholder and foreign ambassadors; and there are a great many fine streets and squares in it. In the inner court all the high colleges and courts of justice hold their assemblies: there also the foot-guards do duty, as the horse-guards in the outer, when the states are sitting. Le Platt is an open airy place, in form of a triangle, adorned with neat and beautiful buildings: the Veyerberg is an eminence, laid out into several fine shady walks, with the Vyeer, a large basin of water, at the bottom: the Voorhout is the most celebrated part of the Hague, and consists of the mall, and walks edged with trees on each side, planted with trees, being much the same as St. James's park at London: the palace of Olydam, or Waalenaar, is built in a very elegant style; the prince and princesses go by way of palace at the north sea; with several trees, laid out in several streets, and surrounded with falsely houes. The Jewish synagogue is well worth being seen by a curious traveller; as also the palaces of the prince of Orange, the hotel of Spain, the new Voorhout, the mausoleum of the baron of Olydam in the great church, and the several hospitals. The environs of the Hague are exceedingly pleasant. Among other agreeable objects are the wood, with the palace of Orange at the extremity of it, called the haus in the wood; the village of Scheveling; and the lands-bills along the north sea; with the village of Voorburg, and the charming seats and fine gardens round it. Two miles from the Hague is Blywick, a village: and, a quarter of a mile from that, a noble palace belonging to the prince of Orange, famous for the treaty of peace concluded there in 1677. Leodouwien, where Margaret, countess of Hennepurg, and daughter of Florence IV, count of Holland and Zealand, is laid to have been delivered of 365 children at a birth in 1276, is about five miles from the Hague. Five miles beyond Leodouwien, and not far from the beautiful village of Graevenside, is Honlarucuck, another palace belonging to the prince of Orange, and one of the finest structures in the Low Countries.

HAHN (Simon Frederick), a celebrated German historian. At ten years of age he was not only far advanced in the Latin, but understood several living languages. Four years after he pronounced a speech on the origin of the cloyer at Bergen, the place of his birth, which was printed with some other pieces; and in 1708 he published a Continuation of Meliumius's Chronicle of Bergen. After having for several years given public lectures at Hall, he became, at the age of 24, protector of history at Helmitand, and was at length counsellor, historian, and librarian, to the king of Great Britain, elector of Hanover. He died in 1729, aged 27. Besides the above, and some other works, he wrote, 1. The first volume of the History of the Empire. 2. Colleccio monimentorum veterum et recentium meditatorum, 2 vols 8vo.

HAI-NAN. See HAINAN.

Hai-Tang, a beautiful Chinafe shrub, originally brought from the bottom of the rocks which border the sea-coast. It has been cultivated in China for more than 14 centuries; and is celebrated as often in the works of the Chinese poets, as roses and lilacs are in those of ours. Painters and embroiderers ornament almost all their works with its foliage and flowers. The stalk of the hai-tang is of a cylindric form, and grows almost opposite another on the branches, and at the same distance as the knots. Their colour above is a deep green; that below is much lighter, and almost effaced by their fibres which are large, and of a delicate purple: all these leaves together have a beautiful

Vol. VIII.
Hall-Tang. tifil effect to the eye. The flowers grow in bunches at the extremities of the branches. Each flower is composed of four petals, two great and two small, resembling in colour the bloom of a peach tree, and which have almost the same figure as the blossoms of our cherry trees. The two large are cemented one upon the other, in the form of a purée; and when they blow, the two small also in their turn; and then the whole four represent a crocus. The pistil is composed of very bright yellow grains, which separate for the support of a slender stalk, which rises above the petals. The calyx, which surrounds each of the flowers, is composed of two purple-coloured leaves, united in form of a purée. In proportion as the flowers grow and increase in size, the two leaves of the calyx open, become pale and dry, and drop off. The flowers, supported by small stalks, separate one from the other, and produce of themselves other flowers, which rise up from a new calyx.

This plant is propagated from seed, but with difficulty. It thrives best in a sandy soil; dung or mould destroys it; and great care must be taken to refresh it only with the purest water. As it cannot endure the sun in any season, it is always planted below walls that are exposed to the north. It generally begins to flower about the end of August. After it has produced seed, all its branches are cut; and it commonly shoots forth new ones before the fruiting;

but it is necessary to heap up gravel and pieces of brick round its root, to prevent them from rooting. Notwithstanding all the care that is taken to cultivate this tree at Peking, it does not thrive so well there as in the southern provinces. The smell of it leaves has an affinity both to that of the violet; but it is weaker, and never extends to any great distance.

Hail, in natural history, a meteor generally defined frozen rain, but differing from it in that the hailstones are not formed of single pieces of ice, but of many little spherules agglutinated together, which form figures of snow, as the flowers grow; and when they coming from the clouds, many of which weighed five ounces, and some half a pound, and being five or six inches about, were of various figures; some round, others half round; some smooth, others embossed and crenated; the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them.

In Hertfordshire, May 4. the same year, after a severe storm of thunder and lightning, a flower of hail succeeded, which far exceeded the former; some persons were killed by it, their bodies beat all black and blue; vast oaks were split, and fields of rye cut down as with a scythe. The stones measured from 10 to 15 or 14 inches about. Their figures were various; some oval, others picked, some flat. Philos. Trans. No. 219.

Hail is one of the natural phenomena for which it is almost impossible to account in any satisfactory manner. It is certain, that on the tops of mountains hailstones, as well as drops of rain, are very small, and continually increase in bulk till they reach the lower grounds. It would seem, therefore, that during their passage through the air, they attract the condensed vapour which increases them in size. But here we are at a loss how they come to be solid hard bodies, and not always soft, and composed of many small flakes like snow. The flakes of snow, if once they become ice, as they descend, as well as the drops of rain or hailstones; but why should the one be in soft crystals, and the other in large hard lumps, seeing both are produced from condensed vapour? Some modern philosophers ascribe the formation of hail to electricity. Signior Beccaria supplies hail to be formed in the higher regions of the air, where the cold is intense, and where the electric matter is very copious. In these circumstances, a great number of particles of water are brought near together.

At Life in Flanders, in 1686, fell hailstones of a very large size; some of which contained in the middle a dark brown matter, which thrown on the fire, gave a very great report. Phil. Trans. No. 203.

Dr Halley and others also relate, that in Cheshire, Lancashire, &c. April 29. 1697, a thick black cloud, coming from Carnarvonshire, disposed the vapours to congeal in such a manner, that for about the breadth of two miles, which was the limit of the cloud, in its progress for the space of 60 miles, it did inconceivable damage; not only killing all sorts of fowl and other small animals, but splitting trees, knocking down horfes and men, and even ploughing up the earth; so that the hailstones buried themselves under ground an inch or an inch and a half deep. The hailstones, many of which weighed five ounces, and some half a pound, and being five or six inches about, were of various figures; some round, others half round; some smooth, others embossed and crenated; the icy substance of them was very transparent and hard, but there was a snowy kernel in the middle of them.
HAILING, the salutation or accosting of a ship at a distance, either at sea, or in a harbour. The usual expression is, "Hail, the ship ahoy!" To which she answers, "Holla! Whence came ye? Where are ye bound? Good voyage! What cheer? All well! How fare ye?" &c.

HAILLAN (Bernard de Girard, lord of), a celebrated French historian. After having made some figure in the literary world, and as a translator, he applied himself to history with such success, that in 1571, Charles IX. made him historiographer of France. His history of France extends from Pharamond to the death of Charles VII. and is the first complete history of that kingdom composed in the French tongue. He was honoured by Henry III. with several marks of favour; and proposed to continue his history to the reign of Henry IV. but did not perform his promise. He died at Paris in 1610.

HAIMSUCKEN. See HAMESUCKEN.

HAINAN, a considerable island of Asia, situated in between 18° and 20° N. Lat. It is subject to China, and belongs to the province of Quang-ton. It has on the north the province of Quang-hi; on the south the channel formed between the bank Paracel and the eastern coast of Cochinchina; on the west, the same kingdom and part of Tong-kiao; and on the east, the Chine sea. Its extent from east to west is between 60 and 70 leagues, and from north to south 45; this island therefore is about 160 leagues in circumference. Kiu-tcheou-fon, its capital, stands on a promontory, and ships often anchor at the bottom of its walls. Two different kinds of mandarins command here, as in all the other provinces of China: the first are called literati; the second, mandarins of arms, or military officers. Its jurisdiction extends over three cities of the second class and ten of the third. The greater part of the island is under the dominion of the emperor of China; and the rest is independent, and inhabited by a free people, who have never been subdued. Compelled to abandon their plains and fields to the Chines, they have retreated to the mountains in the centre of the island, where they are sheltered from the insults of their neighbours. These people formerly had a free and open correspondence with the Chinese. Twice a year they exposed, in an appointed place, the gold which they dug from their mines, with their eagle-wood and cambla, so much esteemed by the Orientals. A deputy was sent to the frontiers, to examine the cloths and other commodities of the Chinese, whose principal traders repaired to the place of exchange fixed on; and after the Chinese wares were delivered, they put into their hands with the greatest fidelity what they had agreed for. The Chinese governors made immense profits by this barter.

The emperor Kang-li, informed of the prodigious quantity of gold which passed through the hands of the mandarins by this traffic, forbade his subjects, under pain of death, to have any communication with these islanders: however, some private emigrants of the neighbouring governors still find the means of having intercourse with them; but what they get at present by this clandestine trade is little, in comparison of that which they gained formerly. The natives of this island are very deformed, small of stature, and of a copper colour: both men and women wear their hair thruf through a ring on their forehead; and above they have a small hat, from which hang two strings that are tied under the chin. Their dresses consist of a piece of black or dark-blue cotton cloth, which reaches from the girdle to their knees: the women have a kind of robe of the same stuff, and mark their faces from the eyes to the chin with blue stripes made with indigo.

Among the animals of this island are a curious species of large black apes, which have the shape and features of a man; they are said to be very fond of women: there are also found here crows with a white ring round their necks; starlings which have a small crest on their bills; a species like black-birds of a deep blue colour, with yellow eyes rising half an inch; and a multitude of other birds remarkable for their colour or song. Besides mines of gold and lapis lazuli, which enrich the island of Hainan, it produces in abundance various kinds of curious and valuable wood. The great decorator of the present emperor caused some of it to be transported to Peking, at an immense expense, to adorn an edifice which he intended for a mausoleum. The most valuable is called by the natives hooli, and by the Europeans rose or violet-wood from its finell; it is very durable, and of a beauty which nothing can equal; it is therefore reserved for the use of the emperor.

Hainan, on account of its situation, riches, and extent deserves to be ranked among the most considerable islands of Asia. Not far from thence is another small island, commonly called San-cian. It is celebrated by the death of St Francis Xavier: his tomb is still to be seen on a small hill, at the bottom of which is a plain covered on one side with wood, and on the other ornamented with several gardens. This island is not a desert, as some travellers have pretended; it contains five villages; the inhabitants of which are poor people, who have nothing to subsist on but rice and the fish which they catch.

HAINAUT, a province of the Netherlands, belonging partly to France and partly to the house of Austria. It is bounded to the south by Champagne and Picardy; to the north by Flanders; to the east by the duchy of Brabant, the county of Namur, and the bishopric of Liege; and to the west by Artois and Aosta. Flanders
Hainault, Flanders. Its extent from north to south is about 45 miles, and about 48 from east to west. The air is pleasant and temperate, and the soil fruitful: it abounds in rich pastures, corn-fields, woods, and forests, coal, iron, lead, beautiful marble, flate, and other useful stones: it is well watered by rivers and lakes, and breeds abundance of black cattle, and sheep whose wool is very fine. Its principal rivers are the Schelde, and the Dender. This province is reckoned to contain 24 walled towns, 950 villages, one duchy, and several principalities, earldoms, peerdoms, and baronies. The abbots in it are 27. For spiritual matters, the greater part of it is subject to the archbisho of Cambrai, and the rest to the bishop of Liege and Arras. The flates of the province consist of the clergy, nobility, and commoners. The clergy are the abbots, deputies of the chapters, and rural deans; but the chapters of St Waudru, and St Germain, in Mons, fend no deputies, as they contribute nothing to the public taxes. The nobility consists of the earls and barons, and all those who by their birth have a right to a seat in the assembly of the flates. The commoners are composed of the deputies of the towns. The clergy in this county are uncommonly rich. The flates meet only when they are summoned by the sovereign; but there is a standing committee at Mons which meet weekly. This county had counts of its own, till the year 1456; when Philip the Good, duke of Burgundy, arrived to the possession of it, upon the death of Jaqueline, the heiress, without issue. The French acquired that part of it which they possess, part by the peace of the Pyrenees, and partly by those of Nimeguen and Refwick. The arms of this county are quartered, and contain four lions, in a field or. For the government of it, there is a sovereign council, at the head of which is the high bailiff, who has very great authority; he represents the sovereign, is governor of Mons, and captain-general of the province.

Hair, small filaments issuing out of the pores of the skin of animals; and serving most of them as a tegument or covering*. In lieu of hair, the naked-nails of some animals is covered with feathers, wool, down, &c., &c.

Hair is found on all parts of the human body, except the soles of the feet and the palms of the hands. But it grows longest on the head, chin, breast, in the arm-pits, and about the privities.

The ancients held the hair a part of excrement, fed only with excrementitious matter, and no proper part of a living body. They supposed it generated of the filigious parts of the blood, exhaled by the heat of the body to the surface, and then condensed in passing through the pores. Their chief reasons were, that the hair being cut, will grow again space, even in extreme old age, and when life is very low; that in hectic and consumptive people, where the rest of the body is continually emaciating and attenuating, the hair shall thrive: nay, and that it will grow again in dead carcases. They added, that hair does not feed and grow like the other parts, by intraoeception, &c. by a juice circulating within it; but, like the nails, by juxtaposition, each part next the root, thrufing forward that immediately before it.

But the moderns are agreed, that every hair does properly and truly live, and receive nutriment to fill and dif tend it like the other parts, which they argue hence, that the roots do not turn grey in aged persons sooner than the extremities, but the whole changes colour at once, and the like is observed in boys, &c. which shows that there is a direct communication, and that all the parts are affected alike.

It may be observed, however, that, in propriety, the life and growth of hairs is of a different kind from that of the rest of the body; and is not immediately derived therefrom, or reciprocated therewith. It is rather of the nature of vegetation. They grow as plants do out of the earth; or as some plants shoot from the parts of others; from which though they draw their nourishment, yet each has, as it were, its several life and a distinct economy. They derive their food from some juices in the body, but not from the nutritious juices of the body, whence they may live, tho' the body be starved.—Wulterus, in the Philosophical Collections, gives an account of a woman buried at Nurnberg, whose grave being opened 43 years after her death, there was hair found issuing forth plentifully through the clefts of the coffin; insomuch that there was reason to imagine the coffin had some time been covered all over with hair. The cover being removed, the whole corpse appeared in its perfect shape; but, from the crown of the head to the sole of the foot, covered over with a thick-fet hair, long and curled. The fextion going to handle the upper part of the head with his fingers, the whole furniture fell at once, leaving nothing in his hand but a handful of hair; there was neither skull nor any other bone left; yet the hair was solid and strong enough.—Mr Arnold, in the same collection, gives a relation of a man hanged for theft, who, in a little while, while he yet hung upon the gallows, had his body strangely covered over with hair.

Some moderns, however, deny the authenticity of these and similar instances.

The hairs ordinarily appear round or cylindrical; but the microscope also discovers triangular and square ones; which diversity of figure arises from that of the pores, to which the hairs always accommodate themselves. Their length depends on the quantity of the proper humour to feed them, and their colour on the quality of that humour: whence, at different stages of life, the colour usually differs. Their extremities split into two or three branches, especially when kept dry, or suffered to grow too long; so that what appears only a single hair to the naked eye, seems a brush to the microscope.

The hair of a mouse, viewed by Mr Derham with a microscope, seemed to be one single transparent tube, with a pith made up of fibrous substances, running in dark lines, in some hairs transversely, in others spirally. The darker medullary parts or lines, he observes, were no other than small fibres convolved round, and lying closer together than in the other parts of the hair. They run from the bottom to the top of the hair; and he imagines may serve to make a gentle evacuation of some humour out of the body. Hence the hair of hairy animals, this author suggests, may not only serve as a fence against cold, &c. but as an organ of insensible perspiration.

Though the external surface of the body is the natural place for hairs, we have many well attested instances
The hair of both Jewish and Grecian women engaged a principal share of their attention, and the Roman ladies seem to have been no less curious with respect to theirs. They generally wore it long, and dressed it in a variety of ways, ornamenting it with gold, silver, pearls, &c. On the contrary, the men amongst the Greeks and Romans, and amongst the latter Jews, wore their hair short, as may be collected from books, medals, statues, &c. This formed a principal distinction in dress between the sexes. This observation illustrates a passage in St Paul’s epistle to the Corinthians (1 Cor. xi. 14, 15.)

St Paul forbids the Corinthian women, when praying by divine inspiration, to have their heads dishevelled; probably because this made them resemble the heathen priestesses, when actuated by the pretended influence of their gods.

Amongst the Greeks, both sexes, a few days before marriage, cut off and consecrated their hair as an offering to their favourite deities. It was also customary among them to hang the hair of the dead on the doors of their houses previous to interment. They likewise tore, cut off, and sometimes shaved their hair, when mourning for their deceased friends or relations, which they laid upon the corpse or threw into the pile, to be consumed together with the body. The ancients imagined that no person could die till a lock of hair was cut off; and this act they supposed was performed by the invisible hand of death, or Iris, or some other messenger of the gods. This hair, thus cut off, they fancied consecrated the person to the infernal deities, under whose jurisdiction the dead were supposed to be. It was a sort of frit fruits which sanctified the whole. (See Virg. Æn. 4. 694.)

Whatever was the fashion, with respect to the hair, in the Grecian states, slaves were forbidden to imitate the freemen. The hair of the slaves was always cut in a particular manner called ὑπὸ μετακόλασθος, which they no longer retained after they procured their freedom.

It was esteemed a notable honour among the ancient Gauls to have long hair, and hence came the appellation Gallia comata. For this reason Julius Cæsar, upon subduing the Gauls, made them cut off their hair as a token of submisision. — It was with a view to this, that such as afterwards quitted the world to go and live in clausures, procured their hair to be shaved off; to show that they bid adieu to all earthly ornaments, and made a vow of perpetual subjection to their superiors.

Greg. of Tours assures us, that in the royal family of France, it was a long time the peculiar mark and privilege of kings and princes of the blood to wear long hair, artfully dressed and curled; every body else was obliged to be polled, or cut round, in sign of inferiority and obedience. Some writers assure us, that there were different cuts for all the different qualities and conditions; from the prince, who wore it at full length, to the slave or villain, who was quite smooth.

To cut off the hair of a son of France, under the first race of kings, was to declare him excluded from the right of succeeding to the crown, and reduced to the condition of a subject.

In the eighth century, it was the custom of people of quality to have their children’s hair cut the first time by
by persons they had a particular honour and esteem for; who, in virtue of this ceremony, were reputed a sort of spiritual parents or godfathers thereof: Tho’ this practice appears to have been more ancient; inasmuch as we read, That Constantine sent the pope the hair of his son Heraclius, as a token that he desired him to be his adoptive father.

The parade of long hair became still more and more obnoxious in the progress of Christianity, as something utterly inconsistent with the profession of persons who bore the cross. Hence numerous injunctions and cautions to the contrary. —Pope Anicetus is commonly supposed to have been the first who forbade the clergy to wear long hair: but the prohibition is of an older standing in the churches of the east; and the letter wherein that decree is written, is of a much later date than that pope. —The clerical tonsure is related by Hilarus Episcopæus, as of apostolical institution.

Long hair was anciently held so odious, that there is a canon still extant of the year 1096, importing, that such as wore long hair should be excluded coming into church while living, and not to be prayed for when dead. We have a furious declamation of Luitprand against the emperor Phocas, for wearing long hair, after the manner of the other emperors of the east, all except Theophilus, who being bald, enjoined all his subjects to shave their heads.

The French historians and antiquaries have been very exact in recording the head of hair of their several kings. Charlemagne wore it very short, his son Charles the Bald had none at all. Under Hugh Capet it began to appear again; this the ecclesiastics took in dudgeon, and excommunicated all who let their hair grow. Peter Lombard expostulated the matter so warmly with Charles the Young, that he cut off his hair; and his successors for some generations wore it very short. —A professor of Utrecht, in 1650, wrote expressly on the question, Whether it be lawful for men to wear long hair? and concluded for the negative. —Another divine named Reves, who had written for the affirmative, replied to him.

The ancient Britons were extremely proud of the length of their hair, and were at much pains in dressing and adorning their heads. Some of them carried their tonsure for and admiration of their hair to an extravagant height. It is said to have been the last and most earnest request of a young warrior, who was taken prisoner and condemned to be beheaded; that no flave might be permitted to touch his hair, which was remarkably long and beautiful, and that it might not be stained with his blood. We hardly ever meet with the description of a fine woman or beautiful man, in the poems of Ossian, but the hair is mentioned as one of their greatest beauties. Not contented with the natural colour of their hair, which was commonly fair or yellow, they made use of certain waxes and gums to stain it still brighter. One of these waxes was a composition of lime, the ashes of certain vegetables, and tallow. They made use of various arts also to make the hair of their heads grow thick and long; which last was not only esteemed a great beauty, but was considered as a mark of dignity and noble birth. Boudiccia, queen of the Iceni, is described by Dio with very long hair, flowing over her shoulders, and reaching down below the middle of her back.

The Britons shaved all their beards, except their upper lips; the hair of which they, as well as the Gauls, allowed to grow to a very convenient length.

In after-times, the Anglo-Saxons and Danes also considered fine hair as one of the greatest beauties and ornaments of their persons, and were at no little pains in dressing it to advantage. Young ladies before marriage wore their hair uncovered and untipt, flowing in ringlets over their shoulders; but as soon as they were married, they cut it shorter, tied it up, and put on a head-dress of some kind or other according to the prevailing fashion. To have the hair entirely cut off was to great a disgrace, that it was one of the greatest punishments inflicted on those women who were guilty of adultery. The Danish soldiers who were quartered in the English, in the reign of Edgar the Peaceable and of Ethelred the Unready, were the beaux of those times, and were particularly attentive to the dressing of their hair; which they combed at least once every day, and thereby captivated the affections of the English ladies. The clergy, both secular and regular, were obliged to have the crowns of their heads, and keep their hair short, which distinguished them from the laity; and several canons were made against their concealing their tonsure, or allowing their hair to grow long. The shape of this clerical tonsure was the subject of long and violent debates between the English clergy on the one hand, and those of the Scots and Picts on the other; that of the former being circular, and that of the latter only semicircular. It appears very plainly, that long flowing hair was universally esteemed a great ornament; and the tonsure of the clergy was considered as an act of mortification, and self-denial, to which many of them submitted with reluctance, and endeavoured to conceal as much as possible. Some of them who affected the reputation of superior sanctity, inveighed with great bitterness against the long hair of the laity; and laboured earnestly to persuade them to cut it short, in imitation of the clergy. Thus the famous St. Wulfian bishop of Worcester, is said to have declaimed with great vehemence against luxury of all kinds, but chiefly against long hair as most criminal and most unchristian. The Earl of Warwick (says William of Malmesbury in his life of St. Wulfian) were very vicious in their manners, and plunged in luxury through the long peace which they had enjoyed in the reign of Edward the Confessor. The holy prelate Wulfian reproved the wicked of all ranks with great boldness, but he rebuked those with the greatest severity who were proud of their long hair. When any of those vain people bowed their heads before him to receive his blessing, before he gave it, he cut a lock of their hair with a little sharp knife, which he carried about him for that purpose; and commanded them, by way of penance for their sins, to cut all the rest of their hair in the same manner. If any of them refused to comply with this command, he regarded the most dreadful judgments upon them, reproached them for their effeminacy, and foretold, that as they imitated women in the length of their hair, they would imitate them in their cowardice, when their country was invaded; which was accomplished at the landing of the Normans."

This continued to be long a topic of declamation among the clergy, who even represented it as one of the
Hair may be changed from a red, grey, or other disagreeable colour, to a brown or deep black, by a solution of silver. The liquors sold under the name of hair waters, are at bottom no more than solutions of silver in aquafortis, largely diluted with water, with the addition perhaps of other ingredients, which contribute nothing to their efficacy. The solution should be fully saturated with the silver, that there may be no more acid in it than is necessary for holding the metal dissolved; and besides dilution with water, a little spirit of wine may be added for the further dilution of the acid. It must be observed, that for diluting the solution, distilled water, or pure rain-water, must be used; the common spring-waters turning it milky, and precipitating a part of the dissolved silver. It is to be observed also that if the liquor touches the skin, it has the same effect on it as on the matter to be stained, changing the part moistened with it to an indelible black.—Hair may be dyed of any colour in the same manner as wool. See Dyeing.

Hair which does not curl or buckle naturally is brought to it by art, by first boiling and then baking in the following manner: After having picked and forced the hair, and dipped it in parcels according to lengths, they roll them up and tie them tight down upon little cylindrical instruments, either of wood or earthen ware, a quarter of an inch thick, and hollowed a little in the middle, called pipes; in which fpace they are put in a pot over the fire, there to boil for about two hours. When taken out, they let them dry; and when dryed, they spread them on a sheet of brown paper, cover them with another, and thus tend them to the paffy cook; who making a crust or collin around them of common paste, sets them in an oven till the crust is about three-fourths baked. The end by which hair grew to the head is called the head of the hair; and the other, with which they begin to give the buckle, the point. Formerly the peruke-makers made no difference between the ends, but curled and waved them by either indifferently; but this made them unable to give a fine buckle; hair wov'n by the point never taking a right curl. Foreigners own themselves obliged to the English for this discovery, which was first carried abroad by a peruke-maker of that country.

Hair is also used in various other arts and manufactures.—In particular, the hair of the beavers, hares, co-}

Hairs, in farriery, is generally called the coat; and, with regard to horses, deserves particular consideration.

The hair growing on the fetlock serves as a defence to the prominent part of it in travelling in stoney ways or in frosty weather. If the hair of a horse's neck, and the parts most uncovered, be close, smooth, and sleek, it is an indication of his being in health and good case. In order to make the hair of an horse soft and sleek, he must be kept warm at heart, for the least inward cold will caufe the hair to tare; also sweat him often, for that will loosen and raise the dust and filth that renders his coat foul; and when he is in the heat of a sweat, scrape off all the white foam, sweat, and filth, that is raised up with an old sword-blade: and also when he is blooded, if you rub him all over with his front.
his own blood, repeating it two or three days, and carry and dress him well, it will make his coat shine as if covered with a fine varnish.

Hair falling from the mane or tail is caused either by his having taken some heat, which has engendered a dry maggot; or from some surfeit, which causes the evil humour to resort to those parts. To cure this, anoint the horse’s mane and crest with black soap; make a strong lace of aheres, and wash it all over with it. But if a canker should grow on a horse’s tail, which will eat away both flesh and bone; then put some oil of vitriol to it, and it will consume it; and if you find that the vitriol corrodes too much, you need only to wet it with cold water, and it will put a stop to it.

If you would take away hair from any part of a horse’s body, boil half a pound of lime in a quart of water, till one fourth part is consumed, to which add an ounce of opium; make this into a platter, and lay it on.

Hair, or Down, of plants; a general term expressive of all the hairy and glandular appearances on the surface of plants, to which they are supplied by naturalists to serve the double purpose of defensive weapons and vessels of secretion.

These hairs are minute threads of greater or less length and solidity; some of them visible to the naked eye; whilst others are rendered visible only by the help of glases. Examined by a microscope, almost all the parts of plants, particularly the young flasks or stems, appear covered with hairs.

Hairs on the surface of plants present themselves under various forms; in the leguminous plants they are generally cylindrical; in the mallow tribe, terminated in a point; in agrimony, shaped like fish-hook; in nettle, awl-shaped and jointed; and in some compound flowers with hollow or funnel-shaped florets, they are terminated in two crooked points.

Probable as some experiments have rendered it, that the hairs on the surface of plants contribute to some organical secretion, their principal use seems to be to preserve the parts in which they are lodged from the bad effects of violent frictions, from winds, from extremes of heat and cold, and such like external injuries.

M. Guettard, who has established a botanical method from the form, situation, and other circumstances of the hairy and glandular appearances on the surface of plants, has demonstrated, that these appearances are generally confant and uniform in all the plants of the same genus. The same uniformity seems to characterise all the different genera of the same natural order.

The different forms of hairs which form the down upon the surface of plants were imperfectly distinguished by Grew in 1682, and by Malpighi in 1686. M. Guettard just mentioned was the first who examined the subject both as a botanist and a philospher. His observations were published in 1747.

Hair-Cloth, in military affairs, are large pieces of cloth made with half hair. They are used for covering the powder in waggons, or upon batteries; as also for covering charged bombs or hand-grenades, and many other uses in magazines.

Hair-Powder. See STARCH.
Hair-Worm. See GORDIU.

HAKE, in ichthyology, the English name of a fish common in the English and some other seas, and called by authors the muliceps and lucius marius. This fish was used of old dried and salted. Hence the proverb obtains in Kent, As dry as a bake.

HAKLUYT (Richard), a naval historian, is supposed to have been born in London, about the year 1533, and defended of a genteel family in Herefordshire, as the name frequently occurs in the lift of high sheriffs for that county in former reigns. He was educated at Westminster-school; and thence, in 1570, removed to Christchurch, Oxford; where he applied himself particularly to the study of cosmography, and read public lectures in that science. Sir Edward Stafford being sent ambassador to France in 1585, Mr Hakluyt was one of his attendants, probably in the capacity of chaplain. He was at this time master of arts and professor of divinity. In 1585 he obtained the royal mandate for the next vacant prebend of Bristol to which prebend he succeeded during his residence at Paris. Conspicuous for his favourite cosmographical inquiries, in searching the French libraries, he found a valuable history of Florida, which had been discovered about 20 years before by Captain Laudumine and others; thence he caused to be published at his own expense, in the French language, and soon after revised and republished Peter Martyr’s book De orbis Novo. After five years residence in France, Mr Hakluyt returned to England in company with lady Shefield, sister to the lord admiral Howard. In the year 1589 he published his collection of Voyages in one folio volume, which in 1598 was republished in three. In 1605 our author was made prebendary of Westminster; which, with the Rectory of Wetheringsett in the county of Suffolk, seems to have been the summit of his preferment. He died in 1616, and was buried in Westminster-abbey: bequeathing to his son Edmund his manor of Bridge Place, and several houses in Tothill Street, Westminster. He was an indefatigable and faithful historian. His works are, 1. A Collection of Voyages and Discoveries, a small volume. 2. History of Florida, abovementioned. 3. The principal Navigations, Voyages, and Discoveries of the English Nation, made by Sea or over Land to the farthest distant quarter of the Earth, at any time within the compass of these 1500 years, in three vols folio. 4. The Discoveries of the World, from the first Original to the Year 1555, written in the Portuguese tongue by Ant. Galvano; corrected, much amended, and translated into English, by Richard Hakluyt.

Virginia richly valued, by the Description of the Main Land of Florida, her next neighbour, &c. written by a Portugal gentleman of Elvas, and translated by Richard Hakluyt. Besides these, he left several manuscripts, which were printed in Purchas’s collection.

HALBERSTADT, a small principality of Germany, bounded on the north-east by the duchy of Magdeburg, on the south by the principality of Anhalt, on the west by the diocese of Hildenheim, on the east by part of the electorate of Saxony, and on the north by Brunswic Wolfenbuttle. It is near 40 miles in length and 30 in breadth. The soil in general is fertile in corn and flax; and there are some woods, though in general soil is barren. There are three large towns in it which send representatives to the diet, together with 10 small ones, and 91 country-towns and villages.
HALBERT or HALBARD, in the art of war, a well-known weapon carried by the ferrymen of foot and dragoons. It is a sort of spear, the shaft of which is about five feet long, and made of ash or other wood. Its head is armed with a steel point, not unlike the point of a two-edged sword. Besides this sharp point which is in a line with the shaft, there is a cross piece of steel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent sharp point at the other; so that it serves equally to cut down or to pull withal. It is also useful in determining the ground between the ranks, and adjoining the files of a battalion. The word is formed of the German hal, "hall," and bard, "an hatchet." Voëlius derives it from the German halbe, of hel, "clara, splendens," and baert, "ax.

The halbert was anciently a common weapon in the army, where there were companies of halbardiens. It is said to have been used by the Amazons, and afterwards by the Rhétzians and Vindelicians about the year 526.

It was called the Danisf ax, because the Danes bore an halberd on the left shoulder. From the Danes it was derived to the Scots, from the Scots to the English Saxons, and from them to the French.

HALCYON, in ornithology, a name given by the ancients to the alcedo or king's fisher. See Alcedo.

HALCYON DAYS, in antiquity, a name given to seven days before and as many after the winter solstice; by reason the halcyon, invited by the calmness of the weather, laid its eggs in nests built in the rocks, close by the brink of the sea, at this season.

HALDE (John Baptif du), a learned French Jesuit, born at Paris in 1674. He was extremely well versed in Asiatic geography; and he have of his compilation a work intitled Grand Description de la Chine & de la Tartarie, from original memoirs of the Jesuitical missionaries, in 4 vols folio. He was also concerned in a collection of letters begun by father Gobien, called Des lettres edifiantes, in 18 vols; and published some Latin poems and orations. He died in 1743.

Vol. VIII.
HAL

not suffer the trial to go on till he had paid him for his buck." The gentleman answered, that "he never fold his venison; and that he had done nothing to him which he did not do to every judge who had gone that circuit:" which was confirmed by several gentlemen present. The lord chief baron, however, would not suffer the trial to proceed till he had paid for the present; upon which the gentleman withdrew the record. In short, he was in 1671 advanced to be lord chief justice of the king's bench; but about four years after this promotion, his health declining, he resigned his post in February 1675-6, and died in December following. This excellent man, who was an ornament to the bench, to his country, and to human nature, wrote, 1. An Essay on the Gravitation and Non-gravitation of Fluid Bodies. 2. Observations touching the Torricellian Experiment. 3. Contemplations, moral and divine. 4. The Life of Pomponius Atticus, with political and moral Reflections. 5. Observations on the Principles of Natural Motion. 6. The primitive Origin of Mankind. He also left a great number of manuscripts in Latin and English, upon various subjects; among which are his pleas of the Crown, since published by Mr Emlyn in two volumes folio; and his Original Inmutation, Power, and Jurisdiction of Parliaments.

Hales (Stephen), D. D. a celebrated divine and philosopher was born in 1672. He was the sixth son of Thomas Hales, Esq; the eldest son of Sir Robert Hales, created a baronet by king Charles H. and Mary the heirs of Richard Langley of Abbots-Wood in Hertfordshire. In 1696 he was entered a pensioneer at Bensett-college, Cambridge; and was admitted a fellow in 1703, and became bachelor of divinity in 1711. He soon discovered a genius for natural philosophy. Botany was his first study; and he used frequently to make excursions among Gogmagog hills, Flesh, and other substances. This work, which contained many useful instructions for voyagers, was dedicated to the lords of the admiralty. The same year he exhibited to the Royal Society an account of some further experiments towards the discovery of medicines for dissolving the stone in the kidneys and bladder, and preferring meat in long voyages; for which he received the gold medal of Sir Godfrey Copley's donation. The year following he published some account of Experiments and Observations on Mr Stephen's Medicines for dissolving the stone, on which their disSolvent power is inquired into and demonstrated.

In 1741 he read before the Royal Society an account of an instrument which he invented, and called a ventilator, for conveying fresh air into mines, hospitals, prisons, and the close parts of ships; he had communicated it to his particular friends some months before; and it is very remarkable, that a machine of the same kind, for the same purpose, was in the spring of the same year invented by one Martin Triewald, an officer in the service of the king of Sweden, called captain of mechanics, for which the king and senate granted him a privilege in October following, and ordered every ship of war in the service of that state to be furnished with one of them; a model also of this machine was sent into France, and all the ships in the French navy were also ordered to have a ventilator of the same fort. It happened also, that about the same time one Sutton, who kept a coffee-house in Aldergate-street,
H a l

H a l

inventor of another contrivance to draw off the foul air out of ships by means of the cook-room fire: but poor Sutton had not interest enough to make mankind accept the benefit he offered them; tho' its superiority to Dr Hales's contrivance was evident, and among others, Dr Mead and the late ingenious Mr Benjamin Robins gave their testimony in its favour: (See An-Pipes.) The public, however, is never indebted to the ingenuity and benevolence of Dr Hales, whose ventilators came more easily into use for many purposes of the greatest importance to life, particularly for keeping corn sweet, by blowing through it fresh flowers of air; a practice very soon adopted by France, a large granary having been made, under the direction of Duhamel, for the preservation of corn in this manner, with a view to make it a general practice.

In 1743, Dr Hales read before the Royal Society a description of a method of conveying liquors into the abdomen during the operation of tapping, and it was afterwards printed in their Transactions. In 1745, he published some experiments and observations on tar-water, which he had been induced to make by the publication of a work called Siris, in which the late learned and most excellent Dr Berkley, bishop of Cloyne, had recommended tar-water as an universal medicine: on this occasion several letters passed between them on the subject, particularly with respect to the use of tar-water in the disease of the horned cattle. In the same year he communicated to the public, by a letter to the editor of the Gentleman's Magazine, a description of a back-heaver, which will winnow and clean corn much sooner and better than can be done by the common method. He also, at the same time, and by the same channel, communicated to the public a cheap and easy way to preserve corn sweet in sacks; an invention of great benefit to farmers, especially to poor leavers, who want to keep small quantities of corn for sometime, but have no proper granary or repository for that purpose. He also the same year took the fame method to publish directions how to keep corn sweet in heaps without turning it, and to sweeten it when musty. He published a long paper, containing an account of several methods to preserve corn by ventilators, with a particular description of several forts of ventilators, illustrated by a cut, so that the whole mechanism of them may be easily known, and the machine constructed by a common carpenter. He published also in the same volume, but without his name, a detection of the fallacious boasts concerning the efficacy of the liquid shell in dissolving the stone in the bladder. In 1746 he communicated to the Royal Society a proposal for bringing small passable fomes soon, and with ease, out of the bladder; and this was also printed in their Transactions. In the Gentleman's Magazine for July 1747, he published an account of a very considerable improvement of his back-heaver, by which it became capable of clearing corn of the very small grain, seeds, blacks, smut-balls, &c. to such perfection as to make it fit for seed-corn. In 1748 he communicated to the Royal Society a proposal for checking, in some degree, the progres of fires, occasioned by the great fire which happened that year in Cornhill: And the substance of this proposal was printed in their Transactions. In the same year he also communicated to the Society two memoirs, which are printed in their Transactions; one on the great benefit of ventilators, and the other on some experiments in electricity. In 1749 his ventilators were fixed in the Savoy prifon, by order of the right hon. Henry Fox, Esq.; then secretary at war, afterwards lord Holland; and the benefit was so great, that though 50 or 100 in a year often died of the jail-diffemp, before, yet from the year 1749 to the year 1752 inclusive, no more than four persons died, though in the year 1750 the number of prisoners was 240; and of those four, one died of the small-pox, and another of intemperance. In the year 1750 he published some considerations on the causes of earthquakes; occasioned by the flight shocks felt that year in London. The substance of this work was also printed in the Philosophical Transactions. The same year he exhibited an examination of the strength of several purging waters, especially of the water of Jeffer's Well, which is printed in the Philosophical Transactions.

Dr Hales had now been several years honoured with the esteem and friendship of his royal highnesses Frederick prince of Wales; who frequently visited him at Teddington, from his neighbouring palace at Kew, and took a pleasure in surprizing him in the midst of those curious researches into the various parts of nature which almost incessantly employed him. Upon the prince's death, which happened this year, and the settlement of the household of the princes-dowager, he was, without his solicitation, or even knowledge, appointed clerk of the closet or almoner to her royal highnesses. In 1751 he was chosen by the college of physicians to preach the annual sermon called Crowne's lecture: Dr William Crowne having left a legacy for a sermon to be annually preached on "the wildom and goodness of God displayed in the formation of man." Dr Hales's text was, With the ancient is wisdom, and in length of days understanding. Job xii. 12. This sermon, as usual, was published at the request of the college. In the latter end of the year 1752, his ventilators, worked by a windmill, were fixed in Newgate, with branching trunks to 24 wards; and it appeared that the disproportion of those that died in the gaol before and after this establishment was 100 to 25. He also published alio a farther account of their successes, and some observations on the great danger arising from foul air, exemplified by a narrative of several persons seized with the gaol-fever by working in Newgate.

On the death of Hans Sloane, which happened in the year 1753, Dr Hales was elected a member of the Academy of Sciences at Paris in his room. The same year the published in the Gentleman's Magazine some farther considerations about means to draw the foul air out of the sick rooms of occasional army-hospitals, and private houses in town. He also published many other curious particulars relative to the use and success of ventilators. The same year a description of a sea-gage, which the doctor invented to measure unfathomable depths, was communicated to the public in the same miscellany: this paper was drawn up about the year 1732 or 1733, by the doctor, for the late Col. Campbell, Esq.; who employed the ingenious Mr Hawkglue to make the machine it describes, which was tried in various depths, and answered with great exactness,
H A L  [ 2 7 6 ]  H A L

Hales, yet was at last lost near Bermuda. In 1754, he communicated to the Royal Society some experiments for keeping water and fish sweet with lime-water, an account of which was published in the Philosophical Transactions. He also continued to enrich their memoirs with many useful articles from this time till his death, particularly a method of forwarding the distillation of water by blowing hot air up through the latter during the operation. In 1777 he communicated to the editor of the Gentleman's Magazine an easy method of purifying the air, and regulating its heat in melon-frames and green-houses; also further improvements in his method of distilling sea-water.

His reputation and the interest of his family and friends might causily have procured him farther preferment; but of farther preferment he was not deserving; for being nominated by his late Majesty to a canonry of Windsor, he engaged his princely patron to recollect his nomination. That a man so devoted to philosophical studies and employments, and so conscientious in the discharge of his duties, should not desire any preferment which would reduce him to the dilemma either of neglecting his duty, or foregoing his amulemen, is not strange; but that he would refuse an honourable and profitable appointment, for which no duty was to be done that would interrupt his habits of life, can scarce be imputed to his temperance and humility without impeaching his benevolence; for if he had no wish of any thing more for himself, a liberal mind would surely have been highly gratified by the distribution of so considerable a sum as a canonry of Windsor would have put into his power, in the reward of industri, the alleviation of distress, and the support of helpless indigence. He was, however, remarkable for social virtue and sweetmeats of temper; his life was not only blameless, but exemplary in a high degree; he was happy in himself, and beneficial to others, as appears by this account of his attainments and pursuits; the constant serenity and cheerfulness of his mind, and the temperance and regularity of his life, concurred, with a good constitution, to preserve him in health and vigour to the uncommon age of four-score and four years. He died at Teddington in 1761; and was buried, pursuant to his own directions, under the tower of the parish-church, which he built at his own expense not long before his death. — Her royal highness the princess of Wales erected a monument to his memory in Westminster abbey.

HALESIA, in botany: A genus of the monogynous order, belonging to the dodecandria class of plants; and in the natural method ranking under the 18th order, Bisexuales. The calyx is quadridentate, superior; the corolla, quadrifid; the nut quadrangular and pennis.ous.

HALESWORTH, a town of Suffolk in England, seated on a neck of land between two branches of the river Blith, 101 miles from London. It is a well frequented thriving place, and has a trade in linen yarn and sailcloth. It has one large church, and about 300 good houses, but the freestone is neither wide nor power enough; the town is raised a great deal of hemp, &c. Long. 1 40. N. Lat. 52. 30. 

HALF-BLOOD, in law, is where a man marries a second wife, the first being dead, and by the first venter he has a son, and by his second venter has like wise a son; the two brothers, in this case, are of half-blood. See Consanguinity and Descent.

HALF-MERK; a noble, or 6s. 8d. 

HALF-MOON, in fortification; an outwork composed of two faces, forming a slight angle, whose gorge is in form of a crescent or half-moon, whence the name.

HALFPENNY, a copper coin, whose value is expressed by its name, in reference to the penny.

HALI-BEIGH, first dragoon or interpreter at the Grand Signior's court in the 17th century, was born of Christian parents in Poland; but having been taken by the Tartars when he was young, they sold him to the Turks, who brought him up in their religion in the feraglio. His name, in his native country, was Bobownik. He learnt many languages, and Sir Paul Ricaut owns he was indebted to him for several things which he relates in his Present state of the Ottoman empire. He held a great correspondence with the English, who persuaded him to translate some books in the Turkish language, and had him sent back to the bosom of the Christian church, but died before he could accomplish the design. Dr Hyde published his book Of the liturgy of the Turks, their pilgrimages to Mecca, their circumcision and visiting of the sick. He translated the catechism of the church of England, and the bible, into the Turkish language. The MS. is lodged in the library of Leyden. He wrote like wise a Turkish grammar and dictionary.

HALICARNASSUS, (anc. geog.) a principal town of Caria, said to be built by the Argives, and situated between two bays, the Ceramicus and Jaxius. It was the royal residence, (called Zephyr's formerly); especially of Mausolus, who made more illustrious by his monument. This monument was one of the seven wonders, and erected by Artemisia. Halicarnassus, or Halicarnassitis, was the gentilicious name of Herodotus and Dionysius. The former was called the Father of History; and the latter was not only a good historian but also a critic.

HALIEUTICS, HALIETICA ALETTICA, formed of aniet, fisherman, which is derived from an; sea; books treating of fishes, or the art of fishing.—We have still extant the halieutics of Opian.

HALIFAX, the capital of the province of Nova Scotia in America, situated in W. Long. 64. 30. N. Lat. 44. 45. It was founded in 1749, in order to secure the British settlements there from the attempts of the French and Indians. It was divided into 35 squares, each containing 16 lots of 40 by 60 feet; one established church, and one meeting-house, and a small number of houses out of the regular streets. The town was surrounded by pickettngs, and guarded by forts on the outside; but since the commencement of the American troubles, it has been very strongly fortified. Along the river Chebucto, to the southward of the town, are buildings and fish-flakes for at least two miles, and to the northward on the river for about one mile. The plan, however, has been greatly improved by the Earl of Halifax, who was the original writer. The proclamation issued for this settlement, offered 50 acres of land to every soldier and sailor who would settle in that part...
Halifax, part of America, without paying any rent, or doing any service for ten years; and no more than one shilling per annum for each 50 acres ever afterwards: to every soldier and tailor who had a wife and children, ten acres more were added to every individual of his family, and for every increase that should afterwards happen in the same proportion: To each subaltern officer 80 acres, and 15 for each of his family; 200 acres to each ensign; 500 to each lieutenant; 400 to each captain; 600 to every officer in rank above a captain, and 30 for each of his family. The government also engaged to transport and maintain the new setters for one year at its own expense, and to furnish them with such arms, provisions, utensils, implements, &c. as should be necessary to put them in a way to cultivate their lands, to build habitations, and to commence a fishery. The same conditions were likewise offered to all carpenters and other handicraftsmen; and surgeons were offered the same conditions with the ensigns.—This proclamation was published in March and by the month of May 27,000 persons had embarked themselves. They accordingly embarked, and established themselves in the bay of Chebucto; calling their city Halifax from the title of their patron. Before the end of October the same year, 350 comfortable wooden houses were built, and as many more during the winter.—The same year in which the settlers embarked, the government granted them 40,000 acres for their expenses. In 1750, they granted 57,582; 1751, 35; for the same purpose; in 1752, 53,927; 1755, 148,461; in 1752, 61,492; 1751, 203,451; in 1753, 94,615; 1754, 38,447; 1755, 40,018, 76, 68.—The place has at length attained a degree of splendor beyond what might have been expected; for which it has been equally indebted to the late war, to the great increase of population from the exiled loyalists, and the fostering care of Great Britain; inomuch, that the number of inhabitants has been more than doubled during the last ten years.

The harbour is perfectly sheltered from all winds at the distance of 12 miles from the sea, and is so spacious, that a thousand full of ships may ride in it without any apprehension. Upon the beach are built a number of commodious wharfs, which have from 12 to 18 feet water at all times of the tide, for the convenience of loading and unloading ships. The streets of the town are regularly laid out, and crofs each other at right angles; the whole riding gradually from the water upon the side of a hill, whose top is regularly fortified, but not so as to be able to withstand a regular attack. Many considerable merchants reside at this place, and are possessed of shipping to the amount of several thousand tons, employed in a flourishing trade both with Europe and the West Indies. There is a small but excellent carreling yard for ships of the British navy that are upon this station, or that may have occasion to come in to refit, and take water, fuel, or fresh provisions on board, in their passage to and from the West Indies. It is always kept well provided with naval stores; and ships of the line are hove down and repaired with the greatest care and safety. Several batteries of heavy cannon command the harbour, particularly those that are placed upon George's Island, which being very steep and high, and situated in mid-channel, a little way below the town is well calculated to annoy vessels in any direction, as they must of necessity pass very near it before they are capable of doing any mischief. Above the carreling yard, which is at the upper end of the town, there is a large basin or piece of water, communicating with the harbour below, near 20 miles in circumference, and capable of containing the whole navy of England, entirely sheltered from all winds, and having only one narrow entrance, which, as we observed before, leads into the harbour. There are a number of detached settlements lately formed by the loyalists upon the basin; the lands at a small distance from the water being generally thought better than those near to Halifax; but what success may attend their labours, will require some time to determine. An elegant and convenient building has been erected near the town for the convalescents of the navy; but the healthiness of the climate, has as yet prevented many persons from becoming patients, scarcely any ships in the world being so free from complaint of every kind; as those that are employed upon this station. There is a very fine light-house, standing upon a small island, just off the entrance of the harbour, which is visible, either by night or day, six or seven leagues off at sea.

Halifax, earl of. See Savile.

Halifax, a town in the west riding of Yorkshire in England, seated on the river Calder, in W. Long. 2°. N. Lat. 55°. 45. It has the title of an earldom, and is very eminent for the clothier trade. The parish is said to be the most populous, if not the most extensive, in England: for it is above 30 miles in circumference; and, besides the mother church at Halifax, and 16 meeting-houses, has 12 chapels, 1,000 of which are parochial. What is a little singular, all the meeting-houses here, except the quakers, have bells and burying-grounds. The woollens principally manufactured here are kerseys and shawls. Of the former it is affirmed, that one dealer hath sent by commission 60,000 pounds worth in a year to Holland and Hamburg; and of the latter, it is said, 100,000 pieces are made in this parish yearly. The inhabitants here and in the neighbouring towns are so entirely employed in woollen manufactures, that agriculture is but little minded. Most of their provisions of all sorts are brought from the north and east riding, and from Lancashire, Cheshire, Nottinghamshire, and Warwickshire. The markets are very much crowded for the buying and selling provisions and manufactures. The cloths, at the first erection of the woollen manufactures in these parts, having been frequently stolen off the tenters in the night, a law was made, by which the magistrates of Halifax were empowered to pass sentence on, and execute all offenders, if they were taken in the fact, or owned it, or if the stolen cloth was found upon them, provided also the crime was committed, and the criminal apprehended, within the liberties of the forest of Hardwick. Those found guilty were executed in the following manner: an axe was drawn by a pully to the top of a wooden engine, and fastened by a pin, which being pulled out, the axe fell down in an infiant, and did its work. If they had stole an ox, horse, or any other beast, it was led with them to the scaffold, and there fastened by a chord to the pin, that held up the axe; and when the signal was given...
given by the jurors, who were the first burgheins within the several towns of the forest, the beast was driven away, and the pin plucked out, upon which the axe fell and did its office. This severe and summary course of justice gave occasion to a litany, which is still more frequent in the mouths of the beggars and vagrants of these parts, than is the common prayer, viz.

"From hell, hell, and Halifax, good Lord deliver us," though neither the engine, nor manner of proceeding against them, are now in use.

HALIOTIS, the ear-shell, a genus of infects belonging to the order of vermes testacea. This is an animal of the snail-kind, with an open shell resembling an ear. There are seven species, distinguished by the figure of their shells. See Plate CXXXIV.

HALTZ, a town of Poland, and capital of a territory of the same name, in Red Russia, in the territory of the Baltic Sea, and opposite to Jutland. It contains a fine hour of a fine house and palace. Vitruvius mentions three kinds of halls: the rectangular, with four columns supporting the platform or ceiling; the Corinthian, with columns all round let into the wall, and vaulted over; and the Egyptian, which had a peristyle of inflated Corinthian columns, bearing a second order with a ceiling.

The hall is properly the finest as well as first member of an apartment: and in the houses of ministers of state, magnificates, &c. is the place where they dispatch business, and give audience. In very magnificent buildings, where the hall is larger and loftier than ordinary, and placed in the middle of the house, it is called a saloon.

The length of a hall should be at least twice and a quarter its breadth; and in great buildings, three times its breadth. As to the height of halls, it may be two-thirds of the breadth; and, if made with an arched ceiling, it will be much handier, and less liable to accidents by fire. In this case, its height is found by dividing its breadth into five parts, five of which will be the height from the floor to the under side of the key of the arch.

Hall is also particularly used for a court of justice; or an edifice wherein there is one or more tribunals.

In Westminster-hall are held the great courts of England, viz. the king's bench, chancery, common pleas, and exchequer. In adjoining apartments is likewise held the high court of parliament.

Westminster-hall was the royal palace or place of residence of ancient British kings; who ordinarily held their parliaments, and courts of judicature, in their dwelling-houses (as is still done by the kings of Spain), and frequently sat in person in the courts of judicature, as they still do in parliament. A great part of this palace was burnt under Henry VIII. what remains is still reserved for the said judicatures. The great hall, where the courts of the king's bench, &c. are kept, is said to have been built by William Rufus; others say by Richard I. or II. It is reckoned superior in point of dimensions, to any hall in Europe; being 300 feet long and 100 broad.

Hall (Joseph), an eminent prelate of the church of England, was born in 1574, and educated at Cambridge. He became professor of rhetoric in that university, and then successively was made rector of Halifax in Suffolk, prefected to the living of Waltham in Essex, made prebendary of Wolverhampton, dean of Worcester, bishop of Exeter, and lastly of Norwich. His works testify his zeal against Popery, and are much esteemed. He lamented the divisions of the Protestants, and wrote something concerning the means of putting an end to them. July 1616, he attended the embassy of lord Doncaster into France, and upon his return was appointed by his majesty to be one of the divines, who should attend him into Scotland. In 1618 he was sent to the synod of Dort with other divines, and pitched upon to preach a Latin sermon before that assembly. But being obliged to return from thence before the synod broke up, on account of his health, he was by the states presented with a gold medal. He wrote, 1. Miscellaneous epistles. 2. Mundus alter et idem. 3. A just cenure of travellers. 4. The Christian Seneca. 5. Satires, in five books. A century of meditations; and many other works, which besides the above farti, make in all five volumes in folio and quarto. He died in 1656.

Hall (John), a poet of distinguished learning, was born at Durham, and educated at Cambridge, where he was esteemed the brightest genius in that university. In 1646, when he was but 19 years of age, he published his Horae Vaticae, or Essays; and the same year came out his poems. He translated from the Greek Hierocles upon the golden verses of Pythagoras; before which is an account of the ingenious translator and his works, by John Davies of Kidwelly. He died in 1656, aged 29.

HALLAGE, a fee or toll paid for cloth brought to be sold in Blackwell-hall, London.

HALLAMAS, in old English writers, the day of all-hallows, or all-faints, viz. November 1. It is one of the cross quarters of the year which was computed, in ancient writings, from Hallamas to Candlemas.

HALLAND, a country of Sweden, in the island of Schonen, lying along the sea-coast, at the entrance of the Baltic Sea, and opposite to Jutland. It is 60 miles along the coast, but is not above 12 in breadth. Hallstadt is the capital town.

HALLATON, a town of Leicestershire, in England. It is seated on a rich soil, 12 miles south-east of Leices ter, in E. Long. 0. 50. N. Lat. 52 35. 40.

HALLE, a little dimpstoned town of the Austrian Netherlands, in Hainault. The church of Notre Dame contains an image of the Virgin Mary, held in great veneration. E. Long. 2. 15. N. Lat. 50. 44. 50.

Halle, a handsome and considerable town of Germany, in the circle of Upper Saxony, and in the duchy of Magdeburg, with a famous university and falt-works. It belongs to the king of Prussia; and is seated in a pleasant plain on the river Sdle, in E. Long. 12. 23. N. Lat. 51. 36.

Halle, a free and imperial town of Germany, in Slesvia, famous for its falt-pits. It is seated on the river Kocher, among rocks and mountains, in E. Long. 10. 50. N. Lat. 49 49.

HALLEIN, a town of Germany, in the circle of Bavaria, and archbishopric of Salzburg; seated on the
HAL

Hallelujah, the river Salza, among the mountains, wherein are
mines of salt, which are the chief riches of the town
and country. E. Long. 12. 15. N. Lat. 47. 32.

Hallelujah, a term of rejoicing, sometimes
sung or reheard at the end of verses on such occasions.
The word is Hebrew; or rather, it is two Hebrew
words joined together; one of them yah, hallelu, and
the other m yah; an abridgment of the name of God,
who is Jehovah. The first signifies laudare, "praise ye," and
the other, Dominum, "the Lord."

St. Jerome first introduced the word hallelujah into
the church service; for a considerable time it was only
used once a year in the Latin church, viz. at Easter:
but in the Greek church it was much more frequent.
St. Jerome mentions its being sung at the interments
of the dead, which still continues to be done in that
city, as also on some occasions in the time of Lent.

In the time of Gregory the Great, it was appointed
to be sung all the year round in the Latin church,
which raised some complaints against that pope, as
providing too much into the Greek way, and introducing
the ceremonies of the church of Constantinople into
that of Rome. But he excused himself by alleging,
that this had been the ancient usage of Rome; and
that it had been brought from Constantinople at
the time when the word hallelujah was first introduced un-
der pope Damascus.

HALLER (Albert Van), an eminent physician,
was born at Bern, on the 16th of October 1708. He
was the son of an advocate of considerable eminence
in his profession. His father had a numerous family,
and Albert was the youngest of five sons. From the
first period of his education, he showed a very great
genius for literature of every kind; to forward the
progress of his studies, his father took into his family
a private tutor, named Abraham Billodz; and such was
the discipline exerted by this pedagogue, that the accidental
light of him, at any future period of life, excited in Haller very great uneasiness, and renewed all
his former terrors. According to the accounts which
are given us, the progress of Haller's studies, at the
earliest periods of his life was rapid almost beyond belief.
When other children were beginning only to read, he
was studying Bayle and Moreri: and at nine years of
age he was able to translate Greek, and was beginning
the study of Hebrew. Not long after this, however, the
course of his education was somewhat interrupted
by the death of his father; an event which happened
when he was in the 13th year of his age. After this
he was sent to the public school at Bern, where he ex-
hibited many specimens of early and uncommon genius.
He was distinguished for his knowledge in the Greek
and Latin languages; but he was chiefly remarkable
for his poetical genius; and his essays of this kind,
which were published in the German language, were
read and admired throughout the whole empire. In the
26th year of his age he began the study of medicine
at Tubingen, under those eminent teachers Duvernoy
and Camerarius, and continued there for the space of
two years, when the great reputation of the jolly cele-
brate Boerhave drew him to Leyden. Nor was this
distinguished teacher the only man from whose su-
premier abilities he had there an opportunity of profi-
ing. Ruych was still alive, and Albinus was rising
into fame. Animated by such examples, he spent all
the day, and the greatest part of the night, in the most
intense study; and the proficiency which he made,
gained him universal esteem both from his teachers and
fellow students. From Holland, in the year 1727, he
came to England. There, however, his stay was but
short; and it was rather his intention to visit the illu-
trious men of that period, than to prosecute his stu-
dies at London. He formed connections with some of
the most eminent of them. He was honored with the
friendship of Douglas and Cheifelden; and he met with
a reception proportioned to his merit from Sir Hans
Sloane, president of the Royal Society. After his vif-
fit to Britain, he went to France; and there, under
the latter of whom he resided during his stay in Paris,
he had opportunities of prosecuting anatomy, which
he had not before enjoyed. But the zeal of our young
anatomist was greater than the prejudices of the people
at that period, even in the enlightened city of Paris,
could admit of. An information being lodged against
him to the police for defecring dead bodies, he was
obliged to cut short his anatomical investigations by a
precipitate retreat. Still, however, intent on the farther
prosecution of his studies, he went to Basil, where he
became a pupil to the celebrated Bernoulli.

Thus improved and instructed by the lectures of the
most distinguished teachers of that period, by uncom-
non natural abilities, and by unremitting industry, he
returned to the place of his nativity in the 26th year
of his age. Not long after this, he offered himself as a
candidate, first for the office of physician to an hospital,
and afterwards for a professorship. But neither the cha-
acter which he had before he left his native country,
nor the fame which he had acquired, and supported
while abroad, were sufficient to combat the interest op-
posed to him. He was disappointed in both; and it
was even with difficulty that he obtained, in the fol-
lowing year, the appointment of keeper of a public
library at Bern. The exercise of this office was indeed
by no means limited to his great abilities: but it was
agreeable to him, as it afforded him an opportunity
for that extensive reading by which he has been so judi-
ciously distinguished. The neglect of his merit which marked
his first outfit, neither diminished his ardour for medi-
cal pursuits, nor detracted from his reputation either
at home or abroad. And soon after he was nominated
a professor in the university of Gottingen, by King
George II. The duties of this important office he dis-
charged, with no less honour to himself than advantage
to the public, for the space of 17 years; and it afforded
him an ample field for the exertion of those great talents
which he possessed. Extensively acquainted with the
sentiments of others respecting the economy of the
human body, struck with the diversity of opinions
which they held, and sensible that the only means of
investigating truth was by careful and candid exper-
iments, he undertook the arduous task of exploring the
phenomena of human nature from the original source.
In these pursuits he was no less industrious than suc-
cessful, and there was hardly any function of the body
on which his experiments did not reflect either a new or a
stronger light. Nor was it long necessary for him, in

HALLERIA (Dr Edmund), an eminent astronomer, was the only son of a soap-boiler in London, and was born in 1656. He first applied himself to the study of the languages and sciences, but at length gave himself up wholly to that of astronomy. In 1676 he went to the island of St Helena to complete the catalogue of fixed stars, by the addition of those which lie near the south pole; and having delineated a planisphere in which he laid them all down in their exact places, he returned to England in 1678. In the year 1680 he took what is called the grand tour, accompanied by his friend the celebrated Mr Nellon. In the midway between Calais and Paris, Mr Halley had a sight of a remarkable comet, as it then appeared a second time that year, in its return from the sun. He had the November before seen it in its descent; and now hastened to complete his observations upon it, in viewing it from the royal observatory of France. His design in this part of his tour was, to settle a friendly correspondence between the two royal astronomers of Greenwich and Paris: and in the mean time to improve himself under so great a master as Cassini. From thence he went to Italy, where he spent great part of the year 1681; but his affairs calling him home, he returned to England. In 1683, he published his Theory of the Variation of the Magneticall Compass; in which he supposes the whole globe of the earth to be a great magnet, with four magneticall poles, or points of attraction: but afterwards thinking that this theory was liable to great exceptions, he procured an application to be made to King William, who appointed him commander of the Paramour Pink, with orders to seek by observations the discovery of the rule of variations, and to lay down the longitudes and latitudes of his majesty's settlements in America.——He set out on this attempt on the 24th of November 1698: but having crossed the line, his men grew sickly; and his lieutenant mutinying, he returned home in June 1699. Having got the lieutenant tried and califhired, he set sail a second time in September following, with the same ship and another of less bulk, of which he had also the command. He now traversed the vast Atlantic ocean from one hemisphere to the other as far as the ice would permit him to go; and having made his observations at St Helena, Brazil,
Halmstadt. The name is still retained at Lufton, and other places in Herefordshire, England. See Motte.

HALMSTEAD. See Helmstadt.

HALO, or CORONA, in natural history, a coloured circle appearing round the body of the sun, moon, or any of the large stars. See Corona.

HALORAGUS, in botany: A genus of the tetragnita order, belonging to the octandria class of plants. The calyx is quadrifid above: there are four petals; a dry plum, and a quadrilocular nut.

HALSTEAD, a town of Eifex in England, seated on the river Coln, 43 miles from London. It has an old church, the fleece of which was once burnt down by lightning, but rebuilt at the expense of an individual.

(Halland, Efq.) The town consists of about 600 pretty good houses, and is situated on a rising ground, but the streets are not paved. The inhabitants are about 4000 in number. Here is a good manufactury of says, bays, callimancoes, &c. also a good free school for 40 boys, and a very antique Bridewell. Its market on Friday is noted for corn.

HALT, in war, a paufe or stop in the march of a military body.—Some derive the word from the Latin haltus, "breath," it being a frequent occasion of halting to take breath; others from aliter, because in halting they raised their pikes on end, &c.

HALTER, in the manege, a head-stall for a horse, of Hungary leather, mounted with one, and sometimes two straps, with a second throat-band, if the horse is apt to unhalter himself.

HALTER-CAF, is an excoriation of the pattern, occasioned by the halter's being entangled about the foot, upon the horse's endeavouring to rub his neck with his hinder feet. For the cure of this, anoint the place, morning and evening, with equal quantities of linseed oil and brandy, well mixed.

HALTERISTA, in antiquity, a kind of players at dices; denominated from a peculiar kind of discus called by the Greeks ἀρτός, and by the Latins halter. See Discus.

Some take the discus to have been a leaden weight or ball which the vaulters bore in their hands, to secure and keep themselves the more steady in their leaping. Others will have the halter to be a lump or mass of lead or stone, with an hole or handle fixed to it, by which it might be carried; and that the halterists were those who excercised themselves in removing these masses from place to place.

Hier. Mercorialis, in his treatise De arte gymnastica, l. ii. c. 12. distinguishes two kinds of halterita; for though there was but one halter, there were two ways of applying it. The one was to throw or pitch it in a certain manner; the other only to hold it out at arm's end; and in this posture to give themselves divers motions, swinging the hand backwards and forwards according to the engraven figures thereof given us by Mercorialis.—The halter was of a cylindrical figure, smaller in the middle, where it was held, by one diameter, than at the two ends. It was always a foot long, and there was one for each hand; it was either of iron, stone, or lead.

Galen, De tend. valetud. lib. i. v. & vi. speaks of this-
HAM [ 282 ]

HAM

this exercise, and show of what use it is in purging the body of peccant humours; making it equivalent both to purgation and phlebotomy.

HALTON, or Haulton, i.e. High Town, a town of Cheshire, 186 miles from London. It stands on a hill, where a castle was built anno 1071, and is a member of the duchy of Lancaster; which maintains a large jurisdiction in the country round it, by the name of Haulton Fee, or the honour of Halton, having a court of record, prison, &c. within themselves. About Michaelmas every year, the king’s officers of the duchy keep a law-day at the castle, which still remains a flate-

fully building: once a fortnight a court is kept here, to determine all matters within their jurisdiction; but felons and thieves are carried to the shire of Lincoln, Nottingham, York, Lancafer, of Kent, to receive their sentence. By the late inland navigation, it has communication with the rivers Mersey, Dee, Ribble, Ouse, Trent, Darwent, Severn, Humber, Thames, Avon, &c. which navigation, including its windings, extends about 500 miles, in the counties of Lincoln, Nottingham, York, Lancaster, Welfmoreland, Stafford, Warwick, Leicester, Oxford, Worcester, &c.

Haltwhistle, a town of Northumberland in England, situated in E. Long. 2° c. N. Latt. 55° 0. It is a pretty well-built, and affords good entertainment for travellers.

Halymore, properly signifies an holy or ecclesiastical court. See Halmote.

There is a court held in London by this name before the Lord Mayor and sheriffs, for regulating the bakers. It was annually held on Sunday next before St Thomas’s day, and for this reason called the Halmote, or Holy-court.

Halyss, (anc. geog.) the noblest river of the Hither Asia, through which it had a long course, was the boundary of Creesus’s kingdom to the east. Running down from the foot of mount Taurus, through Cataonia and Cappadocia, it divided almost the whole of the Lower Asia, from the sea of Cyprus down to the Euxine, according to Herodotus; who seems to extend its course too far. According to Strabo, himself a Cappadocian, it had its springs in the Great Cappadocia. It separated Paphlagonia from Cappadocia; and received its name ορός τος αλας, from falt, because its waters were of a falt and bitter taste, from the nature of the foil over which they flowed. It is famous for the defeat of Creesus king of Lydia, who was misled by the ambiguous word of this oracle:

χριστος ουδεν διηνεμευται αλγε δια νους.

If Creesus passes over the Halyss he shall destroy a great empire.

That empire was his own. See CREESUS and LYDIA.

halysford, in old writers, were persons who enjoyed land, by the pious service of repairing some church, or defending a sepulchre.

This word also signifies such persons in the diocese of Durham, as held their lands to defend the corps of St Cuthbert, and who from thence claimed the privilege of not being forced to go out of the bishopric.

HAMP, or Sham (anc. geog.) the country of the Buzzima (Gen. xiv. 5.) the situation whereof is not known.

HAM, the youngest son of Noah. He was the father of Cush, Mizraim, Phut, and Canaan; each whereof had the several countries peopled by them.

With respect to Ham, it is believed that he had all Africa for his inheritance, that he peopled it with his children. As for himself, it is thought by some that he dwelt in Egypt; but M. Bagnac is rather of opinion, that neither Ham nor Mizraim ever were in Egypt, but that their posterity settled in this country, and called it by the name of their ancestors. And as to Ham’s being worshipped as a god, and called Jupiter Hammon, he thinks people may have been led into this mistake by the similitude of names; and that Jupiter Hammon was the fun, to which divine honours have been paid at all times in Egypt. However that may be, Africa is called the land of Ham, in several places of the psalms, (Psal. lxvii. 51. civ. 23. cv. 22.)

In Plutarch, Egypt is called Chemia; and there are some footsteps of the name of Ham or Cham observed in Ptolemaisin, Pithia-chemmis, which are cantons of Egypt.

HAM, a saxon word used for “a place of dwelling;” a village or town; hence the termination of some of our towns, Nottingham, Buckingham, &c. Also a home close, or little narrow meadow, is called a ham.

HAM is also a part of the leg of an animal; being the inner or hind part of the knee, or the ply or angle in which the leg and thigh, when bent, incline to each other.

HAM, in commerce, &c. is used for a leg or thigh of pork, dried, seasoned, and prepared, to make it keep, and to give it a brisk agreeable flavour.

Wellphalia hams, so much in vogue, are prepared by salting them with saltpetre, pricking them in a pretentious or ten days, then steeping them in juniper-water, and drying them by the smoke of juniper-wood.

A ham may be salted in imitation of those of Wellphalia, by sprinkling a ham of young pork with salt for one day, in order to fetch out the blood; then wiping it dry, and rubbing it with a mixture of a pound of brown sugar, a quarter of a pound of saltpetre, half a pint of bay salt, and three pints of common salt, well stirred together in an iron pan over the fire till they are moderately hot: let it lie three weeks in this salting, and be frequently turned, and then dry it in a chimney.

HAM, a city of Germany, in the circle of Wellphalia, capital of the county of Mark, and subject to the king of Prussia. It is seated on the river Lippe, on the frontiers of Munster. The adjacent country abounds in corn, hemp, and flax; and the inhabitants get a good deal of money by travellers. It was formerly a Hanse-town, but is now reduced. E. Long. 7°. 53. N. Lat. 51° 42.

HAM, a town of Picardy, in France, seated on the river Somme, among marshes. It has three parishes, and there is here a round tower whose walls are 36 feet thick. It was taken by the Spaniards in 1557, but restored by treaty. E. Long. 3°. 9. N. Lat. 49° 45.

HAMADAN. See Amaday.

HAMADRYADES (formed of μακα together, and ὑδρά, of ὑδρα oke), in antiquity, certain fabulous deities reverend among the ancient heathens, and believed to preside over woods and forests, and to be in-
The Hamades were supposed to live and die with the trees they were attached to; as is observed by Servius on Virgil, Eclog. x. ver. 62. after Mneфонmachus, the scholiast of Apollo, &c. who mentions other traditions relating thereto.

The poets, however, frequently confound the Hamadryads with the Naiades, Nymphs, and rural nymphs in general; witness Catulus, Carm. ixvii. ver. 23. Ovid, Fast. Iv. 229. Met. i. ver. 605. xiv. ver. 628. Propertius, Eleg. xx. 32. Virg. Ecl. x. ver. 64. Georg. iv. ver. 382, 383. Pallas calls them Querquetulane, as being ified or sprung from oaks. An ancient poet, Pherecydes, in Athenaeus, lib. iii. calls the vine, fig-tree, and other fruit-trees, Hamadryades, from the name of their mother the oak.

This common idea among the ancients, of nymphs or intellectual beings annexed to trees, will account for their worshipping of trees; as we find they did, not only from their poets but their historians. Livy speaks of an ambassador's addressing himself to an old oak, as to an intelligent person and a divinity, Lib. iii. § 25.

HAMAH, a town of Turkey in Asia, in Syria, situated in E. Long. 36. 15. N. Lat. 35. 15. By some travellers it is corruptly called Amael and Amant. Some mistake it for the ancient Apaneus; but this is now called Aṣiāmiyāb, and is situated a day's journey from Hamah. Hamah is situated among hills, and has a castle seated on a hill. It has all along been a considerable place, and in the 13th century had princes of its own. It is very large, and being seated on the ascent of a hill, the houses rise above one another, and make a fine appearance. It is, however, like most other towns under the Turkish government, going to decay. Many of the houses are half ruined; but those which are still standing, as well as the mosques and cafle, have their walls built of black and white stones, disposed in such a manner as to form various figures. The river Afis, the ancient Orontes, runs by the side of the castle, and fills the ditches round it, which are cut very deep into the rock. This river, leaving the castle, passes through the town from south to north, and has a bridge over it, though it is pretty broad. In its course through the town it turns 18 great wheels, called by the natives fell, which raise quantities of water to a considerable height, and through it into canals supported by arches, by which means it is conveyed into the gardens and fountains. There are some pretty good bazaars or market-places in Hamah, where there is a trade for linen, which is manufactured there, and sent to Tripoli to be exported to Europe.

HAMAMELIS, WITCH HAZEL; A genus of the digynna order, belonging to the tetrastria class of plants; and in the natural method ranking with those of which the order is doubtfull. The involucrum is triphyllous, the proper calyx tetrphyllous; there are four petals; the nut horned and bilocular. There is but one species, a native of Virginia. It hath a shrubby or woody stem, branching three or four feet high; oval, indented, alternate leaves, resembling those of common hazel; and flowers growing in clusters from the joints of the young branches, but not succeeded by seeds in Britain.—The plant is hardly, and is admitted as a variety in gardens; but its flowers are more remarkable for their appearing in November and December, when the leaves are fallen, than for their beauty. It may be propagated either by seeds or layers. HAMAM LEET, a town 12 miles east from Tunis, noted for its hot baths, which are much referred to by the Tunisians, and are efficacious in rheumatism and many other complaints. Here the Bey has a very fine bath, which he frequently permits the consuls and other persons of distinction to use.

HAMATH, a city of Syria, capital of a province of the same name, lying upon the Orontes. "The entering into Hamath," which is frequently spoken of in scripture. (Job. xiii. 5. Judges iii. 2. Kings xxv. 2. and 2 Chron. vii. 1.) in the narrow pass leading from the land of Canaan through the valley which lies between Libanus and Antilbanus. This entrance into Hamath is set down as the northern boundary of the land of Canaan, in opposition to the southern limits, the Nile or river of Egypt. Josephus, and St Jerome attribute it to Hamath to be Syriamirtot, the Thracian, and many other good geographers maintain it to be Emefa in Syria. Joshua (xix. 35.) assignds the city of Hamath to the tribe of Naphtali. Toi king of Hamath cultivated a good understanding with David, (2 Sam. viii. 9.) This city was taken by the king of Judah, and retaken from the Syrians by Jeroboam the second, (2 Kings xiv. 28.) The kings of Assyria made themselves masters of it upon the declension of the kingdom of Israel, and transplanted the inhabitants of Hamath into Samaria (2 Kings xvii. 24. and xviii. 34. &c.)

HAMAXOBI, HAMAXOBIAKS, in the ancient geography, a people who had no houses, but lived in carriages. The word is formed from ևעָנָא a carriage or chariot, and וָלֶשׁ.life.

The Hamaxoebi, called also Hamaxobites, were an ancient people of Sarmatia Europea, inhabiting the southern part of Muscovy, who instead of houfes had a fort of tents made of leather, and fixed on carriages to be ready for shifting and travel.

HAMBDEN (John), a celebrated patriot, descended from the ancient family of Hambden in Buckinghamshire, was born in 1654. From the university he went to the inns of court, where he made a considerable progress in the study of the law. He was chosen to serve in the parliament which began in Westminster February 5. 1626; and served in all the succeeding parliaments in the reign of Charles I. In 1636 he became universally known, by his refusal to pay ship-money, as being an illegal tax; upon which he was prosecuted, and his carriage throughout this transgression gained him a great charactar. When the long parliament began, the eyes of all men were fixed on him as their fater patriae. On January 5. 1642, the king ordered articles of high treason and other misdemeanours to be prepared against Lord Kimbolton, Mr. Hambden, and four other members of the House of Commons, and went to that house to seize them; but they were then retired. Mr. Hambden afterwards made a speech in the house to clear himself of the charge laid against him. In the beginning of the wars he commanded a regiment of foot, and did good ser-
Hamburg, vice to the parliament at the battle of Edgehill. He received a mortal wound in an engagement with prince Rupert, in Chalgrave-field in Oxfordshire, and died in 1643. He is said to have had the art of Socrates to a great degree, of interrogating, and under the notion of doubts, intimated objections, so that he infused his own opinions into those from whom he pretended to learn and receive them. He was, says his panegyrist, a very wise man and of great parts; and polished of the most absolute spirit of propriety to govern the people, that ever was in any country: he was master over all his appetites and passions, and had thereby a very great ascendant over other mens: he was of an industry and vigilance never to be tired out, of parts not to be imposed upon by the most subtle, and of courage equal to his best parts.

Hamburg, an imperial city of Germany, seated in E. Long. 9° 40', N. Lat. 54° 0'. Its name is derived from the old German word Hamme, signifying a wood, and Burg, a castle; and stands on the north-side of the river Elbe. This river is not less than four miles broad opposite the city. It forms two spacious harbours, and likewise runs through most part of it in canals. It flows above Hamburg many miles; but when the tide is accompanied with north-west winds, a great deal of damage is done by the inundations occasioned thereby. There are a great many bridges over the canals, which are mostly on a level with the streets, and some of them have houses on both sides. In the year 833, Ludovicus Pius erected Hamburg first into a bishopric, and afterwards into an archbishopric; and Adolphus III. duke of Saxony, among many other great privileges, granted it the right of fishing in the Elbe, eight miles above and below the city. The king of Denmark, since they have succeeded to the counts of Holstein, have continually claimed the sovereignty of this place, and often compelled the citizens to pay large sums to purchase the consent of their liberties. Nay, it has more than once paid homage to the kings of Denmark; who, notwithstanding, keep a minister here with credentials, which is a sort of acknowledgment of its independency and sovereignty. Though Hamburg has been constantly summoned to the diet of the empire ever since the year 1618, when it was declared a free imperial city by a decree of the aulic council; yet it waves this privilege, in order to keep fair with Denmark. By their situation among a number of poor princes, the Hamburgers are continually exposed to their rapacious enemies, especially that of the Danes, who have extorted vast sums from them. The city is very populous in proportion to its bulk; for though many must walk with ease round the ramparts in two hours, yet it contains, exclusive of Jews, at least 100,000 inhabitants. Here are a great many charitable foundations, the regulations of which are greatly admired by foreigners. All persons found begging in the streets are committed to the house of correction to hard labour, such as the raising of Brazil and other kinds of wood. There is an hospital into which unmarried women may be admitted for a small sum, and comfortably maintained during the residue of their lives. The number of hospitals in this place is greater in proportion to its greatness than in any other Protestant city in Europe. The revenue of the orphan-house alone is said to amount to between 50 and 60,000 l. There is a large sumptuous hospital for receiving poor travellers that fall sick. In one of their work-houses or houses of correction, those who have not performed their task are hoisted up in a basket over the table in the common-hall while the rest are at dinner, that they may be tantalized with the fire and smell of what they cannot taste. The established religion of Hamburg is Lutheranism; as for the Calvinists and the Reformed-catholics, they go to the ambassador's chapels to celebrate their divine service and worship. They have here what they call a private confession, previous to the holy communion, which differs in nothing from that of the church of England, and the abolition is the same, only the poorest of the people here are forced to give a fee to the priests on these occasions. Their churches which are ancient large fabrics, are open thorough-fares, and in some of them there are book-sellers' shops. The pulpit of St Catherine's is of marble, curiously carved and adorned with figures and other ornaments of gold; and its organ, reckoned one of the best in Europe, has 6000 pipes. The cathedral is very ancient, and its tower lean as if just going to fall; yet on account of the singularity and beauty of its architecture, the danger attending it has been hitherto overlooked. There are still a dean and chapter belonging to this church, though secularized; from whose court there lies no appeal, but to the imperial chamber at Wetzlar. The chapter consists of a provost, dean, 13 canons, eight minor canons, and 30 vicarii immunes, besides others who are under the jurisdiction of the city. The cathedral, with the chapter, and a number of houses belonging to them, are under the immediate protection of his Britannic majesty as duke of Bremen, who disposes of the prebends that fall in six months of the year, not faceely, but alternately with the chapter. Hamburg is almost of a circular form, and six miles in compass. In one part, the gates, and three entrances by water, viz. two from the Elbe and one from the Alster, being divided into the old and new, which are strongly fortified with moats, ramparts, bastions, and out-works. The ramparts are very lofty, and planted with trees; and of such a breadth, that several carriages may go abreast. In the New-town, towards Altena, are several streets of mean houses inhabited by Jews. Through that entrance from the Elbe, called the lower Brum, pass all ships going to or coming from sea. Every morning, at the opening of it, is seen a multitude of boats or small barks, whose cargoes consist of milk, fruits, and all kinds of provisions, rubbing in at the same time. There are some fine chimes here, especially those of St Nicholas, which play every morning early, at one o'clock in the afternoon, and on all festivals and solemnities. The other public structures in this city, besides the churches, make no great appearance: however, the yard, arsenal, and two armories, are well worth seeing. There are several convents or cloisters still remaining; which having been secularized, are now possessed by the Lutherans. One of them holds its lands by this tenure, "That they offer a glass of wine to every malefactor who is carried by it for execution." There is a fine exchange, though inferior
HAMBURG, to the amount of several hundred thousand pounds a year: they have also a great trade with Spain, Portugal, and Italy, which is carried on mostly in English bottoms, on account of their Mediterranean pales. Their whale-fishery is also very considerable, 50 or 60 ships being generally sent out every year in this trade. Add to these a variety of manufactories, which are performed here with great felicity; the chief of which are, sugar-baking, calico-printing, the weaving of damasks, brocades, velvets, and other rich silks. The inland trade of Hamburg is superior to that of any in Europe, unless perhaps we should except that of Amsterdam and London. There is a paper published here at stated times called the Preiseurant, specifying the course of exchange, with the price which every commodity and merchandise bore last upon the exchange. There is also a board of trade, erected on purpose for the advancing every project for the improvement of commerce. Another great advantage to the merchants is, the bank, or stock-office, was established in 1659, which has a flourishing credit. To supply the poor with corn at a low price, here are public granaries, in which great quantities of grain are laid up. By charters from several emperors, the Hamburgers have a right of coinage, which they actually exercise. The English merchants, or, Hamburg Company, as it is called, enjoy great privileges; for they hold a court with particular powers, and a jurisdiction among themselves, and have a church and minister of their own.—This city has a district belonging to it of considerable extent, which abounds with excellent pastures, inhabited by a considerable number of cattle, and in a considerable revenue to the state. Besides the militia or trained bands, there is an establishment of regular forces, consisting of 12 companies of infantry, and one troop of dragoons, under the commandant, who is usually a foreigner, and one who has distinguished himself in the service. There is also an artillery company, and a night-guard; the last of which is posted at night all over the city, and calls the hours.

HAMEL (John Baptiste du), a very learned French philosopher and writer in the 17th century. At 18 he wrote a treatise, in which he explained in a very simple manner Theodorus's three books of Sphcerics; to which he added a tract upon trigonometry, extremely peripnisous, and designed as an introduction to astronomy. Natural philosophy, as it was then taught, was only a collection of vague, knotty, and barren questions; when our author undertook to establish it upon right principles, and published his Astrationes Physicae. In 1666 Mr Colbert proposed to Louis XIV. a scheme, which was approved of by his majesty, for establishing a royal academy of sciences;
HAMELIN, a strong town of Germany, in the duchy of Calenberg in Lower Saxony. It is situated at the extremity of the duchy of Brunswick, to which it is the key, near the confluence of the rivers Hamel and Wefer, in E. Long. 9. 55. N. Lat. 52. 13.

HAMELLIA, in botany: a genus of the mono-gynia order, belonging to the pentandria class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is quinquedental; the berry quinquelocular, inferior, polypermous.

HAMESECKEN, BURGARY, or NOITURAL HOUSE. breaking, was by the ancient English law called Hame-secken, as it is in Scotland to this day. — Violating the privilege of a man's house in Scotland is as severely punished as ravishing a woman.

HAMI, or Ham, a country of Asia, subject to the Chinese. It is situated to the north-east of China, at the extremity of that desert which the Chinese call Chana, and the Tartars Cobi; and is only 20 leagues distant from the most westerly point of the province of Chenfi. This country was inhabited in the early ages by wandering people, named Long. About the year 950 before the Christian era, they revolted from their Tartar masters, and sent deputies to pay homage to the emperor of China, and preferred some fabrics by way of tribute. The civil wars by which China was torn about the end of the sixteenth century, the same vicissitudes, the same misfortunes, the same calamities, they experienced; Hami was sometimes united to the province of Chenfi, sometimes independent of it, and sometimes even of the whole empire. The situation of these people (separated by vast deserts from China, to which, besides, they had no relation, either in language, manners, or customs) must have greatly contributed to facilitate these revolts. All the tributary states of the empire having revolted in 610, that of Hami followed their example; but it again submitted to the yoke, under Tai-tsong, second emperor of the dynasty of Tang, who had sent one of his generals with an army to reducte it. This great prince paid particular attention to his new conquest. He divided it into three districts, and connected its civil and military government in such a manner to that of the province of Chenfi and other neighboring countries, that tranquillity prevailed there during his reign and several of those that followed. Through Hami all the caravans which went from the west to China, or from China to the west, were obliged to pass. The emperors, predecessors of Tai-tsong, were satisfied with causing wine to be transported from Hami in skins carried by camels; but " Tai-tsong (says the Chinese history) having subdued the kingdom of Hami, or ordered some vines-plant of the species called jujubes, to be brought him, which he caused to be planted in his gardens; he, besides, learned the manner of making wine, the use of which proved both serviceable and hurtful to him." Luxury and effeminacy having weakened the dynasty of Tang, the Mahometans (who had made a rapid progress in all the countries that are situated between Persia, Cobi, and the Caflpian sea) advanced as far as Hami, which they conquered. It appears, that this country afterwards had princes of its own, but dependent on the Tartars, who successively ruled these immense regions. The Yuen or Mogul Tartars again united the country of Hami to the province of Chenfi; and this union subsisted until 1360, at which time the emperor formed it into a kingdom, on condition of its princes doing homage and paying tribute. The king of Hami was honoured with a new title in 1404, and obtained a golden seal. After a contest of several years for the succession to the throne, the kingdom of Hami fell a prey to the king of Tou-cullan-fan. This yoke soon became uneasy to the people of Hami: they revolted from their new masters, and made conquests from them in their turn. The new king which they made choice of, did not long possess the throne: he was conquered and killed in a bloody battle which he fought with the king of Tou-cullan-fan, who also perished some time after. Since this epocha, the country of Hami has been successively expropriated to anarchy, or governed by its own princes. The prince which filled the throne in 1696, acknowledged himself a vassal of the empire, and sent as tribute to Peking, camels, horses, and fabrics. Kanghi received his homage with the usual ceremonies, and published a diploma, which established the rank that the king of Hami should hold among the tributary princes, the time when he should come to render homage, the nature of the presents necessary for his tribute, the number of auxiliaries he was bound to furnish in time of war, and the manner of his appointing a successor. All these regulations have subsisted till this time.

The country of Hami, though surrounded by deserts, is accounted one of the most delightful in the world. The soil produces abundance of grain, fruits, leguminous plants, and paturage of every kind. The rice which grows here is particularly esteemed in China; and pomegranates, oranges, peaches, raisins, and prunes, have a most exquisite taste; even the jujubes are fojucy, and have to delicious a flavour, that the Chinese call them perfumed jujubes. There is no fruit more delicate or more in request than the melons of Hami, which are carried to Peking for the emperor's table. These melons are much more wholesome than those of Europe; and have this singular property, that they may be kept fresh during great part of the winter. But the most useful and most esteemed production of this country is its dried raisins. These are of two kinds: The first, which are much used in the Chinese medicine, seem to have a perfect resemblance to those known in Europe by the name of Corinthian. The second, which are in much greater request for the table, are smaller and more delicate than those of Provence. The Chinese authors perfectly agree with Mellers Lencery and Geoffroy, respecting the virtue and qualities of these dried grapes or raisins; but they attribute
tribute so much more efficacy to those of Hami than to those of China, that they prefer them in smaller doses. They observe, that an infusion of the first is of great service in facilitating an eruption of the small pox about the fourth day, when the patient either is or seems to be too weak; and to promote a gentle perspiration in some kinds of pleurisy or malignant fevers. The dose must be varied according to the age, habit of body, and strength of the patient; great care must be taken to administer this remedy reasonably and with judgment. The emperor caused plants to be transported from Hami to Peking, which were immediately planted in his gardens. As those plants were cultivated with extraordinary care, under his own eyes, they have perfectly succeeded. The raisins produced by them are exceedingly sweet, and have a most exquisite flavour.

Although the country of Hami (the latitude of which is 42° 53' 10") lies farther towards the north than several of the provinces of France, we are assured that its climate is more favourable to the culture of vines, and that it gives a superior degree of quality to the grapes. The temperature at Hami is so moderate; the fogs are scarcely ever seen there; the country is never rains at Hami; even dew and perspiration in the age, habit of body, and strength of the patient; great care must be taken to administer this remedy reasonably and with judgment. As those plants were cultivated with extraordinary care, under his own eyes, they have perfectly succeeded. The raisins produced by them are exceedingly sweet, and have a most exquisite flavour.

Although the country of Hami (the latitude of which is 42° 53' 10") lies farther towards the north than several of the provinces of France, we are assured that its climate is more favourable to the culture of vines, and that it gives a superior degree of quality to the grapes. The temperature at Hami is so moderate; the fogs are scarcely ever seen there; the country is never rains at Hami; even dew and perspiration in the age, habit of body, and strength of the patient; great care must be taken to administer this remedy reasonably and with judgment. The emperor caused plants to be transported from Hami to Peking, which were immediately planted in his gardens. As those plants were cultivated with extraordinary care, under his own eyes, they have perfectly succeeded. The raisins produced by them are exceedingly sweet, and have a most exquisite flavour.

H A M L E T, a prince celebrated in the annals of Denmark; and whose name has been rendered familiar in this country, and his story interesting, by being the subject of one of the noblest tragedies of the immortal Shakespeare.—Adjoining to a royal palace, which stands about half a mile from that of Cronborg in Elsinore, is a garden, which, Mr. Coxe informs us, is called Hamlet's Garden, and is said by tradition to be the very spot where the murder of his father was perpetrated. The house is of modern date, and is situated at the foot of a sandy ridge near the sea. The garden occupies the side of the hill, and is laid out in terraces rising one above another. Elsinore is the scene of Shakespeare's Hamlet; and the original history from which our poet derived the principal incidents of his play is founded upon facts, but so deeply buried in remote antiquity that it is difficult to discriminate truth from fable. Saxo-Grammaticus, who flourished in the 12th century, is the earliest historian of Denmark that relates the adventures of Hamlet. His account is extracted, and much altered, by Bellefourt, a French author; an English translation of whole romance was published under the title of the History of Hamlet: and from this translation Shakespeare formed the groundwork of his play, though with many alterations and additions. The following short sketch of Hamlet's history, as recorded in the Danish annals, will enable the reader to compare the original character with that delineated by Shakespeare.

Long before the introduction of Christianity into Denmark, Horwendillus, preëst or king of Jutland, was married to Geruthra, or Gertrude, daughter of Rurikking of Denmark, by whom he had a son called Amlethus, or Hamlet. Fengo murders his brother Horwendillus; marries Gertrude; and ascends the throne. Hamlet, to avoid his uncle's jealousy, counterfeits folly; and is represented as such an abhorrist of falsehood, that though he constantly frames the most evangelical and even absurd answers, yet artfully contrives never to deviate from truth. Fengo, suspecting the reality of his madness, endeavours by various methods (a) to discover the real state of his mind: amongst others, he departs from Elsinore, executes a meeting between Hamlet and Gertrude, concluding that the former would not conceal his sentiments from his own mother and her husband.

(a) Among other attempts, Fengo orders his companions to leave him in a retired spot, and a young woman is placed in his way, with a view to extort from him a confession that his folly was counterfeited. Hamlet would have fallen into the snare, if a friend had not secretly conveyed to him intelligence of this treachery. He carries the woman to a more secret place, and obtains her promise not to betray him; which he readily contents to, as he had been brought up with him from his infancy. Being asked, upon his return home, if he had indulged his passion, he answers in the affirmative; but renders himself not believed by the most artful subterfuses, which, though true, seemed evidently to mark a disordered understanding, and by the positive denial of the woman. "Upon this woman," as Capell observes, "is grounded Shakespeare's Ophelia: and his deliverance from this snare by a friend suggested his Horatio:"—"the rude outlines," as Mr. Malone remarks, "of those characters. But in this piece there are no traits of the character of Polonius; there is indeed a counsellor, and he places himself in the queen's chamber behind the arras; but this is the whole. The ghost of the old Hamlet is likewise the offspring of our author's creative imagination." See Capell's School of Shakespeare, vol. iii. p. 20: and Malone's Supplement, p. 253.
Hamlet and orders a courier to conceal himself, unknown to
both, for the purpose of overhearing their conversation.

The courier repairs to the queen's apartment, and
hides himself under a heap of straw (s). Hamlet, up-
own entering the cabinet, suspecting the presence of
some spy, imitates, after his usual affectation of folly,
the crow of a cock, and, making his arms like wings,
jumps (c) upon the heap of straw; till, feeling the
courier, he draws his sword, and instantly dispatches
him. He then cuts the body to pieces, boils it, and
then sets fire to the palace; and
which he
his daughter to Hamlet, who gives many
and courtiers, he draws
infamy,
virtue by these admonitions. Fengo returns to
jinnins ignorniniam
neur, sends Hamlet to England under the care of two
Courtiers, he stands, his
being crafty and
should speak severely and wisely
attempts to do it, falls by the hand of
Hamlet. The next morning, when the populace
were assembled to view the ruins of the palace, Hamlet
burns the remaining nobles; and in a matterly speech,
which is too long to insert in this place, lays open the
motives of his own conduct, proves his uncle to have
been the assassin of his father; and concludes in the
following words, "Tread upon the ashes of the monster,
who, polluting the wife of his murdered brother, joined
incest to parricide; and ruled over you with the
most oppressive tyranny. Receive me as the minifier
of a just revenge, as one who felt for the sufferings
of his father and his people. Consider me as the person
who has purged the disgrace of his country; extinguished
the infamy of his mother; freed you from the
depotism of a monster, whose crimes, if he had lived,
would have daily increased, and terminated in your
destruction. Acknowledge my services; and if I have
defereed it, present me with the crown. Behold in me
the author of these advantages: no degenerate person,
no parricide; but the rightful successor to the throne,
and the pious avenger of a father's murder. I have
rescued you from slavery, restored you to liberty,
and re-established your glory: I have destroyed a tyrant,
and triumphed over an assassin. The recompense is in
your hands; you can estimate the value of my services,
and in your virtue I left my hopes of reward." This
speech has the desired effect: the greater part of the
assembly fled tears, and all who are present unanimously
proclaim him king amid repeated acclamations.

VOL. VIII.

(a) The reader will recollect, that straw used formerly to be spread over the floors as an article of great
luxury.

(c) This part stands thus in the English account: "The counsellor entered secretly into the queen's
chamber, and there hid himself behind the arras, and long before the queen and Hamlet came thither:
who being crafty and politic, as soon as he was within the chamber, doubting some treachery, and fearing
if he should speak severely and wisely to his mother touching his secret practices he should be understood,
and by that means intercepted, used his ordinary manner of dilimulation, and began to come (c, crow) like a
cock, bearing with his arms (in such a manner as cocks used to strike with their wings) upon the hangings of
the chamber; whereby feeling something terrorizing him, he cried, Arat! a rat! and presently drawing
his sword, thrust it into the hangings; which done, he pulled the counsellor (half dead) out by the heels,
made an end of killing him; and, being plain, cut his body in pieces, which he caused to be boiled, and then cast
it into an open vault or privy." Malone's Supplement, vol. i. p. 357.

(d) The closet-scene, which is so beautiful in Shakespeare's Hamlet, is thus concisely, but not less finely,
described by the Dandish historian: "Cumque mater magnis ejus salutibus esse praecipit, quale praecipit
esse, scilicet, quod inleriudum formas, in formis, in modis, in neutris, in signis, in similibus, in signis,

Hamlet soon after his elevation fails to England, and orders a shield to be made on which the principal actions of his life are represented. The king receives him with feigned demonstrations of joy, falsely assures him that his daughter is dead, and recommends him to repair to Scotland as his ambassador, and to pay his addresses to the queen Gertrude. He gives this insidious advice with the hopes that Hamlet may perish in the attempt; as the queen, who was remarkable for her churlish and cruelty, had such an aversion to all proposals of marriage, that not one of her suitors had escaped falling a sacrifice to her vengeance. Hamlet, in opposition to all difficulties performed the embassy; and, by the affiance of his shield, which inspires the lady with a favourable opinion of his wisdom and courage, obtains her in marriage, and returns with her to England. Informed by the princes to whom he had been betrothed, that her father meditated his assassination, Hamlet avoids his fate by wearing armour under his robe; puts to death the king of England; and rage, obtains her marriage, and returns with her to Denmark with his two wives, where he is soon failures to England, where he is soon

HARE, a well known tool used by mechanics, consisting of an iron head, fixed crosswise upon a handle of wood. There are several forms of hammers used by blacksmiths; as, 1. The hand-hammer, which is of such weight that it may be wielded or governed with one hand at the anvil. 2. The up-hand fledge, used with both hands, and seldom lifted above the head. 3. The about-fledge, which is the biggest hammer of all, and held by both hands at the farther end of the handle; and being swung at arm's length over the head, is made to fall upon the work with as heavy a blow as possible. There is also another hammer used by smiths, called a dressing hammer; which is the smallest of all, and is seldom used at the forge unless upon small work.

—Carpenters and joiners have likewise hammers accommodated to their several purposes.

HAMMERSMITH, four miles west from London, is a hamlet belonging to Fulham, has two charity-schools, a workhouse, a Presbyterian meeting-house, and a fair May 1. There are a number of handmade seats about it, especially towards the Thames; among which the most remarkable is the late lord Melcombe's, which is a very elegant house, and contains a marble chimney, said to be a very great expense.

HAMMOCK, or Hamac, a kind of hanging bed, suspended between two trees, posts, hooks, or the like, much used throughout the West-Indies, as also on board of ships. The Indians hang their hammocks to trees, and thus secure themselves from wild beasts and insects, which render lying on the ground there very dangerous. According to F. Plumier, who has often made use of the hammock in the Indies, it consists of a large strong coverlet or shift of coarse cotton, about six feet square; on two opposite sides are loops of the same stuff, through which a ring is run, and the rest other loops are formed, all which are tied together with a cord: and thus is the whole fastened to two neighbouring trees in the field, or two hooks in houses. This kind of couch serves at the same time for bed, quilts, sheets, pillow, &c.

The hammock used on board of ships is made of a piece of canvas six feet long and three feet wide, gathered or drawn together at the two ends. There are usually from fourteen to twenty inches in breadth allowed between decks for every hammock in a ship of war; but this space must in some measure depend on the number of the crew, &c. In time of battle the hammocks and bedding are firmly corded and fixed in the nettings on the quarter-deck, or wherever the men are too much exposed to the view or fire of the enemy.

HAMPSON (Henry), D. D. one of the most learned English divines in the 17th century, was born in 1605. He studied at Oxford, and in 1629 entered into holy orders. In 1633 he was inducted into the rectory of Penhurst in Kent. In 1643 he was made archdeacon of Chichester. In the beginning of 1645 he was made one of the canons of Christ-church, Oxford, and chaplain in ordinary to king Charles I., who was then in that city; and he was also chosen public orator of the university. In 1657 he attended the king in his confinement at Woodburn, Cavendish, Hampton-Court, and the Isle of Wight, where he continued till his majesty's attendants were again put from him. He then returned to Oxford, where he was chosen sub-dean; and continued there till the parliament-visitors first ejected him, and then imprisoned him for several weeks in a private house in Oxford. During this confinement he began his Annotations on the New Testament. At the opening of the year 1660, when every thing visibly tended to the restoratation of the royal family, the doctor was designed by the bishops to repair to London to afford assistance to the people in the compolure of the breaches of the church, his station in which was designated to be the bishopric of Worcester; but on the 4th of April he was seized by a fit of the stone, of which he died on the 24th of that month, aged 55. Besides the above work, he wrote many others; all of which have been published together in four volumes folio.

HAMPSON (Anthony, Esq.), an ingenious English poet, descended from a good family of Somersetshire Place in Huntingdonshire, was born in 1668. After a liberal education at St John's college, Cambridge, he was chosen member of parliament, and soon distinguished himself as a fine speaker. He became a commissioner of the royal navy, which place he quitted in 1712. He published A Miscellany of Original Poems by the most eminent hands; in which himself, as appears by the poems marked with his own name, had no inconsiderable share. He wrote the Life of Walter Moyle, Esq; prefixed to his works. He was the intimate friend of that gentleman, and died about the year 1726.

HAMPSON (James), known to the world by the Love-Elegies which, some years after his death, were published.
Hamphire. affinity the earl of Chesterfield, was the son of Anthony Hammond abovementioned, and was preferred to a place about the person of the late prince of Wales, which he held till an unfortunate accident deprived him of his fates. The cause of this calamity was a pull he entertained for a lady, who would not return it: upon which he wrote those love-elegies which have been so much celebrated for their tenderness. The editor observes, that he compos'd them before he was 21 years of age: a period, says he, when fancy and imagination commonly riot at the expense of judgment and correctness. He was sincere in his love as his friendship; and wrote to his mistresses, as he spoke to his friends, nothing but the genuine sentiments of his heart. Tibullus seems to have been the model our author judiciously preferred to Ovid; the former writing directly from the heart to the heart, the latter too often yielding and addressing himself to the imagination. Mr. Hammond died in the year 1743, at Stow, the seat of Lord Cobham, who, as well as the earl of Chesterfield, honoured him with a particular intimacy.

Hampshire, or Haunts, a county of England, bounded on the west by Dorsetshire and Wiltshire, on the north by Berkshire, on the east by Surrey and Sussex, and on the south by the English channel. It extends 57 miles in length from north to south, and 40 in breadth from east to west, and is about 220 miles in circumference. It is divided into 59 hundreds, and contains 9 forests, 29 parks, one city, 20 market- towns, 23 parishes, above 36,000 houses, and by the most modest computation 180,000 inhabitants, who elect 26 members of parliament, two for the county, two for the city of Winchester, and two for each of the following towns, Southampton, Portsmouth, Petersfield, Yarmouth, Newport, Stockbridge, Andover, Whitchurch, Lymington, Christ-church, and Newton. — The air is very pure and pleasant, especially upon the downs, on which vast flocks of sheep are kept and bred. In the champaign part of the county, where it is free of wood, the foil is very fertile, producing all kinds of grain. The country is extremely well wooded and watered; for besides many woods on private estates, in which there are vast quantities of well-grown timber, there is the new forest of great extent, belonging to the crown, well flored with venerable oaks. In these woods and forests, great numbers of hogs run at large, and feed on the acorns; and hence it is that the Hampshire bacon is far excel'd that of most other counties. The rivers are the Avon, Anton, Tefe, Stour, and Itchen; besides several smaller streams, all abounding in fish, especially trout. As its sea-coast is of a considerable extent, it possesses many good ports and harbours, and is well supplied with salt-water fish. Much honey is produced in the country, and a great deal of mead and metheglin made. Here is also plenty of game, and on the downs is most delightful hunting. The manufacture of cloth and kerseys in this county, though not so extensive as that of some others, is yet far from being inconsiderable, and employs great numbers of the poor, as well as contributes to the enriching of the manufacturers by what is sent abroad. The new intended canal in this county, from Basing-stoke to the Wye in Surrey, and from thence to the Thames, cannot but be a great advantage to the county in general, and the parishes it is to pass through in particular; to carry which into Hampshire, an execution above L.86,000 have been raised amongst 150 proprietors in 1789, and it will extend 35 miles when completed.

New Hampshire, a state of North America, in New England. It is bounded on the north by Quebec; northeast by the province of Maine; south-east by the Atlantic Ocean; south by Massachusetts; west and north-west by Connecticut river, which divides it from Vermont. The shape of New Hampshire resembles an open fan; Connecticut river being the curve, the southern line the shortest, and the eastern line the longest side. It is divided into five countries, viz. Rockingham, Stafford, Hillborough, Cheshire, Grafton. In 1776, there were 165 settled townships in this state. Since that time the number has been greatly increased. The chief town is Portsmouth. Exeter, 15 miles south-westwardly from Portsmouth, is a pretty town on the south side of the Exeter river. And Concord, situated on the west side of Merrimack river, is a pleasant flourishing town, which will probably, on account of its central situation, soon be the permanent seat of government. There are two great rivers, the Piscataco and the Merrimack. The former has four branches, Berwick, Cocheche, Exeter, and Durham, which are all navigable for small vessels and boats, some 15 others 20 miles from the sea. These rivers unite about eight miles from the mouth of the harbours, and form one broad, deep, rapid stream, navigable for ships of the largest burden. This river forms the only port of New Hampshire. The Merrimack bears that name from its mouth to the confines of Pemigewasset and Winnisquam rivers; the latter has its source in the lake of the same name. In its course, it receives numberless small streams issuing from ponds and swamps in the valleys. It tumbles over two considerable falls, Ammonoosuc and Pannock great falls. From Haverhill the river runs winding along, through a pleasant rich vale of meadow, and falling between Newbury Port and Salisbury empties itself into the ocean. The land next to the sea is generally low, but as you advance into the country, it rises into hills. Some parts of the state are mountainous. The White mountains are the highest part of a ridge which extends northeast and southwest to a length not yet ascertained. The whole circuit of them is not less than 50 miles. The height of these mountains above an adjacent meadow, is reckoned to be about 3500 feet, and the meadow is 3500 feet above the level of the sea. The snow and ice cover them nine or ten months in the year; during which time they exhibit that bright appearance from which they are denominated the white mountains. From this summit in clear weather is exhibited a noble view, extending 60 or 70 miles in every direction. Although they are more than 70 miles within land, they are seen many leagues off at sea, and appear like an exceeding bright cloud in the horizon. These immense heights, being copiously replenished with water, afford a variety of beautiful cascades. Three of the largest rivers in New England receive a great part of their waters from these mountains. Amonoosuck and Isaac rivers, two principal branches of Connecticut, fall from their western side, Peabody river, a branch of the Amagnetic, falls from the northeast side; and almost the whole of the
Hampshire. Saco descends from the southern side. The highest summit of these mountains is about latitude 44°.

The air in New Hampshire is serene and healthful. The weather is not so subject to change as in more southern climates. This state embracing a number of very high mountains, and lying in the neighborhood of others whose towering summits are covered with snow and ice three quarters of the year, is intensely cold in the winter season. The heat of summer is great, but of short duration. The cold braces the constitution, and renders the labouring people healthful and robust.

On the sea coast, and many places inland, the soil is sandy, but affords good pasturage. The intervals at the foot of the mountains are generally enriched by the freës, which bring down the soil upon them, forming a fine mould, and producing corn, grain, and herbage, in the most luxuriant plenty. The back lands which have been cultivated are generally very fertile, and produce the various kinds of grain, fruits, and vegetables, which are common to the other parts of New England. The uncultivated lands are covered with extensive forests of pine, fir, cedar, oak, walnut, &c. This state affords all the materials necessary for ship building.

By the return of the Census August 19th 1791, the number of inhabitants in this state appeared to be 141,815. There is no material difference between the inhabitants of this state and the other New England states. The ancient inhabitants of New Hampshire were emigrants from England. Their poverty, mixed with emigrants from Massachusetts, fill the lower and middle towns. Emigrants from Connecticut compose the largest part of the inhabitants of the western towns adjoining Connecticut river. Slaves there are none. Negroes, who were never numerous in New Hampshire, are all free by the first article of the bill of rights.

In the township of Hanover, in the western part of this state, is Dartmouth College, situated on a beautiful plain, about half a mile east of Connecticut river, in latitude 43° 33'. It was named after the right honorable William Earl of Dartmouth, who was one of its principal benefactors. It was founded in 1769, for the education and instruction of youth, of the Indian tribes, in reading, writing, and all parts of learning which should appear necessary and expedient for civilizing and christianizing the children of Pagan as well as in all liberal arts and sciences, and all of English youths and others. Its situation, in the frontier country, exposed it during the late war to many inconveniences, which prevented its rapid progress. It flourished, however, amidst all its embarrassments, and is now one of the most growing seminaries in the United States. It has in the four classes about 150 students, under the direction of a president, two professors, and two tutors. It has 12 trustees, who are a body corporate, invested with the powers necessary for such a body. The library is elegant, containing a large collection of the most valuable books. Its apparatus consists of a competent number of useful instruments, for making mathematical and philosophical experiments. There are three buildings for the use of the students. Such is the fertility of the air, that no influence of mortality has happened among the students since the first establishment of the college.

At Exeter there is an academy; at Portsmouth a grammar school; and all the towns are bound by law to support schools. The inhabitants of New Hampshire are chiefly Congregationalists. The other denominations are Presbyterians, Baptists, and Episcopalians.

The first discovery made by the English of any part of New Hampshire was in 1614, by Captain John Smith, who ranged the shore from Penobscot to Cape Cod; and in this route discovered the river Piscataqua. On his return to England, he published a description of the country, with a map of the coast, which he presented to prince Charles, who gave him the name of New-England. The first settlement was made in 1623.

New Hampshire was for many years under the jurisdiction of the governor of Massachusetts, yet they had a separate legislature. They ever bore a proportionable share of the expences and levies in all enterprises, expeditions, and military exertions, whether planned by the colony or the crown. In every stage of the opposition that was made to the encroachments of the British parliament, the people, who ever had a high sense of liberty, cheerfully bore their part.

HAMPSTEAD, a pleasant village of Middlesex, four miles northwest of London, stands in a healthy air, on a fine rise, at the top of which is a heath of about a mile every way, that is adorned with several pretty seats, in a most irregular romantic situation, and has a most extensive prospect over London, into the counties all round it, viz. Bucks and Hertfordshire, and even Northampton, Epping, Kent, Surrey, Berks, &c. with an uninterrupted view of Shooter's Hill, Banfield-Downs, and Windsor Castle. Its church was anciently a chapel of ease to Heendon, till about 1748. This village used to be referred to formerly for its mineral waters, which have lately been neglected; but the wells are still frequented. It is now crowded with good buildings, even on the very steep of the hill, where there is no walking six yards together without meeting a hillock; but in the reign of Henry VIII. it was chiefly inhabited by the laundresses who washed for the Londoners. Its old ruinous church, the lord of the manor's chapel, was lately pulled down, and a new one erected in its room. There is, besides, a handsome chapel near the wells, built by the contribution of the inhabitants, who are chiefly citizens and merchants of London.

HAMPTON, a town of Gloucestershire in England, seated on the Cotswold hills, and had formerly a nunnery. W. Long. 2. 15'. N. Lat. 51. 51.'

Hampstead, a town of Middlesex in England, seated on the river Thames, 12 miles west of London, and two from Richmond and Kingston. It is chiefly famous for the royal palace there, which is the finest in Britain. It was built by cardinal Wolsey, who had 280 silk beds for strangers only, and furnished it richly with gold and silver plate. The buildings, gardens, and the two parks, to which William III. made considerable additions, are about four miles in circumference, and are watered on three sides by the Thames. The inward court, built by king William, forms a piazza, the pillars of which are so low, that it looks more...
more like a cloister than a palace; however, the apartments make ample amends, being extremely magnificent, and more exactly disposed than in any other palace in the world, and adorned with most elegant furniture. Since the accession of his present majesty, however, this palace hath been much neglected, as the king has generally made choice of Windsor for his summer retreat. Those inimitable paintings by Raphael Urbino called the cartous, which were placed there by king William, have been removed to the queen’s palace at Weitzmann. For these pieces Louis XV. is said to have offered 100,000 l.

HAMESOKEN, or HAMSECKEN. See HAMSECKEN.

HANAPER, or HAMPER, an office in the English chancery, under the direction of a master, his deputy and clerks, answering, in some measure, to the scenes among the Romans.

HANAPER, (clerk of the) sometimes styled warden of the hanaper, an officer who receives all money due to the king for seals of charters, patents, commissilous, and writs, and attends the keeper of the seal daily in term time, and at all times of sealing, and takes into his custody all sealed charters, patents, and the like, which he receives in bags, but anciently, it is supposed, in to hanapers, which gave denomination to the office.

There is also an officer, who is comptroller of the hanaper.

HANAU, a town of Germany; and capital of a county of the same name, is pleasantly situated on the river Kenzigh near its confluence with the Mayne. The river divides it into the old and new town, both of which are fortified. The new town, which was built at first by French and Flemish refugees, who had great privileges granted them, is regular and handsome. The caffle, in which the counts used to reside, and which stands in the old town, is fortified, and has a fine flower-garden with commodious apartments, but makes no great appearance. The Jews are tolerated here, and dwell in a particular quarter. The magistracy of the new town, and the disposal of all offices in it, belong to the French and Dutch congregations. Here is a university, with several manufactures, particularly that of roll tobacco, and a very considerable traffic.

E. Long. 9. 0. N. Lat. 49. 58.

HANAU-HANZENBERG, a county of Germany. The greatest part of it is surrounded by the electorate of Mentz, the bishopric of Fulda, the lordships of Reinick, Hamburg, and Solms; as also by the territories of Heffe-Homburg, Banz-Friedburg, and Frankfort. Its length is near 40 miles, but its greatest breadth not above 12. It is exceedingly fertile in corn, wine, and fruit: yielding also salt springs, with some copper, silver, and cobalt. The chief rivers are, the Mayne, the Kenzigh, and the Nida. The prevailing religion is Calvinism, but Lutherans and Catholics are tolerated. The country is populous, and trade and manufactures flourish in it. In 1736, the whole male line of the counts of Hanaa falling in John Reinhard, William VIII. landgrave of the Heffe-Caell, by virtue of a treaty of mutual succession between the families of Hanaa and Heffe-Caell, took possession of the county, satisfaction having been first made to the house of Saxony for their claims; and in the year 1754 transferred it to prince William, eldest son to the then hereditary prince Frederick, afterwards landgrave. The revenues of the last count, arising from this and other territories, are said to have amounted to 500,000 florins. The principal places are Hanaa, Bergen, Steinau, and Glenhauffen.

HAND, a part or member of the body of man, making the extremity of the arm. See Anatomy, n° 53, &c.

The mechanism of the hand is very curious; excellently contrived to fit it for the various uses and occasions we have for it, and the great number of arts and manufactures it is to be employed in. It conflists of a compages of nerves, and little bones joined into each other, which give it a great degree of strength, and in the same time an unusual flexibility, to enable it to handle adjacent bodies, lay hold of them, and grasp them, in order either to draw them toward us or thrust them off. Anaxagoras is represented by ancient authors, as maintaining, that man owes all his wisdom, knowledge, and superiority over other animals, to the use of his hands. Gales represent the matter otherwise; man, according to him, is not the wiselest creature, because he has hands; but he had hands given him because he was the wiselest creature: for it was not our hands that taught us arts, but our reason. The hands are the organs of reason, &c.

In Scripture the word hand was variously applied. To pour water on any one’s hand, signifies to serve, him. To wash the hands was a ceremony made use of to denote innocence from murder or manslaughter. To kiss the hand was an act of adoration. To fill the hand signified taking possession of the priesthood, and performing its functions. To lean upon any one’s hand was a mark of familiarity and security, or make alliance. The right hand was the place of honour and trust. To pour water on anyone’s hand, signifies the conferring of holy orders; a ceremony wherein the hands are laid on the head of another, as a sign of a mission, or of a power given him to exercise the functions of the ministry belonging to the order.

The apostles began to appoint missionaries by the imposition of hands. See Imposition.

HAND, in falconry, is used for the foot of the hawk. To have a clean, strong, tender, glutinous hand, well clawed, are some of the good qualities of a hawk or falcon.

HAND, in the manage, sometimes stands for the fore-feet of a horse. It is also used for a division of the horse into two parts, with respect to the riders hand. The fore-hand includes the head, neck, and fore quarters; the hind-hand is all the rest of the horse.

HAND is likewise used for a measure of four inches, or of a clenched fist, by which the height of a horse is computed.

Hand is also figuratively used in painting, sculpture, &c. for the manner or style of this or that matter.
HA[N][294]D

Hanse are borne in coat-armour, dexter and sinister; that is, right and left, expanded or open; and after other manners. A bloody hand in the centre of the escutcheon is the badge of a baronet of Great Britain.

Hand-Breadth, a measure of three inches.

Handel (George Frederick) a most eminent master and composer of music; was born at Hall, a city of Upper Saxony in Germany. His father was a physician andsurgeon, of that place, and was upwards of 60 years of age when Handel was born. During his infancy young Handel is said to have amused himself with musical instruments, and to have made considerable progress before he was seven years of age, without any instructions. His propensity for music at last became so strong, that his father, who designed him for the study of the civil law, thought proper to forbid him even at this early period of life, to touch a musical instrument, and would suffer none to remain in his house. Notwithstanding this prohibition, however, Handel found means to get a little clavichord privately conveyed to a room in the uppermost story of the house, to which room he constantly stole when the family were asleep; and thus made such advances in his art, as enabled him to play on the harpsichord. He was first taken notice of by the duke of Saxe Weifenfels on the following occasion. His father went to pay a visit to another son by a former wife, who was valant de chambre to the duke, and refused at his court. Young Handel, being then in his seventh year, earnestly desired permission to go along with him; but being refused, he followed the chaise on foot, and overtook it, the carriage being probably retarded by the roughness of the way. His father at first chid him for his disobedience, but at last took him into the chaise along with him. While he was in the duke's court, he still continued to show the same inclination for music; it was impossible to keep him from harpsichords; and he used sometimes to get into the organ-loft at church, and play after service was over. On one of these occasions, the duke happening to go out later than usual, found something so uncommon in Handel's manner of playing, that he inquired of his valet who it was; and receiving for answer that it was his brother, he desired to see him. This nobleman was so much taken with the musical genius shown by young Handel, that he persuaded his father to let him follow the bent of his inclination. He made the boy a present; and told him, if he minded his studies, no encouragement should be wanting.

On his return to Hall, Handel was placed under one Zicklaw, the organist of the cathedral church; and one young musician was even then able to supply his master's place in his absence. At nine years of age he began to compose church-services for voices and instruments, and continued to compose such services every week for three years successively. At the age of 14, he far excelled his master, as he himself owned; and he was sent to Berlin, where he had a relation in some place about the court, on whose care and fidelity his parents could rely. The opera was then in a flourishing condition, being encouraged by the grandmaster of the late king of Prussia, and under the direction of many eminent persons from Italy, among whom were Buononcini and Attilio. Buononcini, being of a haughty disposition, treated Handel with con

rents; but Attilio behaved to him with great kindness, and he profited much by his instructions. His abilities soon recommended him to the king, who frequently made him presents, and at last proposed to send him into Italy under his own patronage, and to take him under his immediate protection as soon as his studies should be completed. But Handel's parents not thinking proper to submit their child to the caprice of the king, declined the offer; upon which it became necessary for him to return to Hall.

Handel having now obtained ideas in music far exceeding everything that could be found in Hall, continued there very unwillingly, and it was resolved to send him into Italy; but as the expense of this journey could not then be spared, he went to Hamburg, where the opera was little inferior to that of Berlin. Soon after his arrival in this city, his father died; and his mother being left in narrow circumstances, her son thought it necessary to procure some scholars, and to accept a place in the orchestra: by which means, instead of being a burden, he became a great relief to her.

At this time, the first harpsichord in Hamburg was played by one Kefer, a man who also excelled in composition; but he, having involved himself in some debts, was obliged to abscond. Upon this vacancy, the person who had been used to play the second harpsichord claimed the first by right of succession: but was opposed by Handel, who founded a claim to the first harpsichord upon his superior abilities. After much dispute in which all who supported or directed the opera engaged with much vehemence, it was decided in favour of Handel, but this good success had almost cost him his life. His antagonist renounced the supposed affront so much, that, as they were coming out of the orchestra together, he made a push at Handel's breast with a sword, which must undoubtedly have killed him, had there not fortunately been a music-book in the bottom of his coat.

Handel, though yet but in his 15th year, became composer to the house; and the successes of Almira, his first opera, was so great, that it ran 30 nights without interruption. Within less than a twelvemonth after this, he set two others, called Florinda and Nerone, which were received with the same applause. During his stay here, which was about four or five years, he also composed a considerable number of sonatas, which are now left. Here his abilities procured him the acquaintance of many persons of note, particularly the prince of Tuscany, brother to John Gallon de Medicis the grand duke. This prince pressed him to go with him to Italy, where he offered him that no convenience should be wanting; but this offer Handel thought proper to decline, being resolved not to give up his independency for any advantage that could be offered him.

In the 15th year of his age, Handel took a journey to Italy on his own bottom; where he was received with the greatest kindness by the prince of Tuscany, and had at all times access to the palace of the grand duke. His Serene Highness was impatient to have something composed by so great a master; and notwithstanding the difference between the style of the Italian music and the German, to which Handel had hitherto been accustomed, he set an opera called Rodea..
Handel was rewarded with 100 sequins and a service of plate. After staying about a year in Florence, he went to Venice, where he is said to have been first discovered at a masquerade. He was playing on a harpsichord in his vistor, when Scarlatti, a famous performer, cried out, that the person who played could be none but the famous Saxon or the devil. But a story similar to this is reported of many eminent persons whose abilities have been discovered in disguise. Here he composed his opera called *Agrippina*, which was performed 27 nights successively, with the most extravagant applause.

From Venice our musician proceeded to Rome, where he became acquainted with cardinal Ottoboni and many other dignitaries of the church, by which means he was frequently attacked on account of his religion; but Handel declared he would live and die in the religion in which he had been educated, whether it was true or false. Here he composed an oratorio called *Resurrezione*, and 150 cantatas, besides some sonatas, and other music. Ottoboni also contrived to have a trial of skill between him and Dominici Scarlatti, who was considered as the greatest master on that instrument in Italy. The event is differently reported. Some say Scarlatti was victorious, and others give the victory to Handel; but when they came to the organ, Scarlatti himself ascribed the superiority to Handel.

From Rome, Handel went to Naples; after which, he paid a second visit to Florence; and at last, having spent six years in Italy, set out for his native country. In his way thither, he was introduced at the court of Hanover with so much advantage by the baron Kilmanseck, that his Electrical Highness offered him a pension of 500 crowns a year as an inducement for him to continue there. This generous offer he declined on account of his having promised to visit the court of the Elector Palatine, and likewise to go over to England in compliance with the repeated invitations of the Duke of Manchester. The elector, however, being made acquainted with this objection, generously ordered him to be told, that his acceptance of the pension should neither restrain him from his promise nor resolution; but that he should be at full liberty to be absent a year or more if he chose it, and to go wherever he thought fit. Soon after the place of master of the chapel was bestowed upon Handel; and our musician having visited his mother, who was now extremely aged and ill, and his old master Zachew, and spent some time at the court of the Elector Palatine, set out for England, where he arrived in 1710.

At that time operas were a new entertainment in England, and were conducted in a very absurd manner; but Handel soon put them on a better footing; and set a drama called *Rinaldo*, which was performed with uncommon success. Having stayed a year in England, he returned to Hanover; but in 1712 he again came over to England; and the peace of Utrecht being concluded a few months afterwards, he composed a grand Te Deum and Jubilate on the occasion. He now found the nobility desirous that he should return the direction of the opera house in the Hay Market; and the queen having added her authority to their solicitations, and conferred on him a pension of L. 200 a year, he forgot his engagements to the Elector of Hanover and remained in Britain till the death of the queen in 1714. On the arrival of king George I., Handel, conscious of his ill behaviour, durst not appear at court; but he was extricated from his dilemma by the baron Kilmanseck. Having engaged several of the English nobility in his behalf, the baron persuaded the king to a party of pleasure on the water. Handel was aproved of the design, and ordered to prepare some music for the occasion. This he executed with the utmost attention, and on the day appointed it was performed and conducted by himself. The king with pleasure and surprize inquired who it was, and how the entertainment came to be provided without his knowledge. The baron then produced the deliquent; and asked leave to present him to his majesty as one too sensible of his fault to attempt an excuse, but sincerely desirous to atone for it. This intercession was accepted. Handel was restored to favour, his water music was honoured with the highest approbation, and the king added a pension of L. 200 a year that formerly bestowed on him by queen Anne; which he soon after increased to L. 400, on his being appointed to teach the young princes muick.

In the year 1715, Handel composed his opera of *Amadigi*; but from that time to the year 1720 he composed only *Tasso* and *Paflags Fato*, Buononcini and Attilio being then composers for the operas. About this time a project was formed by the nobility for erecting a kind of academy at the Hay Market, with a view to secure to themselves a constant supply of operas to be composed by Handel, and performed under his direction. No less than L. 50,000 was subscribed for this scheme, of which the king himself subscribed L. 1000, and it was proposed to continue the undertaking for 14 years. Handel went over to Dresden, in order to engage singers, and returned with Senesino and Durante. Buononcini and Attilio had still a strong party in their favour, but not equal to that of Handel; and therefore in 1720 he obtained leave to perform his opes of *Rudameto*. The house was so crowded, that many fainted through excessive heat; and 40s. were offered by some for a seat in the gallery, after having in vain attempted to get one elsewhere. The contention, however, still ran very high between Handel's party and that of the two Italian masters; and at last it was determined that the rivals should be jointly employed in making an opera, in which each should take a distinct act, and he who by the general suffrage was allowed to have given the best proof of his abilities should be put in possession of the house. This opera was called *Mucio Senevola*, and Handel got the last act. It is said that Handel's superiority was owned even in the overture before it; but when the act came to be performed, there remained no pretence of doubt or dispute. The academy was now therefore firmly established, and Handel conducted it for nine years with great success; but about that time an irreconcileable enmity took place, between Handel himself and Senesino. Senesino accused Handel of tyranny, and Handel accused Senesino of rebellion. The merits of the quarrel are not known: the nobility, however, became mediators for some time; and having failed in that good design, they became parties in the quarrel. Handel was resolved to dismiss Senesino, and the nobility seemed also resolved not to permit him to do so. The haughtiness of Handel's
Handel's temper would not allow him to yield, and the affair ended in the total dissolution of the academy.

Handel now found that his abilities, great as they were, could not support him against the powerful opposition he met with. After the death of Senecke, his audience sensibly dwindled away, and Handel entered into an agreement with Mr. Heidegger to carry on operas in conjunction with him. New singers were engaged from Italy; but the offended nobility raised a subscription against him, to carry on operas in the playhouse in Lincoln's-Inn fields. Handel bore four years against this opposition, three in partnership with Heidegger, and one by himself; but though his musical abilities were superior to those of his antagonists, the astonishing powers of the voice of Farinelli, whom the opposite party had engaged, determined the victory against him. At last Handel, having spent all he was worth in a fruitless opposition, thought proper to desist. His disappointment had such an effect upon him, that for some time he was disordered in his understanding, and at the same time his right arm was rendered useless by a stroke of the palsy. In this deplorable situation, it was thought necessary that he should go to the baths of Aix-la-Chapelle; and from them he received such extraordinary and sudden relief, that his cure was looked upon by the most miraculous.

In 1736, Handel again returned to England; and soon after his return his Alexander's Feast was performed with applause at Covent Garden. The success and splendor of the Hay Market was by this time so much reduced by repeated mismanagements, that Lord Middlesex undertook the direction of it himself, and once more he applied to Handel for composition. He accordingly composed two operas called Farinone and Alessandro Severo, for which in 1737 he received £1000. In 1738 he received £1500 from a single benefit, and nothing seemed wanting to retrieve his affairs, excepting such concessions on his part as his opponents had a right to expect. These concessions, however, he could not be prevailed upon to make; and that he would not longer be under obligations to act as he was directed by others, he refused to enter into any engagements upon subscription. After having tried a few more operas at Covent Garden without success, he introduced another species of music called oratorios, which he thought better suited to the native gravity of an English audience. But as the subjects of these pieces were always taken from sacred history, it was by some thought to be a profanation to fet them to music and perform them at a playhouse. In consequence of this prejudice, the oratorios met with very indifferent success; and in 1741 Mr. Handel found his affairs in such a bad situation, that he was obliged to quit England, and go to Dublin.

He was received in Ireland in a manner suitable to his great merit; and his performing his oratorios called the Messiah for the benefit of the city-prison, brought him into universal favor. In nine months time he had brought his affairs into a better situation; and on his return to England in 1742, he found the public much more favorably disposed. His oratorios were now performed with great applause: His Messiah, which before had been but coldly received, became a favorite performance; and Handel, with a generous humanity, determined to perform it annually for the benefit of the foundling hospital, which at that time was only supported by private benefactions. In 1743, he had a return of his paralytic disorder; and in 1751 came quite blind by a gutta peruna in his eyes. This last misfortune for some time sunk him into the deepest depression; but at last he was obliged to acquiesce in his situation, after having without any relief undergone some very painful operations. Finding it now impossible to manage his oratorios alone, he was assisted by Mr. Smith, who at his request frequently played for him, and conducted them in his stead; and with this assistance they were continued till within eight days of his death. During the latter part of his life, his mind was often disordered; yet at times it appears to have resumed its full vigour, and he composed several songs, choruses, &c. which from their dates may be considered almost as the last sounds of his dying voice.

From about October 1758 his health declined very fast; his appetite, which had been remarkably keen, and which he had gratified to a great degree, left him; and he became sensible of the approach of death. On the 6th of April 1759, his last oratorio was performed, at which he was present, and died on the 14th of the same month. On the 20th he was buried by the right reverend Dr Pearce, bishop of Rochester, in Westminster Abbey, where, by his own order, and at his own expense, a monument was erected to his memory.

With regard to the character of this most eminent musician, he is universally allowed to have been a great epicure: In his temper he was very haughty, but was seldom or never guilty of mean actions. His pride was uniform; he was not by turns a tyrant and a slave. He appears to have had a most extravagant love for liberty and independence; in which, that he would, for the sake of liberty, do things otherwise the most prejudicial to his own interest. He was liberal even when poor, and remembered his former friends when he was rich. His musical powers can perhaps be best expressed by Arbuthnot's reply to Pope, who seriously asked his opinion of him as a musician: 'Conceive (said he) the highest you can do his abilities, and they are much beyond any thing you can conceive.'

Commemoration of Handel: a musical exhibition instituted some years ago, and the grandest of the kind ever attempted in any nation. Of the rife and progress of the design, together with the manner in which the first celebration was executed, an accurate and authentic detail is given, as might be expected, by Dr. Burney in the 4th and last volume of his History of Music, from which the following account is extracted.

"In a conversation between lord viscount Fitzwilliam, Sir Watkin Williams Wynn, and Josiah Bates, Esq. commissioner of the victualling-office, the beginning of last year, 1783, at the house of Lord Pelham, after remarking that the number of eminent musical performers of all kinds, both vocal and instrumental, with which London abounded, was far greater than in any other city of Europe, it was lamented that there was no public periodical occasion for collecting and consolidating them into one band; by which means a performance might be exhibited on so grand and magnificent a scale as no other part of the world could equal. The birth and death of Handel naturally occurred to three
Handel's three such enthusiastic admirers of that great master; and it was immediately recollected, that the next year (1764) would be a proper time for the introduction of such a custom, as it formed a complete century since his birth, and an exact quarter of a century since his decease.

"The plan was soon after communicated to the governors of the Musical Fund, who approved it, and promised their assistance. It was next submitted to the directors of the concert of Ancient Music; who, with an alacrity which does honour to their zeal for the memory of the great sir Handel, voluntarily undertook the trouble of managing and directing the celebrity. At length, the design coming to the knowledge of the king, it was honoured with his majesty's sanction and patronage. Westminster-abbey, where the bones of the great musician were deposited, was thought the properest place for the performance; and application having been made to the bishop of Rochester for the use of it, his lordship, finding that the scheme was honoured with the patronage of his majesty, readily consented; only requiring, as the performance would interfere with the annual benefit for the Westminster Infirmary, that part of the profits might be appropriated to that charity, as an indemnification for the loss it would sustain. To this the projectors of the plan acceded; and it was afterwards settled, that the profits of the first day's performance should be equally divided between the Musial Fund and the Westminster Infirmary; and those of the subsequent days be solely applied to the use of that fund which Handel himself so long helped to sustain, and to which he not only bequeathed a thousand pounds, but which almost every musician in the capital annually contributes his money, his performance, or both, in support. Application was next made to Mr. James Wyatt, the architect, to furnish plans for the necessary decorations of the abbey; drawings of which having been shown to his majesty, were approved. The general idea was to produce the effect of a royal musical chapel, with the orchestra terminating one end, and the accommodation for the royal family, the other. The arrangement of the performance of each day was next settled; and it was at his majesty's instigation that the celebrity was extended to three days instead of two, which he thought would not be sufficient for the display of Handel's powers, or fulfilling the charitable purposes for which it was intended to devote the profits. It was originally intended to have celebrated this festival on the 20th, 22d, and 23d of April; and the 20th being the day of the funeral of Handel, part of the music was, in some measure, selected as to apply to that incident. But, in consequence of the sudden dissolution of parliament, it was thought proper to defer the festival to the 26th, 27th, and 29th of May, which seemed to have been for its advantage: as many persons of tender considerations, who ventured to go to Westminster abbey in warm weather, could not have had the courage to go thither in cold. Impressed with a reverence for the memory of Handel, no sooner was the project known, but most of the practical musicians in the kingdom eagerly manifested their zeal for the enterprise; and many of the most eminent professed, waving all claims to precedence in the band, offered to perform in any subordinate station in which their talents could be most useful.

"In order to render the band as powerful and complete as possible, it was determined to employ every species of instrument that was capable of producing grand effects in a great orchestra and spacious building. Among those the fagbut or double tromper, was sought; but so many years had elapsed since it had been used in this kingdom, that neither the instrument, nor a performer upon it, could easily be found. It was, however, discovered, after much tedious enquiry, not only here, but by letter, on the continent; that in his majesty's military band there were two musician who played the three several species of fagbut, tenor, base, and double base.

"The double bassoon, which was so conspicuous in the orchestra, and powerful in its effect, is likewise a tube of 16 feet. It was made, with the approbation of Mr. Handel, by Stainby, the flute-maker, for the coronation of his late majesty George II. The late ingenious Mr. Lampe, author of the justly admired music of The Dragon of Wantley, was the person intended to perform on it; but, for want of a proper reed, or for some other cause, at present unknown, no one was made of it at that time; nor indeed, tho' it has been often attempted, was it ever introduced into any band in England till now, by the ingenuity and perseverance of Mr. Alhly, of the Guards.

"The double-base kettle-drums were made from models of Mr. Aisbridge, of Drury Lane orchestra, in copper, it being impossible to procure plates of brass large enough. The Tower drums, which, by permission of his grace the duke of Richmond, were brought to the abbey on this occasion, are those which belong to the guards, who played the three species of kettle-drums, which may be called tenor, base, and double-base, were an octave below each other.

"The excellent organ, erected at the west end of the abbey, for the commemorative performances only, is the workmanship of the ingenious Mr. Samuel Green in Ullington. It was fabricated for the cathedral of Canterbury; but before its departure for the place of its destination, it was permitted to be opened in the capital on this memorable occasion. The keys of communication with the harpsichord, at which Mr. Bates the conductor was seated, extended to feet from the body of the organ, and 20 feet 7 inches below the perpendicular of the set of keys by which it is usually played. Similar keys were first contrived in this country for Handel himself at his oratorios; but to convey them to so great a distance from the instrument, without rendering the touch impracticably heavy, required uncommon ingenuity and mechanical resources.

"In celebrating the disposition, discipline, and effects of the most numerous and excellent band, the merit of the admirable architect, who furnished the elegant designs for the orchestra and galleries, must not be forgotten; as, when filled, they constituted one of the grandest and most magnificent specacles which
Handel, imagination can delineate. All the preparations for receiving their majesties, and the first perfonages in the kingdom, at the east end; upwards of 500 musicians at the west; and the public in general, to the number of between 3000 and 4000 persons, in the area and galleries; so wonderfully corresponded with the style of architecture of this venerable and beautiful structure, that there was nothing visible either for use or ornament, which did not harmonize with the principal tone of the building, and which may not metaphorically have been said to have been in perfect tune with it. But, besides the wonderful manner in which this construction exhibited the band to the spectators, the orchestra was so judiciously contrived, that almost every performer, both vocal and instrumental, was in full view of the conductor and leader; which accounts, in some measure, for the uncommon ease with which the performers confefs they executed their parts.

At the east end of the aisle, just before the back of the choir-organ, some of the pipes of which were visible below, a throne was erected in a beautiful Gothic style, corresponding with that of the abbey, and a centre box, richly decorated and furnished with crimson satin, fringed with gold, for the reception of their majesties and the royal family: on the right hand of which was a box for the bishops, and, on the left, one for the dean and chapter of Westminster: immediately below, and two boxes were formed, one on the right for the families and friends of the directors, and the other for those of the pebbonaries of Westminster. Immediately below the king's box was placed one for the directors themselves, who were all distinguished by white wands tipped with gold, and gold medallions, struck on the occasion, appendant from white ribbons. These their majesties likewise condescended to wear at each performance. Behind, and on each side of the throne, there were seats for their majesties' suite, maids of honour, grooms of the bedchamber, pages, &c.—The orchestra was built at the opposite extremity, ascending regularly from the height of seven feet from the floor, upwards of forty from the base of the pillars, and extending from the centre to the top of the side aisle.—The intermediate space below was filled up with level benches, and appropriated to the early subscribers. The side aisles were formed into long galleries ranging with the orchestra, and ascending so as to contain 12 rows on each side: the fronts of which projected beyond the pillars, and were ornamented with festoons of crimson morse.—At the top of the orchestra was placed the occasional organ, in a Gothic frame, mounting to, and mingling with, the faken and martyrs represented in the painted glass on the west window. On each side of the organ, close to the windows, were placed the kettle-drums described above. The choral bands were principally placed in view of Mr Bate, on steps seemingly ascending into the clouds, in each of the side aisles, as their termination was invisible to the audience. The principal singers were ranged in the front of the orchestra, as at oratorios, accompanied by the choirs of St Paul, the abbey, Windsor, and the chapel royal.

Few circumstances will perhaps more astonish veteran musicians, than to be informed, that there was but one general rehearsal for each day's performance: an indubitable proof of the high state of cultivation to which practical music is at present arrived in Britain; for if good performers had not been found ready made, a dozen rehearsals would not have been sufficient to make them so. Indeed, Mr Bates, in examining the list of performers, and inquirmg into their several merits, suggested the idea of what he called a drilling rehearsal, at Tottenham-street Concert Room, a week before the performance; in order to hear such volunteers, particularly chorus singers, as were but little known to himself, or of whose abilities his assistant was unable to speak with certainty. At this rehearsal, though it consisted of 120 performers, not more than two of that number were desired to attend no more.

At the general rehearsal in the abbey, mentioned above, more than 500 performers found means to obtain admission, in spite of every endeavour to shut out all but the performers; for fear of interruptions and perhaps of failure in the first attempts at incorporating and condensing such a numerous band: consisting not only of all the regulars, both native and foreign, which the capital could furnish, but of all the irregulars, that is, different, and provincial musicians of character, who could be mufiered, many of whom had never heard or seen each other before. This intrusion, which was very much to the dissatisfaction of the managers and conductor, suggested the idea of turning the eagerness of the public to some profitable account for the charity, by fixing the price of admission to half a guinea for each person.

But, besides the profits derived from subsequent rehearsals, the consequences of the first were not without their use: for the pleasure and astonishment of the audience, at the small mistakes, and great effects of this first experiment, which many had condemned by anticipation, were soon communicated to the lovers of music throughout the town, to the great increase of subscribers and solicitors for tickets. For though the friends of the directors were early in subscribing, perhaps from personal respect, so much as expectation of a higher musical result than usual; yet the public in general did not manifest great eagerness in securing tickets till after this rehearsal, Friday May 21. which was reported to have astonished even the performers themselves by its correctness and effects. But so interesting did the undertaking become by this favourable rumour, that from the great demand of tickets it was found necessary to close the subscription.

Many families, as well as individuals, were attracted to the capital by this celebrity; and it was never remembered to have been so full, except at the coronation of his present majesty. Many of the performers came unforeseen, from the remotest parts of the kingdom at their own expense: some of them, however, were afterwards reimbursed, and had a small gratuity in consideration of the time they were kept from their families by the two unexpected additional performances.

Foreigners, particularly the French, must be much astonished at so numerous a band moving in such exact measure, without the assistance of a Coryphæus to beat the time, either with a roll of paper, or a noisy baton, or truncheon. Rouleau says, that 'the more time is beaten, the less it is kept; and it is certain, that when the measure is broken, the fury of the musical
HAN

Handel was a remarkable general or director, increasing with the difficulties and confusion of his troops, he becomes more violent, and his strokes and gestures more ridiculous in proportion to their disorder.

"As this commemoration is not only the first instance of a band of such magnitude being assembled together, but of any band at all numerous, performing in a similar situation, without the assistance of a conductor to regulate the measure, the performances in Westminster abbey may be safely pronounced no less remarkable for the multiplicity of voices and instruments employed, than for accuracy and precision. When all the wheels of that huge machine, the orchestra, were in motion, the effect resembled clock-work in every thing but want of feeling and expression. And as the power of gravity and attraction in bodies is proportioned to their masses and density, so it seems as if the magnitude of this band had commanded and impelled adherence and obedience beyond that of any other of inferior force. The pulsations in every limb, and ramifications of veins and arteries in an animal, could not be more reciprocal, isochronous, and under the regulation of the heart, than the members of this body of musicians under that of the conductor and leader. The multitude of sound seemed to proceed from one voice and one instrument; and its powers produced not only new and exquisite sensations in judges and lovers of the art, but were felt by those who never received pleasure from music before. These effects, which will be long remembered by the present public, perhaps to the disadvantage of all other choral performances, run the risk of being doubted by all but those who heard the first performance, the disadvantage of all other choral performances, run the risk of being doubted by all but those who heard.

"It will be remembered, the metropolis of the province of Tsche-kiang in China. See Tse-che-kiang.

- It is, according to the Chinese, the paradise of the earth; and may be considered as one of the richest, best situated, and largest cities of the empire. It is four leagues in circumference, exclusive of its suburbs; and the number its inhabitants amounts to more than a million. It is computed, that there are a thousand workmen within its walls employed in manufacturing silk; which renders this city delightful, is a small lake, called Si-four, which washes the bottom of its walls on the western side; its water is pure and limpid, and its banks are almost everywhere covered with flowers. Halls and open galleries, supported by pillars, and paved with large flag stones, have been erected here on piles, for the convenience of those who are fond of walking; cause-ways, cased with cut stone, traverse the lake in different directions; and the openings which are left in them at intervals, for the passage of boats, are covered by handsome bridges. In the middle of the lake are two islands, to which company generally resort after having amused themselves with rowing, and in which a temple and several pleasure-houses have been built for their reception. The emperor has a small palace in the neighbourhood. The city has a garrison of 2000 Chinese, under the command of the vicerey, and 3000 Tatars, commanded by a general of the same nation. It has under its jurisdiction seven cities of the second and third class.

HANGING, a common name given to the method of inflicting death on criminals by suspending them by the neck.—Physicians are not agreed as to the manner in which death is brought on by hanging. De Haen hanged three dogs, whom he afterwards opened. In one, nothing remarkable appeared in the lungs. In another, from whom half an ounce of blood was taken from the jugular vein, the dura and pia mater were of the natural appearance; but the lungs were much inflamed. In the third, the meninges were found, and there was no effusion of blood in the ventricles of the brain, but the left lobe of the lungs was turgid with blood. Wepfer, Littræus, Alberti, Bruckner, and Boerhaave, affirm that hanged animals die apoplectic. Their arguments for this are chiefly drawn from the lived colour of the face, the disfigurement of the vesels of the brain; the inflammation of the eyes; and from the sparks of fire which those who have survived hanging allege they have seen before their eyes. On the contrary, Bonetus, Petit, Haller, and Lancisi, from observing that death is occasioned by any small body falling into the glottis, have ascribed it to the stoppage of respiration. Others, deeming both these causes ill-founded, have ascribed it to a fixation of the vertebrae of the neck.—De Haen addsuces the authority of many eminent authors to prove the possibility of recovering hanged persons; and observes, in general, that with bleeding in the jugular vein, and anointing the neck with warm oil, the same remedies are to be employed in this case as for the recovery of drowned people. See DROWNING.

HANGINGS, denote any kind of drapery hung up against the walls or wainscoting of a room.

Winds Hangings. See Tapestry.

Hangcliffe, a remarkable point of land on the east coast of the largest of the Florida Keys, is frequently the first land seen by ships in northern voyages. Captain Phipps determined its situation to be in W. Long. 0° 36' 30". N. Lat. 60° 9'.

Hannibal, a famous Carthaginian general, of whose exploits an account is given under the articles Carthage and Rome. After having had the misfortune to lose a sea-fight with the Rhodians, through the cowardice of Apollonius one of the admirals of Antiochus the Great, he was forced to fly into Crete, to avoid falling into the hands of the Romans. On his arrival in this island, he took sanctuary in the temple of Diana, in the presence of the Great; but as he had brought great treasure along with him, and knew the avarice of the Cretans, he thought proper to secure his riches by the following stratagem. He filled several vessels with melted lead, just covering them over with gold and silver. These he deposited in the temple of Diana, in the presence of the Gortynii, with whom he said, he trusted all his treasures: Justin tells us, that he left this with them as a security for his good behaviour, and lived for some time very quietly in these parts. He took care, however, to conceal his riches in hollow flutes of brass; which, according to some, he always carried along with him; or, as others will have it, exposed in a public place as things of little value. At last he retired to the court of Prusias king of Bithynia, where he found means to unite several of the neighbouring states with that prince into a confederacy against Eumenes king of Pergamus, a professed friend to the Romans; and during the ensuing war gave Eumenes several
When a Fabius and a Scipio were sent against him, the first stopped his progress, the other conquered him."

These reasons have been answered by Mr. Hook, who hath taken some pains to vindicate Hannibal's character, by fully and fairly comparing it with that of Scipio Africanus, and other Roman commanders.

"I do not see (says he) why these difficulties should check our author's inclination to declare in favour of the Carthaginian. That Fabius was not beaten by Hannibal, we cannot much wonder, when we remember how steadily the old man kept to his resolution never to fight with him. But from Fabius's taking this method to put a stop to the victories of the enemy, may we not conclude that he knew no other, and thought Hannibal an overmatch for him? And why does our author forget Publius Scipio (Africanus's father), a prudent and able general, whom Hannibal vanquished at the Tichin? Livy relates those victories of Hannibal over the celebrated Marcellus; but neither Marcellus nor any other general ever vanquished Hannibal before the battle of Zama, if we may believe Polybius (lib. xvi. c. 16). Terentius Varro, indeed, is represented as a headstrong rash man; but the battle of Cannae was not by if his imprudence. The order in which he drew up his army is nowhere condemned; and Chevalier Focard thinks it excellent. And as to the conduct of the battle, Scipio, Paulus, a renowned captain, and a disciple of Fabius, had a greater share in it than his colleague. The imprudence with which Varro is taxed, was his venturing, contrary to his colleague's advice, with above 90,000 men to encounter in a plain field an enemy who had only 50,000, but was superior in horse. And does not the very advice of Aemilius, and the charge of temerity on Varro for not following it, imply a censure of Hannibal's superiority in military skill over Aemilius as well as Varro? It ought like wise to be observed, that Hannibal's infantry, bad gained the victory over the Roman infantry, before the latter suffered any thing from the Carthaginian cavalry. It was otherwise when Scipio gained the victory at Zama. His infantry would probably have been vanquished but for his cavalry. Hannibal, with only his third line of foot (his Italian army), maintained a long fight against Scipio's three lines of foot; and seems to have had the advantage over them, when Mamilia and Lælius, with the horse, came to their assistance. Polybius indeed says, that Hannibal's Italian forces were equal in number to all Scipio's infantry; but this is contradicted by Livy, and is not very probable. The authority of Polybius, who was an intimate friend of Scipio Aemilius, is, I imagine, of little weight in matters where the glory of the Scipios is particularly concerned. His partiality and flattery to them are, in many instances, but too visible.

Our author then proceeds to show, that Hannibal was not guilty of any of the faults laid to his charge as a general; and having contrasted the moral characters of the two generals with each other, makes it evident, that as a man, as well as a general, Hannibal had greatly the advantage of his rival. See Hook's Roman History, vol. iv, p. 151 & seq.

Hanno, general of the Carthaginians, was commanded to sail round Africa. He entered the ocean through
Hanover. through the Straits of Gibraltar, and discovered several countries. He would have continued his navigation, had it not been for want of provisions. He wrote an account of his voyage, which was often quoted, but not much credited. Sigismund Gelenius published it in Greek at Baille, by Frobenius, in 1533. He lived, according to Pliny, when the affairs of the Carthaginians were in the most flourishing condition; but this is a very indeterminate expression.

Hanover, an electoral state of Germany, of which the king of Great Britain is elector.—Though the house of Hanover is the last that has been raised to the electoral dignity in the empire, it may vie with any in Germany for the antiquity and nobleness of its family. It is likewise very considerable for the extent of its territories, which at present are the duchy of Calenberg, in which are the cities of Hanover, Calenberg, Hamelen, Neufstadt, Gottingen, &c. the duchy of Grabenhagen, the county of Diepholt, the county of Iloga, in the bishopric of Hildesheim; the bailiwicks of Coldingen, Luther, Badenburg, and Wetterfehoven, with the right of protection of the city of Hildesheim; and the county of Danneberg, ceded by the dukes of Wolfsenbottle to the dukes of Lunenburg, as an equivalent for their pretensions on the city of Bremen.

The elector polishes likewise the county of Delmenhorst, and the duchies of Bremen and Verden, fold by the king of Denmark in 1715: the right of poelling alternately the bishopric of Osnabruck belongs solely to the electoral branch; but if it should happen to fail, the dukes of Wolfsenbottle are to enjoy the same right. This electorate has no navy, but a considerable marine on the great rivers Elbe and Weser.

In consideration of the great services performed by Ernert Augustus, duke of Brunswick-Hanover, in the wars which the emperor Leopold had with Louis XIV. that emperor conferred the dignity of an elector of the holy Roman empire upon him and his heirs male, of which he received the investiture on the 19th of December 1692. This new creation met with great opposition both in the electoral college and the college of princes; at last, by a conclusion of the three colleges on the 30th of January 1708, it was unanimously determined, that the electoral dignity should be confirmed to the duke of Hanover, and his heirs male; but it was added, that if, while that electoral dignity subsisted, the Palatine elector should happen to fall into the hands of a Protestant prince, the first Catholic elector should have a supernumerary vote.

The princes of this house have their seat in the college of princes, immediately after those of the electoral houses; each branch having a vote. The elector, besides his seat in the electoral college, was invested with the office of arch-steward bearer of the empire; but this being disputed with him by the duke of Wurttemberg, the elector Palatine having obtained the office of arch-steward, yielded that of arch-treasurer to the elector of Hanover, who was confirmed in this dignity by a decree of the diet of the 23rd of January 1710.

The sovereign power is administered by the lords of the regency appointed by the elector. Throughout all the provinces they police a considerable share of free-
Han疤, well fortified. It has suffered greatly by the French, who got possession of it in 1757, but were soon after driven out. It is noted for a particular kind of beer, reckoned excellent in these parts. This city was the residence of the elector before he ascended the throne of Great Britain. The palace makes no great show outwardly; but within it is richly furnished. The regency of the country is administered in the same manner as the sovereign was present.

Hanse, or Hans, an ancient name for a society or company of merchants, particularly that of certain cities in Germany, &c. hence called Hanse-towns. See Hanse-Towns.—The word hanse is obsolete High Dutch or Teutonic; and signifies "alliance, confederacy, association," &c. Some derive it from the two German words, am-fec, that is "on the sea;" by reason the first Hanse towns were all situated on the sea-coast: whence the society is said to have been first called am zee flenen, that is, "cities in the sea;" and afterwards by abbreviation, hanse, and hanse.

Hanse-Towns. — The Hanseatic society was a league between several maritime cities of Germany, for the mutual protection of their commerce. Bremen and Amsterdam were the two first who formed it; whose trade received such advantage by their joining out two men of war in each to convoy their ships, that more cities continually entered into the league: even kings and princes made treaties with them, and were often glad of their assistance and protection; by which means they grew so powerful by both sea and land; that they raised armies as well as navies enjoyed countries in sovereignty, and made peace or war, though always in defence of their trade, as if they had been an united state or commonwealth.

At this time also abundance of cities, though they had no great interest in trade, or intercourse with the ocean came into their alliance for the preservation of their liberties; so that in 1020 we find no less than 72 cities in the list of the towns of the Hanse; particularly Bremen, Amsterdam, Antwerp, Rotterdam, Dort, Bruges, Oostend, Dunkirk, Middelburgh, Calais, Rouen, Rochelle, Broudeaux, St-Malo, Bayonne, Bilboa, Lisbon, Seville, Cadiz, Carthage, Barcelona, Marseilleilles, Leghorn, Naples, Melfina, London, Lubeck, Rostock, Stralund, Stein, Wismar, Konigberg, Danzig, Elbing, Marienburg.

The alliance was now so powerful, that their ships of war were often hired by other princes to assist them against their enemies. They not only slew, but often defeated all that opposed their commerce; and particularly in 1358, they took such revenge of the Danish fleet in the Sound for having interrupted their commerce, that Waldemar III. then king of Denmark for the sake of peace, gave them up all Schonen for 16 years; by which they commanded the passage of the Sound in their own right. — In 1428 they made war on Eric king of Denmark with 250 sail, carrying on board 12,000 men. These so ravaged the coast of Jutland, that the king was glad to make peace with them.

Many privileges were bestowed upon the Hanse towns by Louis XI. Charles VIII. Louis XII. and Francis I. kings of France; as well as by the emperor Charles V., who had divers loans of money from them; and by king Henry III. who also incorporated them in a trading body, in acknowledgment for money which they advanced to him, as well as for the good services they did him by their naval forces in 1260.

These towns exercised a jurisdiction among themselves; for which purpose they were divided into four colleges or provinces, distinguished by the names of their four principalities, viz. Lubeck, Cologne, Brunswick, and Dantzig, wherein were held their courts of judicature. They had a common flock or treasury at Lubeck, and power to call an assembly as often as necessary. — They kept magazines or warehouses for the sake of their merchandise in London, Bruges, Antwerp, Bergen in Norway, Ravel in Livonia, Novgorod in Muscovy, which were exported to most parts of Europe, in English, Dutch, and Flemish bottoms. One of their principal magazines was at London, where a society of German merchants was formed called the feelyard company. To this company great privileges were granted by Edward I. but revoked by act of parliament in 1352 in the reign of Edward VI. on a complaint of the English merchants that this company had fo engrossed the cloth trade, that in the preceding year they had exported 30,000 pieces, while all the English together had shipped out 12,000. Queen Mary, who ascended the throne the year following, having resolved to marry Philip the emperor's son, suspended the execution of the act for three years: but after that term, whether by reason of some new statute, or in pursuance of that of King Edward, the privileges of that company were no longer regarded, and all efforts of the Hanse towns to recover this loss were in vain.

Another accident that happened to their mortification was while Queen Elizabeth was at war with the Spaniards. Sir Francis Drake happening to meet 60 ships in the Tagus, laden with corn, belonging to the Hanse towns, took out all the corn as contraband goods which they were forbid to carry by their original patent. The Hanse towns having complained of this to the diet of the empire, the queen sent an ambassador there to declare her reasons. The king of Poland likewise interested himself in the affair, because the city of Dantzig was under his protection. At last though the queen swore hard to preserve the commerce of the English in Germany, the emperor excluded the English company of merchant-adventurers, who had considerable factories at Stade, Embden, Bremen, Hamburg, and Elbing, from all trade in the empire. In short, the Hanse towns, in Germany in particular, were not only so flourishing, but in so formidable a state, from the 14th to the 16th centuries, that they gave umbrage to all the neighbouring princes, who threatened a strong confederacy against them; and, as the first step towards it, commanded all the cities within their dominion or jurisdiction to withdraw from the union or hanse, and be no farther concerned therein. This immediately separated all the cities of England, France, and Italy, from them. The hanse, on the other hand, prudently put themselves under the protection of the empire: and as the cities just now mentioned had withdrawn from them; so they withdrew from several more, and made a decree among themselves, that none should be admitted into their society but such as stood within the limits of the German empire.
HANWAY (Jonas), eminent for his benevolent designs and useful writings, was born at Portsmouth, in Hampshire on the 12th of August 1712. His father Mr Thomas Hanway, was an officer in the naval service, and for some years store-keeper to the dockyard at that place. He was deprived of his life by an accident; and left his widow with four children. Jonas, William, Thomas, and Elizabeth, all of a very tender age. Mrs Hanway, coming to London after the death of her husband, put Jonas to school, where he learned writing and accounts, and made some proficiency in Latin. At the age of 17 he was sent to Lisbon, where he arrived in June 1729, and was bound apprentice to a merchant in that city. His early life, we are informed, was marked with that delicate attention to business, and love of neatness and regularity, which afterwards distinguished his character. At Lisbon his attentions were captivated by a lady, then celebrated for her beauty and mental accomplishments; but the, preferring another for her husband, returned to England, and spent the latter part of her life in London with her family, on terms of friendship with Mr Hanway.—On the expiration of Mr Hanway’s apprenticeship, he entered into business at Lisbon as a merchant or factor; but did not remain there long before he returned to London.

He soon after connected himself as a partner in Mr Dingley’s house in St Peterburg; where he arrived on the 10th of June 1743. The trade of the English nation over the Caspian Sea into Persia at this period had been entrusted to the care of Mr Eton, who not content with the pursuit of commercial affairs, had indiscriminately engaged in the service of Nadir Shah to build ships on the Caspian after the European manner. This had alarmed the merchants in the Russian trade, and a resolution was formed that one of their body should make a journey into Persia. On this occasion Mr Hanway offered his service, and was accepted. He set out on the 9th of September; and after experiencing a variety of hazards in that kingdom during a course of 12 months, returned to St Peterburg January 1, 1745, without being able to establish the intended trade by the Caspian, partly through the jealousy of the Russian court on account of Eton’s connections with the Persians, and partly by the troubles and revolutions of the latter kingdom.

Though Mr Hanway’s conduct during this expedition seems to have been directed by the strictest rules of integrity, yet some difficulties arose in settling his demands on his employers. These, however, in the end were referred to the determination of impartial arbitrators, who at length decided in his favour.

“I obtained (he says) my own; and as to any other personal advantage, it consisted in exercising my mind in patience under trials, and erecting my knowledge of the world.” He now settled at St Peterburg; where he remained five years, with no other variations in his life than such as may be supposed to occur in the dull round of a mercantile employment. During this time he interested himself greatly in the concern of the merchants who had engaged in the Caspian trade; but the independence he had acquired having excited a desire to fec his native country, he, after several disappointments which prevented him from accomplishing his view, left St Peterburg on the 9th of July 1750. On his arrival in his native country, he did not immediately relinquish his mercantile connections, though he seems to have left Russia with that view. He employed himself some time as a merchant; but afterwards, more beneficially to the world, as a private gentleman. In 1753 he published “An Historical Account of the British Trade over the Caspian Sea; with a Journal of Travels from London through Russia into Persia; and back again thro’ Russia, Germany, and Holland. To which are added, the Revolutions of Persia during the present Century, with the particular History of the great Uliferper Nadir Kooli,” 4 vols 4to; a work which was received, as it deferred to be with great attention from the public. In 1754 we find Mr Hanway commending a plan offered for the advantage of Westminister, and fuggeting hints for the further improvement of it, in “A Letter to Mr John Spranger, on his excellent Proposal for Paving, Cleaning, and Lighting the Streets of Westminster, &c.” 8vo. A few years afterwards, when a scheme of the like kind was carried into effect, many of Mr Hanway’s ideas, thrown out in this pamphlet, were adopted. In 1756, he printed “a Journal of Eight Days Journey from Portsmouth to Kington upon Thames, with an Essay on Tea;” which was afterwards reprinted in 2 vols 8vo, 1757.

At this juncture, Great Britain being on the eve of a war with France, the event of which was very important to the nation at large, and required every effort of patriotism, and prudence to ward off the impending danger, Mr Hanway published “Thoughts on the Duty of a good Citizen with Regard to War and Invasion, in a Letter from a Citizen to his Friend,” 8vo. About the same time, several gentlemen formed a plan, which was matured and made perfect by the affiduity of Mr Hanway, for providing the navy with sailors, by furnishing poor children with necessaries to equip them for the service of their country. The success and propriety of this scheme soon became apparent. Mr Hanway wrote and published three pamphlets on this occasion; and the treasurer of the Society, accompanied by Mr Hanway, having waited on the king, the Society received royal from his majesty, 400l. from the Prince of Wales, and 200l. from the Princes Dowager. This excellent institution through life was the favourite object of Mr Hanway’s care, and continued to flourish under his auspices greatly to the advantage of the community. In 1758 he became an advocate for another
In 1759, Mr Hanway wrote "Reasons for an Augmen
tation of at least Twelve Thousand Mariners, to be
employed in the Merchants Service and Coasting Trade
in 33 Letters to Charles Gray, Esq; of Chelsea.
4th." The next year he published several performances:
1. "A candid historical Account of the Hospital for
the Reception of Ekefnet and deferted Young Children;
representing the present Plan of it as productive of
many Evils, and not adapted to the Genius and Happi
ness of this Nation." 8vo.: which being answered by an
anonymous Letter from Halifax in "Candid Remarks,
8vo. 1760," Mr Hanway replied to it, and the Remark
er rejoined. 2. "An Account of the Society for
the encouragement of the Brith Troops in Germany
and North America, &c." 8vo. 3. "Eight Letters
to— Duke of ——, on the Custom of Vails-giving
in England," 8vo. This practice of giving vails
had arrived at a very extravagant pitch, especially
among the servants of the great. It was Mr Han
way who aniered the kind reproach of a friend in
a high station for not coming oftener to dine with
him, by saying "Indeed I cannot afford it." The
nobleman to whom the above letters were addressed
was the Duke of Newcastle. The letters are written
in that humorous style which is most attractive of
general notice, and was best adapted to the subject.
It was Sir Timothy Waldo that first put Mr Hanway on
this plan. Sir Timothy had dined with the duke of N—
and, on leaving the house was contributing to the
support and inocence of a train of servants who aided
the hall; and at last put a crown into the hand of the
cook, who returned it, saying, "Sir, I do not take
silver."—"Don't you indeed?" said the worthy
baronet, putting it in his pocket; then I do not give
gold." Among the ludicrous circumstances in Mr Hanway's letters is one which happened to himself.
He was paying the Servants of a Master of a Dinner
whose master had invited him to one, by one as they appeared; Sir your great-coat; a diffing—
"Your hat;" a defing— "Stick;" a defing—
"Umbrella:" a defing— "Sir, your gloves;"—
"Why, friend, you may keep the gloves they are
not worth a defing." In 1761, Mr Hanway produ
ced "Reflections, Essays, and Meditations on Life and
Religion; with a collection of Proverbs and 28 Let
ters written occasionally on several Subjects," in 2 vols
8vo.

The many useful and public spirited plans which Mr Hanway had promoted for the welfare of the com
munity had now rendered his character most respectably
popular, while his cliques refledd the friendliness of
his intentions, were conspicuous to all. Five citizens
of London, whom the late Mr Hoare the banker
was one, waited on Lord Bute, at that time the
mi
ister; and, in their own names, and the names of
their fellow citizens, requested that some notice might
be taken of a man, who at the expense of his own
private fortune, and unremitting application, had ren
dered to so many and such meritorious services to his
country. In consequence of this request, he was in
July 1762, appointed by a patent one of the com
missioners for victualling, a post which he held above 21 years. The next act of public benefi
cence in which we find him engaged is the collection of
money for the sufferers by the fire which happened
at Montreal, in the province of Quebec, in May 1765,
when a fourth part of the city was consumed. On this
occasion Mr Hanway, in conjunction with two other
gentlemen, collected 8415l—The very next year a
dreadful fire broke out in Bridge Town in Barbadoes,
which consumed buildings and property to the amount
of near 100,000. A subscription was opened, in which
Mr Hanway was a principal actor, and 14,886l. were
collected, and transmitted to a committee appoint
ed at Barbadoes to distribute it to the unfortunate suf
ferers. At subsequent periods he continued to interefthimself in various other plans for relieving the disfref
ses, and promoting the good, of different classes of
the community. His attention was particularly di
rected towards alleviating the miseries of young chim
ney-sweepers. Besides the distresses of these helples
beings, which are open to general observation, such
as a contortion of the limbs, and the prevention of
their growth, they are liable to a disease peculiar to
their occupation, now known by the name of the chim
ney-sweeper's cancer. Four children have been brought
together into a workhouse, all afflicted with this dread
ful and incurable disease. After much inquiry and
confideration, he published in 1773, "The State of the
Chimney-sweepers Young Apprentices; showing the
wretched condition of these distressed Boys; the ill
Conduct of such Masters as do not observe the Ob
ligation of indentures; the Necessity of a strict In
quiry in order to support the civil and religious Rights
of these Apprentices," 12mo. This small pamphlet
has already been productive of some advantage to the
objects intended to be benefited by it. The succeeding
year 1774 he enlarged a former publication, entitled
"Advice from a Farmer to his Daughter, &c." and
republished it under the title of "Virtue in humble Life; containing Reflections on the reciprocal Duties
of the Wealthy and Poor; and the Duty of a Servant," 2 vols 8vo.; a work deserving the particular considera
tion and every magistrate. This edition in a few months being fold, he reprinted it in two quarto volumes, with a dedication to Mrs Montague.

In 1780, finding his health decline, he determined to resign his office at the victualling board, which he
did on the 2d of October that year; and immediately
received a grant of his whole salary by way of a pen
sion, to continue for life. This favour he owed to the esteem which his majesty, to whom he was per
sonally known entertained of him; excided by his various excursions in behalf of his country and mankind.—He
was now released from his most material business, but did not think it wrong to his last line of life: He
engaged again in behalf of the chimney-sweepers boys; and promoted, by every means in his power, the estab
ishment of Sunday-schools, which are now in a fair way to be adopted in every county in England. He likewise promoted a subscription for the relief of the many black poor people who wandered about the metropolis in extreme differe...
Mr Hanway, although never married himself, was yet an advocate for marriage, and recommended it to all young people. He thought it the most effectual restraint on licentiousness, and that an increase of unhappiness was by no means the natural consequence of an increase of domestic cases. A "local habitation," with the society of a sensible woman, the choice of an unbiased affection, he esteemed as the most engagingly persuasive to the love of order and economy; without which he thought life, in whatever station, must be disjointed and perturbed and unhappy. The lady who engaged his first affection was uncommonly handsome; and it is probable he was prevented from marrying only by his failing to obtain her, and the unsettled manner in which the first years of his life were spent; for he loved the society of women; and in the parties which frequently breakfasted at his house the ladies usually made the greater portion of the company.

In his transactions with the world, he was always open, candid, and sincere. Whatever he said might be depended on with implicit confidence. He adhered to the strict truth, even in the manner of his relation; and no brilliancy of thought could induce him to vary from the fact: but although so frank in his own proceedings, he had seen too much of life to be easily deceived by others; and he did not often place a confidence that was betrayed. He did not, however, think the world so degenerate as is commonly imagined;
HAP [306]

HAP

"And if I did (he used to say), I would not let it appear; for nothing can tend to effectually to make a man wicked, or to keep him so, as a marked falpicon. Confidence is the reward of truth and fidelity, and these should never be exerted in vain." In his department of commissioner for vigiluating the navy he was uncommonly affidious and attentive, and kept the contraffors and persons who had dealings with the office at a great distance. He would not even accept a hare or phexiant, nor the smallest present, from any of them; and when any were sent him, he always returned them, not in a morose manner, as if he affected the effects of diffinereftednfs, but with some mild answer; such as, "Mr Hanway returns many thanks to Mr—— for the present he intended him; but he has made it a rule not to accept any thing from any person engaged with the office; a rule which, whilst he acknowledges Mr——'s good intentions, he hopes he will not expect him to break through." With all this goodnefs, Mr Hanway had a certain fignarility of thought and manners, which was perhaps the confequence of his living the greater part of his life in foreign countries, and never having been married. He was not by any means an inattentive observer of the little fformes of politnefs; but as he had fufpended them in various realms, selecting thofe which he approved, his politnefs differed from that of other people; and his converfation had an air of originallity in it that was very pleasing.

Besides the works already mentioned in the course of this article, Mr Hanway was the author of a great number of others; his different publications amounting all together to between fixty and feventy. A complete list of them is given by his biographer Mr Pugh, from whose grateful and well-written performance this article has been chiefly extracted.

HAP, or HAPP, in la\v, signifies to catch or snatch a thing. Thus we meet with, to hap the poiffeion of a deed-poll. Littleton, fol. 8. also, to hap the rent. If partition be made between two parceners, and more land be allowed the one than the other, the that hath most of the land charges it to the other, and hathpeth the rent whereon alizes is brought.

HAPINESS, or FELICITY, absolutely taken, denotes the durable poiffeion of perfect good without any mixture of evil, or the enjoyment of pure poiffeion unalloyed with pain; or a state in which all the wishes are fatisfied: In which fenses, Happinefs is known only by name upon the earth. The word happy, when applied to any fate or condition of human life, will admit of no positive definition, but is merely a relative term: that is, when we call a man happy, we mean that he is happier than fome others with whom we compare him; than the generality of others; or than he himself, was in fome other situation.

This interesting Subjed has been treated by many eminent writers, and in a great variety of ways; but by none does it appear to have been fet in a clearer and more definite point of view than by Archdeacon Paley in the ftifth chapter of his Principles of Phifofopy. "In fubfiftence (says that elegant writer), any condition may be denomnated happy in which the amount or aggregate of poiffeion exceeds that of pain; and the degree of happinefs depends upon the quantity of this excess. And the greatest quantity of it, ordinarily attainable in human life, is that we mean by happinefs, when we inquire or pronounce what human happinefs confines in.

If any positive signification, diftinft from what we mean by poiffeion, can be affixed to the term Happinefs, it may be taken to denote a certain fate of the nervous fystem in that part of the human frame in which we feel joy and grief, passions and affections. Whether this part be the heart, which the turn of most languages would lead us to believe; or the diaphragm, as Buffon, or the upper office of the stomach, as Van Helmont thought; or rather be a kind of fine network, lining the whole region of the præcordia, as others have imagined; it is possible that every painful fenfation may violently shake and disturb the fibres at the time, but that a feries of fuch may at length to derange the very texture of the fystem, as to produce a perpetual irritation, which will flow itself by frefhnefs, refettnefs, and impatience. It is poible alto, on the other hand, that a fuccedence of preparable fenfations may have fuch an effect upon this fable organization, as to cave the fibres to relax, and return into their place and order; and thereby to recover, or if not to preferve, that harmonious conformation which gives to the mind its fenfe of complacency and fatisfaftion. This frate may be denomnated happinefs: And is fo far diftinguifhable from poiffeion, that it does not refer to any particular object of enjoyment, or confilt like poiffeion in the gratification of one or more of the fenfes; but is rather the fecundary effect which fuch objects and gratifications produc upon the nervous fystem, or the fate in which they leave it. The comparative fenfe, however, in which we have explained the term Happinefs, is more popular; and in profecting the fubjed, we may confider, 1. What human happinefs does not confift in; and 2. What it does confilt in.

1. First then happinefs does not confift in the pleasures of fene, in whatever proffufion or variety they be enjoyed. By the pleasures of fene are meant, as well the animal gratifications of eating, drinking, and that by which the species is continued, as the more refined pleasures of music, painting, architecture, gardening, splendid shows, theater exhibitions, and the pleasures, lafly, of active sports, as of hunting, footeing, fishing &c. For, 1. These pleasures continue but for a little while at a time. This is true of them, all, especially of the groffer fort. Laying aside the preparation and the expectation, and computing strictly the actual fenfation, we shall be surprifed to find how inconsiderable a portion of our time they occupy, how few hours in the four and twenty they are able to fill up. 2. By repetition, they lose their releif. It is a property of the machine, for which we know no remedy, that the organs by which we perceive pleasure are blunted and benumbed, by being frequently exercised in the fame way. There is hardly any one who has not found the difference between a gratification when new and when familiar, and any pleasure which does not become indifferent as it grows habitual. 3. The eagerness for high and intense delights takes away the releif from all others; and as fuch delights fall rarely in our way, the greater part of our time becomes from this caufe empty and uneasy. There is hardly any delusion by which men are greater sufferers in their happinefs than by their expecting too much from what
Happiness, what is called pleasure, is, from those intense delights which vulgarly engross the name of pleasure. The very expectation foils them. When they do come, we are often engaged in taking pains to persuade ourselves how much we are pleased, rather than enjoying any pleasure which springs naturally out of the object. And whenever we depend upon being vastly delighted, we always go home secretly grieved at missing our aim. Likewise as hath been observed just now when this humour of being prodigiously delighted has once taken hold of the imagination, it hinders us from providing for or acquiescing in those gently soothing engagements, the due variety and feculation of which are the only things that supply a continued stream of happiness.

The truth seems to be that there is a limit at which these pleasures soon arrive, and from which they ever afterwards decline. They are by necessity of short duration, as the organs cannot hold on their emotions beyond a certain length of time; and if you endeavour to compensate for their imperfection in their nature by the frequency with which you repeat them, you lose more than you gain by the fatigue of the faculties and the diminution of sensibility. We have in this account said nothing of the loss of opportunities or the decay of faculties, which whenever they happen, leave that voluntary definitude and desperation tried by desires that can never be gratified, and the memory of pleasures which must return no more. It will also be allowed by those who have experienced it, and perhaps by those alone, that pleasure which is purchased by the incumbrance of our fortune is purchased too dear: the pleasure never compensating for the perpetual irritation of embarrassed circumstances.

These pleasures, after all, have their value: and as the young are always too eager in their pursuit of them, the old are sometimes too remiss; that is, too stodious of their ease to be at the pains for them which they really deserve.

Secondly, Neither does happiness consist in an exemption from pain, labour, care, business, suspense, melan- tation, and "those evils which are without;" such a state being usually attended not with ease, but with depression of spirits, a taint of sadness in all our ideas, imaginary anxieties and the whole train of hypochondriacal affections. For which reason it is seldom answers the expectations of those who retire from their shops and counting-houses to enjoy the remainder of their days in leisure and tranquility; much less of such as in a fit of chagrin shut themselves up in cloysters and hermitages, or quit the world and their stations in it for solitude and repose.

Where there exists a known external cause of uneasiness, the cause may be removed, and the uneasiness will cease. But those imaginary distresses which men feel for want of real ones (and which are equally tormenting, and to fair equally real), as they depend upon no single or affailable subject of uneasiness, so they admit off-times of no application or relief. Hence a moderate pain, upon which the attention may fall and spend itself, is to many a refreshment; as a fit of the gout will sometimes cure the spleen. And the fame of any moderate agitation of the mind, as a literary controversy, a law-suit, a contested election, and above all gaming; the passion for which, in men of fortune and liberal minds, is only to be accounted for happiness.

Thirdly, Neither does happiness consist in greatness, rank, or elevated station.

Were it true that all superiority afforded pleasure, it would follow, that by how much we were the greater, that is, the more persons we were superior to, in the same proportion, so far as depended upon this cause, we should be the happier; but so it is, that no superiority yields any satisfaction, save that which we possess or obtain over those with whom we immediately compare ourselves. The shepherd perceives no pleasure in his superiority over his dog; the farmer in his superiority over the shepherd; the lord in his superiority over the farmer; nor the king, lastly, in his superiority over the lord. Superiority, where there is no competition, is seldom contemplated; what most men indeed are quite unconscious of. But if the same shepherd can run, fight, or whistle, better than the peasants of his village; if the farmer can show better cattle, if he keeps a better horse, or be supposed to have a longer purse, than any farmer in the hundred; if the lord have more interest in an election, greater favour at court, a better house, or larger estate, than any nobleman in the country; if the king possesses a more extensive territory, a more powerful fleet or army, a more splendid establishment, more loyal subjects, or more weight and authority in adjusting the affairs of nations, than any prince in Europe; in all these cases, the parties feel an actual satisfaction in their superiority. No superiority appears to be of any account but a superiority over a rival. This, it is manifest, may exist wherever rivalships do; and rivalships fall out amongst men of all ranks and degrees. The object of emulation, the dignity or magnitude of this object, makes no difference: as it is not what either possesses that confines the pleasure, but what one possesses more than the other. Philosophy confines at the contempt with which the rich and great speak of the petty trifles and competitions of the poor; not reflecting that these trifles and competitions are just as reasonable as their own, and the pleasure which success affords the same.

It appears evident then, that happiness does not consist in greatness; since what are supposed to be the peculiar advantages of greatness, the pleasures of ambition and superiority, are in reality common to all conditions. But whether the pursuits of ambition be ever wise, whether they contribute more to the happiness or misery of the pursuers, is a different question; and a question concerning which we may be allowed to entertain great doubt. The pleasure of success is exquisite; so also is the anxiety of the pursuit, and the pain of disappointment; and what is the worst part of the account, the pleasure is short lived. We soon cease to look back upon those whom we have left behind; new contests are engaged in, new prospects unfold themselves; a succession of struggles is kept up, whilst there is a rival left within the compass of our views and profession; and when there is none, the pleasure with the pursuit is at an end.

II. We have seen that happiness does not consist in. We are next to consider in what it does consist. In the conduct of life, the great matter is, to know beforehand what will please us, and what pleasures will
Hap [308]

Happiness, hold out. So far as we know this, our choice will be
justified by the event. And this knowledge is more
rare and difficult than at first sight it may seem to be:
For sometimes pleasures, which are wonderfully alluring
and flattering in the prospect, turn out in the posse-
fion extremely inipid; or do not hold out as we ex-
pected: at other times pleasures start up, which never
entered into our calculation, and which we might have
missed of by not forseeing; from whence we have rea-
tion to believe, that we actually do miss of many plea-
tures from the same cause.

By reason of the original diversity of taste, capacity,
and constitution, observable in the human species,
and the still greater variety which habit and fashion have
introduced in these particulars; it is impossible to pro-
pose any plan of happiness which will succeed to all, or
any method of life which is universally eligible or prac-
ticable. All that can be said is, that there remains a
presumption in favour of those conditions of life in
which men generally appear most cheerful and con-
tented. For though the apparent happiness of man-
kind be not always a true measure of their real hap-
iness, it is the best measure we have.

Upon this principle, then, happiness appears to con-
sist in

1. In the exercise of the social affections. Those persons commonly possess good spirits who have about them many objects of affection and endearment; as wife, children, kindred, friends: and to the want of these may be imputed the peculiars of monks, and of such as lead a monastic life. Of the same nature with the indulgence of our domestic affections, and equally refreshing to the spirits, is the pleasure which results from acts of bounty and beneficence, exercised either in giving money, or in imparting to those who want it the assistance of our skill and protection.

2. Another main article of human happiness is, the exercise of our faculties, either of body or mind, in the pursuit of some engaging end. It seems to be true, that no plenitude of present gratifications can make the possessor happy for a continuance, unless he have something in reserve, something to hope for and look forward to. This may he inferred from comparing the alacrity and spirits of men who are engaged in any pursuit which interests them, with the dejection and ennui of almost all who are either born to fo much that they want nothing more, or who have used up their satisfactions too soon, and drained the drosses of them. It is this intolerable vacuity of mind which carries the rich and great to the horfe-cours and the gaming table; and often engages them in contests and pursuits of which the success bears no proportion to the solicitude and expense with which it is sought.

The question now occurs, How are we to provide ourselves with a succession of pleasurable engagements? This requires two things: Judgment in the choice of ends adapted to our opportunities; and a command of imagination, so as to be able, when the judgment has made choice of an end, to transfer a pleasure to the mean; after which the end may be forgotten as soon as we will. Hence those pleasures are most valuable, not which are most exquisite in the fruition, but most productive of engagement and activity in the pursuit.

A man who is earnest in his endeavours after the happiness of a future state, has in this respect an ad-
vantage over all the world. For he has constantly
before his eyes an object of supreme importance, pro-
ductive of perpetual engagement and activity, and of
which the pursuit (which can be paid of no pursuit be-
des) lasts him to his life's end. Yet even he must
have many ends beside the far end; but then they
will conduct to that, he subordinate, and in some way or
other capable of being referred to that, and derive their
satisfaction, or an addition of satisfaction, from that.

Engagement is every thing. The more significant,
however, our engagements are, the better; such as
the planning of laws, institutions, manufactures, char-
ities, improvements, public works, and the endeavour-
ing by our interest, address, solicitation, and activity,
to carry them into effect: Or, upon a smaller scale,
the procuring of a maintenance and fortune for our
families, by a course of industry and application to our
callings, which forms and gives motion to the common
occupations of life; training up a child; protecting
a scheme for his future establishment; making our-
selves masters of a language or a science; improving
or managing an estate; labouring after a piece of prefer-
ment: And, lastly, any engagement which is better
than none; as the writing of a book, the building of a
house, the laying out of a garden, the digging of a fish-pond; even the raiing of a cucumber or a tulip.

Whilf the mind is taken up with the objects or busines before it, we are commonly happy, whatever the object or business be; when the mind is absent, and the thoughts are wandering to something else than what is passing in the place in which we are.

3. The art in which the secret of human happiness
in a great measure consists, is to let the habits in such
a manner, that every change may be a change for the
better. The habits themselves are much the same;
for whatever is made habitual becomes smooth, and
easy, and indifferent. The return to an old habit is
likewise easy, whatever the habit be. Therefore the
advantage is with those habits which allow of indul-
gence in the deviation from them. The luxurious re-
ceive no greater pleasure from their dainties than the
peasant does from his bread and cheese; but the pe-
asant whenever he goes abroad finds a feast, whereas
the epicure must be well entertained to escape diffi-
gult.

Those who spend every day at cards, and those who
go every day to plough, pass their time much alike;
intent upon what they are about, wanting nothing,
regretting nothing, they are both in a state of ease:
But then, whatever impedes the occupation of the card-
player disdresses him; whereas to the labourer, every
interruption is a refreshment: and this appears in the
different effect that the Sabbath produces upon the
two, which proves a day of recreation to the one, but
a lamentable burden to the other. The man who has
learned to live alone, feels his spirits enlivened when-
ever he enters into company, and takes his leave with-
out regret: another, who has long been accustomed to
a crowd or continual succession of company, experi-
cences in company no elevation of spirits, nor any greater
satisfaction than what the man of a retired life finds in
his chimney-corner. So far their conditions are equal;
but let a change of place, change of business, or rate
the companion of his circle, his visitors, his
club,
HAP [309]  HAR

Happiness, club, common-room, or coffee-house, and the difference of advantage in the choice and constitution of the two habits will show itself. Solitude comes to the one clothed with melancholy, to the other it brings liberty and quiet. You will see the one freetul and refractory, at a loss how to dispose of his time, till the hour comes round that he can forget himself in bed; the other easy and satisfied, taking up his book or his pipe as soon as he finds himself alone; ready to admit any little amusement that calls up, or to turn his hands and attention to the first business that presents itself; or content without either to sit still, and let his trains of thought glide indolently through his brain, without much use, perhaps, or pleasure, but without hankering after any thing better and without irritation. A reader who has injured himself to books of science and argumentation, if a novel, a well written pamphlet, an article of news, a narrative of a curious voyage, or the journal of a traveller, fall in his way, sits down to the repast with relish, enjoys his entertainment while it lasts, and can return when it is over to his graver reading without diftaste. Another, with whom nothing will go down but works of humour and pleasantry, or whose curiosity must be interested by perpetual novelty, will confine a bookseller's window in half a forenoon: during which time he is rather in search of diversion than diverted; and as books to his taste are few and short and rapidly read over, the flock is soon exhausted, when he is left without resource from this principal supply of innocent amusement.

So far as circumstances of fortune conduce to happiness, it is not the income which any man possest, but the increase of income that affords the pleasure. Two persons, of whom one begins with 100l. and advances his income to 300l. a year; and the other sets off with 100l. and dwindles down to 100l. may, in the course of their time, have the receipt and spending of the same sum of money; yet their satisfaction, so far as fortune is concerned in it, will be very different: the series and sum total of their incomes being the same, it makes a wide difference which end they begin at.

4. Happiness consists in health: understanding by health, not only freedom from bodily distempers, but also that tranquillity, firmness, and serenity of mind, which we call good spirits. For the sake of health, according to this notion of it, no sacrifices can be too great. Whether it require us to relinquish lucrative situations, to abstain from favourite indulgences, to undergo tedious regimens; whatever difficulties it lays us under, a man, who pursues his happiness rationally and resolutely, will be content to submit to. When we are in perfect health and spirits, we feel in ourselves a happiness independent of any particular outward gratification whatever, and of which we can give no account. This is an enjoyment which the Deity has annexed to life; and probably constitutes, in a great measure the happiness of infants and brutes, especially of the lower and sedentary orders of animals, as of oyster, peri-winkle, and the like.

The above account of human happiness will justify these two conclusions, which, although found in most books of morality, have feldom been supported by any sufficient reasons: 1. "That happiness is pretty equally distributed amongst the different orders of civil society;" and, 2. "That vice has no advantage over virtue, even with respect to this world's happiness." 

HAQUE, in old writers, a little hand-gun, prohibited to be used for destruction of game, &c. by statute 33 Hen. VIII. cap. 6. and 2 & 3 Ed. VI. cap. 14. There is also the half-haque, or demi-haque, within the said acts.

HARAM. See Seraglio.

Haran, otherwise Charis in Mecopotamia, a city celebrated for having been the place where Abraham first retreated after he left Ur (Gen. xi. 31, 32); and where Terah, Abraham's father, died and was buried. Thither it was likewise that Jacob retired to Laban when he fled from the indignation of his brother Edom (id. xxvii. 45, xxviii.10, &c.) Lastly at Haran or Charis in Mecopotamia, Charis the Roman general was defeated and killed by the Parthians. Haran was situated between the Euphrates and the river Chezar, at a good distance from the place where these two rivers join.

Harangue, a modern French name for a speech or oration made by an orator in public,—Menage derives the word from the Latin aranea, which signifies the same; formed, according to Ferrari, from aringe, "a jurt, or place of justicing." Others derive it from the Latin ara, "altar;" by reason the first harangues were made before altars; whence the verbe de Juvenal

Ant Legumensis victor discurus ad aram.

Harangues were usually made by the generals, previous to an engagement both amongst the Greeks and Romans. An harangue on such occasions was called allocutio. See Allocutio.

The word is also frequently used in an ill sense, viz. for a too pompous, prolix, or unfashionable speech or dissertation.

Harbinger, an officer of a king's household, having four yeomen under him, who ride a day's journey before the court when it travels, to provide lodgings, &c.

HARBOUROUGH, a town of Leicestershire, 84 miles from London. It is a great thoroughfare in the road to Derby, near the source of the river Welland; and was famous in Camden's time, for its market fair, where the belt hores and colts are still sold. Its fairs are April 29 and Oct. 19. The market is on Tuesday, for the use of which the Earl of Harbrough has lately built a neat market-house at his own expense. Here is a good free-school, and a fair chapel of ease to Great-bowden in its parish.

Harbour, a general name given to any sea port or haven, as also to any place convenient for mooring shipping, although at a great distance from the sea.

The qualities requisite in a good harbour are, that the bottom be entirely free from rocks or shallows; that the opening be of sufficient extent to admit the entrance or departure of large ships without difficulty; that it should have good anchoring ground, and be easy of access; that it should be well defended from the violence of the wind and sea; that it should have room and convenience to receive the shipping of different nations, and those which are laden with different merchandizes; that it be furnished with a good light-house, and have a variety of proper rings, posts, moorings,
HAR[310]HAR

Harburger

n in order to remove or secure the vessels contained therein; and, finally, that it have plenty of wood, and other materials for firing, besides hemp, iron, mariners, &c.

HARBURG, a small town in Germany in the circle of Lower Saxony, and dutchy of Lauenburg seated on the river Elbe over against Hamburg. It was surrounded with walls in 1535, and 30 years after, a strong castle, which still remains, was built by the bishop. E. Long. 941. N. 53. 51.

HARDENING, the giving a greater degree of hardness, to bodies than they had before.

There are several ways of hardening iron and steel, as by hammering them; quenching them in cold water, &c. See STEEL.

Case-hardening. See CasH hardened.

HARDERWICH, a town of the United Provinces, in Dutch Guelderland. It is a well-built town, and the chief of the sea-ports of this province. It has several good buildings, particularly the great church, which is much admired. In 1648 the public school here was turned into an university. The French did it a great deal of damage in 1672; since which time it has been on the decline. E. Long. 5. 57. N. Lat. 52° 14.

HARDNESS, in bodies, a property directly opposite to fluidity; by which they refit the impression of any other substance, sometimes in an extreme degree. Hardness has been found to consist in the motion of the particles of a body upon one another in consequence of a certain action of the universal fluid or elementary fire among them; we must conclude that hardness consists in the absence of this action, or a deficiency of what is called latent heat. This is confirmed by observing, that there is in intermediate state between hardness and fluidity, in which bodies will yield to a certain force, though they still make a considerable resistance. This is principally observed in the metals, and is the foundation of their ductility. It appears, indeed, that this last property, as well as fluidity, is entirely dependent on a certain quantity of latent heat absorbed, or otherwise acting within the substance itself; for all the metals are rendered hard by hammering, and loose by being put again into the fire and kept there for some time. The former operation renders them hot as well as hard; probably, as Dr Black observes, because the particles of metal are thus forced nearer one another, and those of fire squeezed out from among them. By keeping them for some time in the fire, that element infinuates itself again among the particles and arranges them in the same manner as before, so that the ductility returns. By a second hammering this property is again destroyed, returning on a repetition of the heating, or annealing as it is called; and so on, as often as we please.

Hardness appears to diminish the cohesion of bodies in some degree, though their fragility does not by any means keep pace with their hardness. Thus, glass is very hard and very brittle; but sinter, though still harder than glass, is much less brittle. Among the metals, however, these two properties seem to be more connected, though even here the connection is by no means complete. Steel, the hardest of all the metals is indeed the most brittle; but lead, the softest, is not the most ductile. Neither is hardness connected with the specific gravity of bodies; for a diamond, the hardness, hardest substance in nature, is little more than half Hardouin, the weight of the lightest metal. As little is it connected with the coldness, electrical properties, or any other quality with which we are acquainted; so that though the principle above laid down may be accepted as a general foundation for our inquiries, a great number of particulars remain yet to be discovered before we can offer any satisfactory explanation.

All bodies become harder by cold: but this is not the only means of their doing so, for some become hard by heat as well as cold. Thus water becomes hard by cold when it is frozen, but it becomes much harder when its steam is passed over red-hot iron, and it enters the substance of the metal, by an union with which it becomes almost as hard as glass.

Mr Quift and others have constructed tables of the hardness of different substance. The method pursued in constructing these tables was by observing the order in which they were able to cut or make any impression upon one another. The following table, extracted from M. Magellan's edition of Croftend's Mineralogy, was taken from Dr Quift, Bergman, and Mr Kirwan.

The first column shows the hardness, and the second the specific gravity.

Haro. See York.

Hares are the swiftest of all quadrupeds, and are much dreaded by sportsmen in the chase. They are more nimble than deer, and are much more difficult to catch. They are also the most dangerous to follow; for they are cunning in the ways and mazes of the fields, and know the nearest ways, run up the hills and rocks, to the confusion of the dogs, and the discouragement of the hunters. See the article Hunting.

Hares and rabbits are very mischievous to new planted orchards, by peeling off the barks of the tender and young trees for their food. They do also the same sort of mischief to nurseries; for they are cunning in the ways and mazes of the fields, and overhear all that passes. They then seize, and cover with the earth, and where they are buried, the saplings are killed. This is the cause of our eating in terror, and running from them. Some feed on the barks of trees, and despise all other food; others prefer grass and young trees for their food. They do also the same mischief to warrens, pretend to an exclusive right of property in them, and drive off the sportsmen. The farther they are from the habitation of men, the more mischievous they are. They are in the habit of this animal, a member of Eton school, and from that foundation became a member of Eton college, Cambridge; where he had the tuition of the marquis of Blandford, only son of the illustrious duke of Marlborough, who appointed him chaplain-general to the army. He afterwards obtained the deanship of Worcester, and from thence was promoted to the
collection of useful and curious manuscripts, begun near the end of the last century, by Robert Harley of Brampton Bryan, Esq.; in Herefordshire, afterwards earl of Oxford and lord high-treasurer; and which was conducted upon the plan of the great Sir Robert Cotton. He published his first considerable collection in August 1703; and in less than ten years he got together near 2500 rare and curious MSS. Soon after this, the celebrated Dr George Hoiks, Mr Anthis gaining king at arms, bishop Nicolson, and many other eminent antiquaries, not only offered him their assistance in procuring MSS. but presented him with several that were very valuable. Being thus encouraged to perseverance by his success, he kept many persons employed in purchasing MSS. for him abroad, giving them written instructions for their conduct. By these means the MS. library was in the year 1721, increased to near 6000 books, 14,000 original charters, and 500 rolls.

On the 21st of May 1724 lord Oxford died; but his son Edward, who succeeded to his honours and estate, still further enlarged the collection; so that when he died, June 16th 1745, it contained of 8000 volumes, several of them containing distinct and independent treatises, besides many loose papers which have been since forted and bound up in volumes; and above 40,000 original rolls, charters, letters patent, grants, and other deeds and instruments of great antiquity.

The principal design of making this collection was the establishment of a MS. English historical library, and the rescuing from destruction such national records as had eluded the diligence of preceding collectors; but lord Oxford's plan was more extensive; for his collection abounds also with curious MSS. in every science. This collection is now in the British Museum and an enumeration of its contents may be seen in the Annual Register, vi. 1740, &c.

HARLEM, a town of the United Provinces, in Holland, situated on the river Sparren, in E. Long. 5. 17. N. Lat. 53. 22. It is a large and populous city, and stands near a lake of the same name, with which it has a communication, as well as with Amsterdam and Leyden, by means of several canals. Schemes have been often formed for draining of this lake, but were never put in execution. To the south of the town lies a wood, into delightful walks and villas. The town is famous for the siege which it held out against the Spaniards for ten months in 1573; the townsmen before they capitulated being reduced to eat the vilest animals, and even leather and grubs. The inhabitants corresponded with the prince of Orange for a considerable time by means of carrier-pigeons. Harlem is as well known, claims the invention of printing; and in fact, the first efforts of the art are indisputably to be ascribed to Laurentius, a magistrate of that city. [See Laurentius, and History of printing.] Before the Reformation, Harlem was a bishop's see; and the Papists still greatly outnumber the Protestant. An academy of sciences was founded here in 1752. Vast quantities of linen and thread are bleached here; the waters of the lake having a peculiar quality, which renders them very fit for that purpose. - A fair for the sale of silk is held with regard to flowers, particularly tulips, once prevailed here, in consequence of which the most beautiful sorts were bought and sold at an extravagant price.

HARLEQUIN, in the Italian comedy, a buffoon, Harlequin dressed in party-coloured cloaths; answering much the same purpose as a merry-andrew or jack-pudding in our drolls, on mountebanks stages, &c. We have also introduced the harlequin upon our theatres; and this is one of the flandering characters in the modern grotesque or pantomime entertainments. - The term took its rise from a famous Italian comedian who came to Paris under Henry III., and who frequented the house of M. de Harlay, his companions used to call him Harlequin, q. d. little Harlay; a name which has descended to all those of the same rank and pro

HARLEY (Robert), earl of Oxford and Mortimer, was the eldest son of Sir Edward Harley, and born in 1661. At the Revolution, Sir Edward and his son raised a troop of horse at their own expense; and after the accession of king William and queen Mary, he obtained a seat in parliament. His promotions were rapid: in 1702, he was chosen speaker of the house of commons; in 1704, he was sworn of queen Anne's privy council, and the same year made secretary of state; in 1706, he served as one of the millioners for the treaty of Union; and in 1710, was appointed a commissiioner of the treasury, and chancellor and under-treasurer of the exchequer. A daring attempt was made on his life, March 8. 1711, by the marquis of Guilford a French Papist; who, when under an examination before a committee of the privy council, stabbed him with a penknife. Of this wound, however, he soon recovered; and was the same year created earl of Oxford, and lord high-treasurer, which office he resigned just before the queen's death. He was impeached of high treason in 1715, and committed to the Tower; but was cleared by trial, and died in 1724. His character has been variously represented, but cannot be here discussed. He was not only an encourager of literature, but the greatest collector in his time of curious books and MSS. his collection of which makes a capital part of the British Museum. See HARLEIAN Collection.

HARLING. See HERLING.

HARLINGEN, a sea-port town of the United Netherlands, in West Friesland. It stands on the coast of the Zuyder see, at the mouth of a large canal, in E. Long. 5. 23. N. Lat. 53. 12. It was only a hamlet till about the year 1504, when it was destroyed by the sea; and being afterwards rebuilt, became a considerable town. In 1570, it was considerably enlarged by the care of William prince of Orange. It is now very well fortified, and is naturally strong, as the adjacent country can very easily be laid under water. The city is square; and the streets are handsome, straight, and clean, with canals in the middle of them. It has five gates; four towards land, and one towards the sea; but though the harbour is good, yet vessels of great burden cannot get into it until they are lightened for want of water. The admiralty college of Friesland has its seat here. The manufactures are salt, bricks, and tiles; a considerable trade is also carried on in all sorts of linen cloth; and the adjacent country yields abundance of corn and good pastures.

HARLOCK, or HARLEIGH, a town of Merionethshire, in North Wales, 223 miles from London, on the sea coast, near the north west point of the county. It
HARLOT, a woman given to inconstancy, or that makes a habit or a trade of prostituting her body. — The word is supposed to be tided for the diminutive sarxet, a "little whore." — Others derive it from Arletta, a mifref to Robert duke of Normandy, and mother to William the Conqueror; Camden derives it from one Arlotha, connoting to William the Conqueror: Others from the Italian Arletta, "a proud whore."

Harlots were tolerated among Jews, Greeks, and Romans. Fornication indeed was prohibited among the Jews, under severe penalties; but these are explained as extending only to women of their own nation. The public news were therefore flocked with foreign prostitutes, who seem to have been taken under the protection of government. Hence appears the reason why the word strange woman is often found to signify a harlot. Prostitutes at first wore veils or masks; but by and by their modesty was entirely put to flight, and they went abroad bare-faced. At Athens the prostitutes were generally strangers; and such as debauched an Athenian female were liable to a penalty. To frequent the public news was not held disgraceful! The wife of the Hellen fagges allowed by Solon permitted common "whores" to go publically to the young men who had engaged them, and encouraged the youth of Athens to gratify their lust with these, rather than seduce and debauch the wives and daughters of citizens. Cato the Censor was of the same sentiments; and Cicero challenges all perverts to name atime when men were either reprobate for this practice, or not countenanced in it. Amongst the Jews, the harlots used to ply in the highways and streets of cities; at Athens they frequented the circuses, and the old forum. — In some places they were distinguished by their drees from other women. Corinth was a remarkable nursery of harlots, and gave birth to the noted Lais. Their accomplishments were oftentimes great, in all the polite and elegant parts of female education, viz. philosophy, dancing, singing, rhetoric, &c. Alpasia, the mifref of Pericles, was admired by Socrates for her learning. The more accomplished prostitutes frequently amallled large fortunes; a remarkable instance of which we have in Phryne, who offered to rebuild the walls of Thebes, when destroyed by Alexander, on condition that they would perpetrate her memory and profession by an inscription. Prostitutes at Rome were obliged to fix a bill over their doors, indicating their character and profession. It was also customary for them to change their names, after they had signified to the praxor, their intention of leading such a dissolute life: this they did, because their trade was unbecoming their birth and condition; but they re-assumed their family names when they quitted their infamous mode of living. Women whose grandfather, father, or husband, had been a Roman knight, were forbidden by the laws to make a public profession of lewdness.

HARMATTAN, the name of a remarkable periodical wind which blows from the interior parts of Africa towards the Atlantic ocean. Of this wind we have the following account in the Philosophical Transactions, vol. 71, furnished by Mr Norris, a gentleman who had frequent opportunities of observing its singular properties and effects.

On that part of the coasts of Africa which lies between the Cape Verd and Cape Lopez, an easterly wind prevails during the months of December, January, and February, which by the Fantees, a nation on the Gold coast, is called the Harmattan. Cape Verd is in 15 N. latitude, and Cape Lopez in 1 S. latitude; and the coast between these two Capes runs in an oblique direction, nearly from W. S. W. to E. S. E., forming a range of upwards of 2000 miles. At the isles de Los, which are a little to the northward of Sierra Leone, and to the southward of Cape Verd, it blows from the E. S. E. on the Gold coast from the N. E. and at Cape Lopez, and the river Gabon, from the N. N. E. This wind is by the French and Portuguese, who frequent the Gold coast, called simply the N. E. wind, the quarter from which it blows. The English, who sometimes borrow words and phrases from the Fanteese language, which is less guttural and more harmonious, than that of their neighbours, adopt the Fanteese word Harmattan.

The harmattan comes on indiscriminately at any hour of the day, at any time of the tide, or at any period of the moon, and continues sometimes only a day or two, sometimes five or six days, and it has been known to last fifteen or sixteen days. There are generally three or four returns of it every season. It blows with a moderate force, not quite so strong as the sea-breeze (which every day sets in during the fair season from the W. W. S. W. and S. W.); but somewhat stronger than the land wind at night from the N. and N. N. W.

1. A fog or haze is one of the peculiarities which always accompanies the harmattan. The gloom occasioned by this fog is so great as sometimes to make even near objects obscure. The English stands about the midway between the French and Portuguese forts, and not quite a quarter of a mile from either; yet very often from thence either of the other forts can be discovered. The sun, concealed the greatest part of the day, appears only a few hours about noon, and then of a milcl red, exciting no painful iritation on the eye.

2. Extreme dryness makes another extraordinary property of this wind. No dew falls during the continuance of the harmattan; nor is there the least appearance of moisture in the atmosphere. Vegetables of every kind are very much injured, all tender plants and most of the productions of the garden, are destroyed; the grass withers, and becomes dry like hay; the vigorous ever-greens likewise feel its pernicious influence; the branches of the lemon, orange, and lime trees droop, the leaves become scalded, wither, and if the harmattan continues to blow for 10 or 12 days, are so parched, as to be easily rubbed to dust between the fingers; the fruit of these trees, deprived of its nourishment, and flinted in its growth, only appears to ripen, for it becomes yellow and dry, without acquiring half the usual size. The natives take this opportunity of the extreme dryness of the grass and young trees to set fire to them, especially near

their
HARMATTAN. their roads, not only to keep these roads open to travellers, but to destroy the shelter which long grass, and thickets of young trees, would afford to skulking parties of their enemies. A fire thus lighted flies with such rapidity, as to endanger those who travel in that direction. A common method of escape is, on discovering a fire to windward, to set the grass on fire to leeward, and then follow your own fire. There are other extraordinary effects produced by the extreme dryness of the harmattan.

The parching effects of this wind are likewise evident on the external parts of the body. The eyes, nostrils, lips, and palate, are rendered dry and uneasy, and drink is often required, not so much to quench thirst, as to remove a painful aridity in the faucets. The lips and nose become sore and even cracked; and thirst, though the air be cool, yet there is a troublesome sensation of prickling heat on the skin. If the harmattan continues four or five days, the scarf skin peels off, first from the hands and face, and afterwards from the other parts of the body if it continues a day or two longer. Mr Norris observed, that when sweat was excited by exercise on those parts which were covered by his cloaths from the weather, it was peculiarly acrid, and tasted, on applying his tongue to his arm, something like spirits of hartnthon diluted with water.

3. Salubrity forms a third peculiarity of the harmattan. Though this wind is so very prejudicial to vegetable life, the occasional favorable parching effects on the human species, yet it is highly conducive to health. Those labouring under fluxes and intermitting fevers generally recover in a harmattan. Those weakened by fevers, and sinking under evacuations for the cure of them; particularly bleeding, which is often injudiciously repeated, have their lives saved, and vigour restored, in spite of the doctor. It stops the progress of epidemics; the small-pox, remittent fevers, &c. not only disappear, but those labouring under these diseases when an harmattan comes on, are almost certain of a speedy recovery. Infection appears not then to be easily communicated even by art.

In the year 1779, there were on board the Unity, at Whydah, above 300 slaves; the small-pox broke out among them, and it was determined to inoculate; those who were inoculated before the harmattan came on got very well through the disease. About 70 were inoculated a day or two after the harmattan set in, but no one of them had either sickness or eruption. It was imagined that the infection was effectually dispersed and the flux clear of the disorder; but in a very few weeks it began to appear among these seamen. About 50 of them were inoculated the second time; the others had the disease in a natural way; an harmattan came on, and they all recovered, excepting one girl, who had an ugly ulcer on the inoculated part, and died some time afterwards of a locked jaw."

This account differs remarkably from that given by Dr Lind, who calls the harmattan a malignant and fatal wind; (see his Diaries of Hot Climates.) As to the nature of the soil over which it blows, it appears that excepting a few rivers and some lakes, the country about and beyond Whydah is covered for 400 miles back with verdure, open plains of grass, clumps of trees, and some woods of no considerable extent. The surface is sandy, and below that a rich reddish earth; it rises with a gentle ascent for 150 miles from Harmodius the sea, before there is the appearance of a hill, without affording a stone of the size of a walnut. Beyond these hills there is no account of any great ranges of mountains.

HARMODIUS, a friend of Aristogiton, who delivered his country from the tyranny of the Pilitrates. (See Aristogiton.) The Athenians, to reward that patriotism of these illustrious citizens, made a law that no one should ever after bear the name of Aristogiton and Harmodius.

HARMONIA, in fabulous history, the wife of Cadmus, both of whom were turned into serpents. See Cadmus.

Though many of the ancient authors made Harmonia a princess of divine origin, there is a passage in Athenaeus from Euhemerus, the Nothini of his time, which tells us, that she was by profession a player on the flute, and in the service of the prince of Zidon previous to her departure with Cadmus. This circumstance, however, might encourage the belief, that as Cadmus brought letters into Greece, his wife brought harmonium thither; as the word ἅρμονία, has been said to have no other derivation than from her name: which makes it very difficult to ascertain the feminine in which the Greeks made use of it in their music; for it has no roots by which it can be decomposed, in order to deduce it from their etymology. The common account of the word, however, is given by lexicographers, and generally adopted by the learned, does not confirm this opinion. It is generally derived from ἄρμα, and this from the old verb ἄρω, to fit or join.

HARMONIC. As an adjective, it signifies in general anything belonging to harmony; though in our language the adjective is more properly written harmonical. In this case it may be applied to the harmonical divisions of a monochord; or, in a word, to confonances in general. As a substantive, it imports all the concomitant or accessory sounds which, upon the principles resulting from the experiments made on sonorous bodies, attend any given sound whatever, and render it appreciable. Thus all the aliquot parts of a musical firing produce harmonical sounds, or harmonics.

HARMONICA. This word, when originally appropriated by Dr Franklin to that peculiar form or mode of musical glasses, which he himself, after a number of happy experiments, had constituted, was written Harmonica. In this place, however, we have ventured to restore it to its native plenitude of sound, as we have no antipathy against the moderate use of aspirations. It is derived from the Greek word ἅρμονια. The radical word is ἅρμα, to suit or fit one thing to another. By the word ἅρμονια the Greeks expressed aptitudes of various kinds; and from the use which they made of that expression, we have reason to conclude, that it was intended to import the highest degree of refinement and delicacy in those relations which it was meant to signify. Relations or aptitudes of sound, in particular, were understood by it; and in this view, Dr Franklin could not have selected a name more expressive of its nature and genius, for the instrument which we are now to describe; as, perhaps, no musical tone can possibly be finer, nor consequently susceptible
In an old English book, whole title we cannot at present recollect, and in which a number of various amusements were described, we remember to have seen the elements or first approaches to music by glaftes. That author enjoins his pupil to choose half a dozen of such as are used in drinking; to fill each of them with water in proportion to the gravity or acuteness of the sound which he intended it should produce; and having thus adjusted them one to another, he might entertain the company with a church-tune. These, perhaps, were the rude and barbarous hints which Mr. Puckridge afterward compiled. But, for a farther account of him, of the flate in which he left the instrument, and of the flate to which it has afterwards been carried, we must refer our readers to the following extracts from Dr. Franklin's letters, and from others who have written upon the same subject.

The Doctor, in his letter to Father Beccaria, has given a minute and elegant account of the Harmonica.

Nor does it appear that his successors have either more sufficiently improved, or more accurately delineated that angelic instrument. The detail of his own improvements, therefore, shall be given in his own words.

"Perhaps (says he) it may be agreeable to you, as you live in a musical country, to have an account of the new instrument lately added here to the great number that charming science was posseffed of before. As it is an instrument that seems peculiarly adapted to Italian music, especially that of the soft and plaintive kind, I will endeavour to give you such a description of it, and of the manner of constructing it, that you or any of your friends may be enabled to imitate it, if you go below your required tone there is not a note too sharp. This is done by grinding them round from the neck towards the brim, the breadth of one or two inches as may be required; often trying the glaftes by a well-tuned harpsichord, comparing the note drawn from the glaftes by your finger with the note you want, as founded by that string of the harpsichord. When you come near the matter, be careful to wipe the glaftes clean and dry before each trial, because the tone is something flatter when the glaftes is wet than it will be when dry; and grinding a greater number of the strings, you will thereby tone it to great exactness. The more care is necessary in this, because if you go below your required tone there is no sharpening it again but by grinding somewhat off the brim which will afterwards require polishing, and thus increase the trouble.

"The glaftes being thus tuned, you are to be provided with a cafe for them, and a fpindle on which they are to be fixed. My cafe is about three feet long, eleven inches every way wide within at the biggest end, and five inches at the smallest end; for it tapers all the way to adapt it better to the conical figure of the set of glaftes. This cafe opens in the middle of its heighth, and the upper part turns up by hinges fixed behind. The fpindle is of hard iron, lies horizontally from end to end of the box within, exactly in the middle, and is made to turn on brass gudgeons at each end. It is round, an inch diameter at the thickest end, and tapering to a quarter of an inch at the smallest. A square hand comes from its thickest end through the box, on which shank a wheel is fixed by a fcrew. This wheel serves as a fly to make the motion equal, when the fpindle, with the glaftes, is turned by the foot like a spinning-wheel. My wheel is of mahogany, 18 inches diameter, and pretty thick, so as to conceal near its circumference about 2 lb. of lead. An ivory pin is fixed in the face of this wheel, about four inches from the axis. Over the neck of this pin is put the loop of the string that comes up from the moveable stop to give it motion. The cafe stands on a neat frame with four legs.

To fix the glaftes on the fpindle, a cork is firft to

Harmony.
be fitted in each neck pretty tight, and projecting a little without the neck, that the neck of one may not touch the inside of another when put together, for that would make a jarring. These cords are to be perforated with holes of different diameters, so as to fasten part of the spindle on which they are to be fixed. When a glass is put on, by holding it firmly between both hands, while another turns the spindle, it may be gradually brought to its place. But care must be taken that the hole be not too small, lest in forcing it up, the neck should split; nor too large, lest the glass, not being firmly fixed, should turn or move on the spindle, so as to touch or jar against its neighbouring glasses. The glasses thus placed are one in another; the largest on the biggest end of the spindle, which is to the left hand: the neck of this glass is towards the wheel; and the next goes into it in the same position, only about an inch of its brim, appearing beyond the brim of the first, thus proceeding, &c., and the next goes into it another; the next into it three quarters of an inch, or half an inch as they grow smaller; beyond the brim of the glass that contains it; and it is from these exposed parts of each glass the tone is drawn, by laying a finger on one of them as the spindle and glasses turn round.

My largest glass is G a little below the reach of a common voice, and my highest G, including three complete octaves. To distinguish the glasses more readily to the eye, I have painted the apparent parts of the glasses within-side, every semitone white, and the other notes of the octaves, which differ by seven prismatic colours viz., C, red; D, orange; E, yellow; F, green; G, blue; A, indigo; B, purple; and C, red again; so that the glasses of the same colour (the white excepted) are always octaves to each other.

This instrument is played upon by fitting before the middle of the set of glasses, as before the keys of divide the notes with so much force, unless the tone is drawn, by laying a finger, and the next goes into it another, by which means the alternate plications of two continued sounds, differing from each other only by a note or semitone. But as these pulsations thus managed cannot be distinct, the result is far from being pleasant; nor is there any succluendum for the close stroke, which in the violin is performed by alternately depressing the finger to the finger-board, and lifting it without entirely removing the finger from it; and which by giving the note that tremulous sound produced by the human voice affected with grief, is a grace peculiarly adapted to pathetic and plaintive airs.

We proceed, however, to a further account of the same instrument, extracted from the Annual Register, vol. iv. p. 169.

Besides these tones (says the author of that account) which every clastic fitting produces by a vibration,
Harmonization of all its parts, it is capable of another set of tones, in which only a part of the string is supposed to vibrate. These sounds are produced by the lightest touches, either by air, as in Oswald's lyre, or by rubbing the bow in the finest manner on the string of a fiddle.

"Analogous to these sounds are those produced by bells: in those last, besides those tones produced by their elliptical vibrations, there are a set of tones which may be brought about by gently rubbing their edges, and in which the whole instrument does not appear to vibrate in all its parts as before.

"Take, for instance, a bell finely polished at the edges; or, what will perhaps be more convenient, a drinking-glass: let the edges be as free from any thing oily as possible; then, by moistening the finger in water (I have found alum-water to be best), and rubbing it circularly round the edge of the glass, you will at length bring out the tone referred to.

"This note is composed of infinite frequencies; it has all the excellencies of the tone of a bell without its defects. It is loud, has a sufficient body, is capable of being swelled and continued at pleasure; and, besides, has naturally that vibratory softening which musicians endeavour to imitate by mixing with the note to be played a quarter-tone from below.

"To vary these tones, nothing more is required than to procure several bells or glasses of different tones, tuned as nearly as possible, which may be done by thinning the edges of either; or, for immediate satisfaction, the glasses may be tuned by pouring in water; the more water is poured in, the graver the tone will be.

"Let us suppose then a double octave of those glasses, thus tuned, to be produced. Any common tune may be executed by the fingers rubbing upon each glass successively; and this I have frequently done without the least difficulty, only chosing those tones which are short and easy. Here then are numbers of delicate tones, with which musicians have been till very lately unacquainted; and the only defect is, that they cannot be made to follow each other with that celerity and ease which is requisite for melody. In order to remedy this, I took a large drinking-glass, and by means of a wheel and gear, as in the electrical machine, made it to turn upon its axis with a moderately quick but equalable motion; then moistening the finger as before, nothing more was required than merely to touch the glass at the edge, without any other motion, in order to bring out the tone.

"Instead of one glass only turning in this manner, if the whole number of glasses were so fixed as to keep continually turning by means of a wheel, it follows, that upon every touch of the finger a tone would be expressed; and thus, by touching several glasses at once, an harmony of notes might be produced, as in a harpsichord.

"As I write rather to excite than satisfy the curious, I shall not pretend to direct the various ways this number of glasses may be contrived to turn; it may be sufficient to say, that if the glasses are placed in the segment of a circle, and then a strap, as in a cutter's wheel, be supposed to go round them all, the whole number will by this means be made to turn by means of a wheel.

"Instead of the finger, I have applied moistened Harleather to the edge of the glass, in order to bring out the tone: but, for want of a proper elasticity, this did not succeed. I tried cork, and this answered every purpose of the finger; but made the tone much louder than the finger could do. Instead, therefore, of the finger, if a number of corks were so contrived as to fall with a proper degree of pressure on the edge of the glass, by means of keys like the jacks of an organ, it is evident, that in fact a new and tolerably perfect instrument would be produced; not so loud indeed as some, but infinitely more melodious than any.

"The mouths of the glasses or bells used in this experiment should not resemble the mouth of a trumpet, but should rather come forward with a perpendicular edge. The corks used in this case should be smooth, even free from those blemishes which are usually found in them, and at the same time the more elastic the better."

In the two accounts here given seems to be comprehended every thing valuable which has been said upon the subject. It remains, however, our permanent opinion, that the form and structure designed and constituted by Dr. Franklin is by much the most eligible; nor can we admit, that a cork, however successfully applied, will produce the same mellowness and equality of tone in general with the finger. It appears to us, that, by this kind of voluntary attraction, a note may be fink or swelled with much more art and propriety than by the sublation of any thing else extrinsic to the hand; and when chords are long protracted, that degree of friction, which renders every found in the chord inelastic to the ear, without harshness, must be the most agreeable. For this reason, likewise, we should recommend alum-water in preference to chalk.

From what has already been said, it will easily be perceived, that this instrument requires to be tuned with the nicest degree of delicacy which the laws of temperament will possibly admit. For these laws the reader will naturally have recourse to the article Music in this Dictionary; where, from M. D'Alembert is given a plain and satisfactory account, both of the method proposed by Rameau, and of that established in common practice, without anticipating the experience and taste of the reader, by dictating which of these plans is preferable. To those who have occasion to tune the instrument, it may likewise be useful to peruse the detached article Temperament in this Work. Without recapitulating the different rules of alteration preferred in these accounts, we shall presuppose the reader acquainted with them; and proceed to describe how, under their influence, the Harmonica may be turned. But it is previously expedient to observe, that the same rules which conduct the proceeds of tuning a harpsichord, will be equally effectual in tuning the Harmonica; with this only difference, that greater delicacy in adjusting the chords should, if practicable, be attempted.

There are different notes from whence the procedure of tuning may commence. Labor A, which is the key that pretty nearly divides the harpsichord, is chosen by some; this is in common spinets is 24 natural keys from the bottom, and 13 from the top: and the A above it, or second C upon the G clef, by others. This last we should rather advise, because we imagine these intervals
intervals which we have called /ounds major to be more
just through the whole octave, when the course of tuning
is begun by a natural semitone. The initiate, there¬
fore, may begin by turning the second ut of his
Harmonica, or C above the treble clef, in unison with its
correspondent C upon the harpichord or any other in¬
strument in concert-pitch; then, descending to its octave
below, adjust it with the ut above, till every pul¬
sation if possible be lost, and the sounds rendered
fearcely distinguishable when simultaneously heard. To
the lowest note of this octave he must tune the f or G
immediately above it, by a fifth, till observing the laws
of temperament: To this G, the re, or D immediately
above it, by the same chord: To the re, or D above,
itself below: To this, by a fifth, the la or A imme¬
diately above it: To la, the mi, or E ascending in the
tune proportion: To mi, its octave below: To this, the f or B immediately above it by a fifth: To the
first ut, or C, which was tuned, the fa or F imme¬
diately below by the same chord.

That the practitioner may be still more secure in the
justice and propriety of his procedures, he may try the
thirds of the notes already adjusted, and alter them as
much as is consistent with the fifths and octaves, so that
among these thirds as may seem grating and disagreeable to his
ear. Thus far having accomplished his operation, he
may tune all the other natural notes whether above or
below by octaves. His next concern is with the femi¬
tones. And here it will be suggested by common
sense, that as in all instruments with fixed scales the
sharp of a lower metric like unfur for the flat of a
higher tone, the semitone ought as nearly as possible
to divide the interval. He may begin with la or A
sharp; which la in its natural flute is a third minor be¬
neth the ut or C, from whence he began in the na¬
tural scale. This semitone should correspond with the F
natural immediately above by a fifth. To it may be
tuned the re or D sharp immediately below by a similar
chord: to D sharp, its octave above: To f or B na¬
tural, immediately above the la or A first mentioned,
may be adjusted the F or fa sharp immediately above
it: To this its octave below: To that octave, the C
or ut-sharp above by a fifth: To the C sharp, its octave
below: To this, by a fifth, the G or fa sharp above. Be¬
tween this G sharp and the D sharp immediately above it, the fifth will probably be too sharp; but if the
others are justly tuned, that discord will not be ex¬
tremely offensive; and it is a necessary consequence of
temperament. The rest of the sharps and flats, like their
naturals, whether ascending or descending, may be
ruled by their octaves.
The notes, with their chords, may be expressed by
letters and figures, thus; where, however, it must be
observed, that the higher notes of any chord are marked
with larger capitals. It should likewise be remarked,
that the figures are not expressive of the different ratios
which the notes bear one to another, considered with re¬
spect to their vibrations; but only significant of their
nominal distances, according to the received de¬
nominations of the intervals. C c G c D b D D A
A E E E B C G. The sharps and flats thus, A x F, B x D,
A x D, F F, F F. In running over the sharps and flats as the
naturals, it will likewise be necessary to try the thirds, and to alter such as may offend the ear; which, if cau¬
tiously done, will not sensibly injure the other chords.

—Though this article has been protracted to a length
which we did not originally intend, we have how¬
ever the satisfaction to find, that it comprehends
everything essential: so that any person who under¬
stands the nature of chords, and the practical prin¬
ciples of music as universally taught, may not only be
able to tune his instrument, but to acquire its whole
efficacy, without the least assistance from a master.

On Plate CCXXXI. is represented an instrument of
this kind, made by Mr Dobb of St Paul’s church¬
yard, London.

Though this topic appeared in itself complete in the
former edition of this extensive work, yet having
since received from Dr Edmund Cullen of Dublin the
following observations, and reflecting that men of mu¬
tical talents have not only different tastes, but different
powers of mechanical operation, we have thought
it proper to submit to the choice of our readers, either
Dr Franklin’s form and arrangement of the glases, or
that which has been adopted by Dr Cullen; but in ei¬
er case, we would recommend it to the initiate in
this instrument, to distinguish by colours, according to
Dr Franklin, the notes and semitones.—We like¬
cannot forbear to think, that the complete bas
practicable on the harmonica, is by many degrees
preferable to the chords with which Dr Cullen pro¬
poses to grace every emphatic note, with which, from the
structure and arrangement of his instrument, he is un¬
der a necessity of defeating instead of satisfying the ear, with
the full effect of the regular procedure of the treble and
bass upon the same instrument.

This instrument the Doctor describes as consisting of
35 glases of different sizes, answering to so many distinct
founds, and ranged in the manner hereafter described.
They are exactly of the form of a cocoa nut when the
usual quantity of the top is cut off, or the sugar-bowls
made of cocoa-nut shells, so much in use will give a pre¬
cise idea of their figure. They are blown with plain long
staves which are fitted to wooden feet screwed on a
board at proper distances, in such a manner that the cir¬
cular tops of all may be in the same horizontal plane,
at the distance of about an inch asunder. Of these 35,
only are allotted for half tones; there remain there¬
fore 25 for the diatonic scale. The lowest note corre¬
sponds to G in the bass clef; hence it extends upward
to the octave about C in altitude. For uniformity, take
the glases which are chosen gradually and regularly diminu¬
ing in size as they ascend in tone. This, however,
is not absolutely necessary, as the tone of the glases does
not entirely depend upon its size, but in a great meas¬
ure upon the proportion of its different parts to one
another: hence the glases corresponding to one note may
be smaller than a glase corresponding to a note three or
four tones higher: however, where it is practical, they
should always be chosen gradually diminishing as they as¬
cend, both on account of the elegance of appearance, and
that an equality in point of loudness may be preferred;
far, as every body knows, an instrument may be liable
to great inequality in point of strength, though per¬
fecfly in tune. This must have a very bad effect; and
therefore we find performers on the violin and other in¬
struments of that kind very solicitous about the propor¬
The glases being chosen in the best manner circumstances will permit, we proceed to arrange them. Here let me observe, that in general the diameter of the largest glas at its mouth is about seven inches, and its solid contents about five English pints, while the highest is of about 4 inch, and its contents about 1/2 of a gill: this, however, is arbitrary, and depends upon the pitch of the instrument. In arranging the glases, we shall, to avoid confusion, take the diatonic scale first, and afterwards the half tones will be easily understood. In the wooden feet before mentioned are to be screwed on a strong board of a proper size, and they are disposed at convenient intervals in rows perpendicular to the longest sides of the rectangular board on which they stand. In these feet the glases are disposed in the following manner: Beginning with the lowest note G, we fix that on the foot which stands in the nearest angle of the board on the left hand, A in the next bottom in the fame perpendicular line, B in the third; when we come to C, however, we do not place it in the fame perpendicular line, but in the nearest bottom of the second perpendicular row to the left hand, D in the second of the same row, E in the third; F again in the nearest bottom of the third row, G in the second of the fame row, A in the third; B again in the nearest bottom of the fourth row, C in the second of the fame, and so on. By this contrivance, it is easy to see an immense compass is obtained! so great a one indeed, that if the glases were disposed according to the old method, regularly ascending in a line parallel to the front of the instrument, to take the same length, no less than a length equal to the sum of all the perpendiculars we before spoke of, which in ordinary size of the glases would amount to upwards of 16 feet; the inconvenience of which it is unnecessary to dwell upon. As to the half tones, perhaps a more judicious and convenient arrangement may be thought of for them: but the present mode is far from inconvenient, except in some keys; and it is sufficiently commodious for performing such airs as are best fitted to the nature and design of the instrument. After explaining the arrangement, we shall speak somewhat more exactly of them. B⁴ in the first line of the treble flave stands in the fourth bottom of the first perpendicular row to the left hand; F⁴ in the first space stands in the fourth place of the second row, G⁴ in the second line of the treble flave stands in the fourth of the third row, C⁴ in the third space of the fame flave stands in the same manner in the fourth row, and so on, ascending to F⁴ in the fifth row, G⁴ in the sixth, A⁴ in the seventh, C⁴ in the eighth. In the ninth perpendicular row, that is, the last to the right hand in the diatonic scale, stands C alone; but immediately behind is placed B⁴ of the middle line of the treble flave, and again behind it D⁴ of the fourth line of the treble flave, which finishes the whole. There is something singular, and perhaps whimsical, in the distribution of the half tones; but it is found sufficiently convenient; and if a better is thought of it may easily be adopted. In the mean time I must observe, that two of them, viz. C⁴ and F⁴, standing immediately behind the D and G respectively above them, are singularly well fitted for performing running passages either up or down in the key of G. Ex. gr. let us suppose that we have that very common A, G, F⁴, E semiquavers. Harmoni.

The performer touches A, which is in the first place of the 6th row, with his left hand, G with the fore-finger of his right, F⁴ with the middle, and E again with the left hand; in the fame manner may E, D, C⁴, and B, be played, or upwards by inverting the motion: thus we can with the utmost ease run either up or down two very frequent passages in a key, which might naturally be supposed difficult upon this instrument, and that with any given rapidity. I wish as much could be said of all the other half tones of which, by the bye, some are altogether wanting; it is obvious, however, that they may easily be added, if we can find convenient places; and I apprehend even that very practicable. Be that as it may, notwithstanding the seemingly inconvenient situation of some half tones, and the total want of others, pieces may be performed on this instrument of considerable rapidity. I myself, though very far from being an accomplished player, can with great ease go through all the parts of Fillier's celebrated Rondeau; nor may I have heard the fifth concerto of Vivaldi played upon it with as much difficulty as much difficulty as is often said. The glases are not necessarily chosen perfectly in tune, but are tuned by the help of a quantity of water. Here however two cautions are necessary: 1st. By no means to take a glas which is, when without water, flatter than the note you intend; as in that case you cannot remedy it, the water making the tone softer, rather let it be somewhat sharper, and you may tune it to the utmost nicety by a little water. The second caution is, not to choose a glas which is very much sharper than the note required; as in that case, so large a quantity of water will be required to tune it as will entirely muffle the tone.

This instrument is to be played somewhat in the manner of the harmonica, viz. the fingers are to be well wetted; and by the application of them to the side, assisted by a proper motion the sound is produced. And here I would observe that the proper motion is, to make the fingers follow the thumb, not the thumb follow the fingers in going round the glases; it is necessary also to observe the circular motion very exactly, as the least deviation from it produces the most horrible sound that can be conceived. It is likewise to be observed, that you must touch the smaller glases upon the very top of the rim: and for that purpose the palm of the hand must be nearly parallel to the top of the glas; but in coming to the larger glases, it is absolutely necessary to make the fingers to touch the side, not the top of the glas; and the larger the glas, the more distant from the top must they be touched. Practice alone can determine this matter.

From this disposition of the glases, it is easy to see that the perfect chord of C is always most completely in our power, namely, by using different fingers to the different notes at the same time; and although a full bass cannot be executed upon this instrument, we have always a great number of accompaniments which can easily be introduced; more perhaps than upon any instrument, the organ and others of that species excepted. The thirds or fifths occasionally can be introduced; and when done with taste and judgment, will scarcely yield to a middling bass. If to this be added a thrilling softnes of the tones, inimitable by any other sublimate, it will readily appear to be an instrument more in the true style of
Han. [320] Harmon.

of music, of that music which the heart acknowledges, than any that either chance or ingenuity has hitherto produced. It is indeed incapable of that whimsical subdivision to which the taste of modern composers, that sworn enemy to harmony and real music, leads; which serves no end but to exhibit the wonderful executions of a favourite performer, and to overwhelm his hearers with stupid admiration. This is not music; and upon these occasions, though I acknowledge the difficulty of doing what I see done, I lament that the honest man has taken so much pains to do little purpose. Our instrument is not capable of this (at least not to exquiste a degree as the harpsichord, violin, and a few others) yet if the true and original intent of music is not to astonish but to please, if that instrument which most readily and pleasingly feizes the hearth thro' the ears is the best, I have not a moment's hesitation in setting it down the first of all musical instruments. There is but one which will in any degree bear the comparison, or rather they are the same instrument, I mean Dr. Franklin's harmonica; but I am inclined to think that the instrument we have been speaking of has some superiority over the harmonica. The first striking difference is in the impracticality of executing quick passages on the latter; whereas it is in most cases extremely easy on the other. Again, the very long continued vibration of the glases, inevitably must produce horrible discord, or at least confusion, except the piece played be so slow that the vibration of one glass be nearly over before the other is heard. Now, in our instrument, this may be remedied by laying pieces of sponge lightly between the glasses, as to allow them only the proper extent of vibration. This, however, is an exceptionable method: and it is much better done by the touch of the performer's finger, which instantly stops the vibration; and the use of this may be learned and the effect of the two sounds is produced, as extremely well imitates a fine shake, and the skilful performer will make the beat in a turned shake with a spare finger. This operation requires some dexterity; but this is a charge common to all musical instruments; and I question not that the Highland bagpipe itself requires some sort of skill.

Upon the whole, I am clearly of opinion, that the harmonica, and more especially this instrument which has as yet got no name, is the most exquisite and noble present that the lovers of true harmony have ever yet received; and it is with much astonishment I find this invaluable treasure almost entirely confined to Ireland, a country not very remarkable for musical taste or talents: But I hope soon to see this elegant species of music very generally known and practiced over all Europe.

Harmony. The sense which the Greeks gave to this word in their music is so much less easy to be determined, because the word itself being originally a substantive proper, it has no radical words by which we might analyze it, to discover its etymology. In the ancient treatises which remain to us, harmony appears to be that department whose object is the agreeable succession of sounds, merely considered as high or low; in opposition to the two others called rhythmsica and metrical, which have their principle in time and measure. This leaves our ideas concerning the ultimate of sound vague and undetermined; nor can we fix them without studying for that purpose all the rules of the art; and even after we have done so, it will be very difficult to distinguish harmony from melody, unless we add to the last the ideas of rhythm and measure; without which, in reality, no melody can have a distinguishing character: whereas harmony is characterized by its own nature, independent of all other quantities except the chords or intervals which compose it.

It appears by a passage of Nichomachus, and by others, that they likewise gave the name of Harmony to the chord of an octave, and to concords of voices and instruments, which performed in the distance of an oc-
Harmony, tave one from the other, and which is more commonly called antiphon.

Harmony, according to the moderns, is a succession of chords agreeable to the laws of modulation. For a long time this harmony had an other principle but such rules as were almost arbitrary, or solely founded on the approbation of a practised ear, which decided concerning the agreeable or disagreeable succession of chords, and whole determinations were at last reduced to calculation. But father Mercurine and N. Savour having found that every found, however simple in appearance, was always accompanied with other founds of sensible, which constitute with itself a perfect chord-major; with this experiment M. Rameau set out, and upon it formed the basis of his harmonic system, which he has extended to a great many volumes, and which at last M. D'Alembert has taken the trouble of explaining to the public.

Signior Tartini, taking his route from an experiment which is newer and more delicate, yet not less certain, has reached conclusions similar enough to those of Rameau, by pursuing a path whose direction seems quite opposite. According to M. Rameau, the treble is generated from the bass; Signior Tartini makes the bass result from the treble. One deduces harmony from melody, and the other supposes quite the contrary. To determine from which of the two schools the best performances are likely to proceed, no more is necessary than to investigate the end of the composer, and discover whether the air is made for the accompaniments, or the accompaniments for the air. At the word System in Rondelet's Musical Dictionary, is given a delineation of that published by Signior Tartini. Here he continues to speak of M. Rameau, whom he has followed through the whole work, as the author of the greatest authority in the country where he writes.

He thinks himself obliged, however, to declare, that this system, however ingenious it may be, is far from being founded upon nature, an affirmation which he incessantly repeats: "That it is only established upon analogies and congruities, which a man of invention may overturn to morrow, by substituting others more natural: that, in short, of the experiments from whence he deduces it, one is detected fallacious, and the other will not yield him the confidences which he would extort from it. In reality, when this author took it in his head to dignify with the title of demonstration the reasonings upon which he established his theory, every one turned the arrogant pretence into ridicule. The Academy of Sciences loudly disapproved a title so ill founded, and so gratuitously assumed; and M. Elive of the Royal Society at Montpellier, has shown him, that even to begin with this proposition, that according to the law of nature, founds are represented by their octaves, and that as the octaves may be substituted for them, there was not any one thing demonstrated, or even firmly established in his pretended demonstration." He returns to his system.

"The mechanical principle of reference presents us with nothing but independent and solitary chords; it neither prescribes nor establishes their succession. Yet a regular succession is necessary; a dictionary of selected words is not an oration, nor a collection of legitimate chords a piece of music: there must be a meaning, there must be connections in music as well harmony. As in language: it is necessary that what has preceded should transmit something of its nature to what is subsequent, so that all the parts conjointly may form a whole, and be framed with the genuine character of unity.

"Now, the complex sensation which results from a perfect chord must be resolved into the simple sensation of each particular sound which composes it, and into the sensation of each particular interval which forms it, ascertained by comparison one with another. Beyond this there is nothing sensible in any chord; from whence it follows, that it is only by the relation between sounds, and by the analogy between intervals, that the connection now in question can be established; and this is the genuine, the only source, from whence flow all the laws of harmony and modulation. If then, the whole of harmony were only formed by a succession of perfect chords-major, it would be sufficient to proceed by intervals similar to those which compose such a chord; for then some one or more sounds of the preceding chord being necessarily protracted into that which is subsequent, all the chords would be found sufficiently connected, and the harmony would, at least in this sense, be one.

"But besides that these successions must exclude all melody by excluding the diatonic series which forms its foundation, it would not arrive at the real end of the art; because, as music is a system of meanings like a discourse, it ought, like a discourse, to have its periods, its phrasing, its pauses, its cadences, its punctuation of every kind; and because the uniformity of a harmonic procedure implies nothing of all this, diatonic procedures require that major and minor chords should be intermixed; and the necessity of dissonances has been felt in order to distinguish the phrases, and render the cadences sensible. Now, a connected series of perfect chords-major can not be productive of perfect chords-minor nor of dissonances, nor can feebly mark any musical phrase, and the punctuation must there be found entirely defective.

"M. Rameau being absolutely determined, in his system, to deduce from nature all the harmony practiced among us, had recourse for this effect, to another experiment of his own invention, of which I have formerly spoken, and which by a different arrangement is taken from the first. He pretended, that any simple found whatever afforded in it multiples a perfect minor or flat chord, of which it was the dominant or fifth, as it furnished a perfect chord-major by the vibration of its aliquot parts, of which it is the tephonic or fundamental found. He has affirmed as a certain fact, that a vocal string caused two others lower than itself to vibrate through their whole extent, yet without making them produce any sound, one to its twelfth major and the other to its seventeenth; and from this joined to the former fact, he has very ingeniously deduced not only the application of the minor mode and of dissonances in harmony, but the rules of harmonic phrases and of all modulation, such as they are found at the words Chord, Accompaniment, Fundamental, Bass, Cadence, Dissonance, Modulation.

"But first (continues Rondeau), the experiment is false. It is discovered, that the strings tuned beneath the fundamental found do not entirely vibrate when
Harmony. When this fundamental sound is given; but that they are divided in such a manner as to return its unison alone, which of consequence can have no harmonics below. It is moreover discovered, that the property of strings in dividing themselves, is not peculiar to those which are tuned by a twelfth and seventeenth below the principal sound; but that oscillations are likewise produced in the lower strings by all its multiples. Whence it follows, that the intervals of the twelfth and seventeenth below not being singular phenomena of their kind, nothing can be concluded in favour of the perfect minor chord which they represent.

"Though the truth of this experiment were granted, even this would by no means remove the difficulty. If, as M. Rameau alleges, all harmony is derived from the recurrence of sonorous bodies, it cannot then be derived only from the vibrations of such bodies as do not resound. In reality, it is an extraordinary theory, to deduce from bodies that do not resound the principles of harmony; and it is a principle in natural philosophy no less strange, that a sonorous body should vibrate without resounding, as if found itself were any thing else but the air impelled by these vibrations. Moreover, sonorous bodies do not only produce, besides the principal sound, the other tones which with itself compose a perfect chord; but an infinite number of other sounds, formed by all the aliquot parts of the bodies in vibration; which do not enter into that perfect harmony. Why then should the former sounds produce consonances, and why should the latter not produce them, since all of them equally result from nature?

"Every sound exhibits a chord truly perfect, since it is composed of all its harmonics, and since it is by them that it becomes a sound. Yet these harmonics are not heard, and nothing is distinguished but a simple sound, unless it be exceedingly strong; whence it follows, that the only good harmony is an unison; and that, as soon as the consonances can be distinguished, the natural proportion being altered, the harmony has lost its purity.

"That alteration is in this case produced in two different ways. First, by causing certain harmonics to resound, and not the others, the proportion of force which ought to prevail in all of them is altered, for producing the sensation of a single sound; whence the unity of nature is destroyed. By doubling these harmonics, an effect is exhibited similar to that which would be produced by suppressing all the others; for that case we cannot doubt, but that, along with the generating sound, the tones of the other harmonics which would be permitted to sound would be heard: whereas, in leaving all of them to their natural operations, they destroy one another, and conspire together in forming and strengthening the simple sensation of the principal sound. It is the same effect which the full sound of a flop in the organ produces, when, by successively removing the stop or register, the third and fifth are permitted to sound with the principal; for then that fifth and third, which remained absorbed in the other sounds, are separately and disagreeably distinguished by the ear.

"Moreover, the harmonics which we cause to sound have other harmonics pertaining to themselves, which cannot be such to the fundamental sound. It is by these additional harmonics that the sounds which produce them are distinguished with a more sensible degree of harmony; and these very harmonics which thus render the chord perceptible, do not enter into its harmony. This is the reason why the most perfect chords are naturally pleasing to ears whose relish for harmony is not sufficiently formed; and I have no hesitation in thinking, that even the octave itself might be displeasing, if the mixture of male and female voices did not inure us to that interval from our infancy.

"With dissonance it is still worse; because, not only the harmonics of the sound by which the discord is produced, but even the sound itself, is excluded from the natural harmony of the fundamental: which is the cause why discord is always distinguished amongst all the other sounds in a manner shocking to the sense.

"Every key of an organ, with the stop fully opened, gives a perfect chord with its third major, which are not distinguished from the fundamental sound, if the hearer is not extremely attentive, and if he does not find the whole flop in succession; but these harmonic sounds are never absorbed in the fundamental, but on account of the prodigious noise, and by such a situation of the registers as may cause the pipes which produce the fundamental sound to conceal by their force the other sounds which produce these harmonics. Now, no person observes, nor can observe, this continual proportion in a concert; since, by the manner of inverting the harmony, its greatest force must in every instant be transferred from one part to another, which is not practicable, and would destroy the whole melody.

"When we play upon the organ, every key in the bass causes to resound the perfect chord major; but because that bass is not always fundamental, and because the music is often modulated in a perfect minor chord, this perfect chord-major is rarely struck with the right hand; so that we hear the third minor with the major, the fifth with the triton, the seventh redundant with the octave, and a thousand other cacophonies, which, however, do not much disgust our ears, because habit renders them tractable; but it is not to be imagined that an ear naturally just would prove so patient of discords, when first exposed to the reft of this harmony.

"M. Rameau pretends, that trebles composed with a certain degree of simplicity naturally suggest their own basses; and that any man having a jujt, though unpractised ear, would spontaneously sing that bass. This is the prejudice of a musician, refuted by universal experience. Not only would he, who has never heard either bass or harmony, be of himself incapable of finding either the bass or the harmony of M. Rameau, but they would be displeasing to him if he heard them, and he would greatly prefer the simple unison.

"When we consider, that of all the people upon earth, who have all of them some kind of music and melody, the Europeans are the only people who have a harmony consisting of chords, and who are pleased with this mixture of sounds; when we consider that the world has endured so many ages, whilst, of all the nations which cultivated the fine arts, not one has found out this harmony: that not one animal, not one bird, not one being in nature, produces any other chord but
but the union, nor any other music but melody; that
the eastern languages, so sonorous, so musical; that
the ears of the Greeks, so delicate, so sensible, prac-
ticed and cultivated with so much art, have never con-
ducted this people, luxurious and enamoured of plea-
sure as they were, to the harmony which we
imagined so natural; that without it their music pro-
duced such astonishing effects; that with it ours is
so impotent: that, in short, it was reserved for the
people of the north, whose grofs and callous organs of
sensation are more affected with the noise and clamour
of voices, than with the sweetmeats of accents and the
melody of infections, to make this grand discovery,
and to vend it as the essential principle upon which all
the rules of the art were founded; when, in short, at-
tention is paid to all these observations, it is very dif-
ficult not to suspect that all our harmony is nothing but
a Gothic and barbarous invention, which would never
have entered into our minds, had we been truly sensible
to the genuine beauties of art, and of that which is
unquestionably natural.

"M. Rameau afferts, however, that harmony is the
source of the most powerful charms in music. But
this notion is contradictory both to reason and to mat-
ter of fact. To fact it is contradictory; because,
since the invention of counter-point, all the wonderful
effects of music have ceased, and it has lost its whole
force and energy. To which may be added that such
beauties as purely result from harmony are only percept-
ed by the learned; that they affect none with
transport but such as are deeply conversant in the art;
whereas the real beauties of music, resulting from na-
ture, ought to be and certainly are, equally obvious
to the adept and the novice. To reason it is contradi-
tory; since harmony affords us no principle of imita-
tion by which music, in forming images and expressing
sentiments, can rise above its native excellence till it
becomes in some measure dramatic or imitative which
is the highest pitch of elevation and energy to which
the art can aspire; since all the pleasures which we can
receive from the mere mechanical influence of sounds
are extremely limited, and have very little power over
the human heart."

Thus far we have heard M. Rameau, in his obser-
vations on harmony, with patience; and we readily
grant, that the system of harmony by M. Rameau
is neither demonstrated, nor capable of demonstration.
But it will not follow, that any man of invention can
so easily and so quickly subvert those aptitudes and ana-
logies on which the system is founded. Every hy-
thetical is admitted to possess a degree of probability pro-
portioned to the number of phenomena for which it
offers a satisfactory solution. The first experiment of
M. Rameau is, that every sonorous body, together
with its principal sound and its octave, gives likewise
its twelfth and seventeenth major above; which being
approximated as much as possible, even to the chords
immediately reprented by them, return to the third,
fifth, and octave, or, in other words, produce perfect
harmony. This is what nature when solicited, sponta-
necessarily gives; this is what the human ear, unpre-
pared and uncultivated, imbibes with ineffable avidity
and pleasure. Could any thing which claims a right
to our attention, and acceptance from nature be im-
pressed with more genuine or more legible signatures of
her function than this? We do not contend for the Har-
mony of M. Rameau's second experiment. Nor is it
necessary we should. The first expanded and carried
into all its consequences, resolves the phenomena of
harmony in a manner sufficient to establish its authenti-
city and influence and inculcates on the mind an idea
affords no solution are too few and too trivial either to
merit the regard of an artist, or a philosopher, as M.
D'Alembert in his elements has clearly shown. The
facts with which M. Roufeau confronts this principle,
the armies of multiplied harmonics generated in infinitum,
which he draws up in formidable array against it,
only show the thin partitions which sometimes may di-
vide philosophy from whim. For, as bodies are infini-
dively divisible, according to the philosophy now estab-
lished, or as, according to every philosophy, they
must be indefinitely divisible, each infinitesimal of any
given mass, which are only harmonics to other prin-
cipal sounds, must have fundamental tones and har-
monics peculiar to themselves; so that if the reasoning
of Roufeau has any force against M. Rameau's ex-
periment, the air must be continually disturbed with a
chaos of inapprehensible harmonics, and melody itself
must be lost in the confusion. But the truth of the
matter is, that, by the wise instituion of nature, there
is such a conformity established between our senses
and their proper objects, as must prevent all these disagree-
able effects. Roufeau and his opponent are agreed in
this, that the harmonics conspire to form one predo-
nant sound; and are not to be detected but by the nicest
organs, applied with the deepest attention. It is equa-
It is equal­ly obvious, that, in an artificial harmony, by a proper
management of this wise precaution of nature, dif-
fuences themselves may be either entirely concealed or
considerably softened, so that, since by nature fono-
rous bodies in actual vibration are predisposed to exhi-
bite perfect harmony; and since the human ear is, by
the same wise regulation, fabricated in such a manner
as to perceive it; the harmonical chaos of M. Roufeau
may be left to operate on his own brain, where it will
probably meet with the warmest reception it can ex-
pect to find. Nor does it avail him to pretend, that
before the harmonics can be distinguished, sonorous bod-
ies must be impelled with a force which alters the
chords, and destroys the purity of the harmony; for was writ-
ten.

M. Roufeau was a

against
The translator of D'Alambert's Elements, as given under the article Music in this Dictionary, has been at particular pains to investigate his earliest recollections upon this subject; and has had such opportunities, both of attending to his original perceptions, and of recognizing the fidelity of his memory, as are not common. He can remember, even from a period of early childhood, to have been pleased with the simplest kinds of artificial harmony; to have distinguished the harmonics of familiar bodies with delight; and to have been struck with horror at the sound of such bodies as, by their structure, or by the cohesion of their parts, exhibited these harmonics false. This is the chief, if not the only cause, of the tremendous and disfiguring sensation which we feel from the sound of the Chineses gong. The same horrible cacophony is frequently, in some degree, produced by a drum unequally braced; from this sound the translator often remembers to have started and screamed, when carried through the streets of the town in which he was born in the arms of his nursemaid; and as he is conscious, that the auditory organs of many are as exquisite as his own, he cannot doubt but they may have had the same sensations, though perhaps they do not recollect the facts. So early and so nicely may the sensations of harmony and discord be distinguished. But after all, it seems that harmony is no more than a modern invention, and even at this late period only known to the Europeans. We should, however, be glad to know, from what oracle our philosopher learned that harmony was not known to antiquity. From what remains of their works, no proof of this position can be derived; and we have at least mentioned one probability against it in our notes to the Preliminary Discourse to the article Music, (see note b.) But the Roufean's mighty objections were granted, that harmony can only be endured by such ears as are habitually formed and cultivated; that the period of its prevalence has been short, and the extent of its empire limited to Europe; still his conclusion, that it is a Gothic and barbarous invention, is not fairly deducible even from these premises. Muft we affirm that epic poetry has no foundation in nature, because, during the long interval which happened from the beginning of the world to the destruction of Troy, no epic poem seems to have appeared? Or because a natural and melifluous verification is left refilled by an unpolished taste, than the uncomely rhymes of a common ballad, shall we infer, that the power of numbers is merely suppositional and arbitrary? On the contrary, we will venture to affirm, that though harmony cannot, as Rameau supposes, be mathematically demonstrated from the nature and vibrations of familiar bodies; yet the idea of its constituent parts, and of their coexistence, is not left established, no less precise and definite, than any mode or property of space or quantity to be investigated by geometrical researches or algebrical calculations. It is certain, that the mimetic or imaginative power of music chiefly confits in melody; but from this truth, however evident, it cannot be fairly deduced, that harmony is absolutely unintelligible or imitative. Perhaps every musical sound, even the most simple, and all modulations of sound, are more or less remotely connected with some sentiment or passion of the human heart. We know that there are instincive expreions of pain or pleasure in their various modes and degrees, which when uttered by any sensitive, and perceived by any conscious being, excite in the mind of the percipient a feeling sympathetic with that by which they are prompted. We likewise know from experience, that all artificial sounds modulated in the same manner, have similar, though not equal, effects. We have seen, that, in order to render harmony compatible with itself the melody of each part must be congenial; and, for that reason, one kindred melody results from the whole. So far, therefore, as any composer has it in his power to render the general melody homogeneous; so far, the imitation may be preferred. And even heightened: for such objects as are majestic and august, or the feelings which they excite are more aptly expressed by a composition of kindred sounds, than by any simple tone whatever. They who suppose the mimetic powers of music to be confinued in the imitation of mere unmeaning sounds or degrees of motion, must entertain limited and unworthy ideas of its province. It is naturally a representative almost of every sentiment or affection of the soul; and, when this end is gained, the art must have reached its highest perfection, and produced its noblest effects. But these effects, however sensible among the ancients, may in us be superceded by other causes which remain yet unexplored. Theatrical performances are likewise, by them laid to have produced the most wonderful effects; yet we do not recognize amongst ourselves, though we have dramatic entertainment perhaps not inferior to theirs.

Roufean proceeds to tell us that among the ancients the enharmonic species of music was sometimes called harmony.

Direct Harmony, is that in which the bass is fundamental, and in which the upper parts preserve among themselves, and with that fundamental bass, the natural and original order which ought to subsist in each of the chords that compose this harmony.

Inverted Harmony, is that in which the fundamental or generating sound is placed in some of the upper parts and when some other sound of the chord is transferred to the bass beneath the others.

Harmony of the Spheres, or Celestial Harmony, a sort of music much talked of by many of the ancient philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals. It is impossible, according to them, that such prodigious large bodies, moving with so much rapidity, should be silent: on the contrary, the atmosphere, continually impelled by them, must yield a set of sounds proportionate to the impression it receives; consequently, as they do not run the same circuit nor with one and the same velocity, the different tones arising from the diversity of motions, directed by the hand of the Almighty, must form an admirable symphony or concert.

They therefore supposed that the moon, as being the lowest of the planets, corresponded to $\text{Mercury}$, to $\text{\textit{f}}$; Venus to $\text{\textit{f}}$; the Sun, to $\text{\textit{a}}$; Mars, to $\text{\textit{a}}$. 
H AROLD, the name of two English kings. See England, no. 77, 83.

HARP, a musical instrument of the stringed kind, of a triangular figure, and held upright between the legs of the performer.

Papilius, and Du Cange after him, will have the harp to have taken its name from the Arpi, a people of Italy, who were supposed the first that invented it; and from whom, they say, it was borrowed by other nations. Ménage, &c. derive the word from the Latin harpa, and that from the German harp or harp. Others bring it from the Latin corpe, because touched or thrummed with the fingers. Dr. Hickes derives it from harpe or harape, which signifies the same thing; the first in the language of the Cinibri, the second in that of the Anglo-Saxons. The English priest who wrote the Life of St Dunstan, and who lived with him in the tenth century, says, cap. ii. 12. Sumnit secunx mori eharum frum, quam pateratingu earpam vocans; which intimates the word to be Anglo-Saxon.

The harp was the favourite musical instrument of the Britons and other northern nations in the middle ages; as is evident from their laws, and from every passage in their history, in which there is the least allusion to music. By the laws of Wales, a harp was one of the three things that were necessary to constitute a gentleman, i.e. a freeman; and none could pretend to that character who had not one of these favourite instruments, or could not play upon it. By the same laws, to prevent slaves from pretending to be gentlemen, it was expressly forbidden to teach, or to permit them to play upon the harp; and none but the king, the king's musicians, and gentlemen, were allowed to have harps in their possession. A gentleman's harp was not liable to be seized for debt; because the want of it would have degraded him from his rank, and reduced him to a slave. The harp was in no less estimation and universal use among the Saxons and Danes. Those who played upon this instrument were declared gentlemen by law; their persons were esteemed inviolable, and secured from injuries by very severe penalties. They were readily admitted into the highest company, and treated with distinguished marks of respect wherever they appeared.

There is some diversity in the structure of harps. That called the triple harp has 97 strings or chords in three rows, extending from C in the tenor clift to double G in alt, which make five octaves; the middle row is for the femitones, and the two outside rows are perfect unisons. On the bass side, which is played with the right hand, there are 36 strings; on the treble side, 56; and in the middle row, 35 strings. There are two rows of pins or frets on the right side, serving to keep the strings tight in their holes, which are fastened at the other end to three rows of pins on the upper side. The harp, within the last 40 years, has been in some degree improved by the addition of eight strings to the unison, viz. from E to double F in alt. This instrument is struck with the finger and thumb of both hands. Its music is much like that of the fiddle, all its strings going from semitone to semitone; whereas some call it an inverted fiddle. It is capable of a much greater degree of perfection than the lute.

There are among us two sorts of this instrument,
Of the principal titles he claimed to this kingdom in the year 1101, at Clontarf. His son Conyngham having murdered his brother Teige, A.D. 1103, and being deposed by his nephew, retired to Rome, and carried with him the crown, harp, and other regalia of his father, which he presented to the Pope in order to obtain absolution. Adrian IV., therefore, Breakspear, alleged this circumstance as one of the principal titles he claimed to this kingdom in his bull transferring it to Henry II. These regalia were kept in the Vatican till the pope lent the harp to Henry VIII. with the title of Defender of the Faith; but kept the crown, which was of massive gold. Henry gave the harp to the first earl of Clanricard; in whose family it remained till the beginning of this century, when it came by a lady of the De Burgh family into that of Mac Mahon of Clenagh in the county of Clare. After whole death it passed into the possession of commissioneer Mac Namara of Limerick. In 1782 it was presented to the right honourable William Conyngham, who deposited it in Trinity college library. It is 52 inches high, and of extraordinary good workmanship; the sounding-board is of oak, the arms of red sally; the extremity of the uppermost arm in part is cast with silver, extremely well wrought and chiselled. It contains a large crystal set in silver, and under it was another stone now lost. The buttons or ornamental knobs at the sides of this arm are of silver. On the front arm are the arms chased in silver of the O'Brien family, the bloody hand supported by lions. On the sides of the front arm within two circles are two Irish wolf dogs cut in the wood. The holes of the sounding board where the strings entered are neatly ornamented with efcutcheons of bras carved and gilt: the larger sounding-holes have been ornamented, probably with silver, as they have been the object of theft. This harp has 23 keys, and as many string-holes, consequently there were as many strings. The foot-piece or rest is broken off, and the parts round which it was joined are very rotten. The whole bears evidence of an expert artif. King David is usually painted with a harp in his hands; but we have no testimony in all antiquity that the Hebrew harp, which they call chinnor, was any thing like ours. On a Hebrew medal of Simon Mac cabæus we see two sets of musical instruments; but they are both of them very different from our harp, and only consist of three or four strings. All authors agree, that our harp is very different from the lyra, cithara, or barbiton, used among the Romans. Fortunately, lib. vii. carm. 8. witnesses, that it was an instrument of the barbarians:

Romanaeque lyra, plebantis ildi Barberiis harps, Gracis Atheniisque, crotta Britannica canis.

Of ancient harps, two are represented on the same plate. N° 2. is a trigonum or triangular harp. It is taken from an ancient painting in the museum of the king of Naples, in which it is placed on the shoulder of a little dancing girl, who supports the instrument with his left hand and plays upon it with his right. The trigonum is mentioned by Athenæus, lib. iv. and by Julius Ptolemy, lib. iv. cap. 9. According to Athenæus, Sophocles calls it a Phrygian instrument; and one of his diplophists tells us, that a certain musician, named Alexander Alexandrinus, was such an admirable performer upon it, and had given such proofs of his abilities at Rome, that he made the inhabitants muusam, musingly, muchly. N° 3 and 4 are varieties of the same instrument. N° 5 is the Theban harp, according to a drawing made from an ancient painting of one of the sepulchral grotos of the first kings of Thebes, and communicated by Mr Bruce to Dr Burney*. The * Vide performer is clad in a habit made like a shirt, such as Burney* the women fill wear in Abylinia, and the men in Nubia. It reaches down to his ankles; his feet are without sandals, and bare; his neck and arms are also bare; his loose white sleeves are gathered above his elbows; and his head is clove shaven. His left hand feems employed in the upper part of the instrument among the notes in alto, as if in an arpeggio; while, floooing forwards, he seems with his right hand to be beginning with the lowest string, and promising to ascend with the most rapid execution: this action, so obviously rendered by an indifferent artist, shows that it was a common one in his time; or, in other words, that great hands were then frequent, and consequently that music was well understood and diligently followed.

On this instrument Dr Burney makes the following observations: "The number of strings, the size and form of this instrument, and the elegance of its ornaments, awaken reflections, which to indulge would lead us too far from our purpose, and indeed out of our depth. The mind is wholly lost in the immense antiquity of the painting in which it is represented. Indeed the time when it was executed is so remote, as to encourage a belief, that that, after having been brought to a great perfection, were again lost and again invented long after this period.—With respect to the number of strings upon this harp, if conjectures may be allowed concerning the method of tuning them, two might be offered to the reader's choice. The first idea that presented itself at the sight of 12 strings was, that they would furnish all the semitones to be found in modern instruments within the compass of an octave, as from C to c, D to d, or E to e. The second idea is more Grecian, and conformable to antiquity; which is, that if the longest string represented profilambanomenos, or D, the remaining 12 strings would supply all the tones, semitones, and quarter-tones, of the diatonic, chromatic, and enharmonic genera of the ancients, within the compass of an octave: but for my part, I would rather incline to the first arrangement, as it is more natural, and more conformable to the structure of our organs, than the second. For with respect to the genera of the Greeks, though no historic testimony can be produced concerning the invention of the diatonic and chromatic, yet ancient writers are unanimous in ascribing to Olympus the Phrygian the first use of the enharmonic: and though in the beginning, the melody of this genus was so simple and natural as to resemble the wild notes and rude essays of a people not quite emerged from barbarism; yet in after-times it became overcharged with finical foppositees and fanciful beauties, arising from such minute divisions of the scale as had no other merit than the great difficulty of forming them. It seems a matter of great wonder, with such a model before their eyes as the Theban harp, that the form and manner of
Balbus and Xanthus, Achilles's horses. Phercydes relates, that the Boreades expelled them from the Aegean and Sicilian seas, and pursued them as far as the islands which he calls Plata and Home Calla; and which have since been called the Strophades.

Volusi, De Idol. lib. iii. cap. 99. p. 63, thinks, that what the ancients have related of the harpies, agrees to no other birds so well as the bats found in the territories of Darien in South America. These animals kill not only birds, but dogs and cats, and prove very troublesome to men by their peckings. But the ancients, as the same Volusi observes, knew nothing of these birds. By the harpies, therefore, he thinks, they could mean nothing else but the winds; and that it was on this account they were made daughters of Eileôra, the daughter of Oceanus. Such is the opinion of the Choliartts of Apollonius, Heliod, and Euuthathus. Their names, Aelo, Ocypte, Celeno, are supposed to figure a farther argument of this.

Mr Bryant supposes that the harpies were a college of priests in Bibyynthia, who on account of their repeated acts of violence and cruelty, were driven out of the country: their temple was called Arpi, and the environs Arpiai, whence the Grecians formed Arpiai; and he observes farther, that Harpya, Arpiai, was certainly of old the name of a place.

HARPING IRON. See Harpoon.

HARPINGS, the fore parts of the whales which encircle the bow of a ship, and are fastened to the stem, being thicker than the after part of the whales, in order to reinforce the ship in this place, where she sustains the greatest shock of resistance in plunging into the sea, or dividing it, under a great pressure of sail.

HARPOCRATES, in mythology, the son of Isis and Osiris. This is an Egyptian deity, whose distinguishing attribute is, that he is represented with his fingers applied to his mouth, denoting that he is the god of silence. The statue of this idol was fixed in the entrance of most of the Egyptian temples, and he was commonly exhibited under the figure of a young man naked, crowned with an Egyptian mitre, holding in one hand a cornucopia, and in the other a flower of louts, and sometimes bearing a quiver.

HARPOCRATION, (Valerius), a celebrated ancient rhetorician of Alexandria, who has left us an excellent Lexicon upon the ten orators of Greece. Aldus first published this lexicon in the Greek at Venice in 1603. Many learned men have laboured upon it; but the best edition was given by James Gronovius at Leyden in 1666.

HARPOON, or Harping-iron, a spear or javelin used to strike the whales in the Greenland fishery. The harpoon, which is sometimes called the harping-iron, is furnished with a long staff, having at one end a broad and flat triangular head, sharpened at both edges, so as to penetrate the whale with facility; the head of this weapon is fastened a long cord, called the whale line, which lies carefully coiled in the boat, in such a manner as to run out without being interrupted or entangled. See Whale-fishery.

Gun-harpoon, a kind of fire-arm for discharging harpoons at whales, and thereby killing them more easily and expeditiously than formerly when the harpoons,
poons were thrown by the hands. Though this method
was projected a good many years ago, it is but
 lately come into use; and premiums have been annually
offered by the Society for encouraging arts, &c. to the
persons who first struck a fish in this manner. In the
Transactions of that Society for 1786, we have an ac-
count of the first fish struck in this manner in 1734.
The gun was of the blunderbuss construction, loaded
with four common tobacco-pipes full of glazed powder;
the fish was shot at the distance of ten fathoms, the
harpoon going into her back up to the ring; and she
was killed in about an hour. In 1785 three whales were
killed in this manner; four in 1786 and three in
1787. Since that time the gun-harpoon has come
more into use, and will probably soon supercede the
other method entirely. In the Transactions of the
Society for 1789, we have accounts of a number of
whales killed in this manner. The instrument appears
to be extremely useful in calm hill weather, as the
whale, though a timorous creature, will frequently
allow a boat to approach it to the distance of 20, 15,
or even 10 fathoms, all of which distances are within reach
of the gun-harpoon, though not within the reach of
that thrown by the hand. The greatest inconvenience
was in case of rain or snow, by which the lock
was apt to get wet. To remedy this, a cafe of leather was
made to fit over the gun and over the lock, lined
with tin and big enough to fire the gun when it was
on. The fish struck with a harpoon discharged in this
manner is soon killed by reason of its penetrating
their bodies to a great depth, not less than five or
five feet, which no man's strength would be able to
accomplish. In the volume just quoted, we have an ac-
count of one which was shot through the tail. The
harpoon broke in the fish, but five fathoms of line
went through the tail. The fish was killed in eight
hours, which is perhaps the only instance of a fish
struck in that part being caught. In another, the
harpoon carried six feet of line into its body; the
creature died in ten minutes. Others were killed in
15 minutes or half an hour; and one had a rib broken
by the violence of the stroke. In the Transactions
of the Society for 1790, there are other accounts simi-
lar to the foregoing, and all agreeing as to the great
usefulness of the instrument both for striking the fish
at a considerable distance, and for killing them in a
different time.

HARPSICHORD, the most harmonious of all
the musical instruments of the string-kind. It is played
on after the manner of the organ, and is furnished
with a fret, and sometimes with two sets of keys; the
touching or striking of these keys moves a kind of
little jacks, which also move a double row of chords or
strings, of brass or iron, stretched over four bridges
on the table of the instrument.

HARQUEBUSS, a piece of fire-arms, of the
length of a musket, usually cocked with a wheel. It
 carried a ball that weighed one ounce seven-eighths.
There was also a larger sort, called the great har-
quebus, used for the defence of strong places, which
carried a ball of about three ounces and a half; but
they are now but little used, except in some old castles,
and by the French in some of their garrisons.

HARRILB, a kind of hound, endowed with an
admirable gift of smelling, and very bold in the pur-
suit of his game. See CANSIS.

HARRINGTON (St John), an ingenious Eng-
lisb poet, was the son of John Harrington, Esq., who
was committed to the Tower by queen Mary for hold-
ing a correspondence with her sister Elizabeth; who,
when she came to the crown, freed godmother to this
son. Before he was 30, he published a translation of
Ariosto's Orlando Furioso, a work by which he was
principally known; for though he afterwards pub-
lished some epigrams, his talent did not seem to have
lain that way. He was created knight of the bath
by James I.; and presented a MS. to prince Henry,
levelling chiefly at the married bishops. He is sup-
posed to have died about the latter end of James's
reign.

HARRINGTON (James), a most eminent English
writer in the 17th century, bred at Oxford, travelled
into Holland, France, Denmark, and Germany, and
learned the languages of those countries. Upon his
return to England, he was admitted one of the privy-
chamber extraordinary to King Charles I. He served
the king with great fidelity, and made use of his inter-
ret with his friends in parliament to procure matter
able to be accommodated with all parties. The king loved
his company except when the conversation happened
to turn upon commonwealths. He found means to
see the king at St James's; and attended him on the
seaboard, where, or a little before, he received a token
of his majesty's affection. After the death of king
Charles, he wrote his Oceana: a kind of political
romance, in imitation of Plato's Commonwealth, which
he dedicated to Oliver Cromwell. It is said, that
when Oliver perused it, he declared, that "the gentle-
man had wrote very well, but most not think to cheat
him out of his power and authority; for that what
he had won by the sword, he would not suffer himself
to be scribbled out of." This work was attacked by
several writers, against whom he defended it. Befide
his writings to promote republican principles, he in-
stituted likewise a nightly meeting of several ingenious
men in the New Palace-Yard, Westminster; which
cbub was called the Roti, and continued till the fe-
cuded members of parliament were restored by ge-
neral Monk. In 1661, he was committed to the
Tower for treasonable designs against the king and
chancellor Hyde, at a conference with the gentlemen
and commons, charged him with being concerned
in a plot. But a committee of the lords and commons
could make nothing of that plot. He was conve-
yed to St Nicholas's island, and from thence to Ply-
mouth, where he fell into an uncommon disorder of
the imagination. Having obtained his liberty by
means of the earl of Bath, he was carried to London,
and died in 1677. He published, besides the above
works, several others, which were first collected by
Toland, in one volume folio, in 1700; but a more
complete edition was published, in 1737, by the reve-
tend Dr Birch.

HARRIOT (Thomas), a celebrated algebraist,
was born at Oxford in 1560, where he was also edu-
cated. In 1579, he completed his bachelor's degree;
and, being already distinguished for his mathematical
learning, was soon after recommended to Sir Walter
Raleigh,
HARRIS (William), a protestant dissenting minister of eminent abilities and character, resided at Honiton in Devonshire. Sept. 20, 1765, the degree of D.D. was conferred on him by the university of Glasgow, by the unanimous consent of the members of that body. He published an Historical and Critical Account of the Lives of James I, Charles I, and Charles II; Cromwell, in five volumes, after the manner of Mr. Bayle. He was preparing a like account of James II. He also wrote the life of Hugh Peters; forms one continued history of the inhabited islands on the coast of Harris. Some of them produce good crops of grain, and all of them good pasture. Harris and its islands fell from 400 to 400 tons of kelp annually; it abounds on the east side in excellent lochs or bays, and its shores on both sides form one continued fishery. The fish on this coast, and along the whole shores of the Long Island, are more numerous, and of a larger dimensions, than those on the opposite continent; on which account, two royal fishing stations were begun in the reign of Charles I. one in Loch Maddy, and the other in the Sound of Harris.

HARRISON (William), a writer much esteemed and patronized by the literati of his time, was fellow of New-college, Oxford, and had another income than 40l. a year as a tutor to one of the duke of Queensbury's sons. In this employment he fortunately attracted the favour of Dr Swift, whose felicitations with Mr St. John obtained for him the reputable employment of Secretary to lord Ruby, ambassador at the Hague, and afterwards earl of Strafford. A letter of his whist at Utrecht, dated Dec. 16, 1712, is printed in the Dean's works. Mr Harrison who did not long enjoy his rising fortune, was dispatched to London with the Barrier-treaty; and died Feb. 14, 1712-13. See the Journal de Steela, of that and the following day; where Dr Swift laments his loss with the most unaffected sincerity. Mr Tickle has mentioned him with respect.
Then: in delivering his meaning by writing, in which preferv:ed as were given up to the board of Harrifon. which he devoted himfelf. His farher was a carpenter.

clofe of anlection are fome pleafing fpecimens of his poetry; this, though not fent to fea, recommended Mr M. A. of was another perform this

inging of wood, in which he applied the of acquiring knowledge

fupcri-or to the board of Harrifon yet stronger to the patronage of his private friends and of the public. His third machine, which he produced in 1749, was will lefs complicated than the second, and superior in accuracy, as erring only three or four seconds in a week. This he conceived to be the ne plus ultra of his attempts; but in an endeavour to improve pocket-watches, he found the principles he applied to surpaß his expectation too much, as to encourage him to make his fourth time-keeper, which is in the form of a pocket-watch, about six inches diameter. With this time keeper his fon made two voyages, the one to Jamaica, and the other to Barbadoes: in both which experiments it corrected the longitude within the nearest limits required by the act of the 12th of queen Anne; and the Inventor therefore, at different times, though not without infinite trouble, received the proposed reward of 20,000l. These four machines were given up to the board of longitude. The three former were not of any ufe, as all the advantages gained by making them were comprehended in the falt; they were worthy, however, of being carefully preferred as mechanical curiosities, in which might be traced the gradations of ingenuity executed with the moft delicate workmanship; whereas they now lie totally neglected in the royal observatory at Greenwic.h. The fourth machine, emphatically distinguished by the name of The time-keeper, has been copied by the ingenious Mr Kendall; and that duplicate, during a three years circumnavigation of the globe in the southern hemisphere by captain Cook, anfwered as well as the original. The latter part of Mr Harrison’s life was employed in making a fifth improved time-keeper on the fame principles with the preceeding one; which, at the end of a ten weeks trial, in 1772, at the king’s private observatory at Richmond, errd only 45 seconds. Within a few years of his death, his constitution visibly declined; and he had frequent fits of the gout, and scarce ever slept, but attacked him before his 77th year: he died at his home in Red-Lion Square, in 1776, aged 83. The reclufe manner of his life in the unremitted pursuit of his favourite objeçt, was by no means calculated to qualify him as a man of the world; and the many discouragements he encountered in folliciting the legal reward of his labours, still lefs disposed him to accommodate himself to the humours of mankind. In converging on his profefion, he was clear, diftinct, and modest; yet, like many other mere mechanics, found a difficulty in delivering his meaning by writing: in which he adhered to a peculiar and uncouth phraseology. This was but too evident in his Description concerning such mechanism as will affiarm a time or tru:cation of time, &c. 8vo. 1775; which his well-known mechanical talents will induce the public to account for from his unacquaintance with letters, from his advanced age, and attendant mental infirmities;
Harrogate is a village in the West Riding of Yorkshire, in the parish of Knaresborough, remarkable for its medicinal springs. There are three in number, all different in their qualities, notwithstanding their contiguity. 1. The Tewet water or Sweet Spa, a vitriolic spring of a fort of milky taste used in gravelly cases, was discovered by Mr. Singby in 1638. 2. The stinking or sulphur spring, useful in dropsical, scrofulous, and gouty cases, rises in the town, and is received in four basins under four different buildings; at one it is drank, at the others used for hot or cold baths. It is perfectly clear; but tastes and smells like a composition of rotten eggs, sea-water, and sulphur, and extremely faint. Bathing is the most general mode of using it. It is the strongest sulphur water in Great Britain; and from the superior strength of the impregnating sulphur, it does not lose the sulphureous smell even when exposed to a scalding and almost boiling heat; and in distilling it, when three pints had been taken off from a gallon of it, the last was as strong as the first, and funk intolerably. It is diffident and attenuating, and a warm bath of it is of great benefit in pains and aches, strains and lameness; dissolving hard swellings, currying old ulcers and scrophulous complaints and is a powerful cleanser of the stomach and bowels. 3. St. Mango's well, it is said from Kentigern, a Scots saint, much honoured hereabouts, whom his tutor Servannus Bishop of Orkney, out of affection for him, called Mangath, which in the North or Norway language signifies a dear friend—the Harrogate season is from May to Michaelmas; and the company assemble and lodge in five or six large houses or inns on the heath, a mile from the village, each house having a long room and an ordinary: the best company used to lodge at Knaresborough, which is three miles off.

Harrow-on-the-Hill, a town of Middlesex, so called from its situation on the highest hill in the county, is 10 miles north-west of London. This parish is noted for a free school, founded in the reign of Queen Elizabeth. A silver arrow is shot for here once a year, viz. August 4th, by a select number of the scholars, who are drest for the purpose in the habit of archers.

Harrow, in agriculture. See there, § 98.

Hart, a flag, or male deer, in the sixth year. See Cervus.

Hart-beef, or Quaga. See Capra.

Hart's-horns, the horns of the common male-deer.

The tearings or railings of the horn of this animal are medicinal, and used in decoctions, plasters, &c. Harthorn jelly is nutritive and strengthening, and is sometimes given in diarrhoeas; but a decoction of burnt harthorn in water is more frequently used for this purpose, and is called harthorn drink.

The coal of harthorn, by being calcined with a long continued and strong fire, is changed into a very white earth, called hartthorn calcined to whiteness. This earth is employed in medicine as an absorbent, and administered in dysestheies and labour-pains, which are supposed to be caused by acid and ill-digested matters. This earth lustrified is the basis of Sydenham's white decoction, which is commonly prescribed in these diseases.

The leaf of harthorn is a great sudorific, and given in fevers with success; and harthorn also yields, by distillation, a very penetrative volatile spirit.

Hartford, the capital of the county of the same name, signifying, as is commonly thought, the "ford of harts," stands on the river Lea, 21 miles from London; and is of considerable antiquity. Here the East-Saxon kings often kept their court; and here, in 673, was held a synod. King Alfred built a castle here, by which the Danish vessels were destroyed, that came up from the Thames by its river as far as Ware, where the Danes had erected a fort, from which they made frequent forays to plunder and destroy the country. The present castle consists of a gate-house, or lodge of brick, and a range of brick buildings, which seem of the time of James or Charles I. and also of a very ancient wall of rubble-stone, with angular towers, supposedly to have been standing ever since its first foundation. The mayor of the town was all along the king's, of whom both the town and castle were formerly held in capitis. The barons took the latter from King John, but Henry III. recovered it. Edward III. gave the town a charter for markets on Thursdays and Saturdays, and in this grant of it to John of Gaunt, it is called The Honour of Hartford. It feft members to parliament in the reign of Edward I., but after the 17th of Henry V. on the petition of the bailiff and burgesses to be exempted by reason of their poverty, that privilege was discontinued till the 22d of James I. Henry VI. who kept his Easter here in 1429, ordained by his charter, confirming their market, that no other should be kept on the same days, within seven miles, on pain of having the goods seized by the bailiffs of Hartford. This manor being then part of queen Margaret's jointure, the courts were held in her name, and she appointed a horse fair to be kept in what part of the town the bailiff and constables thought fit. The standard of weights and measures was fixed here in the reign of Henry VII.; and Mary I. made this a corporation by the name of bailiffs and burgesses, of whom the latter were 16 by her charter. In the 25th and 27th of Elizabeth, Michaelmas-term was kept here, by reason of the plague at both times in London; and that queen, who sometimes resided in its castle, and declared the borough as parcel of her duchy of Lancaster, granted it a new charter, by the style of a bailiff, 11 capital burgesses and 16 assistants, with a market on Saturday. James I. granted it a new charter, with the style of mayor, burgesses, and commonalty, to have 10 capital burgesses, and 16 assistants, the mayor to be chosen out of the former by both of them; and a fair was then appointed here on May 12. Here was once a monastary, founded by a nephew of William...
Ham the Conqueror; and here were formerly five churches which are now reduced to two. In St Andrew's there is a seat not only for the mayor and aldermen, but another for the governors of Christ-church hospital in London, who have erected a house in this town on account of its healthy air and dry situation, to receive such children as wanted either health or room in that hospital; and the house built a gallery in the church, wherein 200 of their children may be accommodated. The town is now governed by a mayor, high-reward, who is generally a nobleman, a recorder, 9 aldermen, a town-clerk, chamberlain, to capital burgesses, and 16 assimilates, and has 2 ferruges at mace. The chief commodities of its market are wheat, malt, and wool; and it is said to send 3000 quarters of malt to London weekly by the river Lea. Besides the abovementioned, there are two fairs on July 5 and November 8, and 2 others for cattle, viz. the Saturday fortnight before Easter, and its Midsummer fair is chiefly for horses. Here is a handsome free grammar school, besides 3 charity schools; but the splendor of the place is much diminished since the north road from London was turned to the south road by King W. The county goal, however, is still kept in the town, and the gaol-delivery in the castle. It gives the title of Earl to the noble family of Seymour-Conway.

HARTFORDSHIRE, a county of England, deriving its name from Hartford the capital; and that from the harts with which it anciently abounded, being then over-run with woods. It is bounded on the east by Essex, on the west by Bedfordshire, and Buckinghamshire, on the south by Middlesex, and on the north by Cambridgeshire. This county is much indented by those that surround it; the longest part is about 33 miles, and the broadest about 27; and the circumference is 190, containing about 451,000 acres. It is divided into eight hundreds, which contain 19 market towns, 54 vicarages, 120 parishes, and near 950 villages, with about 14,500 houses, and 90,000 inhabitants; and sends 5 members to parliament, two knights for the shire, with two burgesses for St Albans, and as many for Hartford. Before the reign of Queen Elizabeth, one sheriff served both for this shire and Essex; but in the ninth year of her reign, it had one allotted for itself. With regard to ecclesiastical jurisdiction, it belongs partly to the diocese of Lincoln, and partly to that of London.

Though the soil in general, especially in the Chiltern and southern parts, is but very indifferent, and much inferior to that of the neighbouring counties; yet the air is so much superior, that lands in this shire generally fall at three or four years purchase more than in many others on that account. But it must be owned, that the soil of Hartfordshire has been much improved of late, by draining, fowing grass-feeds, and other methods. There are few or no manufactories in the county; but its markets are much frequented, in consequence of its being near London, for malt and all sorts of grain, which, with the many thoroughfares through it, make ample amends.

HARTLAND, a town in Devonshire, near the Bristol channel, with a market on Saturdays, much frequented by the people of Cornwall, who come hither in boats. It gives its name to a point, called Hartland Point, at the entrance of Bristol channel. Hartlepool W. Long. 4. 45. N. Lat. 51. 9.

HARTLEPOOL, a sea-port town in the county of Durham. It is commodiously seated on a promontory, and is almost encompassed by the sea. It was an ancient corporation, governed by a mayor and aldermen, with other subordinate officers. It is at present a pretty large but poor place. It depends chiefly on the fishing trade; and its harbour is much frequented by colliers paffing to and from Newcastle. W. Long. c. 55. N. 54. 49.

HARTLEY, a town of Northumberland, on the coast, situated northwest of Tynemouth, where Lord Delaval has constructed a pretty haven, whence coals are shipped for London. Here are large salt works and copper works, and likewise considerable glass works; and there is here a canal cut through a solid rock to the harbour, 52 feet deep, 30 broad, and 900 long. These works are the sole property of Lord Delaval, and yield a revenue of above 20,000 l. per ann.

Hartley (David), M. A. born at Lingworth, where his father was a curate, received his academical education at Jesus college; and his early education he received at Christ's college, of which he was a fellow. He first began to practice physic at Newnham, in Nottinghamshire; from whence he removed to St Edmund's bury in Suffolk. After this, he settled for some time in London; and lastly went to live at Bath, where he died in 1757, aged 52, leaving two sons and a daughter. He published "A view of the present evidence for and against Mrs Stephens's medicines as a solvent for the stone, contain- ing 155 cases, with some experiments and observa- tions." London, 1739. He is said to have also written a letter against Dr Warren, of St. Edmund's bury, in defence of inoculation; and some letters of his are to be met with in the philosophical transactions. The doctor was certainly a man of learning, and reputed a good physician; but too fond of nostrums. But his most considerable literary production is a work intitled, "Observations on man, his frame, his duty, and his expectations, in two parts;" London, 1749, 2 vols. 8vo. The first part contains observations on the frame of the human body and mind, and on their mutual connections and influences. The second part contains observations on the duty and expectations of mankind.

Hartman (John Adolphus), a learned divine and historian, was born at Mannheim in 1680. After being a Jesuit for several years, he became a Calvinist at Calis, in 1715; and soon after was made professor of philosophy and poetry, and in 1722 professor of history and eloquence at Marburg, where he died in 1744. The most esteemed of his works are 1. The state of the sciences at Hesse, in German. 2. Historia Hassiaca, 3 vols. 3. Precepta eloquentiae rationales, &c.

He ought not to be confounded with George Hartman, a German mathematician, who, in 1540, wrote a book on perspective; nor with Wolfgang Hartman, who, in 1596, compiled the Annals of Augsburg.

Hartogia, in botany: A genus of the pentandria order, belonging to the monoeica class of plants; and in the natural method ranking under the 43th order, Aggregata. The male calyx is pentaphyllous, the
HARVEST-fly, in zoology, a large four-winged fly of the family, very common in Italy, and erroneously supposed to be a grasshopper. See Cicada.

HARVEST-home, denotes the feast often observed at the close of harvest, and also the fong used on that occasion. See December.

HARVEY (Dr. William), an eminent English physician in the 17th century, was incorporated Doctor of physic in Cambridge, afterwards admitted into the college of physicians in London, and was appointed lecturer of anatomy and chirurgery in that college. In these lectures he opened his discovery relating to the circulation of the blood; which, after a variety of experiments, he communicated to the world in his Exercitatio anatomica de motu cordis et sanguinis. He was physician to King James I. and to King Charles I., and adhered to the royal cause. His works have ecliped his memory. In 1651, he published his Exercitatio de generatione animalium, a very curious work; but it would have been more fit had not his papers been destroyed during the civil wars. In 1654, he was chosen President of the college of physicians in his absence; but his age and weaknesses were so great, that he could not discharge the duty of that office; and therefore desired to choose Dr. Pringle. As he had so children he retired his paternal citze upon the college. He had three years before built a combination-room, a library, and a museum; and in 1656, he brought the deeds of his estate, and presented them to the college. He was then present at the first feast, instituted by himself, to be continued annually, together with a commemoration speech in Latin, to be spoken on the 18th of October, in honour of the benefactors to the college; he having appointed a hand- some flippend to the orator, and also for the keeper of the library and museum, which are still called by his name. He died in 1657.

This great physician had the happiness in his lifetime, to find the clamours of ignorance, envy, and prejudice against his doctrine, totally silenced, and to see it universally established. It has, by length of time, been more and more confirmed, and every man now sees and knows it from his own experience. It appears to be of the utmost importance in medicine; as it is perhaps impossible to define health and sickness in fewer words, than that the one is a free, and the other an obstructed, circulation.—Dr. Harvey was not only an excellent physician, but an excellent man; his modesty, candour, and piety, were equal to his knowledge; the farther he penetrated into the wonders of nature the more he was inclined to venerate the Author of it.

HARWICH, a town of Essex, in England, 72 miles from London. It is not large; but is well built and populous, has a good maritime trade, and strong works. It is walled in; and the streets are paved for the most part with clay, which tumbling down from the cliff, where is a peregrifying water between the town and Beacon-Hill, soon grows as hard as stone; and the inhabitants boast the wall is as strong and the streets are as clean as those that are of real stone. The harbour or bay is very large, safe, and deep; and is commanded by a strong fort on the Suffolk side, though not in that county. Here is a dock belonging to the government, with all convenience for building, cleaning, and refiting men of war. A little way from the town, on a high hill called Beacon-hill, is a very fine light-house, which is seen at a great distance, and is very useful on this dangerous coast. At this place the packet-boats which pass between England and Holland are stationed, and the town is much benefited by the passengers. The bay is so spacious, by the influx of the Stour from Manningtree, and the Orwell from Ipswich, and such use was made of it in the Dutch war, that 100 sail of men of war have been seen there at one time, with their tenders, besides 300 or 400 sail of colliers; for it is a perfect harbour within two miles of Ipswich, and able to receive ships of 100 guns all the way. The towns here are very good; but the accommodations dear, by reason of the great concourse of passangers to and from Holland, which was the motive of fitting up the Stour to thither directly from the Thames, when the stage-coaches used to ply two or three times a week between this place and London were laid down. This place was first made a free borough, and had a grant of its market on Tuesdays in the reign of Edward II. Its government was settled by charter of King James I. in a mayor, chosen yearly, November 30, out of eight aldermen, who with 24 capital burgesses, the electors, and the recorder, make the corporation. By this charter it had also a power to elect two burgesses.
Harwood
Harwood

geffes to Parliament, the grant of its Friday market, and its two fairs on May-day and October 18. which are each for three days. The town has also an admiralit. jurisdiction within its liberties, and the return of all writs, fines, &c. Though the entrance into the sea here is between two and three miles wide at high-water, yet the channel where the ships must keep to come to the harbour, which is on the Suffolk side, is only 400 yards wide, so that a ship that came in or go out are commanded by the guns of Landguard-Fort on that side. This town was fortified heretofore on the land side, but in the reign of King Charles I. the fortifications were demolished. It has since been ordered to be refortified. The church here, ever since the reformation, has been a chapel to the mother-church at Dover-Court.

HARWOOD, a small but pretty town in the north riding of Yorkshire, with a lofty stone-bridge of 11 arches over the Wharfe, which runs in a bed of stone, and is as clear as rock-water. Near it are the ruins of an ancient castle, built soon after the conquest, which remained a strong fortification in Canbden's time. Here are a variety of ruins from one of whom, to the reign of King John, obtained a grant for a market and fair here. In the reign of Edward III. it was valued at 400 marks a-year. This castle was ruined in the civil wars. It has eight or nine dependent constabularies, wherein are many antiquities. The remains of the castle which seems to have been the keep, is in a condition to exist long. The castle itself covered near an acre of ground. Near it is now Harwood-House, one of the first houses in the county for elegance and superior embellishments, built on part of the site of Gawthorpe-Hall, now no more. In the church are some ancient monuments, particularly that of lord chief-justice Gafcoigne, who committed the prince of Wales to prison for striking him on the bench.

HASLEMER, a town of Sarry, in England, seated on the edge of the county near Hampshire, 45 miles from London, is an ancient place, and was once destroyed by the Danes. It is a borough by prescription, and has fent members to parliament ever since the reign of Edward IV., who are chosen by a bailiff and burgage-tenants. It is said to have had seven parish-churches formerly, though but one church now, which is a chapel of ease to Chilsington: and that it stood heretofore upon a hill more to the south than the present town.

HASSELQUISTA, in botany: A genus of the digynia order, belonging to the pentandria class of plants; and in the natural method ranking under the 45th order, Umbellatae. The fruits are quite smooth; the seeds of the radius oval, plane, marginated, and convex in the middle; those in the disk hemispherical and urceolated or bladder-flapped.

HASSEL, a handsome town of the United Provinces, in Overfief, seated on the river Wecht, in E. Long. 6. 5. N. Lat. 53. 46.

HASSEL, a town of Germany, in the circle of Welfphalia, and in the territory of Liege, situated on the river Deme, in E. Long. 4. 49. N. Lat. 50. 55.

HASSIDEANS, or ASIDEANS. See ASIDEANS.

HASSOCK, a haf made of rushes, to kneel on or rest the feet upon in churches.

HASP and STAPLE, in Scots law, the symbol com-

monly used in burgage tenements for entering and infenting an heir, by delivering into his hands the haf and staple of the door.

HASSTA, or HASTA FRAPA, among medallists, signifies a kind of spear or javelin, not fixed or headed with iron; or rather an ancient sceptre, some what longer than ordinary, occasionally given to all the gods.

Hast, in some countries, is a measure or quantity of ground amounting to thirty paces: thus called, according to M. Du Cange, from the haft or rod where with it was measured.

HASTATED LEAF. See Botany, p. 442.

HASTING-PEAR, a name given by the gardeners to a species of pear, called also by some the green or 666

pear. This is a moderately large pear, and is longish toward the pedicle; its skin is thin, and of a whith green; the pulp is melting, and of a foggy flavour.

It ripens in July.

HASTINGS, a town of Suffolk in England, 64 miles from London. It is the chief of the cinqueports; and was formerly obliged to find 21 ships, within 40 days after the king's summons, well furnished and armed for service, and to maintain the crews a fortnight at its own charge. This town is supposed to have taken its name from Haftings, the famous Danifh pirate, who used to build fortresses where he went a-shore for his prey, to cover his men, and secure his retreat. In the reign Athelstan's reign here was a mint. This town had charters from Edward the Conflffi ef, William I. and II. Henry II. Richard I. Henry III. Edward I. and Charles II. exempting it from toll, and empowering it to hold courts of judicature on life and death. It is incorporated by the style of mayor, jurats, and commonalty. It has handsome houses, and custom-houses offices; but frequent storms have rendered it an indifferent harbour, though a vast sum of money has been laid out at times to make it a good one. It has sent members to parliament ever since Edward III. London is supplied from hence with abundance of fish that are taken on the coast. The town lies between two high cliffs towards the sea, and as high a hill on the land side, having two streets, and in each a parish-church, divided by a stream of fresh water called the Bourne. About the year 1377, this town was burnt by the French: and after it was rebuilt, it was divided into the two parishes. Here are two charity schools, erected for the teaching of 200 or 300 children. There was a castle on the hill, which overlooked the town, but it is now in ruins. The markets here are on Wednesdays and Saturdays: the fairs are on Tuesday and Wednesday in Whit-sun-week, and July 26, October 23, and 24. Here was formerly a priory. Haftings was a barony in the Huntington family, now in the Rawdon family.

This town is remarkable for a battle fought in its neighbourhood, between Harold king of England and William duke of Normandy, on the 15th of October 1066, in which the former was defeated and killed, and by his death William, furnished the Conqueror, became king of England. (See England, p. 86.)—On the night before the battle, the aspect of things was very different in the two camps. The English spent the time in riot, jollity, and disorder; the Normans in prayer and
Hastings. and other duties of religion. The next day both armies prepared for battle. The duke divided his army into three lines: the first, headed by Montgomery, consisted of archers and light-armed infantry; the second, commanded by Marcel, was composed of his bravest battles, heavy-armed, and ranged in close order; his cavalry at whole head he placed himself, formed the third line; and were so disposed that they stretched beyond the infantry, and flanked each wing of the army. He ordered the signal of battle to sound; and the whole army, moving at once, and tinged the magne, advanced, in order and with alacrity, towards taking them in hymn or song of Roland the famous peer of Charle-vanquished dared ill:ill fed his
Gurth and
ground, and
ing their lords, to
which was very

HAT

Plants make a very considerable article in commerce; the finest, and those most valued, are made of pure hair of an amphibious animal, called the caffer or beaver, frequent in Canada and other parts of North America. See BEAVER.

Method of making Hats. Hats are made either of wool, or hair of diverse animals, particularly of the caffer, hare, rabbit, camel, &c. The process is much the same in all; for which reason we shall content ourselves to instance in that of caffers.

The skin of this animal is covered with two kinds of hair; the one long, fluff, glossy, and pretty thin set; this is what renders the skin or fur of so much value; the other is short, thick, and soft, which alone is used in hats.

To tear off one of these kinds of hair, and cut the other, the hatters, or rather the women employed for that purpose, make use of two knives, a large one like a shoemaker's knife for the long hair; and a smaller, not unlike a vina knife, where with they have or scrape off the shorter hair.

When the hair is off, they mix the stuff, to one third of dry caffer, putting two-thirds of old coat, i.e., of hair which has been worn some time by the fawages, and card the whole with cards, like those used in the woollen manufactory, only finer; this done, they weigh it, and take more or less according to the size or thickness of the hat intended. The stuff is now laid on the hurdle, which is a square table, parallel to the horizon, having longitudinal chinks cut through it; on this hurdle, with an instrument called a bow, much like that of a violin, but larger, whose ftring is worked with a little bow flick, and thus made to play on the furs, they fly and mix together, the dust and ftrife, as the same time passing through the chinks; this they reckon one of the most difficult operations in the whole, on account of the juftnefs required in the hand to make the fluff fall precisely together, and that it may be every where of the fame thickness. In lieu of a bow, some hatters make ufe of a fieeve or fcare of hair, through which they pass the stuff.

After this manner they form gores, or two capades, of an oval form, ending in an acute angle at top; and with what stuff remains, they supply and ftrengthen them in places where they happen to be fenderer than ordinary; though it is to be remembered, that they deliberately make them thick, the brim, near the crown, than toward the circumference, or in the crown itself.

The capades thus finished, they go on to harden them into clofer and more convenient flakes by preffing down a hardening skin or leather thereon; this done, they are carried to the bifon, which is a fort of bench with an iron plate fitted therein, and a little fire underneath it; upon which laying one of the hardened capades, sprinkled over with water, and a fort of mould being applied thereon, the heat of the fire, with the water and preffing, imbody the matter into a flight hairy fort of fluff or felt; after which, turning up the edges all round the mould, they lay it by, and thus proceed with the other; this done, the two next are joined together, fo as to meet in an angle at the top, and only form one conical cap, after the manner of a manica Hippocratis, or flannel bag.
Dyeing of Herts. The instructions of Mr Colbert, direct hats to be first strongly caulked, by boiling them a long time in a decoction of galls with a little logwood, that the dye may penetrate the better into their substance: after which a proper quantity of virriol, and decoction of logwood, with a little verdigris, are added, and the hats continued in this mixture also for a considerable time. They are afterwards to be put into a fresh liquor of logwood, galls, virriol, and verdigris; and where the hats are of great price, or of a hair which difficulty takes the dye, the same process is to be repeated a third time. For obtaining the most perfect colour, the hair or wool is to be dyed blue previously to its being formed into hats.—The present practice is more compendious, and affords, as we may daily see, a very good black. According to Dr. Lewis, it does not materially differ from that of the Encyclopedia, which is as follows. An hundred pounds of logwood, 12 pounds of gum, and six pounds of galls, are boiled in a proper quantity of water for some hours; after which, about six pounds of verdigris and ten of green virriol are added, and the liquor kept just simmering, or of a heat a little below boiling. Ten or twelve dozen of hats are immediately put in, each on its block, and kept down by cloths bars for about an hour and an half: they are then taken out and aired, and the same number of others put in their room. The two fists of hats are thus dipped and aired alternately, eight times each; the liquor being refreshed each time, with more of the ingredients, but in less quantity than at first. The process (says Dr Lewis) affords a very good black on woolen and silk stuffs as well as on hats, as we may fee in the small pieces of both kinds which are sometimes dyed by the hatmakers. The workmen lay great stress upon the verdigris, and affirm that they cannot dye a black hat without it; it were to be wished that the use of this ingredient were more common in the other branches of the black dye; for the hatters dye, both on silks and woolens, is reckoned a finer black than what is commonly produced by the woolen and silk dyer. Hats are also made for women's wear, not only of the above stuffs, but of chips, flax, or cane, by plaiting, and fewing the plates together; beginning with the centre of the crown, and working round till the whole is finished. Hats for the same purpose are also wove and made of horse-hair, silk, &c. Hat is also figuratively used for the dignity of a cardinal, or a promotion to that dignity. In this sense they say, “to exped the hat,” to claim, or have pretensions to; the hat,” &c.

Pope Innocent IV. first made the hat the symbol of cognizance of the cardinals, and enjoining them to wear a red hat at the ceremonies and processions, in token of their being ready to spill their blood for Jesus Christ. HATCH, or HATCHWAY, a square or oblong opening in the deck of a ship, of which there are several, forming the poulages from one deck to another, and into the hold or lower apartments. See Plate CLVI., where A represents the main-hatchway of the lower deck; NN the fore-hatchway, and OO the after-hatchway. There are likewise hatchets of a smaller kind, called scottets. See UU in the same figure; as also the article SCUTTLE.—Hatchets is also, though improperly, a name applied to sailors; to the covers or hatchets of the hatchway.

HATCHET, or HATCHET, in the manufacture of flax, hemp, &c. a tool, not unlike a card, for drilling and combing them into fine hairs. They consist of sharp pointed iron pins, or teeth, set orderly in a board.

Of these there are several sorts, some with finer and shorter teeth, others with them coarser and longer.

HATCHES, in mining, a term used in Cornwall, to express any of the openings of the earth either into mines or in search of them. The frightful openings are called off-set-hatches; the real mouths of the veins, true-hatches; and the places where they wind up the buckets of ore, wind-hatches.

Hatches also denote flood gates set in a river, &c. to stop the current of the water, particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the steam-works and tin-walks in Cornwall from running into the fresh rivers.

HATCHET, a small light fort of an axe, with a ball's edge on its left side, and a short handle, as being to be used with one hand.—Hatchets are used by various artificers, and more particularly in hewing of wood.

HATCHING, the maturating of unfertilized eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive.

The art of hatching chickens by means of ovens has long been practiced in Egypt; but it is there only known to the inhabitants of a single village named Berme, and to those that live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country, where each person among them is ready to undertake the management of an oven, each of which is of a different size; but, in general, they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about 386, and they usually keep them working for about six months: as, therefore, each brood takes up in an oven, as under a hen, only 21 days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the person who intrusts him with an oven, only two-thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two-thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two-thirds of the eggs are hatched, and that each brood consists of at least 50,000 chickens; and thus it would appear, that the ovens of Egypt give life yearly to at least 92,650,000 of these animals.

This useful and advantageous method of hatching eggs has been lately discovered in France by the ingenious Mr Reaumur; who, by a number of experiments, has reduced the art to certain principles. He found by experience, that the heat necessary for this purpose is nearly the same with that marked 32° on his thermometer, or that marked 60° on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and, what is remarkable, of the skin, of all other domestic
Hatching, fowls, and probably of all other kinds of birds. The degree of heat which brings about the development of the egg,y, the gosling, and the turkey-poult, is the same as that which suits for hatching the canary song-bird, and, in all probability, the diamond doves; but afterwards they require 27 or 28 degrees, by means of pipes to convey heat into a chamber over an oven. If the heat be not kept sufficiently hot, this will remain fixed in a lump; which may be done by melting a lump of butter of the size of a walnut, with half as much tallow, and putting it into a phial. This will serve to indicate the heat with sufficient exactness: for when it is too great, this mixture will become as liquid as oil; and when the heat is too small, it will remain fixed in a lump: but it will flow like a thick syrup, upon inclining the bottle, if the stove be of a right temper. 

Great attention should therefore be given to keep the heat always at this degree, by letting in fresh air, if it be too great, or shutting the stove more close if it be too small: and that all the eggs in the stove may equally share the irregularities of the heat, it will be necessary to shift them from the sides to the centre; and thus to imitate the hens, who are frequently seen to make use of their bills, to pull to the outer parts those eggs that were nearest to the middle of their nests, and to bring into the middle such as lay nearest the sides.

Mr. Reaumur has invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls artificial parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they profently take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens, for some time, in a room artfully heated and furnished at once, all led about, and defended only by three or four such capons. Nay, cocks may be taught to perform the same office; which they, as well as the capons, will continue to do all their lives after.

Hatching, or Hatching, in designing, &c. the making of lines with a pen, pencil, graver, or the Hatching like; and the interlacing or going across those lines with others drawn a contrary way, is called counter-Hatching. Hattemists, hatting. 

Hatching is of singular use in heraldry, to distinguish the several colours of a shield, without being illuminated: thus gules or red is hatched by lines drawn from the top to the bottom; azure, by lines drawn across the shield; and so of other colours.

HATCHMENT, in heraldry, the coat-of-arms of a person dead, usually placed in the front of a house, whereby may be known what rank the deceased person was of when living: the whole distinguished in such a manner as to enable the beholder to know whether he was a bachelor, married man, or widower; with the like distinctions for women.

Bishop Hatfield. Hatfield, a town of Hertfordshire in the great coach-road to the north, 19 miles from London. It was called Bishop’s-Hatfield, because it did belong to the bishops of Ely. Theodore Archbishop of Canterbury held a synod here, anno 681, against the Eutychian heresy. Here was once a royal palace, from whence both Edward VI. and Queen Elizabeth were conducted to the throne. King James I. exchanged the manor with Sir Robert Cecil, afterwards earl of Salisbury, for Theobald’s, in the parish of Chehalt in this county; and the lordship still remains in that noble family, who have a very fine seat here. The rectory, which is in that earl’s gift, is reckoned worth 800 pounds a-year. Here are two charity schools; and there is a market on Thursdays, with two fairs in April and October.

Hatfield and Chace, a town in the west riding of Yorkshire, four miles from Doncaster. The chace is famous for deer-hunting. There are many intrenchments near the town, as if it had been the camp of some great army. It is said that no rats were ever seen in this town.

Hatfield-Broad-Oak, or King’s Hatfield, a town of Essex in England, seated on a branch of the river Lea, 30 miles from London, is so called from the nature of the soil, from its tenure by king William the Conqueror and his successors, and from a broad oak growing in the town. It has a market on Saturdays, and a fair in August.

Hattem, a town of the United Provinces, in the duchy of Guelderland, seated on the river Uffel, in E. Long. 6° 6 minutes 23 seconds, Lat. 53° 30 minutes.

Hattemists, in ecclesiastical history, the name of a modern Dutch sect, so called from Pontiau Van Hattem, a minister in the province of Zeeland, towards the close of the last century, who being addicted to the sentiments of Spinoza, was on that account degraded from his pastoral office. The Verfchorists and Hattemists resemble each other in their religious systems, though they never so entirely agreed as to form one communion. The founders of these sects deduced from the doctrine of absolute decrees a system of fatalism and an unchangeable necessity. They denied the difference between moral good and evil, and the corruption of human nature: from hence they farther concluded, that mankind were under no form of obligation to correct their manners, to improve their minds, or to obey the divine laws; that the whole of religion consisted...
HAVANNA, a sea-port town of America, in the island of Cuba, and on the north-west part of it, opposite to Florida. It is famous for its harbour, which is in every respect one of the best in the West Indies, and perhaps in the world. It is entered by a narrow passage, upwards of half a mile in length, which afterwards expands into a large basin, forming three Cul de Sacs, and is sufficient, in extent and depth, to contain 1000 sail of the largest ships, having almost throughout fix fathom water, and being perfectly covered from every wind. The town was built by Diego de Velazquez, who conquered the island of Cuba. It was but a small place, and named originally the port of Caracas, but afterwards, when the city by its increase of wealth grew considerable, it was called St Christopher of the Havana. In 1536, it was of so considerable a value, that being taken by a French pirate, he ransomed the place for the paltry sum of 700 pieces of eight. Some time after it was taken by the English, and a second time by the French; nor was its value understood, or any care taken to put it in a posture of defence, till the reign of Philip II.; though what was then done proved insufficient. But since the accession of a branch of the House of Bourbon to the Spanish crown, more pains have been taken to render it a place of strength. The Havana stands on the west side of the harbour, in a pleasant plain; and is the residence of the governor and captain-general of Cuba, and of the royal officers, as well as of an aforesaid for the attendance of the governor and captain general of the West Indies. The bishop of St. Jago de Cuba likewise chooses to fix his residence here. The buildings are elegant, built of stone, and some of them most superbly furnished. Here are eleven churches and monasteries, and two handsome hospitals. Near the middle of the town is a spacious square, surrounded with uniform buildings. The churches are rich and magnificent; the lamps, candlesticks, and ornaments for the altars being of gold and silver; some of the lamps are of the most curious workmanship, and weigh near 100 weight. The Recollet church, which stands on the best ground in the city, has 12 beautiful chapels in it, and in the monastery are cells for 50 fathers. The church of St. Clara has seven altars adorned with plate, and the monastery contains 100 women and servants, all dressed in blue. The church belonging to the Augustines has 13 altars; that of St. Juan de Dios, with an hospital for soldiers of 12,000 pieces of eight revenue. It is not a bishop's see, though the bishop of St. Jago resides here, the revenue of which prelate is not less than 50,000 pieces of eight a-year. In 1700 the inhabitants were computed at 26,000, and we may very well imagine them to be increased since. They are a more polite and social people than the inhabitants of any of the Spanish ports on the continent; and of late imitate the French both in their dress and manners. The city is supplied with water by a small river called Laguida, which rises from the hills on the south-west side of the town, and divides itself into three streams, one of which falls into the sea on the east side of the town, but the other two flow through the place, entering the walls near the middle of the city.

As to the fortifications, it was already remarked, that the entrance to the harbour is by a narrow gut near half a mile in length; this passage is defended on the east side by a strong castle called El Morro, situated on a high rock; and on the west side are mounted 40 pieces of cannon. Under the faces of the south-west bastion of the Morro, and more within the entrance of the harbour, is a battery of stone called the Twelve Apostles, almost level with the water, and the guns of which carry each a ball of 36 pounds. A little higher, and opposite to the Point gate, is the La Divina Pastora, or the Shepherd's Battery, of 14 guns, level with the water. On the west side of the entrance, at the point, is a square fort called the Punta, with four bastions well mounted with cannon, about 200 yards distant from the Punta gate of the town. On the bastions of the town, next the harbour, are a number of cannon; and about the middle of the city is another, called El Fuerte, a square fort with four bastions, mounted with 22 pieces of cannon, of no great strength; but in this last the governor resides, and in it the king of Spain's treasures are depoited till the arrival of the galleons. On the land side, from the Punta gate to the dock-yard, there is a rampart with bastions, faced with stone, and earthen parapets with a ditch, which in several places has fallen in, and is almost filled up, particularly behind the Punta and land-gate, near the stone-quoteries, which, if joined to one another, might be of great detriment to the place in case of a siege, as lodgment might be made in them. The ground here rises with an easy ascent to the land-gate; and is either open pasture or garden ground, well stored with the cabbage-tree. Before the land-gate is a ravelin. The hill on a rising ground from this gate (which is the highest part of the town) to the dock-yard, is steeper than on the other side.

Such are the fortifications of the Havana, which are the best the Spaniards have in the West Indies, as indeed the place is of the greatest importance. But though strong, they have many defects, and from the situation of the town and forts, are commanded by many eminenties, of which an enemy could not fail to take advantage. On the east side of the harbour, the Cavañas, on a part of which the Morro is built,
HAVANA. 

[ 340 ] 

commands in a great measure that fort, but absolutely commands the Punta El Fuerte, and the whole north-east part of the city, which is the best fortified. On the west side of the city runs a suburb, called Granada, whose church is situated on an eminence about half a mile from the land-gate, which it is on a level with, and higher than any other part of the fortifications. From the north side of this rising ground, the Punta gate may be flanked; and from the south side the dock-yard is commanded. Also, the north side runs an aqueduct, which falling into the ditch at the land-gate, runs down to the dock-yard, both for watering the ships and turning a saw-mill. About half a mile from the church, is a bridge made over a rivulet that runs into the bay about 100 yards. That road leads to the centre of the island, and extends to Baracoa, above 600 miles distant. From this bridge to the Lazaretto is about two miles, with a rising ground between them. A trench thrown up between these two places would cut off the communication with the town by land. From these observations it will plainly appear, that the Havana, though well fortified, is not impregnable.

The Havana has greatly contributed to the maritime strength of the crown of Spain, many ships having been built here within these few years, from 60 to 80 guns, the island furnishing the finest materials, such as oak, pine, cedar, and mahogany. The only defect of the harbour is the narrowness of its entry; for though free from bars and shoals, yet only one ship at a time can enter it; from which circumstance the galleons have more than once been detained, and some of them taken, at the mouth of the harbour, the forts there not being able to afford them any assistance.

Upon the rupture with Spain in 1762, the British ministry sent a squadron and army against this place under the command of admiral Pocock and lord Abermarle. The Spaniards had in the harbour at the time a fleet of twelve sail of the line, two of them but just launched, two more on the flocks nearly finished, and several merchant ships. The men of war were almost ready for sea; but no account had reached the governor of the intended attack. The place, however, was gallantly defended, and sustained a siege of two months and eight days before it could be reduced; when a capitulation was signed, and along with the city was yielded a district of 150 miles to the westward. This conquest was without doubt in itself the most considerable, and in its consequences the most decisive, of any they had made since the beginning of the war; and in no operation were the courage, steadiness and perseverance of the British troops, and the conduct of their leaders more conspicuous. The acquisition of this place united in itself all the advantages which can be acquired in war. It was a military achievement of the highest class. By its effect on the enemy’s marine it was equal to the greatest naval victory, and in the plunder it equalled the produce of a national subsidy. Nine sail of the enemy’s line-of-battle ships were taken; three of their capital ships had been sunk by themselves at the beginning of the siege; two more were in forwardness upon the flocks, and were afterwards destroyed by the captors. The enemy on this occasion lost a whole fleet of ships of war, besides a number of considerable merchant ships; and in ready money, in tobacco collected at the Havana on account of the king of Spain, and in other valuable merchandizes, the sum left by the Spaniards perhaps did not fall short of three millions sterling.

The city of Havana was restored by the peace of 1763; and is of the greatest importance to Spain, being the rendezvous for all their fleets to return from America to Europe, lying at the mouth of the gulf of Florida, through which they are all obliged to pass. Here the navy of Spain flies into the Atlantic, and here the galleons, the flota, and other merchant ships from other ports both of the continent and islands, meet in September, to take in provisions and water, with great part of their lading, and for the convenience of returning to Spain in a body. A continual fair is held till their departure, which generally happens before the end of the month, when proclamation is made, forbidding any person belonging to the fleet to stay in town on pain of death; and accordingly, on firing the warning gun, they all retire on board.—The commerce carried on in this port, which is very considerable, may be distinguished into the particular commerce of the island of Cuba, and that more general by the galleons and flota. This latter consists of ships usually styled of the Havana, which are excellent, and of great value; sugar, tobacco, admirable in its kind, &c. Though strangers are prohibited to trade, yet a contraband commerce is carried on by brikcers here than at La Vera Cruz. Some little trade is carried on by other ports of Cuba, but it is very insignificant. As to the general commerce, this port is the place of rendezvous (as already mentioned) for all ships, particularly from Carthagena, Puerto Velo, and La Vera Cruz, which return to Spain from the Indies. The Havana is regularly supplied with European goods only by the regular ships from Cadiz and the Canaries. The flota and galleons bring there no more than the refuse of their cargoes, which they had not been able to dispo of at Carthagena, Puerto Velo, or La Vera Cruz. When the fleet is in the harbour, provisions are excessively dear on shore, and money is plenty, that a Spaniard expects half a piece of eight a day from a male slave, and a quarter from a female, out of what they earn for their labour. The fleet generally fails from thence, through the channel of Bahama, in the month of September; and is the richest in the world; since, in silver and merchandise, there is seldom less than thirty millions of pieces of eight on board, or six millions seven hundred and fifty thousand pounds sterling. It is natural to imagine, that a port of so much consequence as the Havana ought to be well fortified. Since it has been restored to Spain, many new works have been added, to prevent if possible a similar disaster befailing it. W. Long. 82. 13. N. Lat. 23. 12.

HAVEL, a river of Brandenburg, which proceeds from a lake in the duchy of Mecklenburg, and running thro’ the middle Marche, and thro’ Brandenburg and other towns, runs north, and falls into the Elbe.

HAVELBERG, a town of Germany, in the circle of Lower Saxony, and in the electorate of Brandenburg, with a bishop’s see, feudalized in favour of the house of Brandenburg. It is seated on the river Havel, in E. Long. 12. 43. N. Lat. 55. 4.

HAVEN, a sea-port or harbour for ships. See Post.
HAVERCAMP (Sigiibert), a celebrated Dutch scholar and critic, professor of history, eloquence, and the Greek tongue, at Leyden. He was particularly skilled in medals; and was the author of some esteemed works in that way, besides giving good and elegant editions of several Greek and Latin authors. He died at Leyden in 1742, aged 38.

HAVERFORD-WEST, a town of Pembrokehire in South Wales, seated in W. Long. 5. N. Lat. 51. 50. It is a neat, well-built, populous place, all the side of a hill, which forms a part of the west bank of the river Dongleye, 256 miles from London. It is an incorporated town and county of itself, governed by a mayor, sheriff, town-clerk, two bailiffs, serjeants at mace, and other officers. The mayor of the town is admiral, coroner, cohester, and clerk of the markets, within his precincts. The houses are well built and well inhabited, and the people enjoy a good trade. Here the affizes are held and the county-jail kept. The town enjoys several privileges, and has its own courts. There are three parish-churches within the town, and one in the suburbs. Here is also a commodious quay for ships of burden, a cotillon-house, and a fine stone bridge over the Dongleye, with a good free-school, a charity-school for boys and girls, and an almhouse. It was formerly fortified with a rampart and castle, now demolished.

HAVERHILL, a town of England, in the county of Suffolk, where there is a considerable manufactury of checks, cottoms, and stuffs. By the ruins of a church and castle still to be seen, it appears to have been formerly a place of much greater consequence than at present. It has now only about 300 poor clay-houses, and one wide street not paved.

HAUL, an expression peculiar to seamen, implying to pull a single rope, without the assistance of blocks or other fish mechanical powers. When a rope is otherwise pulled, as by the application of tackles, or the connection with blocks, &c. the term is changed into haue.

To haul the Wind, is to direct the ship's course nearer to that point of the compass from which the wind arises. Thus, supposing a ship to sail south-west, with the wind northerly, and some particular occasion requires to haul the wind more westward; to perform this operation, it is necessary to arrange the sails more obliquely with her keel; to brace the yards more forward, by slackening the larboard and pulling in the larboard braces, and to haul the lower jib forward, or, in other words, by shifting the wind to west. She may still go two points nearer to the direction of the wind, by disposing her sails according to their greatest obliquity, or, in the phrase, by trimming all sharp; and in this situation she is said to be close hauled, as sailing well-north-west.

HAUM, HAU, or HAVOU, among farmers, denotes the stem or stalk of corn, pease, beans, &c. from the root to the ear.

HAUNCH, or HANCH, the Hip, or that part of the body between the last ribs and the thigh. The haunches of a horse are too long, if when standing in the stable he limps, with his hind-legs farther back than he ought; and when the top or root of his tail is not in a perpendicular line to the top of his hocks, as it always does in horses whose haunches are of a just length. There are some horses which, though they have too long haunches, yet commonly walk well; such are good to climb hills, but are not at all sure upon a descent; for they cannot ply them hams, and never gallop slowly, but always nearly upon a full speed. The art of riding the great horse has not a more necessary lesson than that of putting a horse upon his haunches, which, in other words, is called coupling him well, or putting him well together, or compact. A horse that cannot bend or lower his haunches, throws himself too much upon his shoulder, and lies heavy upon the bridge.

HAUIRE, in geography, a French term signifying the same with haven or harbour.

Havre de Grace, a sea-port town of France, and capital of a district of the same name, is seated in the province of Normandy, on the English Channel, in a large plain at the mouth of the river Seine. It is a small fortified town, nearly of a square figure, divided into two parts by the harbour, surrounded with a wall and other works, and defended by a very strong citadel. It is one of the most important places in France, on account of its foreign trade and convenient harbours; for which reason it was made a district government from the rest of Normandy. It was fortified in 1562 by the Protestants, who delivered it to queen Elizabeth; but it was lost next year. In 1604 it was bombarded by the English, and also in the year 1758. E. Long. o. 11. N. Lat. 49. 29.

HAURANT, in heraldry, a term peculiar to fibbies; and signifies their standing upright, as if they were refreshing themselves by sucking in the air.

HAUTE FEUILLE (John), an ingenious mechanic born at Orleans in 1647. Though he embraced the fate of an ecclesiastic, and enjoyed several benefactions he applied himself to civil mechanical arts, in which he made a great progress. He had a particular taste for clock-work, and made several discoveries in it that were of singular use. It was he who found out the secret of moderating the vibration of the balance by means of a small steel spring, which has since been made use of. This discovery he laid before the members of the Academy of Sciences in 1674; and these watches are, by way of eminence, called pendulum-watches; not that they have real pendulums, but because they nearly approach to the justness of pendulums. M. Huygens perfected this happy invention; but having claimed himself the inventor, and obtained from Louis XIV. a patent for making watches with spiral springs, the Abbé Feuillac opposed the registering of this privilege, and published a piece on the subject against M. Huygens. He wrote a great number of other pieces, most of which are small pamphlets containing of a few pages, but very curious; as, 1. Discourses on perpetual pendulum, quarto. 2. New inventions, quarto. 3. The art of breathing under water, and the means of preserving a flame shut up in a small place. 4. Reflections on machines for raising water.
HAWKS is a term also applied to those who go up and down London streets and country towns, selling newspapers, pamphlets, &c.

D. VKESWORTH (1719), a celebrated English writer, was born about the year 1719, though his epitaph, as we find it in the Gentleman’s Magazine for Aug. 1731, makes him to have been born in 1715. He was brought up to a mechanical profession, that of a watchmaker as is supposed. He was of the Presbyterian persuasion, and a member of the celebrated Tom Bradbury’s meetings, from which he was expelled for some irregularities. He afterwards devoted himself to literature, and became an author of considerable eminence. In the early part of life his circumstances were rather confined. He resided some time at Bromley in Kent, where his wife kept a boarding school. He afterwards became known to a lady who had great property and interest in the East India Company, and through her means was chosen a director of that body. As an author, his Adventurer is his capital work; the merits of which, if we mistake not, procured him the degree of LL.D. from Herring, archbishop of Canterbury. When the design of compiling a narrative of the discoveries in the South Seas was on foot, he was recommended as a proper person to be employed on the occasion: but in truth he was not a proper person, nor did the performance answer expectation. Works of taste and elegance, where imagination and the passions were to be affected, were his province; not works of dry, cold, accurate narrative. However, he executed his task, and is said to have received for it the enormous sum of 6000l. He died in 1773; some say of high living; others, of chagrin from the ill reception of his Narrative: for he was a man of the keenest sensibility, and obnoxious to all the evils of such irritable natures. On a handomme marble monument at Bromley in Kent is the following inscription, the latter part of which is taken from the last number of The Adventurer:

To the memory of

JOHN HAWKESWORTH, LL. D.
Who died the 16th of November
MDCCCLXIII, aged 58 years.
That he lived ornamental and useful
To society in an eminent degree
Was among the boasted felicities
Of the present age;
That he laboured for the benefit of society,
Let his own pathetic admonitions
Record and realize.

"The hour is hastening, in which whatever praise
"or censure I have acquired will be remembered
"with equal indifference. Time, who is impatient
"to date my last paper, will shortly moulder the
"hand which is now writing it in the dust, and still
"the breath that now throbs at the reflection. But
"let not this be read as something that relates
"only to another; for a few years hence you will divide
"the eye that is now reading from the hand that
"has written."

HAWKING, the exercise of taking wild-fowl by means of hawks. The method of reclaiming, manning, and bringing up a hawk to this exercise, is called falconry. See FALCONRY.

There
There are only two countries in the world where we have any evidence that the exercise of hawking was very anciently in vogue. These are, Thrac and Britain. In the former, it was pursued merely as the diversion of a particular district; if we may believe Pliny's, whose account is rendered obscure by the darkness of his own ideas of the matter. The primitive Britons, with a fondness for the exercise of hunting, had also a taste for that of hawking; and every chief among them maintained a considerable number of birds for that sport. It appears also from a curious passage in the poems of Ossian; that the same diversion was fashionable at a very early period in Scotland. The poet tells us, that a peace was endeavoured to be gained by the proffer of 100 managed hawks, 100 foreign captives, and "100 hawks with fluttering wings, that fly across the sky." To the Romans this diversion was scarce known in the days of Vespasian; yet it was introduced immediately afterwards. Most probably they adopted it from the Britons; but we certainly know that they greatly improved it by the introduction of species into the land. In this state it appears among the Roman Britons in the sixth century. Gildas, in a remarkable passage in his first epitite, speaks of Maglocmirus, on his relinquishing the sphere of ambition, and taking refuge in a monastery; and probably compares him to a dove, that has flown away at the noisy approach of the dogs, and with various turnings and windings takes her flight from the talons of the hawk.

In after times, hawking was the principal amusement of the English: a passion of rank scarce stirred out without his hawk on his hand; which, in old paintings, is the criterion of nobility. Harold, afterwards king of England, when he went on a most important embassy into Normandy, is painted embarking with a bird on his fist, and a dog under his arm; and in an ancient picture of the mupials of Henry VI. a nobleman is represented in much the same manner; for in those days, it was thought sufficient for noblemen to winde their horn, and to carry their hawk fair, and leave study and learning to the children of mean people. The former were the accomplishments of the times; Spenser makes his gallant Sir Tristram boast,

Ne is there hawk which manteth her on pearch,
Whether high towering, or assailing low,
But I the measure of her flight doe fetch,
And all her prey, and all her diet know.

In short, this diversion was, among the old English, the pride of the rich, and the privilege of the poor; no rank of men seems to have been excluded the amusement: we learn from the book of St Alban's, that every degree had its peculiar hawk, from the emperor down to the holy water clerk. Vaff was the expense that sometimes attended this sport. In the reign of James I. Sir Thomas Monfon is said to have given 1000l. for a call of hawks: we are not then to wonder at the rigour of the laws that tended to preserve a pleasure that was carried to such an extravagant pitch. In the 34th of Edward III. it was made felony to steal a hawk; to take its eggs, even in a person's own ground, was punishable with imprisonment for a year and a day, besides a fine at the king's pleasure: in queen Elizabeth's reign, the imprisonment was reduced to three months, but the offender was to find security for his good behaviour for seven years, or

Hawking. lie in prison till he did. Such was the enviable fate of the times of old England; during the whole day, the gentry were given to the fowls of the air and the beasts of the field; in the evening, they celebrated their exploits with the most abandoned and brothel festivities; in the same time, the inferior rank of people, by the most unjust and arbitrary laws, were liable to capital punishments, to fines, and loss of liberty, for destroying the most noxious of the feathered tribe.

According to Olearius, the diversion of hawking is more followed by the Tartars and Persians than ever it was in any part of Europe. Il n'y avoit point de hauke (says he) qui n'eussi fouleig ou foufanc.

The falcons or hawks that were in use in these kingdoms, are now found to breed in Wales, and in North Britain and its islands. The Peregrine Falcon inhabits the rocks of Caernarvonshire. The same species, with the gyrfalcon, the gentil, and the gothawk, are found in Scotland, and the Janner in Ireland.

We may here take notice, that the Norwegian breed was, in old times, in high esteem in England; they were thought bibles worthy a king. Jeffrey Fitz-pierre gave two good Norway hawks to king John, to obtain for his friend the liberty of exporting 100 wt. of cheese: and Nicholas the Dane was given to the king a hawk every time he came into England, that he might have free liberty to traffic throughout the king's dominions.

They were also made the tenures that some of the nobility held their estates by, from the crown. Thus Sir John Stanley had a grant of the Isle of Man from Henry IV. to be held of the king, his heirs, and successors, by homage and the service of two falcons, payable on the day of his or their coronation. And Philip de Hextang held his manor of Comberton in Cambridgehire, by the service of keeping the king's falcons.

Hawking, though an exercise now much diffused among us, in comparison of what it anciently was, does yet retain a great variety of significant terms, which still obtain in our language. Thus, the parts of a hawk have their proper names. - The legs, from the thigh to the foot, are called apar; the toes, the petty single; the claws, the pouces. - The wings are called the faits; the long feathers thereof, the beaus: the two longest, the principal feathers; those next thereto, the flag. - The tail is called the trait; the breast-feathers, the mains; those behind the thigh, the pendant feathers. - When the feathers are not yet full grown, the is said to be unbranched; when they are complete, the is said to be branched. The claw, or crop, is called the gorg: - The pipe next the fundament, where the faces are drawn down, is called the pannel. - The silky plustre lying in the pannel, is called the glut: - The upper and crooked part of the bill is called the beak; the nether-part, the clap: the yellow part between the beak and the eyes, the fur or fore; the two small holes therein, the nars.

As to her furniture. - The leather, with bells buttoned on her legs, are called beets. - The feathers thong, whereby the falconer holds the hawk, is called the leafe or leath; the little straps, by which the leafe is fastened to the legs, jesses; and a line or pack thread fastened to the leafe, in disciplining her, a而不ce.
Hawking. A cover for her head, to keep her in the dark, is called a blind; a large white hood, open behind, to be worn at first, is called a veil. To save her from theiring, that the hood may be readily removed to put up the prey, is called unholing the head. — The blinding a hawk just taken, by pulling a thread through her eye-lids, is called raug:—Her unholing-place, when off the falconer's silt, is called the perch. — The place where her meat is laid, is called the back; and that wherein she is set, while her feathers fall and come again, is the mew.

Something given a hawk, to cleanse and purify her gorge, is called casting. — Small feathers given her to make her cast, are called plumage. — Gravel given her to help to bring down her stomach, is called range. — Her throwing up, from the gorge after casting, is called gleaning. — The purging of her greese, &c. is called munging. — A being flushed is called gurgitting. — The inserting a feather in her wing, in lieu of a broken one, is called imping. — The giving her a leg, wing, or pinion of a fowl to put at, is called tiring: — The neck of a bird the hawk preys on, is called the neck. — What the hawk leaves of her prey, is called the pell or pelf.

There are also proper terms for her several actions.

When she flutters with her wings, as if striving to get away, either from perch or silt, she is said to hate.

When standing too near them fight with each other, it is called crahing. — When the young ones quiver, and shake their wing in obedience to the elder, it is called cowering. — When she wipes her beak after feeding, she is said to feak: — When she uses her tongue, or truss the duck, permit her to kill it, and reward her by giving her a reasonable gage. After you have practiced this two or three times, your hawk will leave the stand, and, delighted to be on the wing, will be very obedient.

It is not convenient, for the first or second time, to follow your hawk a large fowl, for it frequently happens, that the escape from the hawk, and her, not recovering them, makes her trouble, and frequently occasions the loss of the hawk. But if she happens to pursue a fowl, and being unable to recover it, gives it over, and comes in again directly, then cast out a sealed duck; and if she flies and truss it across the wings, permit her to take her pleasure, rewarding her also with the heart, brains, tongue, and liver. But if you have not a quick duck, take her down with a dry lure, and let her plume a pullet and feed upon it. By this means a hawk will learn to give over a fowl that rakes out, and on hearing the falconer's lure, will make back, and know the hold in the head.

Some hawks have a difficult coyness, proceeding from their being high fed: such a hawk must not be rewarded though she should kill; but you may give her leave to plume a little; and then taking a sheep's heart cold, or the leg of a pullet, when the hawk is busy in pluming, let either of them be conveyed into the body of the fowl, that it may savour of it; and
HAW

Haw Meadows when the hawk has eaten the heart, brains, and tongue of the fowl, take out what is inclosed, call her to your side, and feed her with it; afterwards give her some of the feathers of the fowl's neck, to fower her, and make her fat.

If your hawk be a flately high-flying one, she ought not to take more than one flight in a morning; and if she be made for the river, let her not fly more than twice: when she is at the highest, take her down with your lure; and when she has plummed and broken the fowl a little, feed her; by which means you will keep her a high-flyer, and fond of the lure.

HAWKWOOD (Sir John), a famous English general, was the son of a tanner at Heddington-Sibil in Essex, where he was born in the reign of Edward III. He was bound apprentice to a tailor in London; but being fortunately prefixed into the army, was sent abroad, where his genius soon expanded itself, and surmounted the narrow prejudices which adhered to his birth and occupation. He signalized himself as a soldier in France and Italy, and particularly at Pisa and Florence.

He was bound apprentice to a tailor in London; but having had a great liking for the army of Galeasia duke of Milan; and was in such high esteem with Barnabas his brother, that he gave him Domitia his natural daughter in marriage, with an ample fortune. He died at Florence, full of years and military fame, in 1394.

HAUSE, or HAUSE, is generally understood to imply the situation of the cables before the ship's stem, when she is moored with two anchors out from forward, viz. one on the forecastle, and the other on the larboard bow. Hence it is usual to say, she has a clear haufe, or a foul haufe. It also denotes any small distance a head of a ship, or between her head and the anchors employed to ride her, as, "He has anchored in our haufe, The brig fell athwart our haufe," &c.

A ship is said to ride with a clear haufe, when the cables are directed to their anchors, without lying athwart the stem, or crossing, or being twisted round each other by the ship's windings about, according to the change of the wind, tide, or current.

A foul haufe, on the contrary, implies that the cables lie across the stem, or bear upon each other, so as to be rubbed and chafed by the motion of the vessel. The haufe accordingly is foul, by having either a crofs, an elbow, or a round turn. If the larboard cable, lying across the stem, points out on the forecastle side, while the forecastle cable at the same time grows out on the larboard side, there is a crofs in the haufe. If, after this, the ship, without returning to her former position, continues to wind about the same way, so as to perform an entire revolution, each of the cables will be twisted round the other, and then directed out from the opposite bow, forming what is called a round turn. An elbow is produced when the ship floops in the middle of that revolution, after having had a crofs; or, in other words, if the ships with her head northward with a clear haufe, and afterwards turns quite round so as to direct her head northward again, she will have an elbow.

HAUSE-Holes, certain cylindrical holes cut through the bows of a ship on each side of the stem, through which the cables pass in order to be drawn into or let out of the vessel as occasion requires. They are fortified on each side by the HAUSE-Pieces, a name given to the foremost timbers of a ship, whose lower ends rest on the knuckle-timber, or the foremost of the cant-timbers. They are generally parallel to the stem, having their upper ends sometimes terminated by the lower part of the beak-head; and otherwise, by the top of the bow, particularly in small ships and merchantmen.

HAWSER, a large rope which holds the middle degree between the cable and tow-lines, in any ship where it belongs, being a size smaller than the former, and as much larger than the latter.

HAY, any kind of gras cut and dried for the food of cattle.

The time of mowing gras for hay must be regulated according to its growth and ripeness; nothing being more prejudicial to the crop than mowing it too soon; because the sap is not then fully come out of the root, and when made into hay, the gras shrinks away to nothing. It must not, however, be let stand too long till it has filled its feeds. When the tops of the gras look brown, and begin to bend down, and the red honeffuckle flower begin to wither, you may conclude it ripe for mowing.

Sain-Foin HAY, is of several sorts, which may be distinguished by the following terms, viz. 1. The virgin. 2. The blossomed. 3. The full-grown. And, 4. The threshed hay. The first of these is beyond comparison the best. It must be cut before the blossoms generally appear; for when it stands till it is fully blown, the most spirituous and nourishing parts of its juice are spent, and the hay is much impoverished, and the sain-foin can never recover that richness it had in its virgin state. But this fine hay cannot well be had of uncultivated sain-foin; because that may not be much above an handful high when it is in a condition to be cut; it would then make a very light crop, and would be a great while before it sprang up again; but the rich will have two or three tuns to an acre, and spring again immediately for a second crop; so that little or none in quantity would be lost by so great an improvement of its quality.

The second sort is that cut in the flower, which, though much inferior to the virgin-hay, far exceeds any other kind as yet commonly propagated in Britain; and if it be a full crop, it may amount to three tuns an acre. This is that sain-foin which is commonly made; and the larger it is, the more nourishing it is for horses.

The next sort of sain-foin is the full grown, cut when the blossoms are gone or going off; this also is good hay, though it falls short by many degrees of the goodness of the other two sorts; but it makes a greater crop than either of them, because it grows to its full bulk, and shrinks little in drying.

The last sort is the threshed hay; which, when not damaged by wet weather, has been found more nourishing to horses than coarse water-meadow hay; and, when it is cut small by an engine, is good for cattle, and much better than the chaff of corn. The best time to cut it is, when the greatest part of the feed is well filled; the first-blown ripe, and the last-blown beginning to be full.

The goodness of the hay depends greatly upon the manner
Hay. [346]

Hay. —manner of ordering it. The best hay in all England is made of fain-foin, without ever spreading it. This method though it be longer before it be finished, cost less labour than the other. If fain-foin be laid up pretty green, it will take no damage, provided it be set in small round ricks, with a large basket drawn up in the middle of each, to have a vent-hole, through which the superfluous moiture of the hay may transpire. As soon as its heating is over, these ricks ought to be thatched; and all fain-foin ricks, that are made when the hay is full dried in the coeks, ought to be thatched immediately after the making them. That which is laid up moist dried, will come out of the rick of a green colour; but that which has been much heated in the rick, will be brown.

The feed affords the owner another opportunity of making a profit of his fain-foin: but this, if the hewing of fain-foin be general would not be vendible in great quantities for planting; because the ordinary cropl of an acre will produce feed enough to drill an hundred acres, which would not want planting for a long time. The other use then of this feed is for provender; and it has been affirmed by some who have made trials of it, that three bushels of good fain-foin seed given horses, will nourish them as much as four bushels of oats; and when well ordered, is so sweet, that most sorts of cattle are greedy of it.

Hay, a town of Brecknockshire, in Wales, seated near the confluence of the rivers Wye and Dulas. It was a town of good note in the time of the Romans; it being then fortified with a castle and a wall, which were ruined in the rebellion of Owen Glendower. It is at present a pretty good town; and the market is large for corn, cattle and provisions. W. Long, p. 56. N. Lat. 52 10.

Hay (William, Esq.), an agreeable English writer, was born at Gleneburn in Suffolk, about 1700, as is conjectured; and educated at Headley-school. In 1730, he published a poem, called Mount Caburn, dedicated to the duchess of Newcastle; in which he describes the beauties of his native country, and celebrates the virtues of his friends. When Lord Hardwick was called up to the house of lords in 1734, he was chosen to succeed him in representing the borough of Scarborough among the commons: and he represented this borough for the remainder of his life. He defended the measures of Sir Robert Walpole, and was the supposod author of a ministerial pamphlet, intitled, A Letter to a Freetholder on the late Reduction of the Land-tax to one Shilling in the Pound; which had been printed in 1732. In 1735, he published remarks on the Laws relative to the Poor, with proposals for their better Relief and Employment; and at the same time brought in a bill for the purpose. He made another attempt of this kind, but without effect. May 1738, he was appointed a commissioner of the Victualling-office. In 1753, appeared Religio Philofophi; or, the Principles of Morality and Christianitv, illustrated from a View of the Universe, and of Man's Situation in it. This was followed, in 1754, by his Essay on Deformed Men, in which he rallies his own imperfection in this respect with much liveliness and good humour. "Bodily deformity (says he), is very rare. Among 558 gentle-
HAZEL, or Hazel, in botany. See Corylus. The kernels of the fruit have a mild farinaceous, oily taste agreeable to most palates. Squirrels and mice are fond of them, as well as some birds, such as jays, nutcrackers, &c. A kind of chocolate has been prepared from them and there are instances of their having been formed into bread. The oil expressed from them is little inferior to the oil of almonds: and is used by painters and by chemists for receiving and retaining odours. The charcoal made of the wood is used by painters in drawing.—Some of the Highlanders, where superstitition is not totally subdued, look upon the tree itself as unlucky; but are glad to get two of the nuts naturally conjoined, which is a good omen. Theye call eno-chomblach, and carry them as an efficacious charm against witchcraft.

Evelyn tells us that no plant is more proper for thickening of copse than the hazel, for which he directs the following expedient method. Take a pole of hazel (which or pole may also be used) of 20 or 25 feet in length, the head a little lopped into the ground, giving it a chop near the ground to make it fucumb; this fastened to the earth with a hook or two, and co- 

ved with some fresh mould at a competent depth (as gardeners lay their carnations), will produce a great number of suckers; and thicken and furnish a copse speedily.

HAZLE, or Hazley-Earth, a kind of red loam, which is said to be an excellent mixture with other forts of earth; uniting what's too loofe, cooling what is too hot, and gently retaining the moisiture.

Witch-Hazel. See Hamamalis.

HEAD, the uppermost or foremost part of the body of an animal. See Anatomy, Part I. fect. ii.

Head-ache, a most troublesome sensation in the head, produced by various causes, and attended with different symptoms, according to its different degrees and the place where it is seated. See the Index subjoined to Medicine.

Dragon's Head, in astronomy, is the ascending node of the moon or other planet.

Head of a Ship, an ornamental figure erected on the continuation of a ship's stem, as being expressive of her name and emblematical of war, navigation, commerce, &c.

Head, is also used in a more enlarged sense to signify the whole front or fore-part of the ship, including the bows on each side: the head therefore opens the column of water through which the ship passes when advancing. Hence we say, head-sails, head-sea, headway, &c.

Thus, fig. 1. Plate CCXXVI. represents one side of the fore-part and head of a 74 gunship, together with part of the bow, keel, and gunnel. The names of the several pieces, exhibited therein, are as follows:

A A Fore-part of the keel, with a a the two false keels beneath it.

AC the stem.

a a The cat-head.

b The supporter of the cat head.

cc The knight-head, or bollard-timber, of which there is one on each side, to secure the inner end of the bow-fprit.

dd The haufe-holes.

e e The naval-hoods, i.e. thick pieces of plank laid upon the bow to strengthen the edges of the haufe-holes.

f The davit-clock, by which the davit is firmly wedged while employed to fill the anchor.

g The bulk-head, which terminates the forecastle on the fore-side, being called the break-head bulk-head by shipwrights.

H The gun ports of the lower deck.

b The gun ports of the upper deck and fore-cable.

I, I The channels, with their dead eyes and chains.

i The gripe or fore-foot, which unites the keel with the stem forming a part of either.

k k Thee dotted lines represent the thicknees and deficient of the different decks from the fore-part of the ship towards the middle. The lowest of the three dor-
The difference between the height of the deck in the middle of its breadth and at the ship's side. This is also exhibited more clearly in the Midship-Frame; where the red curve of the beam is delineated. N. B. Their lines must be always parallel to the lines which terminate the gun-ports above and below.

The timbers of the head, and part of the bowsprit.

The rails of the head which lie across the timbers.

Fore-part of the main-wale.

Fore-part of the channel-wale.

The head water-line.

Fig. 3: presents a head view of a ship, with the projection of her principal timbers, and all her planks laid on one side.

It is evident that the fore-part of a ship is called its head, from the affinity of motion and position it bears to a hippopotamus, and in general to the horizontal situation of all animals whilst swimming.

By the head, the state of a ship, which is laden deeper at the fore-end than at the after-end.

The head-bow, or head-borough, signifies the person who is the chief of the frank-pledge, and had anciently the principal direction of those within his own pledge.

He was also called burrow-head, burrow-shoulder, now bordier, third-borow, tything-man, chief-pledge, and burrow elder, according to the diversity of speech in different places. This office is now usually called a high-constable. The head-bow was the chief of ten pledges; the other nine were called bordiers, or ploughman's, &c.

Head-Mould-shot, a disease in children wherein the futures of the skull, generally the coronal, rise; that is, have their edges shot over one another: and are so close locked together, as to compress the internal parts; the meninges, or even the brain itself. This disease usually occasions convulsions, and is supposed to admit of no cure from medicine, unless room could be given by manual operation or division of the futures.

The head-mould-shot is the disorder opposite to the horse-shoe head.

Head Piece, an excision of a certain fur formerly collected by the sheriff of Northumberland from the inhabitants of that county, without any account to be made to the king. This was abolished by the statute 23 Hen. VI., cap. 7.

Head Tin, in metallurgy, is a separation of tin ore towards the fitting it for working into metal. When the ore has been pounded and twice washed, that part of it which lies uppermost, or makes the surface of the mass in the tub, is called the head tin: this is separated from the rest, and after a little more washing becomes fit for the blowing house.

Head Fals, a rope employed to fasten a ship to a wharf, chain, or buoy, or to some other vessel along side.

Head Land, a name frequently given to a cape or promontory.

Head Drafs, amongst the Jewish, Grecian, and Roman ladies, as amongst ourselves, was various, according to the different periods of time, and the fluctuations of fashion. In general, it principally consisted of the hair differently tricked out. It was usually divided before, with a bodkin, into two equal parts; sometimes it was covered with a net, or put into a kind of purse, or tied behind in the form of a knot, or bound back and plaited with ribbons. It was washed with great care; essence and perfumes were applied to it, and gold-dust sometimes made use of as powder. Pearls and jewels made a part of their ornaments; and pendants were worn in the ear. To cover the defects of hair, perukes were made use of by the gentlemen of Rome. And we read that Otho had a covering of false hair, because he had not much of his own. See Hair-Jewels.

Both Grecian and Roman ladies wore têtes. But whether they ever built up their heads so high as the English, or their continental neighbours, will admit of a dispute.

Head-most, the situation of any ship or ships which are the most advanced in a fleet, or line of battle.

Head-Rope, that part of the bolt-ropes which terminates any of the principal fails on the upper edge, which is accordingly fewed thereto. See the article Bolt-ropes.

Head-Sails, a general name for all those sails which are extended on the fore-mast and bowsprit, and employed to command the fore-part of the ship: such are the fore-fail, fore-top-sail, fore-top-gallant-sail, jib, fore-flying-sail, and the sprit-sail with its top-sail. This term is used in opposition to after-sails, viz. all those which are extended on the mizen mast, and on the stays between the mizen and main masts.

Head-to-wind; the situation of a ship or boat, when her head is turned to windward.

Head-Way, the motion of advancing at sea. It is generally used when a ship first begins to advance; or when it is doubtful whether she is in a state of rest or motion. It is in both senses opposed to retreating, or moving with the stern foremost. See the article Stern-way.

Healfang, Healsfang, or Halsfang, in ancient customs, signifies calvarium, or the punishment of the pillory. The word is compounded of two Saxon words; halp, neck, and pangen "to contain:" Puna felicit qua alicae collum flingatur. The healfang, however, cannot signify a pillory in the charter of Canutus, De forfeitis, cap. xiv. Et pro culpa folestat regi duas solidos, quos Dani vocant halsefang.

Healsfang is also taken for a pecuniary punishment or mulef, to commute for standing in the pillory; and is to be paid either to the king or the chief lord. Qui falsum testimoniun detis, reddet regi vel terra dominus healfang.

Healing, in its general sense, includes the whole process of curing or removing a disorder; and recovering health. In this sense medicine is defined the art of healing. In its more restrained sense, as used in surgery, &c. healing denotes the uniting or consolidating the lips of a wound or ulcer. The medicines proper for this intention are called incantations, agglutinations, vulneraries, &c.

Healing, in architecture, denotes the covering the roof of a building. The healing is various; as of lead, tiles, slate, Horshamstone, hingles, or reed and straw.

Health, is a right disposition of the body, and of...
HEALTH

Health, in all its parts; consisting in a due temperature, a right conformation, just connection, and ready and free exercise of the several vital functions.

Health admits of latitude, as not being the same in all subjects, who may yet be said to enjoy health.

That part of medicine which shows the means of preserving health, is termed hygiene. See MEDICINE.

Dittany, applied in the diaphragm, between the two laminae of the mediastinum, wherein the veins all terminate, and from which all the arteries arise; and which, by its alternate contraction and dilatation, is the chief instrument of the circulation of the blood, and the principle of life. See ANATOMY, no. 121, 122.

Several ingenious persons have from time to time attempted to make estimates of the force of the blood in the heart and arteries; who have as widely differed from each other, as they have from the truth, for want of a sufficient number of data to argue upon. This fet the truly ingenious Dr Hales upon making proper experiments, in order to ascertain the force of the blood in the veins and arteries of several animals.

If, according to Dr Kell's estimate, the left ventricle of a man's heart throws out in each systole an ounce or 1.638 cubic inches of blood, and the area of the orifice of the aorta be 0.4187, then dividing the former by this, the quotient 3.9 is the length of the cylinder of blood which is formed in passing thro' the aorta in each systole of the ventricle; and in the 75 pulses of a minute, a cylinder of 292.5 inches in length will pass: this is at the rate of 1462 feet in an hour. But the systole of the heart being performed in one third of this time, the velocity of the blood in that interval will be three as much, viz. at the rate of 4386 feet in an hour, or 73 feet in a minute. And if the ventricle throws out one ounce in a pulse, then in the 75 pulses of a minute, the quantity of blood will be equal to 4.41b. 110z. and, in 34 minutes, a quantity equal to a middle-sized man, viz. 158 lb. will pass through the heart. But if, with Dr Harvey and Dr Lower, we suppose two ounces of blood, that is, 3.236 cubic inches, to be thrown out at each systole of the ventricle, then the velocity of the blood in entering the orifice of the aorta will be double the former, viz. at the rate of 146 feet in a minute, and a quantity of blood equal to the weight of a man's body will pass in half the time, viz. 17 minutes.

If we suppose what is probable, that the blood will rise 74.5 feet high in a tube fixed to the carotid artery of a man, and that the inward area of the left ventricle of his heart is equal to 15 square inches, these multiplied into 74.5 feet, give 1335 cubic inches of blood, which presides on that ventricle, when it first begins to contract, a weight equal to 75.5 pounds.

What the doctor thus calculates, from supposition, with regard to mankind, he actually experimented upon horses, dogs, fowls, does, &c. by fixing tubes in orifices opened in their veins and arteries; by observing the several heights to which the blood rose in these tubes, as they lay on the ground; and by measuring the capacities of the ventricles of the heart and orifices of the arteries. And, that the reader may the more readily compare the said estimates together, he has given a table of them, ranged in the following order.

| Table |
Heart. Heat.

The several animals.

<table>
<thead>
<tr>

Heart-burn, a disease usually called cardialgia by physicians. In fevers, or upon swallowing without due mastication; when meats are eat tough and fat or with farinaceous substances unfermented; or when by any accident the saliva is vitiated, too scanty or not intimately mixed with the food, the fermentation, becomes tumultuous; the stomach swells with air, and this extraordinary commotion being attended with an unusual heat brings on the unpleasantries called the heart-burn; which is remedied by whatever promotes a greater secretion of saliva, or helps to mix it with our aliment. The taffaceous powders, as oyster-shells, crabs-eyes, chalk, &c. are the usual remedies for the heart-burn.

Heart, that part of the pavement of a room on which the fire is immediately placed.

Heart-Money. See Chimney-Money.

Heat, in physiology, has a double meaning; being put either for that peculiar sensation which is felt on the approach of burning bodies, or for the cause of that sensation; in which last sense it is synonymous with Fire. This mode of speaking, however, is inaccurate, and by confounding the effect with the cause, sometimes produces obscurity; it were to be wished therefore that the word heat was used only to denote the effect; and fire, or some other term, to denote the cause of that effect.

The disputes which formerly were so much agitated in the learned world concerning the nature of heat, viz., whether it consisted merely in the motion of the terrestrial particles of bodies, or in that of a subtle fluid, are now mostly ceased, and it is almost universally believed to be the effect of a fluid. Unluckily, however, from the promiscuous use of the words fire and heat, an opinion seems to have gained ground, that there is in nature a fluid essentially hot; and that wherever the opposite sensation prevails, the former fluid is in part absent. Hence have arisen numberless speculations concerning the attraction, absorption, and capacities of bodies for heat; all of which being built on a false principle, have served no other purpose but to involve this part of natural philosophy in obscurity and confusion. Under the articles Chemistry, Combustion, Electricity, &c. it is so fully shown that heat properly so called is not a fluid, but the modification of a fluid, that it is superfluous to say any more on the subject at present. This being admitted, it will evidently follow, that heat can neither be absorbed nor attracted; neither can any body have a greater capacity for it than another, except in proportion to its bulk, which allows a larger quantity of the fluid to enter and to assimilate the particular motion which constitutes heat. From some of Dr Black's experiments indeed it would appear at first view, that heat was absorbed, or attracted in the fiercely fented of the word; but this must be attributed merely to the transferring of the modification of the fluid from one substance to another, without regarding whether it is the identical quantity of fluid which acts as heat in one substance that is transferred to the other, or whether only by some unknown means a similar motion is produced in another portion of the same. At any rate, however, some word must be made use of to express this operation; and absorption or attraction will answer the purpose.
purposes as well as any others: but still we ought to remember, that these are inaccurate; and when we begin to argue from them as if they fully and exactly determined the mode in which the fluid acts, or rather is acted upon (for both these words suppose heat to be passive, and not active), we must certainly err. As to the phrase, *capacity for containing heat, absolute heat,* &c., they are still more inaccurate than the words *absorption and attraction,* and cannot convey any distinct idea; whence the systems founded upon the explanations of these terms, assumed *gratia dictum* without the least proof, have never been able to support themselves, but are liable to endless and insuperable objections.

It is by no means indeed easy, nay we may boldly say that it is absolutely impossible, for human genius to investigate all the phenomena of this subtle and invisible element. All that can be done is, to discover a few general rules according to which the fluid acts in certain cases. From these we can only reason analogically to cases where its action is less obvious. But we are not to expect that by reasoning in this manner we can solve every phenomenon; nor can it be any recommendation to an hypothesis, merely that it solves some phenomena, unless we were able by its means to solve them all; but this no wise man will pretend to do, nay, not even to know them all. It appears exceedingly erroneous therefore to invent solutions of certain phenomena, and then to argue for the truth of the hypothesis from the facility with which the phenomena are explained by it. The true and proper method of proceeding in this case is to lay down certain principles established from the obvious phenomena of nature, and to reason from them fairly as far as we can; but where this ends, our knowledge must stop, and we cannot by any means proceed farther upon a sure foundation.

The only general principles as yet certainly established from obvious phenomena upon this subject are the following: 1. Heat and cold are found to expel one another. Hence we ought to conclude, that heat and cold are both *passive,* for a negative can neither be expelled nor accumulated. 2. Heat is visibly occasioned by the rays of the sun concentrated, and likewise by the fluid of electricity concentrated. If fire, therefore, properly so called, be the cause of heat, than which nothing can be more evident to our senses, we are certainly intitled to conclude, that both the light of the sun and the electric fluid are *elementary fire.* Hence also we conclude their identity; for two different substances cannot by any means produce constantly the same effect when put in the same circumstances, which both light and electricity do in this case, merely by *concentration,* or discharging a great quantity of the fluid upon a small portion of any terrestrial body. 3. Heat expands bodies in every direction: whence we conclude, that the fluid, when producing heat, acts from a centre towards a circumference; and by analogy, that when it produces cold it acts from a circumference towards a centre. 4. It appears from undeniable experiments, that heat, somehow or other, is the cause of fluidity. As the action of the fluid has already been shown, when it produces heat, to be from a centre to a circumference, it follows, that when the expansive action of the fluid is confined within the surface of any body, this may be called its *latent heat,* because it extends not beyond the surface, and therefore cannot affect the thermometer, or be known to us as heat by the sense of feeling. But when this expansive action is transferred from the internal parts of the substance to the surface, it then affects the thermometer and the body is said to be become *hottier* at the same time that it congeals or is said to be *frozen.* This is what some philosophers call the conversion of the latent into sensible heat; others, the alteration of the *capacity:* but whatever term we give to the effect, the cause must remain the same, viz. the opposite actions of the same fluid; the expansive power in some cases counteracting or overcoming the condensing one, and *vice versâ.* 5. Though sometimes the expansive action is sufficiently strong to produce fluidity naturally, and in most cases may be made to proceed artificially as to make bodies fluid, yet in all cases it is not so. A certain degree of expansive power exists in all bodies whatever, and this is called the *specific heat* of the body. 6. Whatever is called the *cooling* of any body is only the diminution of the expansive action upon its surface, or, if we may use the expression, on the surface of its particles. This is accomplished by an opposite power or modification of the fluid, taking place on the outside; but when this becomes sufficiently strong to penetrate the whole substance, it then expels part of the fluid acting in the opposite direction, and then some change takes place in the texture of the body. It is, however, impossible to speak very periphrastically upon this subject, as the visibility and invisibility of the fluid render all reasonings upon it very precarious. 7. It is altogether impossible to calculate the quantity of absolute heat contained in any substance, because this depends upon the proportion between the quantity of fluid acting expansively and that acting in the opposite direction in the same. These two must some way or other counterbalance each other throughout the whole system of nature; and we may fly with certainty, that any substance in which the one exists without the other, is none of those subject to the investigation of our senses, and all speculations concerning it must be vain. 8. When the fluid contained in any substance is vehemently agitated, this naturally produces an expansion in it; and therefore bodies become hot by violent friction, percussion, &c. In these cases, however, we have no right to say that the fluid is *expelled,* but only that its mode of action is altered; for this is constantly sufficient to produce heat, and in this indeed the very essence of heat consists. 9. When the expansive action of elementary fire within any substance becomes greater than is sufficient with the cohesion of that substance, it is disjoined or resolved into vapour. This, however, may be done in such a manner that the heat still acts upon the separated parts of the body without spending any of its force upon external substances. Hence vapour continues to exist in a temperature much below that in which it was originally produced; nay, will sometimes be excessively cold to the touch, when it really contains as much heat, though in a *latent* state, as before. 10. When this latent heat is transferred to external bodies, the vapour then sets to be vapour, or is *condensed,* and in some cases returns to its original state; in others, it is productive of light and vehement sensible heat; whence
whence all the phenomena of Distillation, Evaporation, Flame, Ignition, Combustion, &c.

These are the principal facts which can be looked upon as established with regard to heat considered in a philosophical view. In common discourse it is always spoken of as a certain substance distinct from all others, and may properly enough be reckoned so with regard to the purpose of life. In this manner, he related to certain bodies in a much greater proportion than others. Dr Franklin made the experiment with pieces of cloth of various colours laid upon snow and exposed to the sunshine, and in all cases found that the pieces dyed with the darkest colours sunk deepest in the snow. Mr Cavallo examined the matter more accurately first by observing the height to which a thermometer with a blackened bulb rose in comparison with one of clear glass, and then by comparing the heights of different thermometers whose bulbs were painted of various colours. Having therefore constructed two thermometers whose scales exactly corresponded with each other, he fixed them both upon the face of an inch square, having the bulbs quite detached from the frame; and in this manner exposed them to the light of the sun or of a lamp. When these were exposed to the sun or kept in the shade, with the glasses of both bulbs clear, they showed precisely the same degree; and the difference between the degree shown by the thermometers when exposed to the sun and when kept in the shade, at about the same time of the day, was very trifling.

The ball of one of the thermometers being painted black, and that of the other left clean, they showed different degrees of temperature on being exposed to the sun, the difference sometimes amounting to 10° but was never constant, varying according to the clearness of the sun's light as well as of the air, and likewise according to the different degrees of temperature in the atmosphere.

On keeping the thermometer with the painted ball on the inside of a window, Mr Cavallo observed that strong daylight had an effect in raising the mercury as well as the sun's light. To ascertain this, he cleaned the bulb of the painted thermometer, and blackened that of the other; but the effect was constant, viz. the quicksilver in the tube of the thermometer, whose ball was painted black, was constantly higher than the other whenever they were exposed to the strong daylight. The difference was commonly about one-third of a degree, but sometimes it amounted to one-fourth, or even to a whole degree; and the experiment answered even when the sun was hid by clouds, which seems to indicate that every degree of light is accompanied with a corresponding heat of one.

By this consideration Mr Cavallo was induced to try whether, by directing the concentrated light of the moon upon the blackened bulb of a thermometer, it would be raised higher than a clean one standing in the same. The experiment was several times tried with a large lens, and afterwards with a burning mirror of 18 inches diameter; yet sometimes for want of proper means of observing the height of the mercury in the tubes of the thermometers, sometimes for want of a continued clear light of the moon, or in short from some unfavourable circumstance or other, he was never able to make a fair and decisive trial of this experiment.

Making trial of the heat of a lamp, he found that it also had a considerable effect. The ball of one being blackened, and both set at two inches distance from the flame of a lamp, they both rose from 38 to 65° deg. and the thermometer which was blackened to 67°. Another time the uncoloured thermometer rose to 67°, and the coloured one to 69°. From a number of trials it at first appeared, that the difference at this distance from the lamp amounted generally to about a degree. When the thermometers were removed farther than two inches from the lamp, the difference decreased; and at the distance of about 14 or 15 inches it vanished entirely.

On this occasion Mr Cavallo had an opportunity of making a curious observation concerning the decrease of heat at different distances from the centre. It is mathematically true, that emanations which proceed from a centre, and expand in a sphere, must become more and more rare in proportion to the figures of the distances from the centre. Thus it is said, that the intensity of light proceeding from a luminous body at a distance of double, treble, quadruple, &c. distance from that body, must be respectively four, nine, sixteen, &c. less dense. The same thing may be said of heat; but with respect to the latter, it appeared, that its intensity did not decrease exactly in the duplicate proportion of the distances from the flame of the lamp, but showed a very odd irregularity. It seemed to decrease faster than the duplicate proportion of the distances for the space of two inches and a half or three inches, after which it decreased much slower; but whether this proceeded from some different state of the air's purity at different distances from the flame of the lamp, or from the vapours coming from the flame, I cannot take upon me to determine.

Mr Cavallo next made some experiments upon thermometers, the balls of which were painted of various colours. His view was to examine with precision the degrees of heat imbibed by differently coloured substances, in order to determine whether they kept any proportion to the spaces occupied by the prismatic colours in the prismatic spectrum, or if they followed any other law. In these experiments he met with considerable difficulties, chiefly arising from the different nature of the colours with which the bulbs were painted. By reason of this diversity the bulbs could not be made equally smooth, which occasioned a considerable difference in the effect, as he found by painting two bulbs of thermometers with the same colour, only making the one smooth and the other rough.

To avoid this inconvenience, he attempted to make thermometers with tubes of differently coloured glasses but when a ball was formed with any of these, the glafs of the ball was so thin, that it differed very little from that which was entirely colourless. He then included the thermometers in boxes, where the rays entered through coloured glasses; but here the rays were not only far from being homogeneous, but there was such a difference in the transparency of some of the coloured glasses, that this method, proved also ineffectual. The least ambiguous method therefore was that of painting the bulbs of the thermometers with water-colours, taking care to lay them on as equally and smooth as possible. In this manner the experiments were repeated, using sometimes a dozen of thermometers.
HE A

Heat.

meters at once, whose balls were painted with various colours, and were exposed to the sun; but from a vast number of experiments, and some weeks observation, it could only be deduced, that if the colours with which the balls of the thermometers were painted had any considerable resemblance to those of the prism, those which were nearest to the violet showed a greater degree of heat than the others; but they were all, even that painted with white lead, in some intermediate degree between the blackened thermometer and that which was left quite clear. If the quarts had not the proper density, the effects were different: thus, a thermometer painted with a light blue fluid lower than another painted with good carmine.

In the course of his thermometrical experiments, Mr Cavallo likewise discovered a new method of determining the expansion of mercury by weight, which seemed capable of being carried to a greater degree of exactness than any other hitherto proposed. Having first blown a ball to a capillary tube, such as are commonly used for thermometers, he weighed it, and found the weight when empty to be 79.25 grains; and he observes, that in this experiment it is a precaution absolutely necessary to have the glass as accurately cleaned as possible. Some mercury was then introduced into the stem of the thermometer, taking care that none of it entered the ball; and by adapting a scale of inches to the tube, observed that 4.3 inches of it were filled with the mercury. The thermometer was now weighed again; and from this the weight of the glasses being subtracted, the remainder, viz. 0.24 gr., showed the weight of that quantity of mercury which was left quite clear. If the quarts had filled the 4.3 inches of the tube. Now, the ball of the thermometer, and also part of the tube, were entirely filled with quicksilver; and in order to find out the weight of the mercury contained in it, the thermometer was weighed for the last time; and the weight of the glasses being subtracted from this, the remainder, viz. 3205 grains, showed the weight of the whole quantity of quicksilver contained in the thermometer.

By comparing this instrument with a graduated thermometer of Fahrenheit, and by applying a scale of inches, he found, that 20° on the new thermometer was equal to 1.37 inches. But 0.24 grains was the weight of as much mercury as filled 4.3 inches of the tube. Therefore, by the rule of proportion, it will be found that the weight of as much quicksilver as fills 1.33 inches of the tube, viz. the length of 20°, is equal to 0.0742 of a grain nearly, and that the weight of as much quicksilver as fills a length of the tube equivalent to one degree, is equal to 0.00371 grains. Now it is clear, that the weight of the whole quantity of quicksilver contained in the thermometer is to the weight of as much as fills the length of one degree of the tube, as the bulk of the whole quantity of quicksilver in a given degree of heat to the increase of bulk that the same whole quantity of quicksilver acquires when heated but one degree; viz. 32.05 grains is to 0.00371 grains as 1 to 0.00114. By which experiment it appears, that one degree of Fahrenheit's thermometer increases the bulk of mercury not above eleven hundred thousandth parts. A small deviation from mathematical exactness is indeed produced by the difference of weight between the quicksilver of the tube when first weighed and when it is afterwards heated to one degree; but by an easy calculation it will be found, that this difference is so exceedingly small that it cannot be perceived with our most exact instruments of either weight or measure.

On repeating this experiment with other thermometers, each process varied a little from the other; which irregularity, Mr Cavallo thinks, was certainly owing to the imperfection of his scales: but by taking a mean of various experiments, it appears, that one degree of heat, according to his thermometer, increases the bulk of a quantity of quicksilver in the temperature of 50° by about nine parts in 100,000; that is, if the bulk of any quantity of quicksilver in the temperature of 50° be 100,000, it will be 100,009 in the temperature of 51°.

In making experiments of this kind, it is necessary to have the bores of the tubes absolutely cylindrical; and the scales should be so exact as to turn with the hundredth part of a grain when charged with half an ounce weight.

Heat of Burning Bodies. See ComBustion.

Heat of Chemical Mixtures. This is a phenomenon necessarily resulting from the change of form produced in the different substances which are mixed together; and the manner in which it happens may be easily understood from the example of oil of vitriol and water. If equal quantities of concentrated vitriolic acid and water are mixed together, a very great degree of heat immediately takes place; infomuch that if the vessel which contains the mixture is made of glass it will probably break; and after it is cool, the mixture will be found to have shrunk in its dimensions, or will occupy less space than the bulk of the water and acid taken separately. In this case we know that the water, while in its fluid state, hath as much latent heat as it can contain; i.e. the elementary fire within it expands or separates its parts from each other, as much as is consistent with the constitution of the body. If any more is added, it cannot be absorbed, or direct its force upon the particles of the water without raising them in vapour; of consequence, part of this additional expansive power will be employed in the formation of vapour, and the rest will be discharged upon the neighbouring bodies, i.e. will be converted into sensible heat. The vitriolic acid, in its concentrated state, contains a great quantity of latent heat, which is necessary to preserve its fluidity. But when it is mixed with the fluid water, the latent heat contained in the latter is abundantly sufficient for both: of consequence, the great expansive power in the oil of vitriol itself becomes now totally useless, and therefore exerts its force upon the neighbouring bodies; and when the mixture returns to the original temperature of the oil of vitriol and water, it shows a lot of substance by its diminution in bulk. This may serve to explain all cases in chemistry where heat or cold is produced: and it will generally be found, that where bodies, by being mixed together, produce heat, they shrink in their dimensions; but when they produce cold, they are enlarged.

Methods of Measuring Heat. See Thermometer.

Expansion of Metals by Heat. See Pyrometer.

Degree of Heat which animals are capable of bearing.

—The ancients were of opinion, that all countries lying
lying within the tropics were uninhabitable by reason of their heat: but time has discovered their mistake; and it is now found, that no part of the world is too hot for mankind to live in. The learned professor Boerhaave, in his own country, relates certain experiments made with great accuracy by the celebrated Fahrenheit, and others, at his desire, on this subject, in a sugar-baker's-office; where the heat, at the time of making the experiments, was up to 146 degrees of Fahrenheit's thermometer. A sparrow, subjected to the air thus heated, died after breathing very laboriously, in less than seven minutes. A cat refitted this great heat somewhat above a quarter of an hour; and a dog about 28 minutes, discharging before his death a considerable quantity of a ruddy coloured foam, and exhaled a fench too peculiarly offensive, as to throw one of the attendants into a fainting fit. This disfellation of the humour, or great change from a natural state, the professor attributes not to the heat of the stove alone, which would not have produced any such effect on the flesh of a dead animal; but likewise to the violent motion, by which a still greater degree of heat, he supposes, was produced in the fluids circulating through the lungs, in consequence of which the oils, fats, and spirits of the animal became so highly excited.

Mélears Du Hamel and Tillet having been sent into the province of Angoumois, in the years 1760 and 1761, with a view of endeavouring to destroy an insect which infested the grain of that province, effected the same in the manner related in the Memoirs for 1761, by exposing the affected corn, with the insects included in it, in an oven, where the heat was sufficient to kill them without injuring the grain. This operation was performed at Rochefoucault, in a large public oven, where, for economical views, their first step was to affuage themselves of the heat remaining in it on the day after bread had been baked in it. They did, by conveying in a thermometer on the end of a shovel, which, on its being withdrawn, indicated a degree of heat considerably above that of boiling water; but M. Tillet, convinced that the thermometer had fallen several degrees in drawing to the mouth of the oven, and appearing under some embarrassment on that head, a girl, one of the attendants on the oven, offered to enter, and mark with a pencil the height at which the thermometer stood within the oven. The girl smiled on M. Tillet's appearing to hesitate at this strange proposition; and entering the oven, with a pencil given her for that purpose, marked the thermometer, after staying two or three minutes, standing at 100 degrees of Reaumur's scale, or, to make use of a familiar expression in this country, at near 268 degrees of Fahrenheit's. M. Tillet began to express an anxiety for the welfare of his female assistant, and to press her return. This female salamander, however, amusing him that she felt no inconvenience from her situation, remained there 10 minutes longer: that is, near the time when Boerhaave's cat parted with her nine lives under a much less degree of heat, when the thermometer standing at 288 degrees, or 76 degrees above that of boiling water, came out of the oven, her complexion indeed considerably heightened, but her respiration by no means quick or laborious. After M. Tillet's return to Paris, these experiments were repeated by Monf. Marantini, commissaire de guerre, at Rochefoucault, an intelligent and accurate observer, on a second girl belonging to the oven, who remained in it, without much inconvenience, under the same degree of heat, as long as her predecessor; and even breathed in the air heated to about 325 degrees for the space of five minutes.

M. Tillet endeavoured to clear up the very apparent contrariety between these experiments and those made under the direction of Boerhaave, by subjecting various animals, under different circumstances, to great degrees of heat. From his experiments, in some of which the animals were swaddled with cloths, and were thereby enabled to resist for a much longer time the effects of the extraordinary heat, he infers, that the heat of the air received into the lungs was not, as was supposed by Boerhaave, the only or principal cause of the anxiety, laborious breathing, and death, of the animals on whom his experiments were made; but that the hot air, which had free and immediate access to every part of the surface of their bodies, penetrated the substance on all sides, and brought on a fever, from whence proceeded all the symptoms: on the contrary, the girls at Rochefoucault, having their bodies in great measure protected from this action by their clothes, were enabled to breathe the air, thus violently heated, for a long time without great inconvenience. In fact, we should think too, that the bulk of their bodies, though not thought of much consequence by M. Tillet, appears to have contributed not a little to their security. In common respiration, the blood, in its passage through the lungs, is cooled by being brought into contact with the external inspired air; in the present experiments, on the contrary, the vessels and vessels of the lungs receiving at each inspiration an air heated to 300 degrees, must have been continually cooled and refreshed, as well as the capillary and venous vessels, by the successive arrival of the whole mass of blood contained in the interior parts of the body, whose heat might be supposed at the beginning of the experiment not to exceed 100 degrees. Not to mention, that M. Tillet's two girls may not possibly have been subjected to so great a degree of heat as that indicated by the thermometer; which appears to us to have always remained on the shovel, in contact with the earth.

These experiments soon excited other philosophers to make similar ones, of which some very remarkable ones are those of Dr Dobson at Liverpool, who gives the following account of them in the Philosophical Transactions, vol. lxv.

"I. The sweating-room of our public hospital at Liverpool, which is nearly a cube of nine feet, lighted from the top, was heated till the quicksilver stood at 224° on Fahrenheit's scale, nor would the tube of the thermometer indeed admit the heat to be raised higher. The thermometer was suspended by a string fixed to the wooden frame of the sky-light, and hung down about the centre of the room. Myself and several others were at this time inclosed in the stove, without experiencing any oppressive or painful sensation of heat proportioned to the degree pointed out by the thermometer. Every metallic about us soon became very hot.

"II. My friend Mr Park, an ingenious surgeon of this place, went into the stove heated to 204°. After
HEA [ 355 ]

And to determine the increase of the animal-heat, another thermometer was handed to him, in which the quicksilver already stood at 98°; but it rose only to 99°, whether the bulb of the thermometer was included in the palms of the hands or received in the mouth (a). The natural rate of this gentleman's pulse is about 65.

III. Another gentleman went through the same experiment in the same circumstances, and with the same effects.

IV. One of the porters to the hospital, a healthy young man, and the pulse 75, was included in the fove when the quicksilver stood at 210°; and he remained there with little inconvenience for 20 minutes. The pulse, now 164, and the animal-heat, determined by another thermometer as in the former experiments, was 107.

V. A young gentleman of a delicate and irritable habit, whose natural pulse is about 80, remained in the fove ten minutes when heated to 224°. The pulse rose to 145, and the animal-heat to 102°. This gentleman, who had been frequently in the fove during the course of the day, found himself feeble, and disposed to break out into sweats for 24 hours after the experiment.

VI. Two small tin vessels, containing each the white of an egg, were put into the fove heated to 224°. One of them was placed on a wooden seat near the wall, and the other suspended by a string about the middle of the fove. After ten minutes, they began to coagulate, but the coagulation was sensibly quicker and firmer in that which was suspended, than in that which was placed on the wooden seat. The progress of the coagulation was as follows; it was first formed on the sides, and gradually extended itself, the whole of the bottom was next coagulated; and last of all, the middle part of the top.

VII. Part of the shell of an egg was peeled away, leaving only the film which surrounds the white; and part of the white being drawn out, the film fufpended. This fufpended fome of the albumen ovii, which was frequently detached as much as possible from every thing but the contact of the air and of the film which formed the cup. The lower part of the egg froid upon some light tow in a common gaiiopon, and was placed on the wooden seat in the fove. The quicksilver in the thermometer still continued at 224°. After remaining in the fove for an hour, the lower part of the egg which was covered with the shell was firmly coagulated, but that which was in the little cup was fluid and transparent. At the end of another hour it was still fluid, except on the edges where it was thinneft; and here it was still transparent. One fufficient proof that it was dried not coagulated.

VIII. A piece of bees-wax, placed in the fame situation with the albumen ovii of the preceding experiment, and exposed to the fame degree of heat in the fove, began to melt in five minutes: another piece fufpended by a string, and a third piece put into the tin vessel and fufpended, began likewise to liquefy in five minutes.

Even these experiments, though more accurate than the former, do not show the utmost degrees of heat which the human body is capable of enduring. Some others, still more remarkable (as in them the body was exposed to the heat without clothes), by Drs Fordyce and Blagden, are also recorded in the Philosophical Transactions. They were made in rooms heated by flues in the floor, and by pouring upon it boiling water. There was no chimney in them, nor any vent for the air, excepting through crevices at the door. In the firit room were placed three thermometers, one in the hottest part of it, another in the cooler part, and a third on the table, to be used occasionally in the course of the experiment. Of these experiments, the two following may be taken as a specimen.

About three hours after breakfast, Dr Fordyce having taken off all his clothes, except his shirt, and being furnished with wooden shoes tied on with lint, went into one of the rooms, where he layed five minutes in a heat of 90°, and begun to sweat gently. He then entered another room, and froid in a part of it heated to 110°. In about half a minute his shirt became fo wet that he was obliged to throw it aside, and the water poured down in streams over his whole body. Having remained in this heat for ten minutes, he removed to a part of the room heated to 120°; and after laying there 20 minutes, found that the thermometer placed under his tongue, and held in his hand, froid at 100°, and that his urine was of the fame temperature. His pulse had gradually rifen to 145 pulsations in a minute. The external circulation was greatly increased, the veins had become very large, and an universal redness had diffused itself all over the body, attended with a strong feeling of heat; his respiration, however, was little affected. He concluded this experiment by plunging in water heated to 100°; and after being wiped dry, was carried home in a chair; but the circulation did not subside for two hours.

Dr Blagden took off his coat, waistcoat, and shirt, and went into one of the rooms, as soon as the thermometer had indicated a degree of heat above that of boiling water. The first impression of this hot air upon his body was exceedingly disagreeable, but in a few minutes all his uneafinefs was removed by the breaking out of a sweat. At the end of 12 minutes he left the room very much fatigued, but no otherwise disordered. His pulse beat 136 in a minute, and the thermometer had rifen to 220 degrees.

In others of these experiments it was found, that a heat even of 260° of Fahrenheit's thermometer could be submitted to with tolerable ease. But it must be observed, that in these great heats every piece of metal they carried about with them became intolerably hot.

(a) The scale of the thermometer, which was fufpended by the string about the middle of the room, was of metal; this was the only one I could then procure on which the degrees ran to high as to give any scope to the experiment. The scale of the other thermometer, which was employed for ascertaining the variations in the animal-heat, was of ivory.
Heat.

Hot. Small quantities of water placed in metallic vessels quickly boiled; but in a common earthen vessel it required an hour and a half to arrive at a temperature of 140°, nor could it ever be brought near the boiling point. Neither durst the people, who with impunity breathed the air of this very hot room at 264 degrees, bear to put their fingers into the boiling water, which indicated only a heat of 212°. So far from this they could not bear the touch of quicksilver heated only to 120°, and could not but just bear spirit of wine at 130°.

Animal-heat. Of this there are various degrees; some animals preserving a heat of 100° or more in all the different temperatures of the atmosphere; others keep only a few degrees warmer than the medium which surrounds them; and in some of the more imperfect animals, the heat is scarcely one degree above the air or water in which they live.

The phenomenon of animal-heat hath, from the earliest ages, been the subject of philosophical discussion; and, like most other subjects of this nature, its cause is not yet ascertained. The belief that has appeared on the subject is that of Dr. Dugue Le Lille, published in 1778; and Mr. Adair Crawford, in 1779. From the first of these performances, we may infer that the opinions on this subject were extruded.

"The ancients professed not the requisites for minutely investigating the science of nature; and, prone to superstitious, attributed every phenomenon that eluded their investigation, to the influence of a supernatural power. Hippocrates, the father and founder of medicine, accounted animal heat a mystery, and believed in many attributes of the Deity. In treating of this subject, he says in express terms, "what we call heat, appears to me to be something immortal, which underlacks, fees, heats, and knows every thing present and to come."—Aristotle seems to have considered the subject particularly, but nothing is to be met with in his works that can be laid to throw light upon it. Galen tells us that he dispute between the philosophers and physicians of his time was, whether animal-heat depended on the motion of the heart and arteries; or whether, as the motion of the heart and arteries was innate, the heat was or was not innate." Both these opinions, however, he rejects; and attempts a solution of the question on his favourite system, namely, the peripatetic philosophy: but his leading principles being erroneous, his deductions are of course inadmissible.

To enter into a minute detail of all the opinions offered by the moderns on the cause of animal-heat, would far exceed our limits. Most of them, however, may be referred to one or other of the three general causes of heat, viz. mixture, fermentation, and mechanical means, each of which we shall particularly consider.

1. Chemical mixture. When chemical philosophy first came into vogue, and prevailed in the theory as well as practice of medicine, almost every operation in the animal machine was said to be the effect of mixture. From observing, that on the mixing of certain bodies far below the temperature of the human body, a degree of heat sometimes rising to actual inflammation was produced; they, without further investigation, pronounced mixture the sole cause of animal heat. Various, however, were the opinions, not only respecting the place where the mixture happened, but also concerning the nature of the fluids of which it consisted. Van Helmont, Sylvius, and several others, supposed that the mixture took place in the intestinal tube; and ascribed it to an effervescence between the pancreatic juice and the bile. Others discovered acids in one place, and alkalies in another; but the general opinion for near two centuries was, that acid fluids taken in, meeting with others of an alkaline nature already prepared in the body, gave rise to the degree of heat peculiar to animals. But those who are in the least acquainted with the laws of the animal economy, need not be told that these opinions are mere conjectures, founded on facts gratuitously affirmed. No experiments have shown either an acridity or alkaloidea in the bile that is sufficient to unite with the other animal juices, and generate the heat of animals. But though we should admit the supposition in its full extent, still it would be no means be sufficient to account for the stability of animal heat in different climates and seasons; its equality all over the body when in health; its partial increase in topical inflammations; or hardly indeed for any one phenomenon attending its production.

Since, then, it appears that the fluids supposed to be mixed, the place in which the mixture is made, and every other circumstance relating to it, are neither ascertained nor seconded by analogy, none will, we presume, hesitate to reject every hypothesis of the cause of animal heat founded on the effects of mixture.

2. Fermentation. When a more accurate and extensive knowledge of the various operations of nature had convinced physiologists of the absurdity of explaining the vital functions of animals, and the several changes which take place in the living body by the effect of chemical mixture, fermentation was substituted in its stead. All had observed, that fermentation was generally accompanied by heat; and few were ignorant, that that identical process, or one extremely similar to it, was constantly going forward in living animals; and it was not without some appearance of truth, that physiologists attributed animal heat to that cause.

Formerly there were various modifications of this opinion; but of late it has been chiefly confined to one species of fermentation, viz. the putrefactive, which indeed is more concomitant to experience and sound philosophy. For although animal substances are either directly or indirectly produced from vegetables, as all animals live on vegetables; or on animals that have lived on them; and though they may be ultimately resolved into the same principles; yet they are certainly combined in a different manner: for they constitute compounds, the natures of which are essentially different; and the three stages of fermentation, the vinous, aceto, and putrid, the last is the only one to which they show a tendency. Milk indeed tends to the vinous, and to the aceto fermentation; but as it can hardly be considered as perfectly animalized, it ought not to be considered as an exception to the general position. And though it be readily admitted, that animal matter is extremely apt to putrefy, and that even
Heat. in the living body there is a tendency to that process; yet it may be shown, that the degree to which it takes place can have little or no share in generating the heat of animals. In the first place, the effect of any degree of putrefaction in producing heat, is to this day so ill ascertained, that, with many ingenious philosophers, it is altogether problematical, whether or not animal substances, during the putrefactive process, do ever generate heat. Neither M. Beausé, nor Dr. Pearson, who made several accurate experiments with a view to ascertain this point, could, by the assistance of the most sensible thermometers, discover the least difference between the temperature of the putrefying mixtures and the surrounding medium; and were the putrefaction of animal substances readily attended with the generation of heat, we might expect to find it greater in proportion to the bulk of the putrefying mass.

This, however, is not the case; for it has often been found, that the largest masses of animal matter, such as the carcass of a large whale laid out and exposed in the air in such a putrid condition as to affect all the neighbourhood with an intolerable stench, did not to the Perkins handling it feel sensibly hotter than the circumambient air. But what at once overthrows every thing that can be advanced in favour of the generation of animal heat on the principles of putrefaction is, that heat is so far more considerable in a living than in a dead body; and no rational physiologist will deny, that the putrid fermentation is going forward more rapidly in the latter than in the former.

3. The mechanical generation of heat. This opinion first took its rise from an observation, that animal heat generally keeps pace with the state of the circulation: while the action of the heart and arteries continues unimpaired, a high degree of animal heat is produced; but when that action becomes more languid, the heat of the animal is diminished also. This, till very lately, was the favourite opinion of physicians, and was introduced immediately after Harvey had discovered the circulation of the blood, and indeed seems to have been supported by many physiologists looked upon it: as a matter almost capable of mathematical demonstration; yet they could not agree whether the heat of animals is occasioned by the friction of the blood against the vessels which contain it, or by the internal friction and agitation of the particles among one another. Various hypotheses accordingly were framed, and many ingenious arguments brought in support of them: but all suppositions of the mechanical kind are overthrown by some thermometrical observations of De Haen and others, from which it appeared, that the heat of the body was sometimes greater than is usual with healthy people, at the time the person was just expiring, when the action of the vessels was very weak; nay, even after he was dead, when it had entirely ceased. The abovementioned physician relates two very remarkable cases of this kind. In one, he found that the temperature of his patient, which during the course of an inflammatory fever had never exceeded 103 degrees, at the time he expired, and for two minutes after, stood at 106. From the other it appeared, that the heat of a person who was dying of a lingering distemper, rose in the last agony from 100 to 101, and continued there stationary for two hours; and, even at the expiration of 15 hours, had only fallen to 85°, though the surrounding medium did not exceed 60°. The example also of those who are suffocated by fixed air, entirely overturn not only the mechanical system, but almost every other which hath yet appeared on the subject. [See the article Bloom, n° 31.]

One or other of the abovementioned hypotheses Dr. Cullen continued to be adopted by physicians, till Dr. Cullen attempted a solution on a new set of principles; but adhesive to the difficulty with which novel opinions ought to be broached, he delivered his as little more than a mere conjecture. "May it not (says he) be supposed, that there is some circumstance in the vital principle of animals, which is in common to those of the same class, and of like economy; and which determines the effect of motion upon the vital principle to be the same, though the motion acting upon it may be in different circumstances!" — The doctor was led to this supposition from the difficulty he found in explaining how it was possible for many animals of the same size, and temperament, should possess very nearly the same degree of heat; and in which it is impossible to show, that the motion of the blood in all its circumstances is exactly the same; or that in the different animals in which the degree of heat is considerably different, the motion of the circulating mass is in each correspondent to the difference of temperature. But, granting that the degree of heat does not always obtain in an exact ratio with the motion of the blood, and that it is an impossible objection to its mechanical generation; yet there appear no plausible grounds for supposing that the effect of motion may be the same, while the motion acting upon it is in different circumstances. By this Dr. Cullen means, that the different temperature of different animals is owing to a difference of the vital principle, insomuch that the velocity of the blood may be the same in a frog as in a man; and yet, in consequence of the different vital principle, the heat produced may be different. The facts upon which he seems to lay the greatest stress are, "That neither where the surrounding medium considerably surpasses the temperature of the living body, nor where it is far below it, is there any sensible change in the heat of animals. These, and some similar facts, in appearance countenance his hypothesis; yet we have no solid reason for imagining the principle of life to be different in different animals. And how are we to conceive, that the same degree of motion should in one class of animals always produce a certain degree of heat, and in another class as regularly a different one! A proportion of such a nature should, no doubt, require the most obvious facts and conclusive arguments to establish; but, in the present instance, we do not perceive any probable reason, even from analogy. Besides, to say that the principle of life can generate heat or cold, independent of chemical and mechanical means, is contrary to experience, and seems in itself absurd.

In the 66th volume of the Philosophical Transactions, Dr. Hunter, after reciting some experiments concerning animal heat, affirms, that certain animals entirely subject to the influence of chemical and mechanical means, are contrary to experience, and seems in itself absurd.
HEA

...[358]

HEA

an argumentum crucis against those who account the nervous system the seat of animal-heat. If this is really a fact, it must, no doubt, have all the weight he ascribes to it; but it is plain that no items can be laid upon it, unless it was better ascertained, which is evident it can never be. For though we can positively assert that nerves exist where we feel them, yet we cannot affirm with equal certainty that they do not also exist where we are not able to discover them. For all anatomists allow, that there are thousands of nervous filaments so finely interwoven into the composition of the more perfect animals of every size, that they elude not only the knife and naked eye, but even the best optical instruments hitherto invented. Since then we admit the presence of nerves in one tribe of animals, though we can only perceive them in their effects; what solid reason have we to deny them in another, in which we have the very same evidence, viz. certain indications of sense and motion?

"Another theory, and perhaps the best supported which hath yet appeared upon the subject, is that of Dr Black. That excellent chemist having observed, that not only breathing animals are of all others the warmest, but also that there subsists such a close and striking connection between the state of respiration and the degree of heat in animals, that they appear to be in an exact proportion to one another, was led to believe, that animal-heat depends on the state of the air upon the principle of inflammability, in a manner little dissimilar to what he supposed to occur in actual inflammation; and that it is thence diffused by means of the circulation over the rest of the vital system.

"This opinion is supported by many forcible arguments. 1. It is very generally known to naturalists, that a quantity of phlegmaticated air is constantly exhaling from the lungs of living animals. Since, therefore, atmospheric air, by passing through the lungs, acquires the very same properties as passage through burning fuel, or by being exposed to any other process of phlogification, it is obvious, that the change which the common air undergoes in both cases must be attributed to one and the same cause, viz. its combination with phlogiston. 2. It has likewise been urged in favour of the same hypothesis, that the colour with which the principle of inflammability is separated in respiration, is very closely connected with the degree of heat peculiar to each animal. Thus, man, birds, and quadrupeds, vitiate air very fast; serpents, and all the amphibious kind, very slowly; and the latter are of a temperature inferior to the former, and breathe less frequently. 3. The most cogent arguments that have been brought in support of this opinion are, that no heat is generated till the function of respiration is established; and that the fetus in utero derives all its heat from the mother."

Upon this theory our author makes the following observations, which we shall give in his own words.

"These arguments may, perhaps, on a superficial view of the question, appear conclusive; but a found reasoner, who shall calmly and impartially weigh every circumstance, will, I am confident, allow that they only afford a very ambiguous and imperfect evidence of the doctrine they are meant to establish; and the subsequent animadversion on Dr Black’s theory at large, will, it is hoped, suffice to show, that it is not only founded on dubious and controvertible principles, but that it is, in every point of light, clogged with unanswerable difficulties.

"I. Many and various are the proofs which evince the improbability of the lungs being the source or elaboratory of animal-heat; for, though it be granted, that there subsists a very striking connection between the state of respiration and the degree of heat in animals, and that they are even in proportion to one another; yet it by no means ensues, that the former is positively the cause of the latter. For, were that really the case, it is obvious, that those animals which are defitute of the organs of respiration would generate no heat. That, however, is not true in fact; for those fishes which are even destitute of gills, appear from various experiments to be warmer than the ordinary temperature of the element in which they live; an irrefragable proof that the function of respiration is not absolutely necessary to the production of heat in animals.

"II. If the heat of living animals be generated solely in the lungs, two things necessarily follow; the first, That it can only be communicated to the other parts of the body, through the channel of the arterial system; the second, That the heat must decrease as it recedes from its supposed centre. And a clear and satisfactory evidence of both these points will, no doubt, be deemed requisite to render Dr Black’s opinion in any degree probable. So far, however, are we from meeting with these positive and convincing proofs which we had reason to expect, that we are not presented with a single plausible argument in favour of either of the points. On the contrary, it is more conformable to facts, that the venal blood is, if not warmer, at least as warm as the arterial. Dr Stevenson, an ingenious and accurate physiologist, with a view to ascertain this matter, laid bare the jugular vein and carotid artery of a calf, and then tied and cut them off at once, in order to let equal quantities of blood flow, in a given time, into vessels of an equal capacity, in each of which he had placed a well-adjusted thermometer; the result of the experiment was, that the thermometer immersed in the venous blood rose several degrees above that place in the arterial. But though it is probable that there is not such a difference as that experiment seems to make, yet several reasons incline me to think, that the venal blood, instead of being colder, as Dr Black maintains, is in fact, somewhat warmer than the arterial; and what entirely overthrows his opinion is, that no experiment, though many have been made, has ever shown that the temperature of the blood is higher in the left ventricle of the heart than in the right, which must necessarily be the case, were all the heat of the animal body generated in the lungs.

"III. Having thus rendered it improbable that the generation of animal-heat should be entirely confined to the lungs, we shall venture to repel farther, and endeavour to show, that the vital fluid, so far from acquiring all its heat in the pulmonary system, communicates no inconsiderable portion of what it had received in the course of the circulation to the air alternately..."
Various are the arguments which tend to evince this opinion. Were the blood heated in the lungs, we should certainly need less of their function in a warm than in a cold atmosphere; but we are taught by experience, that when the air is extremely hot, and we wish to be cooled, we breathe full and quick, and that when it is intensely cold, our respiration is slow and languid; which, were the blood heated in the lungs by the action of the air upon it, surely should not be the case. It is therefore more consonant with reason and experience, that the air which we inspire, by carrying off a quantity of evolved phlogiston from the lungs, rather contributes to diminish than increase the heat of breathing animals. Respiration, therefore, has been very properly compared, by an ingenious physiologist, Dr Duncan of Edinburgh, to the blowing of bellows on a hot body. In both cases a considerable degree of heat is communicated to the air; but in neither can the air be said to generate any heat; for if it did, the heat of breathing animals should increase in proportion to the quantity of air inhaled, and a piece of inert matter heated to a certain degree should become hotter by ventilation.

IV. The fætus in utero, according to Dr Black's hypothesis, generates no heat. The arguments by which he supports that position, how ingenious soever they may be, seem not sufficiently cogent to produce conviction; and as the question from its nature hardly admits of any direct experiment, our reasoning upon it must necessarily be analogical. Hence arises our embarrassment; for, as the discovering of analogies depends on the quickness and fertility of fancy, and the truth of all analogical ratiocination on the quickness and nicety of judgment, two powers of the soul seldom united in an eminent degree, we cannot wonder that arguments of this kind, which to one man seem unanswerable, should to another appear futile.

"The only plausible objection to the generation of heat in the fætus, is, the supposition that it would in a short time accumulate in such a manner as to become incompatible with life.

"This argument, however, is more specious than solid; for, granting that the circulation which is carried on between the fætus and the mother, tranfports very nearly the temperature of her blood, that by no means entirely supercedes the necessity of heat being generated in it. Various reasons lead to this opinion.—It is an axiom, that heat decreases as it recedes from the source from which it springs. Now, if we admit for a moment Dr Black's opinion, and believe the heat of animals to be generated solely in the lungs, it is not obvious, that before it reaches the uterus, palates through the very minute tubes by which that organ is connected to the placenta, circulates through the umbilical vessels, and pervades the extreme parts of the fætus. It must be too much diminished to support that equilibrium, which obtains in very part of the living system. Besides, as the fætus in utero may properly enough be accounted a part of the mother, the same objections that are brought against the generation of heat in it would hold equally good against the production of heat in any part or organ of her body, except the lungs. But such a multitude of accurate thermonmetrical observations have evinced the partial increase of heat in local inflammations, that no room is left to doubt, that in every individual part of the vital frame heat is generated; and if the fætus be, from any cause whatever, liable to topical inflammation, a thing which no physiologist has ever pretended to deny, what shadow of reason is there for doubting that such affections are accompanied with the same effects before as after birth, and consequently with a partial increase of heat?"

Our author having now, as he supposes, refuted the objections of others, after showing that heat, though generated, cannot accumulate in the fætus, proceeds to lay down his own theory, which depends on the following principles.

1. That the blood does contain phlogiston.

2. That this phlogiston is evolved, extricated, or brought into a state of activity and motion by the action of the blood-vessels to which it is subjected in the course of circulation.

3. That the evolution of phlogiston is a cause which throughout nature produces heat, whether that heat be apparently excited by mixture, fermentation, perspiration, friction, inflammation, ignition, or any similar cause.

4. That this heat, which must be produced in consequence of the evolution of the phlogiston from the blood of different animals, is in all probability equal to the highest degree of heat which those animals in any case feel (a).

The first and second of these propositions will readily be granted; but the third is liable to a very great objection, namely, that from putrefying bodies, phlogiston is evolved in quantity sufficient to reduce to their metallic form the calces of some metals exposed to the vapour, as Dr Dugald has acknowledged; yet he himself affirms, that no sensible heat is produced by putrefying animal substances. To this he is obliged to reply, that phlogiston is extricated more flowly from mixtures undergoing the putrid fermentation, than from such as are undergoing the vinous and acetic ones; and that the volatile alkali produced from putrefying substances likewise renders the action of the phlogiston. But the first part of this answer is not proved, and is what he himself calls only a probable conjecture. Neither does the second appear to be well founded; for putrefying substances, urine excepted, afford but little volatile alkali; and even putrid urine itself, which affords such a large portion, is not colder than other putrid matters.

It is however needless to insist farther on this theory, since its fundamental principle, namely, that the venous blood is warmer than the arterial, hath been shown to be false by Mr Adair Crawford, of whose hypothesis we must now give an account.

This gentleman, who, in his general doctrine of heat, seems to agree with Dr Irvin of Glasgow, begins with

(a) These theories, inferred in the last edition of this work, we thought it proper to retain, as there seems still a possibility of the phlogistic doctrine regaining its ground, though now threatened with being expelled from the system of nature. A particular account of the dispute concerning Phlogiston is given under that article.
HEAT

an explanation of his terms. The words heat and fire, he tells us, are ambiguous. Heat in common language has a double signification. It is used indiscriminately to express a tension of the mind, and an unknown principle, whether it be called a quantity or a sensation, which is the exciting cause of that sensation. The latter, he, with Dr Irwin, calls absolute heat; the former, sensible heat. The following are the general facts upon which his experiments are founded.

1. Heat is contained in great quantities in all bodies when at the common temperature of the atmosphere.

2. Heat has a constant tendency to diffuse itself over all bodies, till they are brought to the same degree of sensible heat.

3. If the parts of the same homogeneous body have the same degree of sensible heat, the quantities of absolute heat will be proportionable to the bulk or quantity of matter. Thus the quantity of absolute heat contained in two pounds of water, must be conceived to be double of that which is contained in one pound, when at the same temperature.

4. The mercurial thermometer is an accurate measure of the comparative quantities of absolute heat which are communicated to the same homogeneous bodies or separated from them, as long as such bodies continue in the same form. If therefore the sensible heat of a body, as measured by the mercurial thermometer, were to be diminished the one half, or the one third, or in any given proportion, the absolute heat would be diminished in the same proportion.

5. The comparative quantities of absolute heat which are communicated to different bodies, or separated from them, cannot be determined in a direct manner by the thermometer. Thus, if the temperature of a pound of mercury be raised one degree, and that of a pound of water one degree, as indicated by the thermometer, it does not by any means follow, that equal quantities of absolute heat have been communicated to the water and the mercury. [See Heat and Thermometer.]

6. If a pint of mercury be raised one degree, and that of a pint of water one degree, as indicated by the thermometer, it does not by any means follow, that equal quantities of absolute heat have been communicated to the water and the mercury. [See Heat and Thermometer.]

7. If a pint of mercury at 100° be mixed with an equal bulk of water at 50°, the change produced in the heat of the mercury will be to that produced in the water as three to two; or, in other words, that the comparative quantities of their absolute heats are reciprocally proportionable to the changes which are produced in their sensible heats, when they are mixed together at different temperatures. This rule, however, does not apply to those mixtures which generate sensible heat or cold by chemical action.

From the above position, says Mr Crawford, it follows, that equal weight of heterogeneous substances, as air and water, having the same temperature, may contain unequal quantities of absolute heat. There must, therefore, be certain essential differences in the nature of bodies, in consequence of which some have the power of collecting and retaining the element of fire in greater quantities than others, and these differences he calls throughout his treatise the capacities of bodies for containing heat.

Having premised these general facts, our author gives an account of a number of experiments made, in order to ascertain the quantity of absolute heat contained in different bodies. These experiments were made by mixing the bodies to be examined, with water, heated to different degrees; and by the temperature of the mixture, he found the proportion of the capacity of the bodies for containing heat, to water, and, of consequence, to one another. Thus he found the capacity of wheat for containing heat to be that of water as 1 to 2.9; and, of consequence, the absolute heats of the two substances to be in the same proportion. The absolute heat of oats to that of water he found as 1 to 24; of barley, as 1 to 2.4; of beans, as 1 to 1.5; of flesh, as 1 to 1.3; of milk, as 1 to 1.1; and of a mixture of venous and arterial blood from a sheep, as 23.4 to 24.4. By other experiments he determined, that the absolute heat of venous blood was to that of water only as 100 to 112, whereas the absolute heat of arterial blood was to that of water as 100 to 97.58.

By experiments made with air of different kinds contained in bladders, and immersed in water, he found that the absolute heat of atmospheric air was exceedingly great, being to that of water as 18.6 to 1; that of dephlogisticated air was still greater, being to the heat of common atmospheric air as 4.6 to 1. The heat of phlogisticated and fixed air was much less; that of the latter, particularly, being to the heat of atmospheric air only as 1 to 67.

From other experiments made on metals, Mr Crawford concludes, that the absolute heat of tin, in its metallic state, is to that of water as 1 to 14.7; but the heat of calcined tin is to that of water as 1 to 20.4. In like manner, the heat of iron was to that of water only as 1 to 8; but that of the calx of iron was to the heat of water as 1 to 3.1, &c. And from these experiments he is of opinion, that the more phlogiston that is added to any body, the less is its capacity for containing heat.

From these experiments our author deduces the following theory of animal heat.—“It has been proved, that the air, which is expired from the lungs of animals, contains less absolute heat than that which is inhaled in inspiration. It has been shown, particularly, that in the process of respiration, atmospheric air is converted into fixed air; and that the absolute heat of the former is to that of the latter as 67 to 1. Since therefore the fixed air which is exhaled by expiration is found to contain only the one sixtieth part of the heat which was contained in the atmospheric air previous to inspiration, it follows, that the latter must necessarily deposit a very great proportion of its absolute heat in the lungs. It has moreover been shown, that the absolute heat of floriad arterial blood is to that of venous as 114; to 10. And hence, as the blood, which is returned by the pulmonary vein to the heart, has the quantity of its absolute heat increased, it is evident that it must have acquired this heat in its passage through the lungs. We may conclude, therefore, that in the process of respiration, a quantity of absolute heat is separated from the air and absorbed by the blood.

That heat is separated from the air in respiration, is farther confirmed by the experiment with phlogisticated air; from which, compared with Dr Priedley's
Heat discoveries, it is manifest, that the power of any species of air in supporting animal life, is nearly in proportion to the quantity of absolute heat which it contains, and is consequently proportional to the quantity which it is capable of depositing in the lungs.

The truth of this conclusion will perhaps appear in a clearer light from the following calculation, by which we may form some idea of the quantity of heat yielded by atmospheric air when it is converted into fixed air, and allow of that which is absorbed during the conversion of venous into arterial blood.

We have seen that the same heat which raises atmospheric air one degree, will raise fixed air nearly 67 degrees, and consequently that the same heat which raises atmospheric air any given number of degrees, will raise fixed air the same number of degrees multiplied by 67. In the Peterburgh experiment of freezing quicksilver, the heat was diminished 800 degrees below the common temperature of the atmosphere. We are therefore certain, that atmospheric air, when at the common temperature of the atmosphere, contains at least 200 degrees of heat. Hence, if a certain quantity of atmospheric air, not in contact with any body that would immediately carry off the heat, should suddenly be converted into fixed air, the heat which was contained in the former would raise the latter 200 degrees multiplied by 67, or 13400 degrees. And the heat of red-hot iron being 1050, it follows that the quantity of heat, which is yielded by atmospheric air when it is converted into fixed air is such (if it were not diffipated) as would raise the air so changed to more than 12 times the heat of red-hot iron.

If therefore the absolute heat which is disengaged from the air in respiration, were not absorbed by the blood, a very great degree of sensible heat would be produced in the lungs.

Again, it has been proved, that the same heat which raises venous blood 115 degrees, will raise arterial only 100 degrees; and consequently, that the same heat which raises venous blood any given number of degrees, will raise arterial a less number in the proportion of 100 to 115, or 20 to 23. But we know that venous blood contains at least 230 degrees of heat. Hence, if a certain quantity of venous blood, not in contact with any body that would immediately supply it with heat, should suddenly be converted into arterial, the heat which was contained in the former would raise the latter only 1/2 or 220 degrees, or 200 degrees; and consequently the sensible heat would suffer a diminution equal to the difference between 230 and 200, or 30 degrees. But the common temperature of blood is 96; when therefore, venous blood is converted into arterial in the lungs, if it were not supplied by the air with a quantity of heat proportionable to the change which it undergoes, its sensible heat would be diminished 30 degrees, or it would fall from 96 to 66.

That a quantity of heat is detached from the air, and communicated to the blood, in respiration, is moreover supported by the experiments with metals and their calces; from which it appears, that when bodies are joined to phlogiston, they lose a portion of their absolute heat; and that, when the phlogiston is again difengaged, they reabsorb an equal portion of heat from the surrounding bodies.

Now it has been demonstrated by Dr Priestley, that in respiration, phlogiston is separated from the blood, and combined with the air. During this process, therefore, a quantity of absolute heat must necessarily be disengaged from the air by the action of the phlogiston; the blood, at the same moment, being left at liberty to unite with that portion of heat which the air had deposited.

And hence animal heat seems to depend upon a process similar to a chemical elective attraction. The air is received into the lungs, containing a great quantity of absolute heat. The blood is returned from the extremities, highly impregnated with phlogiston. The attraction of the air to the phlogiston is greater than that of the blood. The principle will, therefore, leave the blood to combine with the air. By the addition of the phlogiston, the air is obliged to deposit a part of its absolute heat; and as the capacity of the blood is at the same moment increased by the separation of the phlogiston, it will instantly unite with that portion of heat which had been detached from the air.

We learn from Dr Priestley's experiments with respect to respiration, that arterial blood has a strong attraction to phlogiston: it will consequently, during the circulation, imbibe this principle from those parts which retain it with least force, or from the purest central parts of the system; and hence the venous blood, when it returns to the lungs, is found to be highly impregnated with phlogiston. By this impregnation, its capacity for containing heat is diminished. In proportion, therefore, as the blood, which had been dephlogistificated by the process of respiration, becomes again combined with phlogiston in the course of the circulation, it will gradually give out that heat which it had received in the lungs, and diffuse it over the whole system.

Thus it appears, that, in respiration, the blood is continually discharging phlogiston and absorbing heat; and that, in the course of circulation, it is continually imbibing phlogiston and emitting heat.

It may be proper to add, that as the blood, by its impregnation with phlogiston, has its capacity for containing heat diminished; so, on the contrary, those parts of the system from which it receives this principle, will have their capacity for containing heat increased, and will consequently absorb heat.

Now if the changes in the capacities, and the quantities of matter changed in a given time, were such that the whole of the absolute heat separated from the blood were absorbed, it is manifest that no part of the heat which is received in the lungs would become sensible in the course of the circulation.

That this, however, is not the case, will, I think, be evident from the following considerations:

We know that sensible heat is produced by the circulation of the blood; and we have proved by experiment, that a quantity of absolute heat is communicated to that fluid in the lungs, and is again disengaged from it in its progress through the system. If, therefore, the whole of the absolute heat, which is separated from the blood, were absorbed by those parts
Heat.

of the system from which it receives the phlogiston, it would be necessary to have recourse to some other cause, to account for the sensible heat which is produced in the circulation. But by the rules of philosophizing, we are to admit no more causes of natural things such as are both true and sufficient to explain the appearances; for nature delights in simplicity, and affects not the pomp of superfluous causes.

We may, therefore, safely conclude, that the absolute heat which is separated from the air in respiration, and absorbed by the blood, is the true cause of animal heat.

"It must nevertheless be granted, that these parts of the system which communicate phlogiston to the blood, will have their capacity for containing heat increased; and therefore, that a part of the absolute heat which is separated from the blood will be absorbed.

"But from the quantity of heat, which becomes sensible in the course of the circulation, it is manifest that the portion of heat which is thus absorbed is very inconsiderable.

"It appears therefore, that the blood, in its progress through the system, gives out the heat which it had received from the air in the lungs; a small portion of this heat is absorbed by those particles which impart the phlogiston to the blood; the rest becomes redundant, or is converted into moving and sensible heat."

Mr. Crawford's theory, which doth not essentially differ from Dr. Black's, seems to be the best that hath yet appeared. There is however, one difficulty which seems common to them all, and which, even on Mr. Crawford's principles, seems not to admit of solution. If animal heat entirely depends on something peculiar to a living body, why doth it sometimes continue after life hath ceased? If heat depends on the evolution of phlogiston by the action of the blood-vessels, according to Dr. Dugulb, why should it remain when these vessels cease to act, as, according to Dr. Dugulb himself, it sometimes doth? If, according to Mr. Crawford, it is every moment attracted from the fire, why is it not always in proportion to the respiration? Or, if fixed air contains such a small proportion of absolute heat as, by Mr. Crawford's experiments, it seems to do, why doth it impart such a strong and lasting degree of heat to the bodies of those who are killed by it? See Blood, n. 3.

Other objections have been made by Mr. Pearson, which are related in the Medical Journal. They are founded on some appearances found on the digestion of morbid bodies; where it has been found that the pulmonary artery, and even the lungs themselves, have been totally destroyed by disease, and yet the person has survived for some time. In these cases, however, it is probable, that the blood had still an opportunity of absorbing the vital principle from the air, which might make those produce heat also by some mechanism unknown to us. The whole of Dr. Crawford's doctrine of latent heat has also been attacked in a Treatise by Mr. Leopold Vacca Beringhieri. His objections are derived from the calculations of Dr. Crawford himself; but our limits will not admit of our entering into this dispute.

Internal Heat of the Earth. That there is a very considerable degree of heat always felt in digging to great depths in the earth, is agreed upon by all naturalists: but the quantity of this heat hath seldom been measured in any part; much less is it known, whether in digging to an equal depth in different parts of the earth, the heat is found always the same. In digging mines, wells, &c., they find that at a little depth below the surface it feels cold. A little lower it is colder still, as being beyond any immediate influence of the sun's rays; in much that water will freeze almost at any season of the year; but when we go to the depth of 40 or 50 feet, it begins to grow warm, so that no ice can bear it; and then the deeper we go, still the greater the heat, until at last respiration grows difficult, and the candles go out.
