A NEW AND COMPLETE
DICTIONARY
OF
ARTS and SCIENCES;
COMPREHENDING ALL
The Branches of Useful Knowledge,
WITH
ACCURATE DESCRIPTIONS as well of the
various MACHINES, INSTRUMENTS, TOOLS, FIGURES,
and SCHEMES necessary for illustrating them,
AS OF
The Clasies, Kinds, Preparations, and Uses of NATURAL
PRODUCTIONS, whether ANIMALS, VEGETABLES,
MINERALS, FOSSILS, or FLUIDS;
Together with
The KINGDOMS, PROVINCES, CITIES, TOWNS, and
other Remarkable Places throughout the WORLD.
Illustrated with above Three Hundred COPPER-PLATES,
curiously engraved by Mr. JEFFERYS, Geographer to his Royal
Highness the Prince of WALES.
The Whole extracted from the Best Authors in all Languages.

By a SOCIETY of GENTLEMEN.

Printed for W. OWEN, at Homer's Head, in Fleet-street.

MDCCCLIV.
A NEW AND COMPLETE
DICTIONARY
OF
ARTS and SCIENCES.

D

One of the letters of the alphabet, the fourth in order, and the third consonant, answering to the hebrew daleth, and greek delta.

As a numeral, D denotes 500; and with a dash over it, thus D, 5000. Used in abbreviation, it has various significations: thus, D. stands for doctor, as M. D. doctor of medicine; D. T. doctor of theology; D. D. signifies doctor of divinity, or dono dedit; D. D. D. is used for det, dicat, dedicat; and D. D. D. D. for cognum deo donum dedit.

Among musicians D marks, in thorough basses, what the Italians call descanto, and intimates, that the treble ought to play alone, as T does the tenor, and B the bass. See the article DESCANT.

D. C., in the Italian music, an abbreviation of da capo, that is, from the head, or beginning; these words, or letters, being commonly met with at the end of rondaus, or such airs and tunes as end with the first strain, intimate that the song is to be begun again, and ended with the first part.

Among Roman writers D stands for divus, decimus, deus, diebus, and diutius.

DAB, in ichthyology, the English name of a species of cyprinus, very common in our rivers: it is longer and more slender than the roach, and has ten rays in the fin before the anus. See the article CYPRINUS.

The dace is the slenderest and most rounded in the body of all the cyprini; its usual length is about six or seven inches, though it will grow much larger. See plate LXVI. fig. 1.

DABUIS, a white cotton stuff, made in the East-Indies.

DABUL, a port town in the province of Decan, on the western coast of the hither India, north lat. 17° 30'. east long. 72° 30'.

DAC, the English name of a species of cyprinus, very common in our rivers: it is longer and more slender than the roach, and has ten rays in the fin before the anus. See the article CYPRINUS.

The dace is the slenderest and most rounded in the body of all the cyprini; its usual length is about six or seven inches, though it will grow much larger. See plate LXVI. fig. 1.

DACOLITHUS, in ichthyology, a species of cobitis, or loach, with a forked spine under each eye. See COBITIS.

DACTYL, dactylos, dactylus, in ancient poetry, a metrical foot, consisting of one long and two short syllables, as αδρετοι, and ιμμορέμε.

The dactyl and spondee are the only foot or measures used in hexameter verse; the former being esteemed more frightful, and the latter more solemn and grave. Accordingly, where great activity is signified, we find the dactyls used with much propriety, as in the following verses of Virgil,

5 0 2

Quadru-
DACTYL, among ancient botanists, the name with date. See the article DATE.

DACTYLYC VERSES, in ancient poetry, hexameter verses ending with a dactyl. See DACTYL and HEXAMETER.

DACTYLIOMANCY, dactylomantia, a sort of divination, performed by means of a ring; confessing chiefly in holding the ring fupended by a fine thread over a round table, on the edge whereof were made several marks with the twenty-four letters of the alphabet; and as the ring, in shaking or vibrating over the table, happened to stop over certain of the letters, these being joined together, composed the answer required.

DACTYLIS, in botany, a genus of the triandria digynia class of plants, the flower of which is a bivalve glume, and its fruit a single roundish seed, contained in the cup and flower.

DACTYLYUS, dactyl, in poetry. See the article DACTYL.

DACTYLYUS, in zoology, a name used by the antients for the folen, or razor-fish. See the article SOLEN.

DACTYLYUS IDEUS, the SAME with the belemnites. See BELEMNITES.

DACZAJIE, a silver money current in Persia, and worth five mamoudis. See the article MAMOUDI.

DADO, in architecture, the same with the dye. See the article DYE.

DADUCHI, in antiquity, priests of the goddess Ceres, so called, because at the feasts and sacrifices of that goddess, they ran about the temple, carrying a lighted torch, which they delivered from hand to hand, till it had passed through them all. This they did in memory of Ceres's searching for her daughter Proserpine, by the light of a torch, which she kindled in mount Athenae.

DAEMON, daemon, a name given by the antients to certain spirits, or genii, which appeared to men, either to do them service, or to hurt them. The Platonists distinguishing between gods, demons, and heroes. The gods are those whom Cicero calls Divi majorum gentium. The demons are those whom we call angels. See ANGEL. Christians, by the word demon, understand only evil spirits, or devils. Justin Martyr speaks of the nature of demons, as if he thought them not absolutely spiritual and incorporeal, for which reason he attributes such actions to them as cannot be performed without the intervention of a body. It was a fabulous notion among the antient Hebrews, that Adam begot demons and spirits on certain siccubuses. It is difficult to come at a satisfactory account of the demonology of that people, and therefore it is no easy matter to explain what is meant by the worshipping of demons, or devils, which is the last species of idolatry, according to the division of the rabbins. "The poets, says Minucius Felix, acknowledge the existence of demons; the philosophers make it a matter of dispute. Socrates was convinced of it, for he had a demon always at hand, by whose advice he governed himself in all his actions: the magi are not only acquainted with demons, but perform all their magical operations by the help of demons." The mahometans allow several forts of demons; and the miners of Hungary pretend that, while they are at work in the mines, they often see demons in the shape of little negro boys, doing them no other harm than often extinguishing their lights.

DAEMONIAC, a word applied to a person supposed to be possessed with an evil spirit, or demon. See DAEMON.

In the roman church there is a particular office for the exorcism of Demoniacs. See the article EXORCISM.

DAEMONIACS, in church-history, a branch of the anabaptists, whose distinguishing tenet is, that the devils shall be faved at the end of the world.

DAESON, the macedonian name of the month called by the Athenians, anthesterion. See the article ANTHESTERION.

DAFFODIL, the same with the narciflus of botanists. See NARCISSUS.

DAFFODIL-LILLY, the lilio-narciflus of botanists. See LILIO-NARCISSUS.

SEA-DAFFODIL, a genus of plants called by latin writers pancratium. See the article PANCRATIUM.

DAGO, or DAGERWORT, the capital of an island of the fame name in the Baltic, near the coast of Livonia, subject to Russia, east long. 21° 30', and north lat. 58° 45'.

DAHGESTAN, a country of Asia, bounded by Circasia on the north, by the Caspian Sea on the east, by Chirvein, a province of Persia on the south, and by Georgia on the west. Its chief towns are Tarku and Derbent, both situated on the Caspian Sea.

DAHOME,
DAHOME, a kingdom of Africa, on the Guinea-coast.

DAILE, in the sea-language, signifies the trough for carrying the water off the decks.

DAILY, the same with diurnal. See the article Diurnal.

DAIRY, a house or building where milk, butter, cheese, &c. are made or kept. See the articles Milk, Butter, &c.

DAISY, the english name of a genus of plants, called by authors bellis. See the article Bellis.

Great Daisy, the same with the leucanthemum. See Leucanthemum.

Ox-eye Daisy, a genus of plants, called by botanists boptthalmum. See the article Bupthalmum.

DACKER-HEN, a bird, otherwise called Dalea, in botany, a genus of the Dacker, or Dickers, in our Daleburgh, the capital of the Dalecarlia, a province of Sweden, bounded by Wermeland and the Wener-lake, on the north by Dalecarlia, or Louth, and by Morlachia and the gulf of Venice on the west.

DAM, among lawyers, signifies a boundary or confinement.

DAM, or Dyke. See the article Dyke.

DAMA, the fallow-deer, in zoology, a species of the deer-kind, distinguished by its ramose and compressed, or palmed horns. See Cervus and Deer.

DAMAGE, in law, is generally understood of a hurt, or hindrance attending a person's estate; but, in common law, it is a part of what the jurors are to inquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal: for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article Costs.

DAMAGE-CLEER, was a fee of the tenth part in the common pleas, and twentieth in the king's-bench and exchequer, formerly paid out of all the damages exceeding five marks, recovered in those courts, in actions on the case, covenant, trespass, and all others wherein the damages were uncertain.

DAMAGE-FEASANT, is when a stranger's beasts get into another man's ground, without licence of the owner or occupier of the ground, and there do damage by feeding, or otherwise, to the grass, corn, wood, &c. in which case the tenant whom they damage may therefore take, detain, or impound them, as well in the night as in the day; but in other cases, as for rents and services, and such like, none may detain in the night.

DAMALA, a sea-port town of the Morea in Greece, at the entry of the gulf of Engia.

DAMAN, a port town of the hither India, in the province of Guzurat, or Cambay, situated on the west coast, about eighty miles south of Surat, in 72° 20' east long., and 20° north lat. It is subject to the Portuguese.

DAMARAS, an indian tafta, being a kind of annuisin. See Armoisin.

DAMASCUS, or Scham, the capital city of the south part of Syria, situate ninety

DALLE, a nominal article. 'Butter, cheefe, and north lat. 59°. It is generally understood of a hurt, or hindrance attending a person's estate; but, in common law, it is a part of what the jurors are to inquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal: for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article Costs.

DAMASCUS, or Scham, the capital city of the south part of Syria, situate ninety

DALLE, a nominal article. 'Butter, cheefe, and north lat. 59°. It is generally understood of a hurt, or hindrance attending a person's estate; but, in common law, it is a part of what the jurors are to inquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal: for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article Costs.

DAMASCUS, or Scham, the capital city of the south part of Syria, situate ninety

DALLE, a nominal article. 'Butter, cheefe, and north lat. 59°. It is generally understood of a hurt, or hindrance attending a person's estate; but, in common law, it is a part of what the jurors are to inquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal: for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article Costs.

DAMASCUS, or Scham, the capital city of the south part of Syria, situate ninety

DALLE, a nominal article. 'Butter, cheefe, and north lat. 59°. It is generally understood of a hurt, or hindrance attending a person's estate; but, in common law, it is a part of what the jurors are to inquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal: for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article Costs.

DAMASCUS, or Scham, the capital city of the south part of Syria, situate ninety
DAMASK, a silk-stuff, with a raised pattern, so as to give the appearance of the damask, is that which hath the flowers raised or fattined.

Damaskeen, or Damasking, or Damask, the art or operation of beautifying iron, steel, &c. by making incisions therein, and filling them up with gold and silver wire; chiefly used for adorning sword-blades, guards and grips, locks of pistols, &c.

Damaskeening partakes of the mosaïc, and in botany, a genus of plants called also alisma, and in English the starry-headed water-plantain. See STEEL.

DAMAS, a kind of bilander, used in commerce; a port-town among chemists, damns are generally reckoned of four kinds. The first is the most ordinary; the workmen in the mines know when it is coming, by the flame of their candle's becoming orbicular, and by its lessening gradually till it goes quite out; as also, by the difficulty of breathing. Those that escape fwooning, seldom suffer any harm by it: but such as swoon away, though they miss of downright suffocation, are, on their recovery, tormented with very violent convulsions. Their way of cure is to lay the person down on the earth, in a prone posture, with a hole dug in the ground under his mouth; if this fail, they fill him full of good ale, and if that will not do, they conclude the cafe desperate. The second kind is the pea-bloom damp, being so called from its smell; this damp, they say, always comes in the summer-time, but hath never been known to be mortal. The miners in the Peak of Derbyshire, fancy it arises from the great number of red trefoil flowers, called by them honeyfuckles, with which the limestone meadows of the peak abound. Probably the smell of this damp gives timely notice to get out of the way. The third is the most pestilential, and the strangest of all, if what is said of it be true. They who pretend to have seen it, describe it thus. In the highest parts of the roof of those passages in a mine which branch out from the main grove, they see a round thing that hangs about the bigness of a foot-ball, covered with a film of the thickness and colour of a cobweb. If this bag should be broke by a splinter, or any other accident, the damp immediately flies out, and suffocates all the company. The miners have a way of breaking it at a distance, by means of a stick and long rope; and when they have done this, they purify the place with fire. They will...
will have it, that it flows from the flame of their bodies and candles, ascends up into the highest part of the vault, and there condenses; and that in time, a film growing over it, it becomes peti-

tential.

The fourth is the fulminating, or fire-damp, whose vapour, being touched by the flame of a candle, presently takes fire, and has all the effects of lightening, or fired gun-powder. These are fre-
quentiy met with in the coal-mines, and sometimes, though rarely, in the lead-

The pernicious damp in mines, flew abundantly, that nature affords inflamm-
able air in some cafes; and we have found by experiments, that air can do the fame, and that, very probably, on the same principles with the natural.

Sir James Lowther, having collected the air of some of these dams in bladders, preferred it so well, that when brought up to London, it would take fire at the flame of a candle, on being let out at the orifice of a piece of tobacco-pipe. It is well known to all that are versed in chemical experiments, that most metals emit a great quantity of sulphurous vapours, during the effervescence they undergo in the time of their solutions, in their respective menstrua: this vapour, being received into bladders, in the fame manner with the natural air of Sir James Lowther, has been found to take fire, in the like way, on being let out in a small stream, and answered all the phe-
nomena of the natural kind.

DAMEL, from the french damoiseil, or damoiseau, an appellation antiently given to all young people of either sex, that were of noble or genteel extrac-
tion, as the sons and daughters of princes, knights, and barons: thus we read of Damies Pepin, Damies Louis le Gros, Damies Richard prince of Wales.

From the sons of kings this appellation first passed to those of great lords and barons, and at length to those of gentle-

As prent, damies is applied to all maids or girls, not yet married, provided they be not of the vulgar.

DAMAE, in antiquity, a coin somewhat more than an obolus, used to be put into the mouths of the dead, to pay their passage over the river Acheron.

DANCE, an agreeable motion of the body, adjusted by art to the measures or tune of instruments, or of the voice.

Athenæus concludes, that in the early ages of antiquity, they accounted dancing an exercize becoming perions of honour and wisdom, and that, as such, it had been esteemed by the greatest men in all ages. Thus, Homer calls Merion a fine dancer, and says, that the graceful mein and great agility which he had acquired by that exercize, distinguished him above the rest in the armies of either Greeks or Trojans. Dancing was in very great esteem among the Greeks, even the La-
cedemons encouraged it: but, at Rome, we find the custom was quite otherwize; for there, to ufe the words of Cicero, no man dances unless he is mad or drunk: Cicero reproaches Gabinius with having danced: and we read, that Domitian excluded several members from the senate for having danced.

Dancing in general, was by the antients divided into cubicific, sphericific, and or-

echistic: the cubicific dance was performed with certain wrestlings and contorsions of the body; the sphericific with a fort of ball, or bowl play; but the orcheftic was most usual, and what indeed was dancing properly so called.

Dancing is usuallly an exercize and indication of joy, though Mr. Palleprat af-

ures us, that there are nations in South America, who dance, to shew their sorrow. It has been in ufe among all nations civilized and barbarous, though held in esteem among some, and in contempt among others. It has often been, and still is, sometimes, made an act of religion. Thus David danced before the ark to honour God, and expresses his excess of joy for its return into Sion. Among the Pagans it made a part of the worship paid to the Gods, it being usual to dance round the altars and statues; and at Rome, the falli, who were priests of Mars, danced through the streets in honour of that God. The poets made the Gods themselves dance. The Christians are not free from this superstitution, for in popish countries certain fefivals, particularly those of the sacrament, and passion of our Lord, are celebrated with dancing.

Rope-DANCER, schenobates, a person who walks, leaps, dances, and performs fe-

veral other feats upon a small rope, or wire.

The antients had their rope-dancers, who had four several ways of exercizing their art; the first vaulted, or turned round the rope, like a wheel round its
DANTIA, in botany, a name used by Petiver, for the linaria of Linnæus. See the article Linnæus.

DANTZICK, the capital of regal Prussia, in the kingdom of Poland, situated on the western shore of the river Wefel, or Vistula, which a little below falls into the Baltic Sea: east long. 19°, and north lat. 54°.

It is an excellent harbour, and has the best foreign trade within the Baltic.

DANUBE, one of the largest rivers in Europe, which, taking its rise in the Black Forest in Swabia, runs eastward through Bavaria, Austria, Hungary, and Turky in Europe; discharging itself by several channels into the Pontus Euxinus, or Black Sea.

DAPHNE, in botany, a genus of the oleandria monogynia class of plants, the flower of which consists of a single petal; the tube is cylindric, imperfectly, and longer than the limb, which is divided into four oval, acute, plane, patent segments: the fruit is a roundish berry, containing one cell; the seed is fingle, round and fleshy.

This plant is a strong cathartic, and too rough to be given with safety.

DAPIFER, the dignity or office of grand master of a prince's household. This title was given by the emperor of Constantinople to the czar of Russia, as a testimony of favour. In France the like officer was instituted by Charlemagne, under the title of Dapiferat; and the dignity of dapifer is still subsisting in Germany, the elector of Bavaria assuming the title of arch-dapifer of the empire, whose office is, at the coronation of the emperor, to carry the first dish of meat to table, on horseback.

APPLE-BAY, in the manege; when bay horses have marks of a dark bay, they are called dapple-bays.

APPLE-BLACK; when a black horse has got spots or marks, more black or shining than the rest of his skin, he is called a dapple black.

DARAPTI, among logicians, one of the modes of syllogisms of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

\[
\text{DAR- } \quad \text{Every body is divisible;}
\]

\[
\text{AP- } \quad \text{Every body is a substance;}
\]

\[
\text{TI. } \quad \text{Therefore, some substance is divisible.}
\]

DARBY
DARBY, the capital of Derbyshire, situated on the river Darwent: west long. 1° 25', and north lat. 53°.
It gives the title of earl to the noble family of Stanley, and lends two members to parliament.

DARDANARIUS, or MONOPOLIST, a name antiently given to such as occasioned a scarcity of provisions, particularly corn, by laying it up, to raise its price, in order to sell it again at an extravagant rate. See MONOPOLY.

DARDANELLES, two caskets at the entrance of the Hellespont, where all ships going to Constantinople are examined: east long. 27°, and north lat. 40° 5'.

DARE, in ichthyology, the name with dace. See the article DACE.

DARIEN, a province of Terra Firma, in South America, being the narrow isthmus, which joins north and south America.

DARIUS, in logic, one of the modes of DARK DARK TENT, a portable camera obscura, situated on the river Darkent; east long. 8° 25', and north lat. 50° 25'.

DARTMOUTH, a market-town of Kent, in the Dover-road, fourteen miles south-east of London: east long. 46', and north lat. 5° 25'.

DARTMOUTH, a borough and port-town of Devonshire, situated on the English Channel, twenty-six miles south of Exeter, which lends two members to parliament: west longitude 4°, and north lat. 50° 25'.

DARWENT, a river, which, rising in the Peak of Derbyshire, runs from north to south through that county, and falls into the Trent.

DASYPUS, in zoology, the name with armadillo. See ARMADILLO.

DATA, among mathematicians, a term for such things or quantities as are given or known, in order to find other things thereby that are unknown. Euclid uses the word data (of which he hath a particular tract) for such spaces, lines and angles as are given in magnitude, or to which we can assign others equal.

In algebra, the given quantities, or data, are expressed by the first letters of the alphabet, and the unknown quantities by the last letters; thus, if the problem be, from the sum and product of two quantities given, to find the quantities themselves, the quantities are represented by x and y; and x + y = a the sum given, and y x = b, the product given. See the article EQUATION.

DATA also express, in philosophy and medicine, any quantity which for the sake of a present calculation is taken for granted to be such, without requiring an immediate proof for its certainty, called also the given quantity, number or power.

DATE, in law, is the description of the day, month, year of our Lord, and year of the reign of the king, in which a deed or other writing was made. Antiently deeds had no dates but only of the month and year, and now, if in the date of any deed, the year of our Lord is right, though the year of the king's reign be wrong, it shall not hurt the same. A deed is good, though it has no date of the day, or if that be mistaken, or though it contains an impossible date; but then he that pleads such a deed, must set forth the time when it was delivered: for every deed or writing has a date in law, and that is the day.
DAT [ 838 ]

day of the delivery; and where there is none, a plaintiff, it is laid, may count it of any date.

In writings of importance, the date should be written in words at length. In letters, it is usually written in figures.

An antedate is a date prior to the real time when the instrument was signed.

A post-date is that posterior to the real time when the instrument was paffed.

DATE, doctlylus, the fruit of the phoenix, or great palm-tree. See Phoenix.

Dates are esteemed moderately strengthening and astringent, for which reason they are prescribed for diarrhceas that are habitual, for weakenefles of the stomac'h, and for strengthening the womb; but at present, we make little use of them in England. The best for medicinal purpofes are those of Tunis, and the country thenceabout, of Egypt and many parts of the east; the dates of Spain, and the south of France, though they look well, being never perfectly ripe, and very fubjeft to decay. They are to be chosen large, full, fresh, of a yellow coulour on the surface, soft and tender, not too much wrinkled, and such as have the pulpy part either of a good white throughout, or elle redîff to decay. They are to be carefully looked into, as it has been faid, may count for the time when the instrument was paffed.

DATE-PLUM, in botany, a name ufed by fome for the dioicylus, a difjict genus of plants. See Diospyros.

DATISCA, in botany, a genus of the d. occia-decadria class of plants, the cup of which consists of five leaves: there are no flower-petals; and its fruit is a triangular, unilocular capsule, containing a great number of seeds.

DATISI, in logic, a mode of syllogifms in the third figure, wherein the major is an universal affirmative, and the minor and conclusion particular affirmative propositions. For example,

\( \Gamma a \) - All who serve God are kings,
\( \Sigma i \) - Some who serve God are poor,
\( \Sigma i \) - Therefore fome who are poor are kings.

DATIVE, among grammarians, the third cale in the declension of nouns, expres-

fing the relation of a thing to whose profit or loss some other thing is referred. It is called dative, because usually governed by a verb, implying something to be given to some person. In English, the dative is exprefsed by the signs to or for.

DATURA, thorn-apple, in botany, a genus of the pentandria-monogynia class of plants: the flower consists of an infundibuliform petal; the fruit is a subovated, bilocular, quadrivalvular, and commonly prickly capsule, fixed to the base of the cup; the seeds are numerous and reniform. See plate LXVII. fig. 2.

The thorn-apple is narcotic, and dangerous to be taken internally; but a cataplasm of its leaves and seed is commended for burns.

DAUCUS, the carrot, in botany, a genus of plants belonging to the pentandria diegunia class. The general flower is unequal: the proper one consists of five infless-coxcarded petals, the exterior ones being the largest. There is no pericarpium: the fruit is of an oval figure every way covered with rigid hairs, and is divisible into two parts: the seeds are two, of a fuboval figure, convex and hairy on one side, and plain on the other. See plate LXVII. fig. 3.

There are two kinds of daucus-feeds kept in the shops, distinguished by the name of daucus creticus, and daucus vulgaris. The feeds of the daucus creticus come principally from Germany and the Levant: these feeds are to be chosen fresh, sound, and large, not dusky, and of an acid taste. It is very apt to breed insects, and muft, on that account, be carefully looked into, as it has no virtue when that is the case. The feeds of the cretic and common daucus have the fame general virtues; they are powerful diuretics, and much celebrated as carminatives and uterines: they attenuate thick and viscous humours, and promote the menses. Many people esteem the feed of the common daucus a remedy for the fione: the cretic kind is one of the four leffer hot feeds of the shops.

DAVENTRY, a market-town of Northamptonshire, situated about ten miles north of Northampton: west long. 1° 15', and north lat. 52° 13'.

DAUGHTER, filia, a female child. See the article Children.

As they required greater expences to educate and fettle them in the world, than fons, they were for that reafon more frequently expofed by the antients.
Those who had no legitimate sons, were obliged by the Athenian laws, to leave their estates to their daughters, who were confined to marry their nearest relation, otherwise to forfeit their inheritance, as we find to have been practiced among the Jews, many of whose laws seem to have been transferred by Solon. And if an heiress happened to be married before her father's death, this did not binder the nearest relation to claim the inheritance, and even to take the woman from her husband.

**DAUGHTER of a voice**, among the Jews. See the article BATHOLOL.

**DAVIDISTS**, in church history, a sect of Christian heretics in the XVth century; so called from David George, their leader, who began by giving out that he was the Messiah, and was sent into the world to proclaim the kingdom of heaven, which was quite empty of inhabitants, for want of virtuous and good men; he rejected marriage, and denied the resurrection.

**DAVID'S**, or St. David's, a city, and bishop's see, of Pembroke-shire, situated near the Irish channel, about twenty miles north west of Pembroke; west long. 5° 20', and north lat. 52°.

St. David's is also the name of a town and fort situated on the coast of Cornmandel, in the hither India, about eighty miles south of Fort Saint George; east long. 79° 40', and north lat. 11° 45'.

**DAVIS'S STRAITS** run north west from Cape Farewell, in 60°, north lat. to Baffin's Bay, in 80° north lat. separating Greenland from North America.

**DAVIS'S QUADRANT**, the same with backstaff. See *QUADRANT* and *BACKSTAFF*.

**DAVIT**, in a ship, that short piece of timber with a notch at one end, wherein, by a strap, hangs the fife block. See plate LXVII. fig. 4.

The use of this block is to help up the fluke of the anchor, and to fasten it at the ship's bow, or loof. The davit is liftable from one side of the ship to the other, as there is occasion.

There is also a small davit in the ship's boat, that is set over her head with a shiver, in which is brought the buoy rope, wherewith to weigh the anchor; it is made fast to the earlings in the boat's bow.

**DAUPHIN**, a title given to the eldest son of France, and heir presumptive of the crown, on account of the Province of Dauphiny, which, in 1543, was given to Philip of Valois, on this condition, by Humbert, dauphin of the Viennois. The seigneurs, or lords of Auvergne, have likewise borne the appellation of dauphin, but the dauphins of Auvergne held it not till a good while after those of the Viennois, and even received it from them.

**DAUPHIN, in the history of shell-fish, a species of cochlea, or snail, with a round mouth. See the article COCHLEA.**

**DAUPHIN-FORT**, a fort built by the French on the eastern coast of the island of Madagascar, east long. 48°, and south lat. 24°.

**DAUPHINE, or DAUPHINY**, a province of France, bounded by Burgundy on the north, by Piedmont on the east, by Provence on the south, and by the river Rhone, which separates it from Languedoc and the Lyonois, on the west.

**DAY**, according to the most natural and obvious sense of the word, signifies that space of time during which it continues to be light; in contradistinction to night, being that partition of time wherein it is dark; but the space of time in which it is light, being somewhat vague and indeterminate, the time between the rising and setting of the sun is usually looked on as the day; and the time which lapses from its setting to its rising again, the night.

The word day is often taken in a larger sense, so as to include the night also; or to denote the time of a whole apparent revolution of the sun round the earth, in which sense it is called by some a natural day, and by others an artificial one: but to avoid confusion, it is usual to call it in the former sense simply the day, and in the latter a nychtheaneron, by which term that acceptance of it is aptly denoted, as it implies both day and night.

The nychtheaneron is divided into twenty-four parts, called hours, which are of two sorts, equal and unequal, or temporary. See the article HOUR.

Different nations begin their day at a different hour: thus the Egyptians began their day at midnight, from whom Hippocrates introduced that way of reckoning into astronomy, and Copernicus and others have followed him: but the greatest part of astronomers reckon the day begun at noon, and so count twenty-four hours, till the noon of the next day; and not twice twelve, according to the vulgar computation. The method of beginning the day at mid-night

5 F 2
DAY [ 840 ] DEA

night prevails also in Great Britain, France, Spain, and most parts of Europe. The Babylonians began their day at sunrising, reckoning the hour immediately before its rising again the twenty-fourth hour of the day, from whence the hours reckoned in this way are called the Babylonic. In several parts of Germany, they begin their day at sun-setting, and reckon on till it sets next day, calling that the twenty-fourth hour; these are generally termed Italian hours. The Jews also began their nychthemeron at sun-setting; but then they divided it into twice twelve hours, as we do, reckoning twelve for the day, be it long or short, and twelve for the night; so that their hours continually varying with the day and night, the hours of the day were longer than that of the night, for one half year, and the contrary the other; from whence their hours are called temporary: those, at the time of the equinoxes became equal, because then thole of the day and night are so. The Romans also reckoned their hours after this manner, as do the Turks at this day. This kind of hours, as we do, reckoning twelve for the same becomes due.

Begun their nychthemeron at sun-setting; many hours, as we do, reckoned in this manner, as do the Jews, also dided, it into twice twelve hours, as we do, reckoning twelve for the day, be it long or short, and twelve for the night; so that their hours continually varying with the day and night, the hours of the day were longer than that of the night, for one half year, and the contrary the other; from whence their hours are called temporary: those, at the time of the equinoxes became equal, because then their of the day and night are so. The Romans also reckoned their hours after this manner, as do the Turks at this day. This kind of hours, as we do, reckoned twelve for the same becomes due.

Three days of grace are allowed in England; ten in France and Dantzic; eight at Naples; fix at Venice, Amsterdam, Rotterdam, and Antwerp; four at Frankfort; five at Leipzig; twelve at Hamburg; fix in Portugal; fourteen in Spain; thirty in Genoa, &c. The day of Saturday, Sunday, and Monday, is liable for any robberies committed within that time. Day's man, in the north of England, an arbitrator or person chosen to determine an affair in dispute. Days of prefixing in the exchequer, see the article Remembrancer. Dea Days, dies caniculares. See the article Canicular Days. Intercalary Days. See the article Intercalary Days.

Day-coal, among miners, an appellation given to the upper stratum of the coal, or that which lies next the surface of the earth. See the article Coal. Daze, among miners, denotes the same with the telaugia of naturalists. See the article Telaugia.

DEACON, diaconos, one of the three sacred orders of the Christian church. The word is sometimes used in the New Testament for any one that ministered in the service of God, in which sense bishops and presbyters are filled deacons; but in its restrained sense, it is taken for the third order of the clergy, as appears from the concurrent testimony of antient writers, who constantly file them ministers of the mysteries of Christ, ministers of episcopacy and the church, and the like. The first institution of this order is recorded in Acts, ch. 6.

As to the office of deacons, the most common and ordinary was to be attendant on the bishops and presbyters in the service of the
the altar, to take care of the holy table and all the ornaments and utensils belonging to it, and, in the next place, to receive the offerings of the people, and to present them to the priest; at the same time reciting the names of those that offered. In some churches, tho' not in all, the deacons read the gospel both before and at the communion service; but their most peculiar office was to assist the bishop and prebendaries in the administration of the eucharist, at which their business was to distribute the elements to the people who were present, and carry them to those who were absent. That they were never allowed to condescend at the altar, appears from the testimonies of Hilary, Jerome, and the author of the constitutions. They were permitted, however, to administer solely the sacrament of baptism in some cases. Another part of the office of deacons, was to be a sort of monitors and directors to the people in the exercise of their public devotions in the church; for which purpose they made use of certain known forms of words, to give notice when each part of the service began. Whence they are sometimes called isoprepseis, the holy cryers of the church. Deacons had, by licence and authority from the bishop, a power to preach, to reconcile penitents and grant them absolution, and to represent their bishops in general councils. Their office out of the church was to take care of the necessitous, such as orphans, widows, prisoners, and all the poor and sick who had any title to be maintained out of the public revenues of the church; to enquire into the morals and conversation of the people, and to make their report thereof to the bishop. Whence, on account of the variety of business, it was usual to have several deacons in the same church.

In the roman church, it is the deacons' office to incense the officiating priest or prelate; to lay the corporal on the altar; to receive the paten or cup from the sub-deacon, and present them to the person officiating; to incense the choir; to receive the pax from the officiating prelate, and carry it to the sub-deacon; and at the pontifical mass, when the bishop gives the blessing, to put the mitre on his head, and to take off the archbishop's pall, and lay it on the altar. In England, the form of ordaining deacons, declares that it is their office to assist the priest in the distribution of the holy communion; in which, agreeably to the practice of the antient church, they are confined to the administering the wine to the communicants. A deacon, with us, is not capable of any ecclesiastical promotion, yet he may be a chaplain to a family, curate to a beneficed clergyman, or lecturer to a parish church. He may be ordained at twenty-three years of age, anno currente; but it is expressly provided, that the bishop shall not ordain the same person a priest and deacon in the same day. Deacons, according to St. Paul, should be chaste, sincere, and blameless; neither great drinkers, nor given to filthy lucre; they should hold the mystery of the faith in a pure conscience, and should be well approved before they are admitted to the ministry.

DEACONESS, a female deacon, an order of women, who had their distinct offices and services in the primitive church. This office appears as antient as the apostolical age; for St. Paul calls Phoebe a servant of the church of Cenchrea. The original word is θησυκών, answerable to the latin word ministra. Tertullian calls them viduae, widows, because they were commonly chosen out of the widows of the church; and, for the same reason Epiphanius, and the council of Laodicea, calls them προκῳδιαστις, elderly women, because none but such were ordinarily taken into this office. For, indeed, by some antient laws, these four qualifications were required in every one that was to be admitted into this order. 1. That she should be a widow. 2. That she should be a widow that had born children. 3. A widow that was but once married. 4. One of a considerable age, forty, fifty, or sixty years old. To all these rules admitted of exceptions. Concerning their ordination, whether it was always performed by imposition of hands, the learned are much divided in their sentiments. Baronius and Vulcius think they were not, and make no other account of them than as mere lay-persons. But the author of the constitutions, speaking of their ordination, requires the bishop to use imposition of hands, with a form of prayer which is there recited. We are not, however, to imagine, that this ordination gave them any power to execute any part of the sacredtoral office. They were only to perform some inferior services of the church, and those chiefly relating to the women for whose sakes they were ordained. One part of their office was to assist the minister at the
DEA [842] DEA

the baptizing of women, to undress them for immersion, and to dress them again, that the whole ceremony might be performed with all the decency becoming so sacred an action. Another part of their office was to be private catechists to the women-catechumens who were preparing for baptism. They were likewise to visit and attend women that were sick and in distress; to minifter to the martyrs and confessors in prison; to attend the women gate in the church; and, lastly, to assign all women their places in the church, regulate their behaviour, and preside over the rest of the widows, whence in some canonics they are assigned presbyteros, governesses. This order, which since the tenth or eleventh century has been wholly laid aside, was not abolished everywhere at once, but continued in the Greek church longer than in the Latin, and in some of the Latin churches longer than in others.

DEACONRY, the order or ministry of a deacon or deaconess. See DEACON, &c. DEACONRY, diaconia, is also the name of the chapels and oratories in Rome, under the direction of the several cardinal deacons in their respective quarters. Antiently they were seven in number, as the deaconry of St. Maria in the broad way, the deaconry of St. Eufachio near the Pantheon, &c., answering to the seven regions of the city. They had hospitals annexed to them for the distribution of alms, and an administrator for temporal concerns, called the father of the deaconry, who was sometimes a priest and sometimes a layman. At present, there are fourteen of these deaconries, or hospitals, under the direction of as many cardinals.

DEAD, in general, something void or devenged even by the death of his adversary. DEAD-MAN'S-EYES, DEAD-MAN'S , others. self; DEAD-NETTLE, a genus of plants called the ore on the sea fixes, the main-flats are set taught in them; but then they have only one hole, thro' which the lanyards are passed several times. See plate LXVII, fig. 5.

DEAD-SETTLE, a genus of plants called by botanists lamiun. See LAMIUM.

DEAD-PLEDGE, the same with mortgage. See the article MORTGAGE.

DEAD-RECKONING, in navigation, the calculation made of a ship's place by means of the compass and log; the first serving to point out the course the sails on, and the other the distance run. From these two things given, the skilful mariner, making proper allowances for the variation of the compass, lee-way, currents, &c. is enabled, without any observations of the sun or stars, to ascertain the ship's place tolerably well. See the articles COURSE, SAILING, COMPASS, CURRENT, LEE-WAY, &c.

DEAD-RISING, among sailors, that part of a ship which lies ast, between the keel and the floor-timbers, next adjoining to the stern-post, under the bread-room in a ship of war.

DEAD-ROPEs, on board a ship, such ropes as do not run in any block.

DEAD-SEA, in geography, a lake of Judea, into which the river Jordan discharges itself; being about seventy miles long, and twenty broad.

The water of this lake is both salt, and nauseously bitter; and the bitumen it affords exactly resembles pitch, from which it can only be distinguished by its fulphurous smell and taste.

DEAD-TOPS, a disease incident to young trees, and cured by cutting off the dead parts close to the next good twig or shoot, and claying them over as in grafting. See the article GRAFTING.

DEAD-WATER, at sea, the eddy-water just astern of a ship, so called, because it does not pass away so swiftly, as the water running by her sides does. They say, that a ship makes much dead water, when she has a great eddy following her stern.

DEADLY FEUD, in law, a profession of an irreconcilable hatred, till a person is revenged even by the death of his adversary. This enmity was allowed in the old saxon laws: for where any person was killed, if a pecuniary satisfaction was not made to the kindred of the slain, it was lawful for them to revenge themselves, by arms, on the murderer. See FEUD.

DEADLY-CARROT, a plant called by botanists thapis. See THAPSIA.

DEADLY-NIGHTSHADE, a name given to the belladonna of botanists. See the article BELLADONNA.

DEADS, among miners, denotes the earth or other fusible substances which inclose the ore on every side. Hence, breaking up the deads, is the removing these substances for the convenience of carrying on their work.
DEAFORESTED, a term found in law-books, signifying that a place is discharg-ed from being a forest, or freed from the forest-laws.

DEAFNESS, the state of a person who ei-ther wants the sense of hearing, or has it greatly impaired.

The causes of deafness are a cutting off the external ear, or an obstruction of the auditory passage, from wax, or other things; from a rupture of the membrane of the tympanum; or when it is cor-roded, or ulcerated, or the auditory nerve is obstructed or compressed. External causes, are falls from high places; ex-cessive noise, such as the explosion of can-non; likewise acute diseases near their state, which are like to terminate by a critical hemor-rhage.

As to the prognostics, those who are born deaf are rarely cured. A real deafness is hard to remedy. A deafness in acute diseases, with crude urine, foretells a delirium: but when the signs of coction are good, it portends a critical hemor-rhage.

With regard to the cure, if the obstruc-tion be in the external cavity of the ear, it is discernible by the sight. If there is occasion to syringe the ear, a decoction of fag and rosenary-flowers will be proper, with equal parts of water and white-wine: but great caution should be used. Some pump the head with warm-bath waters: some say, the eggs of ants bruised, and put into the ear, with the juice of an onion, cures the most invertebrate deafnesses.

Others affirm, that a salivation will some-times perform a cure. A critical deafness will cease of itself. Etmüller recom-mends amber and mulk; and hardness of hearing has been often cured by putting a grain or two of mulk into the ear with cotton.

Hoffman says, deafness sometimes arises from a slackness of the auditory nerves, which often happens from too great a humidity, which, if neglected, will ter-minate in a perpetual and incurable deaf-ne ss, and may be dispersed, if taken in time, by proper cephalics and sudorifics. Some, for this purpose, recommend equal parts of spirit of lavender and hungary-water, which should be droped warm into the ear. Lindanus advises the gall of an eel, mixt with spirit of wine; and others, the fumes of sulphur conveyed into the ear with a pipe or funnel: but regard must always be had to the caufe, if dis-coverable.

Heiffer informs us, that medicinal waters drank in the summer time pretty largely, are the best means as preservatives, and for curing disorders of the ears; and that they often perform more than any other remedies whatever.

Those born deaf are also dumb, as not being able to learn any language, at least in the common way: however, as the eyes, in some measure, serve them for ears, they may sometimes understand what is said, by observing the motion of the lips, tongue, &c. of the speaker.

DEAL, a thin kind of fir-planks, of great use in carpentry: they are formed by sawing the trunk of a tree into a great many longitudinal divisions, of more or less thickness, according to the purposes they are intended to serve.

Deals are rendered much harder, by throw-ing them into salt-water as soon as they are fawed, keeping them there three or four days, and afterwards drying them in the air or fun; but neither this nor any other method yet known, will preserve them from shrinking.

Deals called Burgendorp deals, the hun-dred containing fix score, pay on importation 3s. 8½d. and draw back 3s. 5s. the rate 12l. Membro deals, fix score, pay 1s. 28. 7½d. and draw back 1s. 8½. the rate 4l. Norwegian deals, fix score, pay 1s. 8½s. 7½d. and draw back 1s. 8½s. 9d. the rate 15l. Deals from Russia, and all other coun-tries not particularly rated, exceeding twenty foot in length, pay 4l. 5s. 10½d. and draw back 3l. 18s. 9d. the rate 15l. Deals from Sweden, or any other coun-try, of twenty feet in length or under, not otherwise rated, the 120, pay 1s. 8½d. and draw back 1s. 6s. 3d. the rate 5l.

DEAL, in geography, a port-town of the county of Kent, between which and the Goodwin-fands, the shipping-usually rides in the Downs, in going out or coming home: it is about sixty-seven miles eastward of London: east long. 1° 30′, and north lat. 51° 16′.

DEAN, an ecclesiastical dignitary in cathedral and collegiate churches, and head of the chapter.

As there are two foundations of cathedral churches in England, the old and the new, so there are two ways of creating deans. Those of the old foundation, founded before the suppres-sion of mona­siches,
monasteries, as the deans of St. Paul's, York, &c. are raised to that dignity much after the manner of bishops, the king first sending his congé d'élire, the chapter electing, and the king granting his royal consent, the bishop confirms him, and gives his mandate to install him. Those of the new foundation, whose deaneries were raised upon the ruins of priories and convents, such as the deans of Canterbury, Durham, Ely, Norwich, Winchester, &c. are donative, and installed by virtue of the king's letters patent, without either election or confirmation. Canonists distinguish between deans of cathedral and those of collegiate churches. The first, with their chapter, are regularly subject to the jurisdiction of the bishop. As to the latter, they have usually the contentious jurisdiction in themselves, though sometimes this belongs to them in common with the chapter. There are cathedral churches which never had a dean, and in which the bishop is head of the chapter, and in his absence, the archdeacon: such are the cathedrals of St. David and Landaff. There are also deans without a chapter, as the dean of Battle in Sussex, dean of the arches, &c. and deans without a jurisdiction, as the dean of the chapel royal. In this sense the word is applied to the chief of certain peculiar churches or chapels.

Rural Dean, called also archprelbyter, originally exercised jurisdiction over ten churches in the country, and afterwards became only the bishop's substitute, to grant letters of administration, probate of wills, &c. to convocate the clergy, and signify to them sometimes by letters, the bishop's will, and to give induction for the archdeacon. Their office is now lost in that of the archdeacons and chancellor.

Dean of a monastery, was a superior established under the abbot, to eafe him in taking care of ten monks, whence he was called decanus.

Dean and Chapter, are the bishop's council to assist him in the affairs of religion, and to attend to every grant which the bishop shall make to bind his succedors. As a deanery is a spiritual dignity, a man cannot be a dean and prebendary of the same church.

Dean, in geography, the name of a forest in Gloucestershire, lying northward of the river Severn.

DEARTICULATION, the same with diarthrosis. See Diarthrosis.

DEATH, moris, is generally considered as the separation of the soul from the body; in which sense it stands opposed to life, which consists in the union thereof. Physicians teach, that as the life of those animals we call perfect consists in a continued flux and reflux of the blood, nervous juice and air, to and from the principal organs, so a man may be reckoned dead when he no longer breathes, and his heart and arteries have left off all circulation and pulsation. But Dr. Stevens, as we find in the Medical Essays, does not admit this doctrine, being of opinion, that after the motion of the heart, arteries, and lungs ceases, there often remains a small degree of vital principle deserving attention. He then propounds a theory of his own, in consequence of which it seems, that death does not inevitably attend an entire organic rent of what we call the folds of the body; nay, that one cannot be called dead, till the energy of the blood is so far gone, that, though affiʃted by all possible means, it can never be again able to fill and dilate into contraction the right sinus venosus, and auricle of the heart.

Men, says lord Bacon, fear death as children fear the dark; and as that natural fear in children is increased by frightful tales, so is the other. Groans, convulsions, weeping friends and the like, shew death terrible; yet there is no passion so weak but conquers the fear of it, and therefore death is not such a terrible enemy. Revenge triumphs over death, love shrieks it, honour aspires to it, dread of shame prefers it, grief flies to it, and fear anticipates it. The fame noble author thinks it the office of a physician to procure easy deaths, as well as to restore health.

In law, there is a natural death and a civil death: natural, where nature itself expires; civil, where a person is not actually dead, but adjudged so by law. Thus, if any person, for whose life an estate is granted, remains beyond sea, or is otherwise absent seven years, and no proof made of his being living, he shall be accounted naturally dead.

DEATH-WATCH, in zoology, an insect nearly of the size of the common House-fly, frequent among old wood, furniture, &c. It is of an oblong and flat triangular figure, and of a pale brownish-white colour; and the noise,
noife, resembling the beating of a watch, is the love-note of these animals, when the male or female woo each other.

DEAURATA, in ichthyology, a fish of the cyprinus kind, with forty rays in the fin near the anus. See Cyprinus.

DE BENE ESSE', a Latin phrase used in our law in a doubtful meaning, as to take of allowances, bounties or premiums; which tries, in order taken the debentures for foreign goods, all to be done, and pay a duty of eight-pence. If exported to any other foreign ports than Ireland, the word Ireland must be added to the oath after Great Britain. 

DEBENHAM, a market-town of Suffolk, about twenty miles east of Bury; east long. 1° 26', and north lat. 52° 26'.

DEBENTURE, a term of trade used at the custom-house for a kind of certificate signed by the officers of the customs, which intitles a merchant exporting goods to the receipt of a bounty or drawback. All merchandizes that are designed to be taken on board for that voyage being entered and shipped, and the ship being regularly cleared out, and sailed out of port on her intended voyage, debentures may be made out from the exporter's entries, in order to obtain the drawbacks, allowances, bounties or premiums; which debentures for foreign goods, are to be paid within one month after demand. And in making out these debentures, it must be observed, that every piece of vellum, parchment, or paper, containing any debenture for drawing back customs or duties, must, before writing, be stamped, and pay a duty of eight-pence. The forms of debentures vary, according to the merchandise exported. In the execution of debentures for tobacco, it must be particularly observed, 1. That debentures for the same quantity, may be made in one or more parchments. 2. That the exporter's oath must be printed, specifying whether he acts for himself or by commission. If exported to any other

DEBENTURE, among book-keepers, is used to denote a kind of bond or bill first given in 1649, whereby the government is charged to pay the holder creditor, or his assigns, the money due on auditing the account of his arrears. Debenture is likewise used in the exchequer, and given to the king's servants for the payment of their wages.

DEBET, among merchants, signifies the sums due to them for goods sold on credit, for which they have charged their journal or ledger. It is more particularly understood of the remainder of debts, part of which has been paid on account.

DEBET, among book-keepers, is used to express the left-hand page of the ledger, to which are carried all articles supplied or paid, on the subject of an account.

DEBET and SOLET, in law, are formal words used in divers writs; sometimes both together, and sometimes only debet. As if a person by writ sues to recover any right whereof his ancestor was dispossessed, then he sues the word debet alone; but where he sues for any thing that is now first of all denied him, in that case he sues debet and folet.

DEBET & SOLET, be owes and detains, in law, are terms used in bringing of actions. Debt against an heir, must be in the debet and solet; but against
DEBT [846] DEC

DEBT, for money due in the time of the tellator, the action ought to be in the detinnet.

DEBTILITY, among physicians, a relaxation of the solids, occasioning oftentimes weakness and faintings.

DEBRECHEN, a town of upper Hungary, about seventy-seven miles east of Buda; east lon. 21° 10', and north lat. 47° 45'.

DEBRUIZED, in heraldry, a term peculiar to the English, by which is intimated the grievous restraint of any animal, debared of its natural freedom, by any of the ordinaries being laid over it.

DEBT, debitum, in law, any thing due to another, whether it be money, goods, or services; or, the action brought for recovering the same.

Where money is due upon any speciality, an action of debt, and no other, lies. On a bond, debt may be brought against the obligor or his heir, who has lands by descent, if the executors have not sufficient to pay it; and an heir mediate may be sued for debt, as if he were an immediate heir. If a person acknowledges, by deed, that he has so much of another's money in his hands, here the action of debt will lie for it; and where one owes a sum of money to another, who has his note under hand, without a feal, action of debt on a mutuatus lies. Debt lies also on a recognizance; so upon a statute merchant, which is in nature of a bond, or obligation: but it is said to be otherwise, in case of a statute staple.

Whether an action of debt be brought on a bill, bond, leave, &c. the several writings are to be well considered, by which the plaintiff warrants his action, and the sum due must be rightly set forth: thus, if it be for rent, the time of commencement and ending must be specified; and the judgment, where the demand is in the debt and detinnet, is to recover the debt, damages, and costs of suit. But in a debt on a single bill, a defendant may plead payment, before the action brought in bar; and, on bond, he may bring in the principal, interest, and costs pending the action, and thereupon be discharged.

DEBT to the king, comprehends in it all rents, fines, amerciements, and other things due to the king, whose debts are preferred before those of a subject; and until his debt is satisfied, he may protect the debtor from the arrests of others. Pledges shall not be defrauded for these debts, where the principal is sufficient.

DEBTOR, a person who owes any thing to another, in contradistinction to creditor, which is he to whom the debt is owing.

Where debt is a simple contract, it follows the person of the debtor, and, it is said, of the creditor, as to actions brought, &c.

There have been divers statutes discharging debtors out of prison, when they had no effects to pay their creditors. See the article PRISONER.

DEBTOR, in merchants' accounts. See the article BOOK-KEEPING.

DECACHORDON, in antiquity, a musical instrument with ten strings, called by the Hebrews hafur, being almost the same as our harp, of a triangular figure, with an hollow belly, and founding from the lower part.

DECACTIS, a species of star-fish, with ten rays. See the article STAR-FISH.

DECAGON, in geometry, a plane figure with ten sides and ten angles: it is called a regular decagon, when all the sides and angles are equal.

If we suppose the radius of a circle to be $r$, then will $\sqrt{\frac{5}{4}r^2 - \frac{1}{4}r}$, or $\sqrt{\frac{5-1}{4} + r^2}$, be the side of a decagon inscribed in that circle. Again, suppose the side of a decagon to be 1, the area thereof will be 3.69; whence as 1 to 3.69, so is the square of the side of any given decagon to the area of that decagon.

DECATITRON, in antiquity, a coin equivalent to 10 1/2 attic oboli. See OBOLUS.

DECALOGUE, the ten precepts or commandments delivered by God to Moïse, after engraving them on two tables of stone.

There are several refined speculations concerning the promulgation of those divine laws, as whether they were delivered by an angel, deputed by God for that purpose, or by the deity himself; and, if by the latter, whether it was the first or second person of the godhead that took upon him to be the legistrator of the Jews: but these are debates of such a nature, that nothing can be concluded about them. The Jews, by way of excellence, call these commandments the ten words; from whence they had afterwards the name of decalogue: but it is to be observed, that they joined the first and second into one, and divided the last into two: they understand that against stealing, to relate to the stealing of men, or kidnapping,
kidnapping; alleging, that the stealing
one another's goods or property, is for­
bidden in the last commandment.

The Talmudists, and after them Pot­
tellus, pretended that the decalogue was
written, or engraved, in letters of light,
i. e. luminous, shining letters, and that
the engraving went quite thro' the tables.

The emperor Julian objected to the
decalogue, that the precepts it contained
(those only excepted which concern the
worship of false gods, and the observation
of the sabbath) were already so familiar
to all nations, and universally received,
that they were unworthy, for that very
reason, to be delivered, by so great a le­
gillator, to so peculiar a people. The
church of Rome has struck the second
commandment quite out of the deca­
logue, and to make their number com­
plete, hath split the tenth into two. The
reason of which may be easily conceived.

DECAMERIS, a term used by some writ­
ers upon found, to denote a tenth part.
See the article SOUND.

DECAMPING, in military affairs, is the
marching of an army from the ground
where it before lay encamped. See CAMP.

DECAN, a province of the hither India,
bounded by the province of Cambaya, or
Guzurat, on the north; by Golconda and Berar, on the east; by Vifapour, on the south; and by the Indian ocean on
the west. Its chief inland town is Au­
rengabad, and upon the coast the town of Bombay.

DECANDRIA, in the Linnaean system of
botany, a clas of plants, the great cha­acteristic of which is, that they have
hermaphrodite flowers, with ten itamina
in each. See BOTANY, STAMINA, &c.

DECANTATION, among chemists, &c.
the gently pouring off a liquor from its
faces, by inclining the lip or canthus of
the vessel; whence the name.

The design of this operation, is in order
to have the liquor free from the sediment,
which, upon standing, it lets fall to the
bottom of the vessel.

DECANUS, in roman antiquity, an officer
who precided over ten other officers, and
was head of the contubemium, or serjeant
of a file of soldier.

DECAPITE', or DEFALT, in heraldry.
See the article DEFALT.

DECAPROTI, decemprimi, in roman an­
tiquity, officers for gathering the tributes
and taxes.

The decaproti were also obliged to pay
for the dead, or to answer to the empe­
or for the quota parts of such as died,
out of their own estates.

DECASTYLE, in the antient architec­
ture, a building with an ordinance of
ten columns in front, as the temple of
Jupiter Olympius was.

DECEIT, dolus, in law, a subtle trick, or
device, to which may be added all man­
ner of craft and collusion, or underhand
practice, used to defraud another, by any
means whatever.

Deceit is an offence both by common law
and by statute. All practices of defraud­
ing, or endeavouring to defraud, another
of his right, are punishible by fine and
imprisonment, and sometimes pillory,
&c. and there is a writ called deceptione,
that lies for one who receives injury or
damage, &c.

A writ of deceit lies against attorneys,
for loss sustained by their default; also
against bakers, brewers, and other arti­
cfers, for not selling good commodities,
or refusing to perform a bargain: in all
which cases, they are, by statute, liable
to penalties in proportion to their offence.

DECIVED, in the manege: a horse
is said to be deceived, upon a demivault of
one or two treads, when working, for in­
stance, to the right, and not having
yet finished above half the demivault, he
is pressed one time or motion forwards,
with the inner leg, and then is put to a
reprise upon the left, in the same cadence
with which he began; and thus he re­
gains the place where the demivault had
been begun to the right, and works to
the left: thus a horse may be deceived
upon any hand.

DECEMBRE, in chronology, the last
month of the year, consisting of thirty­
one days, and so called as being the tenth
month in the roman year, which com­
enced with march. See the articles
YEAR and MONTH.

DECOMPEDA, stamno, in antiquity, a
rule or rod divided into ten feet, each of
which was subdivided into inches, and
those into digits, used in measuring of
land, and, by architechts, in giving the
proper dimensions and proportions to the
parts of their buildings.

DECEM TALES, in law, a writ that stifles
directed to the sheriff, whereby he is
commanded to make a supply of jury­
men, where a full jury does not appear
on a trial at bar.

DECEMVIRI, in roman antiquity, ten
magistrates chosen annually at Rome, to
govern the commonwealth instead of con­
Q. a

sils,
ful, with an absolute power to draw up and make laws for the people. One of the decemviri had all the ensigns and honours of the function, and the rest had the like in their turn, during the year of their decemvirate. In them was vested all the legislative authority ever enjoyed by the kings, or, after them, by the consuls. It was the decemvir that drew up the laws of the Twelve Tables, thence called leges decemvirae, which were the whole of the roman law, for a considerable time.

There were also other decemviri, created on frequent emergencies, to manage and regulate certain affairs, as conducting colonies, presiding at feasts, taking care of sacrifices, keeping the sibyls books, &c.

DECENNIALIA, ancient roman festivals celebrated by the emperors, every tenth year of their reign, with sacrifices, games, and largesse for the people. The emperor Augustus first instituted these solemnities, in which he was imitated by his successors: at the same time the people offered up vows for the emperor, and for the perpetuity of the empire, which were therefore called vota decennalia. Augustus's view in establishing the decennalia was to preserve the empire and the sovereignty power without offence or restraint to the people.

DECENNARY, in our old law-books, denotes the precinct or district of ten cities. See the next article.

DECENNERS, DECINERS, or DOZINERS, in our ancient law, such as had the oversight of ten cities, for the maintenance of the king's peace, the limits of whose jurisdiction was called decennia.

These seem to have had a great authority in the time of the Saxons, taking cognizance of causes within their circuits, and redressing wrongs, by way of judgment. In later times, the word came to signify such a person as by oath of loyalty to his prince, was settled in the combination or society of such a dozen.

DECEPTIONE, in law, a writ which lies against a juror, for having taken money of either party in a suit, on account of giving his verdict. This writ is so called because it recovers ten times as much as he took. Any person, though not a party in the suit, may bring this writ in the name of the king and himself, and recover the like; one half to the crown, and the other to the informer or prosector, which action the king may not release by pardon, after it is commenced.

DECIL, in astronomy, an aspect or position of two planets, when they are distant from each other a tenth part of the zodiac.

DECIMAE, TITHES. See TITHE.

DECIMAL ARITHMETIC, the art of computing by decimal fractions.

DECIMAL FRACTION, that whose denominator is always 1, with one or more cyphers: thus, an unit may be imagined to be equally divided into 10 parts, and each of these into 10 more; so that a continual decimal subdivision the unit may be supposed to be divided into 10, 100, 1000, &c. equal parts, called tenth, hundredth, thousandth parts of an unit. In decimal fractions, the figures of the numerator are only expressed, the denominator being omitted, because it is known to be always an unit with so many cyphers as there are places in the numerator.

A decimal fraction is distinguished from an integer with a point prefixed; as .2 for 2/10, .34 for 34/100, .67 for 67/100, &c. The same is observed in mixed numbers, as 67.8, 67.89 for 6789/100, 0.0005 for 5/1000, &c.

Ciphers at the right hand of a decimal fraction alter not its value; for .5 or .50 or .500 is each of them of the same value, equal to 1/2, or 1: but cyphers at the left hand, in a decimal fraction, decrease the value in a tenfold proportion; for .05 is 5/100, .005 is 5/1000, &c.

Decimal fractions are easily reduced into a common denominator, by making, or even supposing, all of them to consist of the same number of places; for .3 = .300, .450, .0089, may be written thus, 3/10, 450/1000, 89/10000, all which consisting of four places, their common denominator is an unit with four cyphers, namely 10000.

Addition and subtraction of decimals are the same as in whole numbers, when the places of the same denomination are set under
DEC [849]

under one another, as in the following examples:
To 34.25 From 16.5
Add 3.026 Subtract 1.25
Sum 37.276 Rem. 16.375

In multiplication the work is the same as in whole numbers, only in the multiplier, separate, with a point, so many figures to the right hand as there are fractional places both in the multiplicand and multiplier; then all the figures on the left hand of the point make the whole number, and those on the right a decimal fraction.

It is to be noted, that if there be not so many figures in the multiplier, as ought to be separated by the preceding rule, then place cyphers at the left, to complete the number, as may be seen in Example V.

Ex. I. Mult. 456 Ex. II. Mult. 45.6
by 21.3 by 21.3
1368 Product 971.28
456
912
Product 9712.8

Exam. III. Multiply 456 by 0.213
971.28

Example IV. Multiply 45.6 by 0.213
Product 9.7128

Ex. V. Multiply 0.0456 by 0.213
Product 0.0097128

In division the work is the same as in whole numbers, only in the quotient, separate, with a point, so many figures to the right hand for a decimal fraction, as there are fractional places in the dividend, more than in the divisor, because there must be so many fractional places in the divisor and quotient together, as there are in the dividend.

As division of decimal fractions is extremely difficult, especially with regard to the value of the figures of the quotient, we shall here give a general rule for ascertaining their values, viz.

Rule. Place the first multiple of the divisor under the dividend, as in operations of common division; then will the unit's place of this multiple stand under such a place of the dividend, as the first significant figure of the quotient is to be; that is, the first significant figure of the quotient will be of the same name, or value, with the figure of the dividend which stands above the unit's place of the multiple.

This rule will hold in all cases. 1. When the number of decimals are equal in the divisor and dividend, the quotient will be integers, or whole numbers: for placing the first multiple of the divisor under the dividend.

Example I. according to the rule, 8.45)295.75(35 (Exam. I.) the unit's place 5, is found to stand under 9, the place of tens in the dividend; so that 5, the first figure of the quotient, must be tens also, and 5, the next figure, units. 2. When the number of decimals in the dividend, exceed those in the divisor, as in Example II. where 24.3)780.516(32.12 72.9 the unit's place of the multiple of the divisor, stands under 8, the place of tens of the dividend; whence 3, the first figure of the quotient, must be tens also; and 2, the next figure, units; so that the remaining figures, 12, must be decimals. This is done, more shortly, by making as many figures of the quotient decimals, as there are more decimal places in the dividend than in the divisor. 3. When there are not so many decimal places in the dividend, as there are in the divisor, cyphers must be added to the right hand of the dividend, to make them equal: thus, to divide 192.1 by 7.684, as in Example III, add two cyphers, to make the decimals equal; and, by the above rule, the quotient 25 will be found to be integers, as 5, the place of units, stands under 9, the place of tens. 4. If after division there are not so many figures in the quotient as there ought to be decimal parts, supply this defect by prefixing cyphers to the quotient found: thus, in Example IV.

Example III. 7.684)192.100(25 15.365
38420
38420
669

Example IV. 957.7-25406.00758

6699

Thus, 1 = 1.0 = .5, and 2 = 3.00 = .75, and
DECIPHERING, the art of finding the alphabet of a cipher.

Every language has, besides the form of its characters, something peculiar in the place, order, combination, frequency, and number of the letters; to all which particular regard is to be had in deciphering. In all languages, however, the following rules ought to be observed: 1. One word is to be compared with another, that their resemblance and difference may be known. 2. No word can be without a vowel. 3. A word of one letter is always a vowel, or a consonant with an apostrophe. 4. The vowels recur more frequently than the consonants. 5. Double vowels may be at the beginning of a word, but not double consonants. 6. Double characters at the beginning of a word are always vowels. 7. Short words of two or three letters have two or three, or one or two consonants. 8. The vowels are therefore most easily learned from the short words which are to first be considered by the decipherer. 9. If double characters are preceded by a single letter, the letter is a vowel. 10. In languages abounding with diphthongs, one vowel is often joined with another. 11. The letter that precedes or follows double consonants is, if a consonant, always one of the liquids, l, m, n, r. 12. If two different characters occur, of which the latter is often conjoined with various letters, and the former is never found either by itself, or followed by any other letter, those two are qu. 13. These letters qu are always followed by a vowel. 14. One vowel recurs more frequently than another, as do the consonants, according to the language, &c.

DECLARATION, in law, is a formal pleading in writing the ground of complaint of the plaintiff, in an action against the defendant, where the plaintiff is supposed to have received some injury. This declaration ought to be plain and certain, because it impeaches the defendant and obliges him to answer thereto. It is also an exposition of the writ, with the addition of time, circumstances, &c. and must be true as well as clear, for the court will not take things in it by implication; and it sets forth the names both of the plaintiff and defendant, the nature and cause of the action, &c. and the damage received.

Declaration, in an action real, is termed a count. See the article Count.

DECLARATION is also used for a confession which the Quakers are obliged to make and subscribe, instead of the oaths of supremacy, &c. See Affirmation.

DECLARATION, a term of the court-house, and of commerce in France, contains a particular account or invoice of what is contained in the bales, &c. brought to the offices for entrance inward or outward.

DECLINATION,
DECLINATION, in grammar, an inflexion of nouns according to their divers cases, as nominative, genitive, dative, &c. It is a different thing in the modern languages, which have not properly any cases from what it is in the antient greek and latin. With respect to languages, where the nouns admit of changes, either in the beginning, the middle, or ending, declension is properly the expression of all those changes in a certain order, and by certain degrees called cases. With regard to languages, where the nouns do not admit of changes in the same name, declension is the expression of the different states a noun is in, and the different relations it has; which difference of relations is marked by particles, and called articles, as *a*, *the*, *of*, *to*, *from*, *by*, &c. See Article.

DECLINATION of a disease is when it is past its height.

DECLINATION, in astronomy, the distance of any celestial object from the equinoctial, either northward or southward. It is either true or apparent, according as the real or apparent place of the object is considered.

The declination being an arch of a secondary of the equinoctial intercepted between a given point and the equinoctial, and perpendicular to the same, the declination of a star, &c. is found in the following manner. First observe the altitude of the pole, as *PR* (plate LXVII. fig. 6.) this subtracted from 90°, gives the height of the equator *AH*; then the meridian altitude of the star *HD* being observed, if it be greater than the altitude of the equator *AH*, the latter subtracted from the former, leaves the declination northward *AD*: or if the altitude of the star *HT* be less than that of the equator *AH*, the former subtracted from the latter, leaves the declination southward *TA*. If the star be in the quadrant *ZR*, then the least altitude *MR*, subtracted from the altitude of the pole *PR*, leaves the distance from the pole *PM*; which subtracted again from the quadrant *PQ*, leaves the declination *MQ*.

By this method are constructed the tables of declination of the fixed stars, given us by Ricciolus and Dechales.

To find the sun’s or star’s declination by the globe, bring the sun’s place, or the star, to the meridian, and the degrees from the equinoctial there reckoned, either north or south, are the declination at noon.

The greatest declination of the sun, or of the ecliptic, is commonly computed 23° 30’. See ECLIPTIC.

Circle of Declination. See Circle.

Refraction of the Declination. See the article Refraction.

Declination of the sea-compas, or needle, is its variation from the true meridian of any place. See Variation.

Declination of a wall or plane for dial is an arch of the horizon, contained either between the plane and the prime vertical circle, if you reckon it from the east or west; or else between the meridian and the plane, if you account it from north or south. There are many ways given by authors for finding the declination of a plane, of which all those that depend upon the magnetic needle deserve to be suspected on many accounts. The common method, by finding the sun’s horizontal distance from the pole of the plane, is subject to many errors and difficulties. The way therefore we would recommend as the best for finding the declination of a plane, is by a declinator. See the next article.

DECLINATOR, or DECLINATORY, an instrument contrived for taking the declinations, inclinations, and declinations of planes. It is constructed in the following manner: on a square wooden board, ABCD (plate LXVII. fig. 7. n° 1.) describe a semicircle AED, and divide the two quadrants AE and ED into 90°, each beginning from E, as in the figure: then having fixed a pin in the center F, fit a ruler HI upon the same, moveable thereon, with a box and needle K (ibid. n° 2.) In order to take the declination of a plane, apply the side AD to the plane proposed, as MN (ibid. n° 3.) and move the ruler FG, with the compass G, about the center F, till the needle rest upon the line of the magnetic meridian of the place: if the ruler cut the quadrant in E, the plane is either directly northern or southern; but if it cut between D and E, the plane declines to the west; and if between A and E, to the east, by the quantity of the angle GFE.

Would you take the inclinations and declinations of planes with this instrument, instead of the ruler and needle, a thread with a plummet is fitted on a pin in the center F; then the side BC of the declinator ABCD (ibid. n° 4.) being applied to the proposed plane, as IL, if the plummet FG cut the semi-circle AED,
DECORATION, in architecture, is the reduction of a body into its principles or component parts. See the article ANALYSIS.

DECORATION, in architecture, is used for whatever adorns a building, either without or within. The orders of architecture contribute a great deal to the decoration; but then the several parts of these orders must have their just proportion, characters and ornaments, otherwise the finest order will bring confusion rather than richness. See CORINTHIAN, COMPOSITE, &c. ORDERS.

Decorations, in churches, are paintings, festoons, vases, &c. occasionally applied to the walls, but with such discretion as not to destroy the form and beauty of the architecture, as is practiced in Italy at the solemn feasts. See FESTOON, VASE, &c.

DECORATION also signifies the scenes of theatres. See the article SCENE. In operas and other theatrical performances, they must be often changed, in conformity to the subject.

DECORATION, in architecture, is the Boitahenels of a building, and the several parts and ornaments thereof, to the situation and occasion. Vitruvius is very exact in this point, and gives rules expressly for the appropriating the several orders to their natural characters.

DÉCOUPE, in heraldry, the same with barking of trees. See BARKING.

DÉCOUPE, in heraldry, is the same with the scene of a place made for catching wild-fowl. Hence,

DÉCOUPE, in heraldry, is a duck that flies abroad, and draws into the company of wild ones, which by her allurements she draws into the decoy.

DÉCOUPE, in heraldry, the fame as uncoupled: thus, a chevron decoupled, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DÉCOUPE, in heraldry, the same with decrement. See DÉCREMENT.

DÉCOY, a place made for catching wild-fowl. Hence,

DÉCOY-DUCK is a duck that flies abroad, and lights into company of wild ones, which by her allurements she draws into the decoy.

DECREES, an order made by a superior power, for the regulation of an inferior.

DECREES, in the civil law, is a determination that the emperor pronounces upon hearing a particular cause between plaintiff and defendant.

DECREES of COUNCILS are the laws made by them, to regulate the doctrine and policy of the church.

DECREES in chancery, are the determinations of the lord chancellor, upon a full hearing of the merits of a cause.
DECREET, in the law of Scotland, a final decree or judgment of the lords of session, from which an appeal only lies to parliament, where we find them but too often reversed; a circumstance fortunately not much to the honour of the august bench, from whence the appeal lies.

DECREMEMENT, in heraldry, signifies the wane of the moon from the full to the new. See the article Moon.

The moon in its state is called moon decrecant, or in decrees; and when borne in coat-armour, faces to the left side of the escutcheon, as she does to the right side when in the increment. See the article Crescent.

DECREPITATION, in chemistry, the act of calcining salt over the fire, till it cease to crinkle. The design of this is to free the salt from superfluous moisture; but as it is thereby rendered porous, and apt to imbibe the humidity of the air, it must always be kept very close afterwards, left the air should moisten it anew.

DECREPITATION is also applied to the cracking of the salts during the operation.

DECERTAL, in the canon-law, a letter of a pope, determining some point or question in the ecclesiastical law. The decretales compose the second part of the canon-law. The first genuine one acknowledged by all the learned as such, is a letter of pope Sisiricus, written in the year 381, to Himerus bishop of Tarragona, in Spain, concerning some diforders which had crept into the churches of Spain. Gracian published a collection of decretales, containing all the ordinances made by the popes, till the year 1150.

Gregory IX. in 1227, following the example of Theodosius and Justinian, formed a constitution of his own, collecting into one body all the decisions, and all the cauæs, which served to advance the papal power; which collection of decretales was called the Pentateuch, because it contains five books.

DECTA, in botany, a name used by some for the garden-beet. See Beet.

DECUMANI DENTES, in heraldry, the name with dancette. See the article Dancette.

DECUPELATION, a term used by Harris for decantation. See Decantation.

DECUPEL PROPORTION, that of ten to one. See the article Proportion.

DECURIO, in roman antiquity, a commander of ten men in the army, or the chief of a decury. See Decury.

DECURIO MUNICIPALIS; a name given to the senators of the roman colonies.

DECURIO, as appears from an inscription in Gruter, was also a name given to certain priests, intended for particular sacrifices or other religious ceremonies. Struvius conjectures that their name was derived from their afflicting the sacrifices of private families and houses.

DECURRENT LEAF, one which adheres immediately to the stalk of a plant, without any pedicle, and which has its lower part extended, and running a little way along the branch.

DECURY, ten persons ranged under one chief, or leader, called the decurio. See the article Decurio.

The roman cavalry was divided into decuries, which were subdivisions of a century, each century containing ten decuries.

DECUSATION, a term in geometry, optics, and anatomy, signifying the crossing of any two lines, rays, or nerves, when they meet in a point, and then go on separately from one another.

DECUSORIUM, a surgeon's instrument, which, by pressing gently on the dura mater, causes an evacuation of the pus collected between the cranium and the before-mentioned membrane, through the perforation made by the trepan.

DEDINGTON, a market-town of Oxfordshire, about fifteen miles north of Oxford: west longitude 1° 20', and north latitude 51° 55'.

DEDHAM, a market-town of Essex, about thirty-five miles north-eaft of Chelmsford: east long. 1° 10', and north lat. 52° 3'.

DEDI, in conveyances, imports a warranty given to a feoffee and his heirs. See the article Warranty.

DEDICATION, a solemn devoting, or setting apart, any person or thing, to the service of God, and the purposes of religion. See Consecration.

Dedication of a temple was performed by the heathens in the following manner: early in the morning, on the day of dedication, the college of the pontiffs and other orders met, with a great crowd of people; and surrounding the temple, with garlands of flowers, the vestal virgins holding branches of olive-trees in their hands, sprinkled the outside of the temple with lustral water; then the person who consecrated the temple, being the office of some great magistrate, as praetor, censor, &c. drew near the gate, with a pontif
tiff at his side, to shew him the ceremonies; and holding with one hand the side-post of the gate, spoke thus: *Ades, ades, Lucelle,* (for example) *dum dedico templum hoc, ut mihi praebatis, postequem tenesatis.* Then the pontiff, holding the ceremonial in his hand, pronounced aloud the form of the consecration, which the consecrating person repeated after him, and the ceremony was expressed in these words, *folemnia verba praebente pontifice effari.* After which they consecrated the court of the temple, by sacrificing a beast, whose entrails were laid on an altar of green turf; then, having taken the flate of the deity to whom it was consecrated, they anointed it with oil, and laid it on a pillow, rubbed with oil: the ceremonies being over, the consecrating person had an inscription, containing his name, quality, and the year of the consecration, set upon the temple. This dedication was to be authorized by the senate and people, and the college of pontiffs was to give their consent to it.

The feast of dedication, an anniversary festival among the Jews, in memory of Judas Maccabæus, who repaired and dedicated anew the temple and altar, which had been plundered and profaned by Antiochus Epiphanes. It was observed on the twenty-fifth of Cislev, and continued eight days.

The feast of dedication, or rather the feast of a saint, or patron of a church, called in our law-books *dedicare,* was celebrated not only by the inhabitants of the place, but by those of all the neighbouring villages, who referred thither; and such assemblies were authorized by the king. The custom is still retained in some places, under the name of wakes, or vigils.

Dedication, in matters of literature, the inscribing a book, poem, play, or the like, to some person of distinction, serving both as a protection, and honour to them, and a mark of the author’s respect for the person to whom he dedicates his work.

Conringius has published a collection of dedications, which may be of use to those employed in this way, as containing many observations relative to divinity, history, physics, &c. according to the different subjects of the books. He has subjoined the prefaces and dedications of Puteanus, published by himself under the title of *Pompe Prophonicetis.*

We cannot help observing, that dedications partake much of the nature of panegyric, being not only written in a pompous and florid style, but full of the praises of the patron. See the article *Panegyric.*

One of the most singular dedications we ever met with, and for which the author makes a very good apology, is that of the last part of Mr. Edwards’s History of Birds; it runs thus:

TO GOD,

The One Eternal! the Incomprehensible! the Omnipresent! Omnicient, and Almighty Creator of all things that exist! from Orbs immemorially great, to the minutest Points of Matter, this *Atom* is Dedicated and Devoted, with all possible Gratitude, Humiliation, Worship, and the highest Adoration, both of Body and Mind, by

his most resigned, low,

and humble Creature,

GEORGE EDWARDS.

DEDICATORY, something belonging to a dedication. See the preceding article.

DEDIMUS POTESTATEM, in law, a commission granted to one or more persons, for the forwarding and dispatching some act appertaining to a judge, or some court; as to take answers in chancery, depositions of witnesses in a cause depending in that court, and levy a tax in the common pleas, &c. where persons live in the country, or cannot travel.

DEDUCTION, in commerce, a subtralting or retrenching a little sum paid, from a greater remaining yet unpaid.

DEDUCTOR, in roman antiquity, a client or person who attended his patron on public occasions.

DEDUTTONE, in music, a name given to the rising of the voice, in pronouncing the syllables *ut, re, mi, fa, sol,* &c.; *quia per has deducitur vox;* in contradistinction to *reductio,* when the voice descends by these *la, sol, fa, mi, re, ut; quia per has reductur vox.*

DEE, the name of several rivers, as that on which Chelten stands, that whereon Aberdeen stands, &c. See the articles *Chester* and *Aberdeen.*

DEED, an instrument written on paper or parchment, comprehending some contract, bargain, or agreement between the parties thereto, in relation to the matter therein contained.
The validity of a deed consists in three principal things, viz. writing, sealing, and delivery. There are two kinds of deeds; viz. deeds indented, and deeds poll; which names chiefly import the shape of them, the one being cut in and out at top, and the other plain. A deed indented consists of two or more parts; for there are tripartite, quadripartite, quinqupartite, &c. deeds, in which respective deeds it is expressed, that the parties thereto have interchangeably set their hands and seals. The reason of indenting is, that whereas the several parties have each of them one, the indenture may make it appear, that they belong to one and the same contract, by their tallying. The several parts of deeds by indenture appertain to the feoffor, grantor, or lessee, &c. as to one part; the feoffee, grantee, or lessee, of another part; and some other persons, as trustees, a third, &c. All the parts of an indent ed deed, in law, are judged to make but one entire deed, yet each part is of as great force as all the parts together. A deed poll is that which consists only of one part, without being indented. It is used where a grantor, or vendor in a bill of sale, &c. only seals; there is no need of a counterpart, the nature of the contract being such, that it requires no covenant from the grantee.

Deemsters, or Demsters. All controversies in the Isle of Man are decided without procrets, writings, or any charges, by certain judges, chosen yearly from among themselves, called deemsters; there being two of them for each division of the island: they sit judges in all courts, either for life or property; and, with the advice of the twenty-four keys, declare what is law, in uncommon emergencies.

Deep sea-line, or Dip-sea-line, in the sea-language, a small line to found with, fome an hundred and fifty fathom long, with a hollow plummet at the head, and tallow put into it, to bring up flones, gravel, sand, shells, and the like, from the bottom, in order to know the differences of the ground; which being entered from time to time, in their books, by comparing of observations, they guess by their soundings, &c. what coasts they are on, though they cannot see land.

Deeping, a market-town of Lincolnshire, about thirty-five miles south of Lincoln; west Lon. 20°, and north lat. 52° 35'.

Deer, cervus, in zoology. See the article Cervus.

Deer-hay's, large nets, made of cords, to catch deer. Whoever keeps them, except in his own park, forfeits forty shillings a month.

Deer-stealers are punishable by various laws and statutes, made from time to time. Any offender convicted of deer-stealing, before a judge of gaol-delivery, may be transported by 5 Geo. I. cap. xxviii. And it is felony for persons to appear armed and disguised in a forest or park, and hunt or kill the deer, by 6 Geo. I. cap. xxii.

Deer-weed, a name given to the luteola of botanists. See Luteola.

De esendo quietum de Tolonio, in law, a writ which lies for those, who, by privilege, are free from the payment of toll, whenever they are disturbed there-in.

De expensis militum, in law, an ancient writ, commanding the sheriff to levy the expenses of a knight of the shire, for his attendance in parliament, being four shillings a day. There is also another writ of the like nature, de expenis circium & burgenfium, for levying two shillings a day, for the expenses of every citizen and burgess of parliament.

De facto, something actually in fact, or existing, in contradistinction to de jure, where a thing is only so in justice, but not in fact: as a king de facto is a person that is in actual possession of a crown, but has no legal right to the same; and a king de jure is the person who has a just right to the crown, though he is out of possession thereof.

Defamration, the speaking slanderous words of another; for which the slanderer is punishable, according to the nature of his offence, either by action upon the case at common law, or by statute, or in the ecclesiastical court. No damages are given in the ecclesiastical court, but the punishment of the party is by way of penance.

Default, in law, is generally taken for non-appearance in court, at a day assigned; but imports any omission of that which we ought to do, for which judgment may be given against the defaulter. In the usual sense, if the plaintiff in a suit make default in appearance on a trial, he will be non-suited; and where a defendant makes default, judgment shall be had against him by default. Jurors making default in their appearance, are to lose and forfeit issues.
DEFEASANCE, or DEFEASANCE. See the article DEFEASANCE.

DEFECATE, or DEFECATE, in chemistry, a term applied to a body freed and purged from faces and impurities. See the article CLARIFICATION, &c.

DEFECTION, the deserting, abandoning, or falling off from a party, or interest, a person had been engaged in.

DEFECTIVE, in general, an appellation given to things which want some of the properties that naturally they ought to have. Thus, DEFECTIVE NOUNS are those which want one of the numbers, or one or more cases. See the article NOUN.

DEFECTIVE THIRD, among musicians, the same with diminished third. See the article DIMINISHED.

DEFEASANCE, or DEFACEANCE, in our law, a condition relating to some certain deed, which being performed, the deed is defeated and rendered void, as if it had never been made.

There is this difference between a common condition and a defeasance, viz. that the condition is inferred in, or annexed to the deed; but the defeasance is a deed by itself, which has relation to another deed.

DEFENCE, in fortification, all sorts of works that cover and defend the opposite posts, as flanks, culematens, parapets, and fauldebras.

It is almost impossible to fix the miner to the face of a bastion, till the defences of the opposite one are ruined, that is, till the parapet of its flank is beaten down, and the cannon, in all parts that can fire upon that face which is attacked, are dismounted.

To be in a posture of DEFENCE, is to be in a condition to resist or oppose an enemy.

Line of DEFENCE, a supposed line drawn from the angle of the curtin, or from any other part in the curtin, to the flank-ed angle of the opposite bastion. See the articles CURTIN and BASTION.

A line of defence represents the flight of a musquet-ball from the place where the musqueteeors stand, to scour the face of the bastion, and ought never to exceed the reach of a musquet. It is either chiant or razant; the first is when it is drawn from the angle of the curtin to the flank-ed angle; the last, when it is drawn from a point in the curtin, razing the face of the bastion.

DEFENCE, in law, signifies a plea, or what the defendant ought to make after the plaintiff's count, or declaration, viz. that he defends all the wrong, force, and damages, where and when he ought, &c. If the defendant would plead to the jurisdiction, he must omit the words where and when he ought; and if he would shew any disability in the plaintiff, and demand judgment, if the plaintiff shall be answered unto, then he ought to omit the defence of the damage. There is a full defence usually in personal actions.

DEFENCES, in heraldry, are the weapons of any beast, as the horns of a flag, the tusks of a wild boar, &c.

DEFEND, a term used in our old statutes, for, to prohibit or forbid.

DEFENDANT, in law, the person sued in an action personal; as tenant is he who is sued in an action real. See ACTION.

DEFENDENS, in law, a word formerly used in gifts and grants, having this force, that it binds the donor and his heirs to defend the donee, if any persons claimed right to, or laid any incumbrance on, the thing given, otherwise than it is contained in the deed of gift.

DEFENDER of the faith, a peculiar title, belonging to the king of Great Britain, as Catholic does to the king of Spain, Christian to the king of France, &c.

This title was first given by pope Leo X, to king Henry VIII, for writing against Luther.

DEFENDER SE PER CORPUS SUUM, signified to offer duel or combat. See the articles COMBAT and DUEL.

DEFERRE UNICA MANU, in law-writers, signifies to wage law by denying the accumulation upon oath.

DEFENDERS, in church-history, the same with advocates. See ADVOCATE.

DEFENDING, in fortification, the same with flanking. See the articles DEFENCE and FLANKING.

DEFENSIVE, in surgery, signifies a bandage, plaster, &c. to defend any part from external injuries.

DEFENSOR, DEFENDER, in ecclesiastical writers, the same with advocate. See the article ADVOCATE.

DEFERENT, in anatomy, a term applied to certain vessels in the body, that serve for the conveyance of humours from one part to another. See DEFERENTIA VASA.

DEFERENT, in the ptolemaic astronomy, a circle invented to account for the eccentricity, perigee, and apogee of the planets. See the articles EPICYCLE and PTOLEMAIC SYSTEM.
DEFERENTIA VASA, two white, solid, flattened tubes, one lying on the right side, the other on the left, from the epididymis, of which they are continuations: each of them runs up in the cellular vagina of the spermatic vessels, as high as the openings in the abdominal muscles; the blood vessels lying forward, and the vas deferens behind them. Their use is to carry the semen from the epididymes to the vesiculae seminales; and, in the coitus, to discharge it into the urethra.

DEFFAIR, or DECAPITE, a term used by the French heralds, to signify that a beast has the head cut off smooth; in contradistinction to effete, which we call eared, where the head is, as it were, torn off, leaving the neck ragged.

DEFICIENT, in general, signifies much the same with defective. See DEFECTIVE.

DEFICIENT HYPERBOLA, one with only one asymptote, and two hyperbolical legs running out infinitely towards the asymptote, but contrary ways. See the article HYPERBOLA.

DEFICIENT INTERVAL, in music, one left by a comma than it ought to be. See COMMA and INTERVAL.

DEFICIENT NUMBERS, those whose parts or multiples added together, fall short of the integer whereof they are the parts; such is 8, its parts, 1, 2, 4, making only 7. See the article NUMBER.

DEFILE, in fortification, a strait narrow passage, through which a company of horse or foot can pass only in file, by making a small front; so that the enemy may take an opportunity to stop their march, and to charge them with so much the more advantage, in regard that those in the front and rear, cannot reciprocally come to the relief of one another.

To DEFILE is to reduce an army to a small front, in order to march through a defile.

DEFINITE, in grammar, is applied to an article that has a precise determinate signification; such as the article the in English, le and la in French, &c. which fix and ascertain the noun they belong to some particular, as the king, le roy; whereas in the quality of king, de roy, the articles of and de mark nothing precise, and are therefore indefinite.

DEFINITION, the showing the meaning of one word by several other not synonymous terms. The meaning of words being only the ideas they are made to stand for, by him that uses them, the meaning of any term is then shewed, or the word is defined, when by other words, the idea it is made the sign of, and is annexed to it in the mind of the speaker, is, as it were, represented and set before the view of another; and thus its signification is ascertained. This is the only end and use of definitions, and therefore the only measure of what is, or is not, a good definition.

The names then of simple ideas are incapable of being defined, because the several terms of a definition signifying several ideas, they can altogether by no means, represent an idea which has no composition at all; and therefore a definition, which is properly but shewing the meaning of any one word by several others, not signifying the same each, can in the names of simple ideas have no place.

Definitions, which then take place in compound ideas only, are of two sorts: the definition of the name, which is the explanation of what any word means; and the definition of the thing, which explains in what the nature of that thing consists.

In order to form a definition of any thing, we must employ these three acts of the mind, first compare the thing to be defined with other things that are most like to itself, and see wherein its essence and nature agrees with them; and that is called the general nature or genus in a definition: so, if you would define what wine is, first compare it with other things like itself, as cyder, perry, &c. and you will find that it agrees essentially with them in this, that it is a sort of juice. Secondly, consider the most remarkable and primary attribute, property, or idea, wherein the thing differs from those other things that are most like it, and that is its essential or specific difference: so that wine differs from cyder and perry, and all other juices, in its being pressed from a grape. This may be called its special nature, which distinguishes it from other juices.

Thirdly, join the general and special nature together, or the genus and the difference, and these make up a definition; so the juice of a grape, or juice pressed from grapes, is the definition of wine. Here it must be observed, that in speaking of the genus and difference, as composing a definition, it must always be understood, that the nearest genus and specific difference are required.

The next general nature, or the nearest genus, must be used in a definition, because
caused it includes all the rest: as if I were to define wine, I must say, wine is a juice, which is the nearest genus; and not say, wine is a liquid, which is a remote general nature; or, wine is a sub stance, which is yet more remote, for juice includes both liquid and substance. Besides neither of these two remote general natures would make any distinction between wine and a thousand other substances, or other liquids: a remote genus leaves the thing too much undistinguished. The specific difference is that primary attribute which distinguishes each species from one another, while they stand ranked under the same general nature or genus; so that the specific difference of wine is its pressure from the grape, as cider is pressed from apples, and perry from pears. In definitions we must use the primary attribute that distinguishes the species, or special nature; and not attempt to define wine by its particular tastes, or effects, or rather properties, which are but secondary, or consequent, when its pressure from the grape is the most obvious and primary distinction of it from all other juices. In some cases, indeed, it is not so easily known, which is the primary idea that distinguishes one thing from another; so some would as soon define winter by the coldness of the sea son, as by the shortness of the days, tho' the shortness of the days is double the most jut, primary, and philosophical difference; since winter-days are always the shortest, but not always the coldest: besides, the shortness is one cause of the coldness, but the coldness is no cause of their shortness.

The special rules for a good definition are these: 1. A definition must be universal, or adequate, that is, it must agree to all the particular species or individuals that are included under the same idea. 2. It must be proper, and peculiar to the thing defined, and agree to that alone. These two rules, being observed, will always render a definition reciprocal with the thing defined, that is, the definition may be used in the place of the thing defined; or they may be mutually affirmed concerning each other. 3. A definition should be clear and plain; and indeed it is a general rule concerning the definition both of names and things, that no word should be used in either of them, which has any difficulty in it, unless it has been before defined. 4. A definition should be short, so that it must have no tautology in it, nor any words superfluous. 5. Neither the thing defined, nor a mere synonymous name should make any part of the definition. Though the defining by the genus and difference be the shortest way, yet it may be doubted whether it be the best; certainly it is not the only, and so not absolutely necessary. Thus, man may be defined to be a solid extended substance, having life, sense, spontaneous motion, and the faculty of reasoning: and certainly the meaning of the word man would be as well understood as when it is defined a rational animal.

Definition, in rhetoric, is defined by Cicero, a short comprehensive explanation of a thing. The definitions of the orator, it must be observed, differ much from those of the logician and philosopher: the orators take a large compass, and define things more ornamentally: thus, man is a curious work of an almighty creator, framed after his own image, endued with reason, and born with immortality: but this rhetorical definition, in strictness, comes nearer to the nature of a description, than any accurate definition.

Definitive, a term applied to whatever terminates a process, question, &c. in opposition to provisional and interlocutory. Definitor is used for an alfeor or counsellor of a general or superior in monasteries, or other religious places. See Monastery and Convent. Deflagration, in chemistry, the kindling or setting fire to a salt, mineral, &c. either alone or mixed for that purpose, with a sulphurous one, in order to purify it. The following process is much recommended for its use in trying the strength of brandies, or other vinous liquor: measure out a quantity of the liquor, and then heat it, and set it on fire; if, after it ceases to burn, the quantity remaining is half as much as that measured out for the trial was, then the spirit is found to consist of half water, and half totally inflammable spirit, that is, it is what we understand by perfect proof; and according as the remainder is more or less than half the original quantity, it is so much below or so much above proof. This method is much more certain than that by the crown of bubbles, which arises upon shaking the spirit in a phial. The above process has been greatly improved by M. Geoffroy. See Mem. Acad. Paris, 1718.

Deflection
DEFLECTION, of the rays of light, a property which Dr. Hook observed in 1675, and read an account of before the Royal Society, March 18, the same year. He says, he found it different both from reflection and refraction, and that it was made towards the surface of the opaque body, perpendicularly.

This is the same property, which Sir Isaac Newton calls inflexion. See the article INFLExTION.

DEFLOWERING, the act of taking away a woman's virginity. See the article VIRGINITY.

DEFLUXION, in medicine, the falling of hunours from a superior to an inferior part of the body. See the articles CATARRH and PHthisis.

DEFLUXION on the eye. See the article EYE.

DEFORCEMENT, in law, the confisting any one out of his land, or a with-holding of lands and tenements by force from the right owner.

DEFORCEMENT, in the law of Scotland, is used for refisting, or offering violence to the officers of the law, while they are actually employed in the exercise of their functions, by putting its orders and sentences in execution.

The punishment of this crime is confiscation of moveables, joined with some arbitrary punishment, as fine, imprisonment, banishment, or corporal pains, according to the degrees of violence, and other circumstances which aggravate the crime.

DEFORCEOR, in law, is a person that overcomes and calls forth another from his lands and tenements by force, and differs from a deforcer on this account.

That a man may be deforced without force. 2. A man may deforce another that never was in possession, as where many have a right to lands, as common heirs, and one of them enters and keeps out the rest. A deforceor, likewife differs from an intruder who is made by a wrongful entry only into land, &c. void of a possessor, whilst a deforceor is he that holds out against the right heir. See the articles DISSEISOR and INTRUSION.

DEFORMITY, the want of that uniformity necessary to constitute the beauty of an object. See the article BEAUTY. The deformity of the body may be prevented by forming and moulding it in infancy, as by stroking up the calves of the legs to keep them from falling too low; and by stroking up the forehead to keep it from sinking, by proper bandages, &c.

According to a late ingenious writer, the proper province of a deformed person is the improvement of the mind; and his business, only such as depends on ingenuity. If he cannot be a dancing-master, to adjust the heels, he may be a school-master, to instruct the head. He would appear ill, as a herald in a procession; but may pass very well, as a merchant upon the exchange. He cannot be a graceful actor on the stage, but he may produce a good play. He can acquire no glory by the sword, but he may by the pen. On looking about him, he will find many avenues to fame barred against him: but some are still open, through that of virtue; and those, if he has a right ambition, he will most probably attempt to pass.

In this manner does that truly ingenious writer apologize for, and make the encomium of deformity. See Hay's Essay on Deformity.

DEFOSSION, BURYING ALIVE, a punishment which the Romans inflicted on such of the venalits as were guilty of incontinency. The Hungarians too are said to punish women convicted of adultery in the same manner.

DEFTERDAR, or DEFTARDAR, in the turkish and perian polity, an officer of state, answering to our lord treasurer, who appoints deputies in every province. See the article TREASURER.

DEGENERATION, or DEGENERATING, in general, denotes the growing worse, or losing some valuable qualities whereof a thing was formerly possessed.

Some naturalists have been of opinion, that things are capable of degenerating into a quite distinct species; but this is a chimera. All that happens, in the degeneration of a plant, for instance, is the losing its usual beauty, colour, smell, &c. a misfortune entirely owing to its being planted in an improper soil, climate, &c.

DEGLUTITION, in medicine, the act of swallowing the food performed by means of the tongue driving the aliment into the oesophagus, which, by the contraction of the sphincter, protrudes the contents downwards.

DEGRADATION, the act of depriving a person for ever of a dignity or degree of honour, and taking away the title, barge and privileges of it.
Degradation is also a punishment of delinquent ecclesiastics. The canon-law distinguishes it into two forts, the one summary by word only; the other solemn, by stripping the person degraded of those ornaments and rights which are the enigms of his order or degree. The canonists likewise distinguish degradation from deposition, understanding by the latter the depriving a man of his clerical orders, but by the former, only the removing him from his rank or degree.

In the antient primitive church, degrading a clergyman was reducing him to the state and communion of laymen, by which Vossius and others understand the thrusting down a clergyman to communicate with laymen, without the rails of the chancel. The full import of the phrase, however, is the depriving him of his orders, and reducing him to the simple condition of a layman, a punishment inflicted for several offences, as adultery, theft, or fraud: and clergy-men thus reduced, were seldom allowed to recover their antient station, except upon some great necessity, or very pressing reason. Some have thought that degradation did not reduce the clergy to the state of mere laymen, and that on account of the indelible character acquired by ordination, but this is an opinion unknown to the antient writers of the christian church. Degradation in the roman church is attended with a great deal of ceremony. The offender is stripped of his pontifical vestments, and at the same time the person who degrades him stripes his fingers with a knife, or a little piece of glass, declaring to him that the power of consecrating, blessing and sanctifying, is taken from him: he erases the marks of the tonsure in the same manner, which a barber compleats by shaving his head all over.

Degradation, in painting, expresses the lessening the appearance of distant objects in a landskip, in the same manner as they would appear to an eye placed at that distance from them. See the articles Perspective and Landskip.

Degraded cross, in heraldry, a cross divided into steps at each end, diminishing as they ascend towards the center, called by the french perronée. See plate LXVII. fig. 8.

Degree, in geometry, a division of a circle, including a three hundred and sixth part of its circumference.

Every circle is supposed to be divided into three hundred and sixty parts, called degrees, and each degree divided into sixty other parts, called minutes; each of these minutes being again divided into sixty seconds, each second into thirds, and each third into fourths, and so on. See the articles Minute, Second, &c.

By this means no more degrees or parts are reckoned in the greatest circle than in the least that is, and therefore if the same angle at the center be subtended by two concentrical arches, as many degrees are counted in the one, as in the other; for these two arches have the same proportion to their whole peripheries. For example, Let ACB (fig. LXVII. plate 9.) be an angle, and from the center C let there be described two arches, A B, D E, subtending the angle. There are as many degrees and minutes contained in the arch A B, as in the arch D E, altho' the radius of the arch A B were only a foot long, and the radius of the other reached the fixed stars. It is true indeed that a degree in the arch AB is so much less than a degree of the arch DE, as its radius CB is less than CE. The angle C is laid to be of so many degrees or minutes as the arch which subtends it contains of such parts.

Degree of latitude. See the article Latitude.

Degree of longitude. See the article Longitude.

A degree of the meridian on the surface of the globe is variously determined by various observers. Mr. Picart measured a degree in the latitude of 45° 21', and found it equal to 57560 french toises. But the french mathematicians, who have lately examined Mr. Picart's operations, assure us, that the degree in that latitude is 57183 toises. Our countryman Mr. Norwood measured the distance between London and York, and found it 905731 English feet, and finding the difference of latitudes 2° 38', determined the quantity of one degree to be 367196 English feet, or 69 English miles, 288 yards. Mr. Maupertuis measured a degree in Lapland, in the latitude of 66° 20', and found it 57438 toises. A degree was likewise measured at the equator by other french mathematicians, and found to be considerably less than in the latitude of Paris. Whence it appears, that the earth is not a sphere, but an oblate spheroid. See the articles Earth, Spheroid, &c.
Our theory of navigation being founded upon an hypothesis of the degrees of latitude being all equal, must of consequence be very erroneous, wherefore we here insert a table of the degrees in the quadrantal arch of the meridian, both in the sphere and spheroid with their differences, as calculated by the Rev. Mr. Murdoch.

### A Table of Arches of the Meridian to the Spheroid and Sphere, in Minutes of the Equator.

**Note:** The table continues with similar entries for higher degrees.
DEGREE, in the civil and canon-law, denotes an interval in kinship, by which proximity and remoteness of blood are computed. In computing degrees of consanguinity, the rule of the civil law is universal, either in the direct or collateral, otherwise called the oblique line, for as many generations as there are, so many degrees there are likewise. But in the canon-law, the rule is different for the oblique line. And here a distinction is made between the equal and the unequal oblique line. In the first case the rule is, as many degrees as the persons allied are distant from the common stock, so many they are distant from one another. In the other case the rule is: As many degrees as the most remote is distant from the common stock, so many the persons are distant from one another. Hence the father of a person’s grandfather by the civil law is distant from that person in the fourth degree; whereas, by the canon-law, she is only in the third degree.

DEGREE, in chemistry, denotes the state Conjont Degrees. See Conjoint.

DEGREES of comparison, in grammar. See Comparison and Positive, Comparative and Superlative.

DEGREES, in music, are the little intervals whereof the concords, or harmonical intervals are composed. See the articles INTERVAL and Concord.

Musical degrees are three, 1st. The greater tone, whole ratio is 8:9. 2nd. The less tone, whole ratio is 9:10. and 3rd. The semitone, whose ratio is 9:16. By these alone a sound can be moved upwards or downwards successively, from one extreme of a concord to another, and produce true melody; and by means of these, several voices are also capable of the necessary variety in passing from concord to concord. As to the original of these degrees, they arise out of the simple concords, and are equal to their differences. Thus 8:9, is the difference of a fourth and a fifth; 9:10, is that of a less third and fourth, or of a fifth and greater sixth; and 15:16, is the difference of a greater third and fourth, or of a fifth and a lesser sixth. The degrees being only certain mediums contrived to be put betwixt the extremes of concords, for moderating their inequality, are of use only with regard to concords; so that when the voice has moved one degree, the ear is not satif-

Parodical Degree, in algebra. See the article Parodical.

DEGREE, in universities, denotes a quality conferred on the students or members thereof as a testimony of their proficiency in the arts or sciences, and intitling them to certain privileges. The degrees are much the same in all universities, but the laws thereof, and the previous discipline or exercise differ. The degrees are bachelor, master, and doctor, instead of which last, in some foreign universities, they have licentiate. In each faculty, there are two degrees, bachelor and doctor, which were antiently called bachelor and master. In the arts likewise there are two degrees which still retain the antient denomination, viz. bachelor and master. See Bachelor, Master, Doctor.

With regard to obtaining degrees at Oxford and Cambridge, matters are nearly on the same footing; only at Cambridge, the discipline is somewhat more severe, and the exercises more difficult. For the degree of bachelor of arts, besides residence in the university near four years, it is required that the person in the last year have defended three questions in natural philosophy, mathematics, or ethics, and answered the objections of three several opponents at two several times; as also, that he have opposed three times. After which, being examined by the master and fellows of the college, he is referred to seek his degree in the schools, where he is to sit three days, and be examined by two masters of arts appointed for the purpose. For the degree of master of arts, the candidate is obliged three several times to maintain two philosophical questions in the public schools, and to answer the objections brought against.

fied till we come to the other, which therefore must be concord to the first found. By the fit division therefore, of the concording intervals into lesser ones, the voice will move smoothly from one note to another, and the hearer be prepared for a more exquisite relish of the perfect intervals, whose extremities are the proper notes in which the ear finds the expected rest and pleasure. For the use of the degrees in the construction of the scale of music. See Scale and Gamut.
DEJECTION, in medicine, the act of ejecting or evacuating the excrescences. It is also applied to the excrescences themselves thus evacuated, in which sense it is of the same import with stool. See the article STOOL.

DEJECTION, in astrology, is applied to the planets when they have lost their influence, as is pretended by reason of their being in opposition to some others: It is the contrary of their exaltation. See the article EXALTATION.

DEIFICATION, in antiquity, the same with apotheosis. See APOTHEOSIS.

DEINCLINERS or DEINCLINING DIALS, are such as both decline and incline, or recline at the same time. Thus, if a plane cut the prime vertical circle at an angle of thirty degrees, and the horizontal plane under an angle of twenty-four degrees, the elevation of the pole being fifty-two degrees, a dial drawn on this plane is called a deincliner. See DIAL.

DEIPARA, MOTHER OF GOD. See the article MOTHER.

DEISM, the system of religion acknowledged by the deists. See the next article.

DEISTS, in the modern sense of the word, are those persons in christian countries, who acknowledging all the obligations and duties of natural religion, disbelieve the christian scheme, or revealed religion. They are so called from their belief in God alone, in opposition to Chrisitians. The learned Dr. Clarke taking the denomination in the most extensive signification, distinguishes deists into four sorts. 1. Such as pretend to believe the existence of an eternal, infinite, independent, intelligent Being, and who teach that this supreme Being made the world, though they fancy he does not at all concern himself in the management of it. 2. Those who believe not only the being, but also the providence of God with respect to the natural world, but who not allowing any difference between moral good and evil, deny that God takes any notice of the morally good or evil actions of men; these things depending, as they imagine, on the arbitrary constitutions of human laws. 3. Those who having right apprehensions concerning the natural attributes of God, and his all-governing providence, and some notion of his moral perfections also; yet being prejudiced against the notion of the immorality of the human soul, believe that men perish entirely at death, and that one generation shall perpetually succeed another, without any future reformation or renovation of things. 4. Such as believe the existence of a supreme Being, together with his providence in the government of the world, as also the obligations of natural religion; but so far only, as these things are discoverable by the light of nature alone, without believing any divine revelation. These last are the only true deists; but as the principles of these men would naturally lead them to embrace the christian revelation, the learned author concludes there is now no consistent scheme of deism in the world.

DEITY, a term frequently used in a synonymous sense with God. See GOD.

DELEGATES, commissioners appointed by the king under the great seal to hear and determine appeals from the ecclesiastical court.

Court of DELEGATES. See COURT.

DELEGATION, delegatio, a commission extraordinary given by a judge to take cognizance of, and determine, some cause, which ordinarily does not come before him.

DELEGATION, in the civil law, is a kind of nomination, whereby a debtor appoints one that is debtor to him, to answer a creditor in his place. This delegation differs from transferring, or translation, in that three persons intervene in a delegation, viz. the creditor, the debtor, and a third indebted to the debtor; whereas in a transfer, it is enough that the transferer and transferee be present.

DELETERIOUS, an appellation given to things of a destructive or poisonous nature. See POISON.

DELF, denotes a quarry or mine, where either stone or coal is dug; but is more particularly used for the veins of coal lying
DELF, in heraldry, is by some supposed to represent a square rod or turf, and to be so called from delving, or digging. A delv tenne, is due to him that revokes his own challenge, or any way goes from his word; and to such this is given as an abatement to the honour of their arms, and is always placed in the middle of the escutcheon. However, if two or more delfs are found in an escutcheon, they are not then to be looked upon as signs of an abatement, but of honour. Also, if it be of metal, or charged upon, it then becomes a charge of perfect bearing.

DELPH, a city of the united Netherlands, in the province of Holland, eight miles north-east of Rotterdam, and thirty south-west of Amsterdam: east long. 4° 5', and north lat. 52° 6'.

DELIA, in antiquity, feasts celebrated by the Athenians in honour of Apollo, surnamed Delius, the principal ceremony whereof was an embassy, or rather a pilgrimage to Apollo, performed every five years by a certain number of citizens, deputed for that purpose, called deliaete, and the first person of the embassy architeontus; to him were added, four more of the family of the Ceryci, priests descended from Mercury, who refided all the year at Delos, to assist in the temple. The whole deputation set out in five vessels, carrying with them every thing necessary for the feast and the sacrifices.

DELI also was a quinquennial festival in the island of Delos, instituted by Theseus, at his return from Crete, in honour of Venus, whose statue, given him by Ariadne, he erected on that place, having by her assistance met with success in his expedition.

DELIAC, or DELIACAL PROBLEM, a problem much celebrated in the writings of the antients, concerning the duplication of the cube. See the articles DUPLICATION and CUBE.

DELIBAMENTA, in antiquity, a libation to the infernal gods, always offered and continual delirium is an embalmy. or rather a sembly, is when a person has a right to his expedition. asseeing by her assistance met with success; thofe beneath them have only consultative voices.

DELIBERATIVE, an appellation given to a kind, or branch, of rhetoric, employed in proving a thing, or convincing an assembly thereof, in order to persuade them to put it in execution.

DELIBERATIVE, an appellation given

To have a deliberative voice in the assembly, is when a person has a right to give his advice and his vote therein. In councils, the bishops have deliberative voices; those beneath them have only consultative voices.

DELICT, in the scotch law, denotes much the fame with misdemeanour. See the article MISDEMEANOUR.

DELIGATION, in surgery, the binding up of wounds, dislocations, fractures, &c. See the articles WOUND, DISLOCATION, FRACTURE, &c.

DELIMA, in botany, a genus of plants belonging to the Polygonaria-monogynia class, with an elongated style; it has no flower-petals; the cup consists of five leaves; the fruit is a bivalve capsule, and contains two seeds.

DELINEATION, or Delineating, the thing with designning. See the article DESIGNING.

DELINQUENT, a guilty perfon, or one who has committed some fault, or offence, for which he is punishable.

DELiquium, or Animi DELiquium, the name with lipothymia. See the article LIPOTHYMIA.

DELiquium, in chemistry, signifies the solution of any body, when exposed to a cool and damp place, by the humidity it attracts from the air. The salt of tartar dissolved in the above manner is called oil of tartar per deliquium.

DELIRIUM, in medicine, the production of ideas not answerable to external caufes, from an internal indisposition of the brain, attended with a wrong judgment following from those ideas, and an affectation of the mind, and motion of the body, accordingly; and from these increased through various degrees; either alone or joined together, various kinds of deliria are produced.

The causes of deliria are numerous, such as fevers, wounds in the head, internal inflammations, and immoderate loss of blood, whereby the brain is either disordered or weakened. It also arises from the seed or merce being retained in the womb, from the rotting of a gangrened member, &c. When a fierce and continual delirium is produced by an acute fever, from the brain itself originally affected, it is called a phrenzy; but a simple delirium only attends a violent fit of an intermitting fever, so that when the paroxysm is off, the delirium ceases. See the article PHRENZY.
Many are the signs of a delirium, as gnashing of the teeth, a fierce and wild aspect, a pulsation in the hypochondrium and belly, watchings, vomiting of bile, in pains of the head, a tremor, or trembling of the tongue, &c. to all which Gallen adds, the doing any thing unusual, or indecent.

Various methods of cure, and different remedies are to be chose agreeable to the difference of the causes; but the chief of these remedies are warm bathing of the feet, with the application of blisters to them, and to the hams; frictions upon the same parts; diluent clysters often applied; a thin diet, and healing, quieting, deobstructive and diluent drinks; emollient remedies applied to the head; gentle purges; bleeding in the foot, a bringing down of the piles, or menstrual discharge, &c.

A delirium is always a bad sign in wounds of the head, because it denotes that the brain itself is injured.

DELIVERY, in law. See the article REQUEO.

DELIVERY, CHILDBIRTH, or PARTURITION, in medicine and surgery, the bringing forth a perfect fetus, or child, from its mother's womb, whether it be alive, or dead. See FOETUS.

In order to attain the knowledge of difficult childbirths, it is necessary to form a just idea of those that are natural.

The time of the natural birth is, from the 15th day of the ninth month, to the end of the 20th of the same; yet some women affirm it may be sooner, or later. Hoffman says, the usual time is nine solar months; and Junker, that excretions from the uterus being by women referred to certain lunar plates, they reckon their going withchild by the weeks, and that they usually exclude the fetus forty weeks from the time of their being with child, commonly on that very day they were used to have their menstres.

The signs of an approaching delivery, are a remarkable descent of the womb, and a subsidence of the belly; the head of the fetus falls down to the orifice of the womb, and presses upon it. See plate LXVIII. No 1. The orifice of the womb dilates by the weight; and the chorion and amnions, being driven forward with the waters they contain, form a kind of pouch, or bladder, at the said orifice; which should be suffered to break of itself, or, at least, it should not be burst till the woman is in labour. There is a flux of a whitish matter from the said orifice: pains which extend from the loins and groin towards the genital parts: there is a frequent desire to make water, or to go to stool; or a continual tenem­sus: a flux of the waters from the membranes which contain the child immediately before the birth, or more early: a trembling of the lower joints: sometimes the head ache, and the face looks intensely red.

The infant gradually advances, the above protuberance continually enlarging the passage, that the crown of the head may be felt; the birth is then advanced one third; and the midwife may now afford the exclusion. When the infant is advanced forward, as far as his eyes, he is laid to be in the passage. If the membranes are not already burst, they may now be opened, and the waters by their effusion, will render the vagina slippery, and promote the expulsion of the infant. When the child is born, the midwife should lay him on her knees, so as to give issue to the waters from the mouth, if any has been imbibed: soon after, the placenta appears of itself, if not attached to the uterus: if otherwise, the midwife must separate it gently, by introducing her hand. The navel-string must now be cut, having first made a ligature as well on the child's side as on the mother's, to prevent a haemorrhage. The midwife, at first, having asked a few questions, ought to examine, by the touch, with the fore and middle finger, introducing them from time to time, to know the state of the uterus; and, as the child advances, she must relax the vagina by some oily remedy. The mother should regulate her throws, and use her efforts all at once, not divide them, especially when the head is advanced, that the shouldeys may immediately follow, and the child escape the danger of strangling.

After the child is born, and the afterbirth brought away, let a warm linen cloth be applied to the parts, but not so as to hinder the flowing of the lochia. An hour after, let the mother take a little oil of sweet almonds, to ease the after-pains, and let a cataplasm of the oil of sweet almonds 3 jn. and two or three new laid eggs be boiled together, and laid to the parts, renewing it every six hours, for two days: fifteen days after:
after the birth, the parts may be bathed
with an astringent decoction of red roses,
bay-leaves, or nut-galls, in red wine, in
order to brace them. If the labour is
long and difficult, it will be proper to
bleed, to prevent inflammations, and to
give a little Alicante-wine, or with the
addition of Cinnamon-water, or con-
fection of Algerines, or myrrh, not forgetting an oily
clyster.

A difficult Delivery may be caused by
the mother, the midwife, or the foetus. The
fault is in the mother, if, when the orifice
of the womb is open, and the child
rightly placed, she has not strength to
expel the foetus, especially if the waters
are come away, and the pains cease: or
when the mother will not exert herself;
or there is a natural fault in the genital
parts. In a defect of strength, or pains,
all else being right, a draught of gene-
rous wine should be given, with cinna-
mon and mace, again and again, if the
work does not go forward. If there
wants a greater stimulus, borax, cinnam-
on, or myrrh, may be given, with a
proper drink, which must be repeated in
an hour or two, if occasion requires.
But the abuse of forcing medicines is
dangerous: stimulating clysters may be
injected now and then, especially if the
woman is coffive. The midwife should
also press back the os coccygis, which
tends to excite the pains, and to ease the
labour. If the parts are overfrighted,
as in the first birth, especially if the
woman is not young, emollient balsams
are to be used, and the parts must be
anointed with fresh butter, or oil, and to
be dilated gently with the fingers. If
there is a tumor, caruncle, or membrane,
opposing the birth, a surgeon's assis-
tance is required.

The midwife is in fault, when she hastens
the labour before the time, when there is
no true pain; when the orifice of the uterus
is not open, which alone distinguishes
the true pains from false: the true time
of birth must be waited for: the woman
must be composed, and her spirits kept
up with comfortable liquors.

If the fault is with the foetus; and the
head too large, or the shape monstrous,
or the situation preternatural, then forcing
medicines are fruitless and noxious; and
the foetus is brought forth by the feet, by
a skilful hand, or the instrument called
embyulculus, (ibid. n° 10, 11.) whether
alive or dead. See EMBRYULCUS.

If the feet present first (ibid. n° 2.) the
midwife must be wary, lest there be twins,
and lest the should take a foot of each:
the feet must be wrapped in a dry nap-
kin, and the child must be drawn gently,
till the waist is in the orifice of the uterus:
then the infant's hands should be drawn
close by the sides; and if the head be
towards the os pubis, it should be turned
towards the coccyx, to prevent an ob-
stable. Then, the orifice must be dilat-
ted with the fingers, and the woman's
throws should assist the midwife's efforts
to reduce the child. If the chin is em-
arrassed, the midwife must disengage it,
by putting her finger into the mouth, in
order to turn it to advantage.

If the infant's head presents across, (ibid.
n° 3.) it must be put back, and gently
turned to its natural situation; and if
the shoulder presents, the same art must
be used, (ibid. n° 4.) If the belly, hip,
or thigh, appears first, (ibid. n° 5.) the
child must be extracted by the feet, and
the mother must lie horizontally on her
back. If one or both hands are directed
upwards, and lie close to the head,
(ibid. n° 6.) the cafe is not so bad as
some apprehend, for they will keep
the orifice equally dilated, till the head
pauses, and prevents strangling. If one
hand, or one foot appears, they must be
returned, and the infant brought forth
by the head in the former cafe, and by
the feet in the latter. (n° 7, and 8.)

If the infant is dead, there is generally
a colliquation of the abdomen; the breasts
are flaccid; the infant bears on the lower
part of the pelvis; and the child, upon motion, rolls like a lump of lead.
The bones of the skull are wrapped over
one another; an ichorous lymphatic fancies
flows from the uterus; the mother is
subject to fainting. There is no pul-
fation in the navel string; it is soft and
indolent to the touch, and absolutely de-
prived of motion. If the placenta comes
first, and is hot, the child is alive.
Above all, if any part of the infant's
body appears, and is full of small vessels
livid, soft, and brittle, it is not only
dead, but beginning to purify. In these
cases he must be extracted by the feet,
and if it cannot be done otherwise, with
an instrument; but a man midwife's
assistance must not be neglected.

When the foetus dies before the time of
birth, and the membranes continue
whole: it will not purify: therefore the
work
work must be left to nature, for birth-pains will at length come on sponta-
neously.
If the navel-string appears first, and is compreased soon after by the head of the infant, its life is in danger, and the remedy is to return the infant, and red-
duce the cord, till the head fills the ostifice: but if this cannot be done, the woman must be put in a suitable posture, and the child must be extracted by the feet. When the placenta presents itself, which is known by its spongy, soft, texture, and the great quantity of blood flowing at the same time, it requires speedy assistance. If the membranes are entire, they should be broke; the placenta and membranes should be reduced into the uterus, and the child be extracted by the feet; which is more easily performed in the membranes, than in the uterus, and put into a proper situation: but if the placenta is disengaged from its mem-
branes, and these are broke, and the placenta, or both, appear before the in-
fant, they may be brought away first, and the infant immediately afterwards.
When there is a great flux of blood from outward accidents, the infant should be immediately delivered by art, though the mother is not in true labour. If the uterus is opened, and the vagina relaxed, as in this case they commonly are, the child must be extracted by the feet; if not, they must be mollified with fresh oil, and the infant delivered as before.
After all laborious births, the woman is generally weak, and apt to faint: there-
fore, her spirits should be kept up by a glass of hot wine, or analetic water, which must be repeated as oft as there is occasion.
If after the child is born, the placenta does not soon follow, and it adheres to the womb, the woman is not to change her posture immediately, but the mid-
wife's hand is to be introduced into the womb, as far as the placenta, taking the navel-string for a guide; and taking hold of it, she is to move it gently to and fro, in order to loosen and extract it. (ibid. n° 9.) If it adheres too closely, it is not to be pulled forcibly, or broken: it will be best to wait half an hour, keeping the hand in the uterus, for fear of its closing, till it comes away of itself, or may be separated without force. If, through the unfilkliness of the midwife, the orifice of the womb closes, before it is come away, aloetic pills must be taken every evening. If it putrefies, the pa-
tient dies, or falls into dangerous fevers. See the article PLACENTA.
After delivery, the woman should be put into bed, and a folded sheet put under her hips, in order to receive the lochia. See the article LOCHIA.
Warm linens should be applied to the genital parts, to keep out the air, and a compres, dipped in warm wine, should be applied to the belly, but not too tight.
If there are violent pains after delivery, they generally proceed from the after-
birth's being retained, or part of it; from blood clotted, or concreted, in the uterus; from hard labour; from a defect in the flux of the lochia; or from wind, especially if the woman has not been swathed in a proper way. In this case, hot diluents are proper, or an infusion of camomile flowers, drank as tea, or broths with caraway seeds; or worm-
wood, or camomile flowers; or thin orange peel 31. or a bitter tincture in a proper infusion, taken hot. An ounce or two of oil of sweet almonds, taken in a hot vehicle, is excellent.
DELLY, the capital of a province of the same name, and at present of all the bither India: east long. 79°. and north lat. 23°.
It is a large and populous city, ten miles in circumference.
DELOS, the principal of the Cyclades-islands, in the Archipelago: east long. 25° 50', and north lat. 37°, 26'.
DELPHIN, or DOLPHIN. See the ar-
ticle DOLPHIN.
DELPHINIUM, LARK's SPUR, in botany, a genus of the polyandra-trigynia class of plants, the corolla of which consists of five unequal petals, disposed circularly; of these the upper one is anteriorly more obtruse than the others, and is emarginated, and extended behind into a tubulated horn, which is straight, long, and obtuse; the others are of an ovato-
lanceolated figure, patent and nearly equal: the fruit consists of one or three capsules, of an ovato-tubulated figure, straight, composed of a single valve, and opening inwards: the seeds are numerous and angular: these seeds called Plagi-
fragia, or flavelaers, in the shops, are used to destroy vermin in children's heads. See plate LXIX. fig. 1.
DELPHINUS, in ichthyology, a genus of fishes, of the order of the plagiusi, the characters of which are, that they
DELF 

DELPHINUS, DELSERG, or DELUGE, to this genus belong the dolphin, the porpoise, and the grampus, or overflowin the earth, either wholly, or in part, by water. We have several deluges recorded in history, as that of Ogyges, which overflowed almost all Attica, and that of Deucalion, which drowned all Thessaly, in Greece; but the most memorable was that called the universal deluge, or Noah's flood, which overflowed and destroyed the whole earth, and out of which only Noah, and those with him in the ark, escaped. Men have been very solicitous to account for this catastrophe philosophically, and to discover from whence such an amazing quantity of water could come, as were necessary to cover all our globe, to the height of fifteen cubits, above the highest hills: for to that height Moses expressly faith, Gen. vii. 20. "The waters prevailed." Some have ventured to deny there were any mountains at all before the flood, though he expressly mentions them as a standard for the height of the water. Others have denied the univeractivity of the deluge, though the words of the text be, "That all the hills over the whole earth were covered." Others have had recourse to the shifting of the earth's center of gravity, and therefore, will have all parts drowned incessively; and our famous theorist, Dr. Burnet, fancies an earth made on purpose to be drowned at that time, which being in form of an orbicular crust on the face of the sea, as we now call it, (for he says, there was none before the deluge) fell down into the water, and so drowned its inhabitants. But the holy scriptures tell us, that the waters of the deluge came from two funds; the great deep below, and the rains above. Again, when we look to the internal parts of the earth, even to the greatest depth men have ever reached, we find that the body of the terrestrial globe is composed of strata, or layers, lying over one another, which appear to be sediments of a flood: besides, in the bodies of these strata, though never so solid, nay, even included within the solidity of the firmest flints, marble, stone, &c. we find a prodigious variety of the exuviae, or remains of fishes, such as their shells, teeth, &c. as well marine ones, as those which live in lakes and rivers; and from a due observation of these, and repeated considerations upon them, it was, that the learned Dr. Woodward founded what he delivers upon this subject, which therefore is not so much a theory of the earth, as necessary deductions, and unavoidable consequences, drawn from the matters of fact, as they are laid down in the second part of his natural history of the earth. 1. That these marine bodies, and the other spoils of fresh water fishes, were borne forth out of the sea by the universal deluge, and on return of the water back again from off the earth, they were left behind on land. 2. That during the time of the deluge, all the stone and marble of the antediluvian earth, all the metals in it, all the mineral concretions, and in a word, all fossils whatever, that had before attained any solidity, were totally disolved; their constituent corpuscles disjoined, and their cohesion perfectly ceased; and that the said corpuscles, together with the corpuscles of those which were not before solid, such as sand, earth, and the like; as also, all animal bodies, teeth, shells, vegetables, in short, all bodies whatever, that were either upon the earth, or that constituted the mafs, if not quite down to the abyss, yet to the greatest depths we ever dig, were assimilated into the water, and engulfed therein; so that the water and these bodies made up one common mass. 3. That at length, all the mafs that was thus born up in the water, was again pre-
precipitated, and subsided toward the bottom, and that this subsidence happened generally according to the laws of gravity. See the article Gravity.

That the matter subsiding thus, formed the strata of stone, earth, marble, coal, &c. of which strata the terrestrial globe, or, at least, as much of it as hath been displayed to human view, doth mainly consist.

4. That the first strata or other matter, whereof they consist, arrived at the globe. And afterwards, he concludes from his observations,

1. That Noah's deluge was quite universal, covering the whole earth, even the highest mountains quite round the globe.

2. That, at the time of the deluge, the water of the ocean was first brought out on the earth, and immediately succeeded by that of the abyss.

3. That, upon the disruption of the strata, or the elevation of some, and the depression of others, towards the end of the deluge, this mass of water fell back towards the lowest parts of the earth, into lakes, and other cavities, into the channel of the ocean, and through the fissures, by which this communicates with the ocean, in the abyss which it filled, till it came to an equilibrium with the ocean.

4. That the deluge commenced in the spring season, the waters coming forth upon the earth in the month which we call May.

5. That the deluge did not happen, from an accidental concourse of natural cauities; but that many things then happened, which never could possibly happen, without the assistance of a supernatural power.

Mr. Whifton, on the contrary, in his new theory of the earth, supposes the deluge began on the 18th of November, in the 2365 year of the Julian period, that is, 2349 years before the Christian æra; that a comet descending towards its perihelion, in the plane of the ecliptic, passed quite near the globe of the earth, the very same day that the deluge began: he attributes to the universal deluge all the changes and alterations that have happened in the surface and inside of the globe: he adopts the hypothesis of Dr. Woodward, and indiscriminately makes use of all the observations of this author, with regard to the present state of the globe.

The terrestrial globe having once met with the tail of the comet, consisting of a transparent fog, or aqueous atmosphere, it must, in passing through it, appropriate to itself some part of the matter it contained. All that was found within the sphere of attraction of the globe, must have fallen upon the earth, and that in form of rain, since this tail wholly consisted of aqueous vapours. This tail being "the catarracts of heaven that were opened," the rain may be made as plentiful as one pleases, even to occasion an universal deluge, the waters of which would easily cover the highest mountains. However, Mr. Whifton does not attribute the whole deluge to these waters only, for, agreeably to scripture, he affirms that the earth, upon the approach of the comet, would no doubt feel the force of its attraction; so that the fluid, contained in the great abyss, would be agitated by so violent a flux and reflux, that the superficial crust of the earth could not resist it, but be broken in several places, and the internal waters diffused over the surface, "and the fountains of the deep broken up." Mr. Whifton, to disperse all this water, supposes, that as soon as the earth in continuing its course, had got some way from the comet, the effects of its attraction, the flux and reflux ceased in the great abyss, and then the superior waters were violently precipitated through the same passages by which they came out; the great abyss swallowed up all the superfluous waters, and its cavity was found capable enough to
receive not only the waters which it had already contained, but also all those which the tail of the comet had left behind it; since during the time of its agitation, and the bursting of its crust, it had enlarged the space by breaking down, on all hands, the earth that environed it. It was, in like manner at this time, that the earth, which till then was spherical, became elliptic, occasioned not only by the effect of the centrifugal force caused by its diurnal revolution, but likewise by the action of the comet; and that because the earth, in passing through the tail of the comet, was situated in such a manner, that it presented its equatorial parts to this body; and because the force of the comet's attraction, concurring with this centrifugal force of the earth, took away those parts of the equator which so much the more facility, as the crust was broken and disjoined in a vast many places; and because the action of the flux and reflux of the abyss made a more violent impression upon the parts under the equator, than any where else.

Dr. Halley resolves the deluge into the shock of a comet, or some other such transient body: the great agitation that must have been occasioned by it in the sea, he observes, would be sufficient to account for all those strange appearances of heaping vast quantities of earth, and high cliffs upon the beds of shells, which once were the bottom of the sea, and raising up mountains, where none were before: such a shock as this, impelling the solid parts, would occasion the waters, and all fluid substances that were unconfined, as the sea is, to run violently with an impetus toward that part of the globe where the blow was received, and that with force sufficient to take with it the very bottom of the ocean, and would carry it upon land.

There are various other systems of the universal deluge, several of which may be seen in Monf. Buffon's Natural History, Tom. I.

DELMING, among the miners of Cornwall, a kind of slate more usually called killas. See the article KILLAS.

DEMAIN, or DEMESNE, in its common acceptance, is used for the lands round a manor-house, occupied by the lord. See the article MANOR.

DEMAIN, or DEMESNE, in law, is commonly understood to be the lord's chief manour-place, with the lands thereto belonging, which he and his ancestors have time out of mind kept in their own manual occupation, for the maintenance of themselves and their families. See the article MANOR.

DEMAIN denotes also all the parts of any manor not in the hands of freeholders. And it is frequently used for a distinction between those lands, &c. that the lord of the manor has in his own hands, or of his leafee demifed at a rack rent; or such other land appertaining to the manor, which belongs to free or copyholders.

DEMAIN is sometimes taken in a more special sense, as opposite to frank-fee; such lands as were in the possession of Edward the confessor, being called antient demesne, and all others frank-fee. In England, no private person has any demeines, according to the simple acceptation of the word, because there is no land but what depends mediatly or immediately upon the crown, as of some honour belonging to it, and not granted in fee to any inferior person; wherefore when a person in pleading would signify the land to be his own, he says, that he is fixed thereof in his demain as of fee; by which it appears, that tho' his land be to him and his heirs for ever, yet it is not true demesne, but depending upon a superior lord, and is held by rent or service.

DEMAND, in law, the calling upon a person for any thing that is due.

There are two kinds of demands, the one in deed, and the other in law. And these are again divided into three sorts, one in writing, without speaking, as in every writ of precipice; one other without writing, being a verbal demand of the person who is to perform something; and another made without either words or writing, which is termed a demand in law, as in cases of entries on lands, &c. And, as an entry upon land and taking distress for rent, are a demand in law of the land and rent, so the bringing an action of debt for money due on a bond, is a demand in law of the debt.

A demand is to be legal, and made in such a manner as the law directs; if for rent referred on a lease of a messuage and lands, it ought to be made at the door of the house; and of land, on the most public part thereof. If a lellor or landlord in demanding of rent to re-enter, demands one penny more or less than is actually due to him, or does not shew the certainty of the rent, the day of its payment,

DEMONSTRABLE, in law, is applied to an estate either in fee, for term of life or years, tho' most usually the latter. The king's death in law is termed the demise of the King, which does not discontinue any writ or process, nor determine any com­mission civil or military, nor a parlia­ment till after six months.

DEMOISELLE, a bird of the crane-kind, something less than a heron, known also by the name of the dancing bird, on account of its frequent leaping and turning round, and varying the motion of its head at the same time. Immediately from behind each eye, springs forth a tuft of long, soft, white feathers, which tend backwards in a very graceful manner, and wave with the least air. The fore part of the neck, on the contrary, is covered with soft, long, and slender black feathers, which fall on the breast in a very pretty manner, sometimes close, and at other times detached like a lady's tippet.

DEMONSTRABLE, a term used in the schools, to signify that a thing may be clearly proved. Thus it is demonstrable, that the three angles of a triangle are equal to two right ones.

DEMONSTRATION, in logic, a series of syllogisms, all whose premises are either definitions, self-evident truths, or propositions already established. The knowledge acquired by demonstration, tho' it be certain, is not so clear and evident as intuitive knowledge. It requires pains and attention, and steady application of mind, to discover the agreement or disagreement of the ideas it considers; and there must be a progression by steps and degrees, before the mind can in this way arrive at certainty. Before demonstration there was a doubt, which, in intuitive knowledge, cannot happen to the mind that has its faculty of perception left to a degree capable of dif­tinct ideas. In every step that reason makes in demonstrative knowledge, there is an intuitive knowledge of that agree­ment or disagreement it seeks with the next intermediate idea, which it uses as a proof; for if it were not so, that yet would need a proof, since without the perception of such agreement or disagreement, there is no knowledge produced. This intuitive perception of the agreement or disagreement of the intermediate ideas in each step and progression of the demon­stration, must be exactly carried in the mind; and a man must be sure that no part is left out: hence because in long deduc­tions the memory cannot easily retain each step, this knowledge becomes more imperfect than intuitive; and men often embrace falsehoods for demonstrations. See KNOWLEDGE and INTUITION.

It has been generally taken for granted, that mathematics alone are capable of demonstration. But to have such an agreement or disagreement as may be intuitively perceived being not the privilege of the ideas of number, extension and figure alone, it may possibly be the want of due method and application in us, and not of sufficient evidence in things, that demonstration has been thought to have so little to do in other parts of knowledge. For wherever the mind can perceive the agreement or disagreement of any two ideas by an intuitive perception of the agreement or disagreement they have with any intermediate ideas, there the mind is capable of demonstration, which is not limited to the ideas of figure, number, extension, or their modes.

There are two things required in right demonstration, first, that every proposition of which it consists, considered separately, be true. Secondly, that the consequences drawn from other foreign things, necessarily flow from them; or that all the consequences be contained in the antecedents or premises.

Demonstration is distinguished. 1. Into direct, called also offensive, demonstration, when beginning with definitions, self-evident propositions, or known and allowed truths, we form a train of syl­logisms, and combine them in an orderly manner, continuing the series thro' a va­riety of succeffive steps, until at last we arrive at a syllogism, whose conclusion is the proposition to be demonstrated. 2. Indire&c, or, as it is sometimes called, apoplectic demonstration, when we af­sume a proposition which directly contra­dicts that we mean to demonstrate; and thence by a continued train of reasoning, in the way of a direct demonstration, deduce
DEMOULCENTS, among DEMONSTRATIVE, DEMONSTRATIVE, are not the same center. The existence of light by geometrical demonstration, that frame of reasonings drawn from the elements of Euclid. Mechanical demonstration, that the reasonings which are drawn from the rules of mechanics. Demonstration a priori, that by which the effect is demonstrated from its cause either next or remote, as when we prove the existence of light by the existence of the sun. Demonstration a posteriori, when we demonstrate the cause from the effect; as when from the existence of light, we demonstrate the existence of the sun.

The schoolmen make two kinds of demonstration, the one direct, or proper quod, in which an effect is proved by the next cause. As when it is proved that the moon is eclipsed, on account of the interception of the earth between the sun and moon. The other est, or quia, wherein the cause is proved from the effect, as, that fire is hot because it burns; or when an effect is demonstrated by a remote cause, as when it is proved that plants do not breathe, because they are not animals.

DEMONSTRATIVE, in rhetoric, one of the kinds of eloquence, viz. that which obtains in the composition of panegyrics, inveCTIVES, &c. See the article RHETORIC.

DEMONSTRATIVE, in grammar, a term given to such pronouns, as serve to indicate or point out a thing. Of this number are hic, hic, hoc, among the Latins; and this, that, these, these, in English. See the article PRONOUN.

DEMULCENTS, among physicians, medicines good against acrimonious humours. Such are the roots of marsh-mal-low, of white lilies, of liquorice, and of viper graes, the five emollient herbs, &c. See the article EMOLLIENT.

DEMURRAGE, in commerce, an allowance made to the master of a ship by the merchants, for staying in a port longer than the time first appointed for his departure.

DEMURRER, in law, a stop put to any action upon some point of difficulty which must be determined by the court, before any further proceedings can be had in the suit. Demurrers are either general, without shewing any particular cause; or special, where the causes of it are particularly assigned; and one may not pray the judgment of the court on an insufficient declamation or plea, otherwise than by demurrer, when the matter comes judicially before them. In pleadings, if a matter is insufficiently alleged, that the court cannot give judgment thereon, a general demurrer will suffice, and so for want of substance in any plea, &c. But if there be a want of form, it is required that there be a special demurrer.

DEMMURRER TO EVIDENCE, is where a question of law arises thereon, as if the plaintiff in a suit gives in evidence any records, deeds, writings, &c. upon which a law question arises, and the defendant offers to demur upon it, then the plaintiff must join in such demurrer, or wave his evidence.

DEMMURRER TO INDICTMENTS, is when a criminal joins issue upon a point of law in an indictment or appeal, allowing the fact as laid to be true. And if the indictment, or appeal, prove good in the opinion of the judges by whom the demurrer is to be tried, and not by the inquest, they proceed to judgment and execution, as if the party had been convicted by confinement or verdict.

DEN, a syllable which added to the names of places shews them to be situated in vallies or near woods, as Tenterden.

DEN and STROND, in law, was antiently a liberty for ships to run or come ahere.

DENARIATE OF LAND, denariatus terre, in old law-books, signifies as much as was worth a penny by the year.

DENARIUS, in roman antiquity, the chief silver-coin among the Romans; worth in our money about seven-pence three farthings. As a weight, it was the seventh part of a roman ounce. See the articles COIN and WEIGHT.

DENARIUS is also used in our law-books for an english-penny.
DENARIUS, God's penny, denotes earnest-money, and is so called because in ancient times it was given to the church or the poor.

DENARIUS tertius comitatus, a third part of the profits of county-courts. When these courts had superior jurisdictions, before others were erected, two parts of the profits went to the king, and a third part to the earl of the county.

DENARIUS de caritate, were customary oblations made to cathedral churches charged upon parish priests, though at first they were but a gift of charity.

DENATES, a term used by some for penates. See the article Penates.

DENBY, the capital of Denby hire, in north Wales: west long. 3° 30', and north lat. 53° 15'.

It sends only one member to parliament.

DENCHE', in heraldry, the same with Danche'. See the article Danche'.

DENDERMOND, a fortified town of Ghent: east long. 3° 50', and north lat. 51° 10'.

DENIZEN, in natural history, the name used by the antients for an extremely elegant and beautiful species of agate, the ground of which is whitish, variegated with veins of a brighter white. These veins are beautifully disposed in a number of various figures, but generally in many concentric irregular circles, drawn round one or more points. It is common also, in various parts of this stone, to find very beautiful delineations of trees, mosses, lea-plants, and the like, so elegantly expressed, that many have erroneously taken them for real plants included in the substance of the stone; whence the name dendrachates. See the article Agat.

DENDRANATOMY; a term used by some for a description of the various parts of trees, as root, trunk, branch, bark, wood, pith, flower, fruit, &c. See the articles Root, Trunk, Branch, &c.

DENDRITÆ, in natural history, a name given to those species of reptilia which have representations of trees, &c. See the article Septaria.

DENDROPHORIA, in antiquity, the carrying of boughs or branches of trees, a religious ceremony so called, because certain priests called from thence dendrophori, tree-bearers, marched in procession, carrying the branches of trees in their hands in honour of some god, as Bacchus, Cybele, Sylvanus, &c. The college of the dendrophori is often mentioned in ancient marbles; and we frequently see in basso relievos the bacchanals represented as men carrying little shrubs or branches of trees.

Crites are at a loss to assign the office of the dendrophori who attend the roman army. Some hold that they fashioned the wood for the tents; others, that they provided the wood necessary for the machines of war; and others, that they were the same with the dendrophori of the feals and sacrifices.

DENEB, an arabic term signifying tail, used by astronomers to denote several fixed stars. Thus deneb electus, signifies the bright star in the lion's tail. Deneb adigege, that in the swan's tail, &c.

DENEF, or Aldeneb Alchail, in the writings of the arabian physicians, denotes a plant called equisetum or horsetail. See the article Equisetum.

DENIER, a small french copper-coin, of which twelve make a sol.

There were two kinds of deniers, the one was the king's gift. A denier purchas'd, is enabled in the usual way, to take lands by devise.

DENIZEN, in law, an alien made a subject by the king's letters patent, otherwise called donation, because his legitimation proceeds ex donatione regis, from the king's gift. A denizen is enabled in several respects to act as natural subject, viz. to purchase and possess lands, and enjoy any office or dignity; yet it is short of naturalization, for a stranger, when naturalized, may inherit lands by descent, which a denizen cannot do. If a denizen purchase lands, his issue that are born afterwards may inherit them, but those he had before shall not; and as a denizen may purchase, so he may take lands by devise.

DENMARK, a kingdom situated between 8° and 15° of east longitude, and between 54° and 62° of north latitude: it comprehends the peninsula of Jutland, and the islands of Zeland, Funen, &c.

The kingdom of Denmark likewise belong to the kings of Denmark.

DENNIS, or St. Dennis, a town of France four miles north of Paris, where the kings of France are interred.

DENOMINATION, a name imposed on any thing, usually expressing some predominant quality. Hence, as the qualities and forms of things are either internal...
inal or external, denomination becomes, 1. Internal, which is that founded on the intrinsic form. Thus Peter is denominated learned, on account of his learning, which is something internal. 2. External denomination, that founded on an external form. Thus, a wall is said to be seen and known, from the vision and cognition employed upon it. And thus, Peter is denominated honoured by honour, and known, from the vision upon him. Hence, Peter is denominated honoured by honours.

DENOMINATIVE QUALITY, that quality from which things take their denomination. See the preceding article. DENOMINATOR, in arithmetic, a term used in speaking of fractions. The denominator of a fraction is the number below the line, phrased into how many parts the integer is supposed to be divided. Thus in the fraction \(\frac{a}{b}\), the number 4 shows that the integer is divided into four parts. So in the fraction \(\frac{a}{b}\), 4 is the denominator. See the article FRACTION.

DENOMINATOR of a ratio, is the quotient arising from the division of the antecedent by the consequent. Thus 3 is the denominator of the ratio 40 : 5, because 40 divided by 5, gives 8 for a quotient. It is also called the exponent of a ratio. See the article EXPONENT.

DENON RESIDENTIA CLERICI REGIS, a writ that lies where a person is employed in the king's service, in order to excise him of non-reliance upon his living. DENS, TOOTH, in anatomy. See the article TOOTH.

DENS CANIS, DOG'S TOOTH, in botany, a distinct genus of plants, called by Linnaeus erythronium. See the article ERYTHRONIUM.

DENS LEONIS, DANDELION, a plant otherwise called leontodon. See the article LEONTODON.

DENSISHRING, or DEVENSRING, in husbandry. See DEVENSRING.

DENSAGE, or DENSALIS, a fish more usually called dentex. See DENTEX.

DENSITY of bodies, is that property directly opposite to rarity, whereby they contain such a quantity of matter under such a bulk. Accordingly, a body is said to have double or triple the quantity of matter in the other. The densities and bulks of bodies, are the two great points upon which all mechanics or laws of motion turn. It is an axiom that bodies of the same density contain equal masses under equal bulks. If the bulks of two bodies be equal, their densities are as their masses; consequently, the densities of equal bodies are as their gravities. If two bodies have the same density, their masses are as their bulks; and as their gravity is as their masses, the gravity of bodies of the same density is in the ratio of their bulk. Hence also bodies of the same density are of the same specific gravity; and bodies of different density, of different specific gravity. The quantities of matter in two bodies, are in a ratio compounded of their density and bulk: consequently their gravity is in the same ratio. If the masses or gravities of two bodies be equal, the densities are reciprocally as their bulks. The densities of any two bodies are in a ratio compounded of the direct ratio of their masses, and a reciprocal one of their bulks: consequently since the gravity of bodies is as their masses, the densities of bodies are in a ratio compounded of the direct ratio of their gravities, and a reciprocal one of their bulks. See the method of finding the specific gravities, and consequently the densities, of both solid and fluid bodies, and likewise a table of the specific gravities of bodies, under the articles HYDROSTASTICAL BALANCE, and SPECIFIC GRAVITY.

DENSITY of the air, is a property that has employed the later philosophers since the discovery of the toricellian experiment. It is demonstrated, that in the same vessel, or even in vessels communicating with each other at the same distance from the center, the air has everywhere the same density. The density of the air, \(ceteris paribus\), increases in proportion to the compressing powers. Hence the inferior air is denser than the superior; the density, however, of the lower air, is not proportional to the weight of the atmosphere on account of heat and cold, and other causes perhaps which make great alterations in density and rarity. However, from the elasticity of the air, its density must be always different at different heights from the earth's surface; for the lower parts being pressed by the weight of those above, will be made
DENT [876] DENT

made to accede nearer to each other, and the more so as the weight of the incum­bent air is greater. Hence, the den­sit of the air is greatest at the earth's surface, and decreases upwards in geo­metrical proportion to the altitudes taken in arithmetical progression.

If the air be rendered denser, the weight of bodies in it is diminished; if rarier, increased, because bodies lose a greater part of their weight in denser than in rarer mediums. Hence, if the density of the air be sensibly altered, bodies equally heavy in a rarer air, if their specific gra­vities be considerably different, will lose their equilibrium in the denser, and the specifically heavier body will preponderate. See Air and Condenser.

Density of the planets. In homogeneous, unequal spherical bodies, the gravities on their surfaces are as the diameters, if the densities are equal. But if the bodies be equal, the gravities will be as the den­sities. Therefore, in bodies of unequal bulks and densities, the gravity will be in a compound ratio of the diameters and densities. Consequently, the densities will be as the gravities divided by the diameters, and therefore in the several bodies as follows, \( \text{viz.} \)

In the Sun. Jupiter. Saturn. Earth. Moon:

10000. 9384. 6567. 39539. 48911.

As it is not likely that these bodies are homogeneal, the densities here determined are not to be supposed the true, but rather the mean densities, or such as the bodies would have if they were homogeneal, and of the same mass of matter, and magnitude.

Dentalium, in natural history, a simple shell having no hinge, and formed only of one piece: it is of a figure approaching to cylindric or conic, and is sometimes crooked, sometimes straight; sometimes closed at one end, sometimes open at both: its animal inhabitant is called nereis. See the article Nereis.

The name dentalium has been given this shell, from the great resemblance it has to the denticated canini of quadrupeds. There are several species of it, frequent on the shores of Italy, Portugal, &c. Among us, they are found fossil in clay-pits, some smooth, some striated; but in much greater abundance in the mountains of France and Italy. See plate LXIX. fig. 4.

The true official dentalium is one of the canales, or tubuli marini simplices, of au­thors: and the animal that inhabits it is of the genus of the nereis of Linnaeus. See the article Nereis.

Great things have been recorded of the virtues of the dentalium, but it has in reality no other than those of an alkali or absorbent, so that the readiness of oyster-shells has now put it out of use.

Dentaria, toothwort, in botany, a genus of the tetradynamia-filiquea class of plants, the corolla of which is cruci­form, and consists of four roundish, ob­truse petals, slightly margined, plane, and ending in ungues of the length of the cup: the fruit is a long, roundish, bilo­cular pod, consisting of two valves: the seeds are numerous and roundish. See plate LXIX. fig. 6.

The root of this plant, the only part used in medicine, is accounted drying and astringent.

Dentaria affinis, a name given by some to the orobanche of Linnaeus. See the article Orobanche.

Dentaria facie, in botany, the same with the hydrophyllum. See the article Hydrophyllum.

Dentated leaf, among botanists, one notched at the edges with a number of blunt points in some measure resembling teeth. See the article Leaf.

Dented, or indent ed. See the article Indented.

Dentes, teeth. See Dens.

Dentex, in ichthyology, a species of sparus, of a deep olive-brown colour, elegantly variegated with darker and paler spots: its back is acute or ridged, and it has four large teeth: it is a well tasted fish. See the article Sparus.

Dentiles, or denticles, in architecture, an ornament in cornices bearing some resemblance to teeth, particularly used in the ionic and corinthian orders. They are cut on a little square member, properly called denticulus, and the notches or ornaments themselves, dentils. In an­cient times dentiles were never used in the ionic cornice, yet they are found in the remains of the theatre of Marcellus, which some take for an argument that Vitruvius had not the direction of that building. Vitruvius prescribes the breadth of each dentil to be half its height, and the indenture or interval between each two, he directs to be two thirds of the breadth of the dentil.

Denticuli elephantis, the same with the dentalia. See Dentalium.

Dentiform
DENTIFORM PROCESS, in anatomy. See the article Pyrenoïdes.

DENTIFRICE, in medicine, a remedy for rubbing the teeth, and purging them from fords; and for cleaning and abverting the gums, when replete with humours. There are dentifrices of various kinds and forms, some in form of a powder composed of corals, pumice-stone, salt, allum, egg-shells, crabs-claws, hartshorn, &c. others in form of an electuary, consisting of the same powders mixed up with honey; others are in form of a liquor drawn by distillations from drying herbs, and astringent medicines, &c. See TEETH.

The generality of operators for the teeth allow acids, such as spirit of vitriol, &c. to be the readiest of all dentifrices, to take off the founfiefs and yellowness of the teeth: but yet, they don't advise a frequent use of these remedies, as they wear away too much of the teeth and injure the gums.

The Dutch account the best dentifrice for keeping the teeth white and found, and the Spaniards hold urine to be good for that purpose.

DENTILLARIA, LEADWORT, a plant more usually called plumbago. See the article PLUMBAGO.

DENTISCALPRA, in surgery, an instrument for scouring yellow, livid, or black teeth; to which being applied, near the gums, it scrapes off the foul, morbid crust.

Some of these instruments are furnished with narrow points; others with broader, and with edges; and some again are falciiform; but all of them adapted to one and the same handle.

DENTITION, the breeding, or cutting, the teeth in children.

Among all the disorders which afflict children, there are none generate such grievous symptoms as difficult dentition. About five or six months after birth, the teeth generally begin to make their appearance: first, the incisors, or fore-teeth; next, the canini, or dog teeth; and, lastly, the molares, or grinders.

About the seventh year there comes a new set; and at twenty one the two inner grinders, called denteis saponis, or teeth of wisdom. At the time of cutting their teeth, they flavor very much, and have a diarrhoea, which is no bad sign: but when it is difficult, especially when the canine teeth begin to be in motion, and make their way out through the gums, the child has startings in his sleep, tumours of the gums, gripe, a kinds of colic, or distressings, greenish stools, the thirst, fevers, difficult breathing, suffocating catarrhs, convulsions, epilepsies, which often end in death.

It shews the dentition is like to be bad, if the child is perpetually crying, thrusts his finger into his mouth, and bites the nurse's nipples; if unequal tubercles are perceived in the gums, where the teeth are expected to appear; if there is a heat in the mouth, and the whole body; if they start without a cause, especially in sleep.

Harris observes, that when an inflammation appears, the physicians will labour in vain, if the cure is not begun by applying a leech under each ear. When the swelling of the gum shews it is time to cut it, to make way for the tooth, he would have it done with a pen-knife, not with a fine lancet, left the wound should heal, and form a cicatrix. The food he directs to be no more than lukewarm.

Heilter internally advises aqueous mixtures, temperating powders; externally, oil of sweet almonds, with spirit of violet, or spirit of wild poppies, lightly acidulated with spirit of vitriol, where with often to rub the gums; as also with the coral, or other smooth thing, which will have the same effect. Some reckon the fresh blood of a cock's comb a specific for this purpose. Morgan affirms, in this case, it will be best to abate the efficacy of the blood with dieters; to appease the pain with gentle opiates; to open the body with purges and elysiers; to draw off the fermented serum by blisters; to promote the cutting of the teeth by cooling, relaxing, and opening the gums: for this purpose diacodium is good, or a strong decoction of marshmallows and poppy-heads, in thick milk, cream, or neats-foot oil.

Sydenham observes, that pains in dentition often produce fevers; for which he could find no remedy so effectual as three or four drops of spirit of hartshorn in a spoonful of simple water, or other convenient vehicle, given every four hours: the number of doses may be four, five, or fix.

DENUNCIATION, a solemn publication or promulgation of any thing.

All veils of enemies are lawful prize.
DEODAND, in our customs, implies a thing devoted or consecrated to God, for the pacification of his wrath, in case of any misfortune; as a person's coming to a violent end, without the fault of any reasonable creature; as if a horse should strike his keeper, and so kill him. In this case, the horse is to be a deodand; that is, he is to be sold, and the price distributed to the poor, as an expiation of that dreadful event.

DEODAND, in our customs, implies a thing devoted or consecrated to God, for the pacification of his wrath, in case of any misfortune; as a person's coming to a violent end, without the fault of any reasonable creature; as if a horse should strike his keeper, and so kill him. In this case, the horse is to be a deodand; that is, he is to be sold, and the price distributed to the poor, as an expiation of that dreadful event.

DEPONENT, in the law of Scotland, a person who makes a deposition. See the article DEPOSITION.

DEPOPULATION, the act of committing waste. See the article WASTE.

DEPORTATION, a sort of banishment used by the Romans, whereby some island or other place was allotted to a criminal for the place of his abode, with a prohibition not to stir out of the same on pain of death.

DEPOSIT, among civilians, something that is committed to the custody of a person, to be kept without any reward, and to be returned again on demand.

Deposits are distinguished into simple and judiciary.

Simple Deposit is either voluntary or necessary: necessary, is that done in cases of hoffity, shipwreck, fire, &c.

Judiciary Deposit is that whose property is contended by several persons, and deposited in the custody of some third person, by order of a judge.

DEPOSITARY, in the French law, a person intrusted as keeper or guardian of a deposit. See the preceding article.

Ordinary depositaries are not to warrant the thing left with them, in case it be lost or stolen: they are only to answer for fraud or the like.

DEPOSITION, in law, the testimony given in court by a witness, upon oath.

In chancery, deposition is a testimony set down in writing, by way of answer to the interrogations exhibited in chancery, where such witness is called deponent.

Depositions in one cause may be used at the hearing of another; where they are between the same parties, &c., without any motion: this is not permitted in other courts, without a special order of the court of chancery. The depositions in chancery, after the cause is determined there, may be given in evidence in a trial at bar, in any of the other courts.

Deposition also signifies the sequestrating or depriving a man of some dignity and office.

DEPRECATION, in rhetoric, a figure whereby the orator invokes the aid and assistance of some one; or prays for some great evil or punishment to befall him who speaks falsely, either himself or his adversary.

DEPRECATORY, or DEPRECATIVE, in theology, a term applied to the manner of performing some ceremonies in the form of prayer.

The form of absolution is deprecative in the Greek church, being conceived in these terms, May God absolve you: whereas it is in the declarative form in the Latin church, and in some of the reformed churches, I absolve you.

DEPRESSION of equations. See the article EQUATION.

DEPRESSION of the pole. When a person fails or travels towards the equator, he is said to depress the pole, because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This phenomenon arises from the spherical figure of the earth. See EARTH and POLE.

When a star is under the horizon, it is termed the depression of that star under the horizon. The altitude or depression of any star is an arch of the vertical intercepted between the horizon and that star. See HORIZON and VERTICAL.

DEPRESSOR, or DEPRIMENS, in anatomy, a name applied to several muscles, because they depress the parts they are fastened to.

DEPRESSOR LABII INFERIORIS, or QUADRATUS, is a muscle consisting of some thin fleety fibres, which lie immediately under the skin of the chin; they arise from the edge of the fore-part of the whole under-jaw, and are inserted in the lower part of the orbicularis.

DEPRESSOR LABII SUPERIORIS, or TRIANGULARIS, is a muscle that arises from the lower edge of the under-jaw, between the maffeter and quadratus, and ascends by the angle of the mouth to the upper-jaw. These two muscles acting together, express a sorrowful countenance, because they draw downwards the corners of the mouth and cheeks.

DEPRESSORES NASI, a pair of muscles arising from the os maxillare, above the dente incisores; and are inserted into the extremities of the aæ, which they pull downwards.

DEPRESSOR ANGULI ORIS, a name given by Albinus to the muscle called by others depressor labiorum communis. See the article DEPRESSOR LABII.

DEPRESSORES OCULI, a pair of muscles springing from each corner of the eye, and answered by another pair of the like figure and structure, in the lower eyelid. See EYE.

DEPRIMENS, the same with depressor. See the preceding article.

DEPRIVATION, in the canon law, the depoising a bishop, parson, vicar, &c., from his office and preferment.

5 U 2
There are two forts of deprivation, the one a beneficio, the other ab officio: the deprivation a beneficio, is when, for some great crime, a minister is wholly deprived of his benefice. A deprivation ab officio, is when a minister is for ever deprived of his orders, which is also called deposition or degradation: this is generally for some heinous crime delerving death, and is performed by the bishop.

DEPTFORD, a town three miles east of London, on the southern banks of the Thames; chiefly considerable for its fine docks for building ships, and the king's yard.

DEPUTATION, the name given by Sydenham to a fever which prevailed much in the years 1661, 1662, 1663, and 1664. He called it depuratory, because he observed that nature regulated all the symptoms in such a manner, as to fit the febrile matter, prepared by proper concoction, for expulsion in a certain time, either by a copious sweat, or a freer perspiration.

DEPUTATION, a mission of select persons out of a company, or body, to a prince or assembly, to treat of matters in their name. They are more or less solemn, according to the quality of those who send them, and the business they are sent upon.

DEPUTY, a person sent upon some business, by some community. Deputy is also one that exercises an office in another's right; and the forfeiture or misdemeanour of such deputy shall caufe the person, whom he represents, to lose his office. A principal officer may not appoint his deputy in all cases, unless the grant of the office will justify him in so doing; but when an office descends to an infant, he may make a deputy of course. Judges have no power to hold their courts by deputy: recorders, however, may do it. It is held a coroner cannot appoint a deputy, it being a judicial office of trust, annexed to the person. And if the office of parkership be granted to one, he cannot depute another, because it is an office of trust and confidence.

DEPUTATUS, among the antients, a name applied to persons employed in making of armour: and likewise to brisk active people, whose business was to take care of the wounded in engagements, and carry them off the field.

DEPUTATUS, δεπουτάτος, in the greek church, an inferior officer, like an usher, who in processions kept the crowd off the patriarch.

DE QUIBUS SUR DISSEISIN, in law, a writ of entry. See ENTRY.

DERBENT, a city of Dagistain, on the western coast of the Caspian sea: east lon. 41°, and 41° 15' north lat.

DÉRÈBIA, a name given by some surgeons to the impetigo. See IMPETIGO.

DEREHÁM, a market-town of Norfolk, about fifteen miles west of Norwich: east long. 1°, and north lat. 52° 40'.

DEREIGN, or DARIIGN. See the article DAREIGN.

DERELICTS, in the civil law, such goods as are wilfully relinquished by the owner. DERELICT signifies also a thing forsaken, or cast away by the sea.

DERIVATION, in medicine, is when a humour, which cannot be conveniently evacuated at the part affected, is attracted from thence, and discharged at some more proper place in its vicinity; or is drawn from a noble to a more ignoble part, where it is less capable of doing injury. Thus a blister is applied upon the neck to draw thither the matter, in cases of defluxions upon the eyes.

DERIVATIVE, in grammar, a word which is derived from another called its primitive. See PRIMITIVE.

Thus manhood is derived from man, deity from deus, and lawyer from law.

DERMA, in anatomy, the name with cutis. See the article CUTIS.

DERMÈTES, in zoology, a genus of insects of the order of the coleoptera, the antennae of which are of a clavated figure and perforated transversely. There are a great many species of this genus, confounded by some with beetles. See plate LXIX. fig. 2.

DERNIER RESSORT. See RESSORT.

DEROGATION, in the french law, an act which annuls a preceding one, either in whole, or in part. In general terms, they are not regarded in judicature; they must be in specific, and in formal terms.
DEROGATORY, a clause importing derogation. A derogatory clause in a testament, is a certain sentence, cypher, or secret character, which the testator inferts in his will, and of which he reserves the knowledge to himself alone, adding a condition that no will he may make hereafter is to be reckoned valid, if this derogatory clause is not inserted expressly, and word for word. It is a precaution invented by lawyers against later wills extorted by violence, or obtained by forgery.

DERPT, a town of Livonia, situated on the river Emboec: east lon. 28° 10', and north lat. 58° 10'.

DERVIS, a name given to all mahommedan monks, though of various orders. The most noted among them are the bektafhi, the mevelevi, the kadri, and the feyah. The bektafhi, who are allowed to marry and live in cities and towns, are obliged, by the rules of their order, to visit remote lands, and to salute every one they meet with gazel, or love-ongs, and with ajma, or the invocation of the names of God, and humbly to with him prosperity, which they do by repeating the word sivallah, a solemn exclamation of the wrestlers, by which the conquered yields the palm to the conqueror. The mevelevi, so called from Mevelava their founder, are used to turn round for two or three hours together, with such swiftness that you cannot see their faces; they are great lovers of music: in their monasteries they profess great humility and poverty, and when visited make no distinction of persons; they first bring their guests coffee to drink; and, if the ways have been dirty, they wash their feet and sandals. The kadri, with a peculiar superition, emaciate their bodies; they go quite naked, except their thighs, and often join hands and dance, sometimes a whole day, repeating with great vehemence, bu! bu! bu! (one of the names of God) till, like madmen, they fall on the ground, foaming at the mouth, and running down with sweat: the prime vizir Kupruli Achmed Pasha, thinking this feét unbecoming the mahommedan religion, ordered it to be suppressed; but, after his death, it revived, and is at present more numerous than ever, especially at Constantinople. The feyah are wanderers, and though they have monasteries, yet they often spend their whole life in travelling; when they are sent out, their superiors impose upon them such a quantity of money or provisions, forbidding them to come back till they have procured it, and sent it to the monastery; wherefore when a feyah comes into a town, he cries aloud in the market-place, Ya allah fenden, &c. O God! give me, I pray, five thousand crowns, or a thousand measures of rice. Many of these dervises travel over the whole mahommedan world, entertaining the people wherever they come, with agreeable relations of all the curiosities they have met with. There are dervises in Egypt, who live with their families, and exercise their trades, of which kind are the dancing dervises at Damascus. They are all distinguished among themselves by the different forms and colours of their habits; those of Persia wear blue; the solitaries and wanderers wear only rags of different colours; others carry on their heads a plume made of the feathers of a cock; and those of Egypt wear an octagonal badge of a greenish white alabaster at their girdles, and a high stiff cap, without any thing round it.

DERWENT, a river, which taking its rise in the north riding of Yorkshire, runs south, and falls into the Ouse.

DERWENT-WATER, a river of Cumberland, which falls into the Irish sea below Cockermouth.

DESART, a large extent of country entirely barren, and producing nothing. In this fenfe some are sandy desarts, as those of Lop, Xamo, Arabia, and several others, in Asia; in Africa, those of Lybia and Zara; others are fony, as the desart of Pharan in Arabia Petraea.

The Desart, absolutely so called, is that part of Arabia south of the holy land, where the children of Israel wandered forty years.

DESCANT; in music, the art of composing in several parts. See Composition. Descant is threefold, viz. plain, figuative, and double. Plain Descant is the ground-work and foundation of all musick compositions, consisting altogether in the orderly placing of many concords, anfwering to simple counterpoint. See Counterpoint. Figurative or florid Descant, is that part of an air of musick, wherein some disconcs are concerned, as well, though not so much, as concords. This may be termed the ornamental and rhetorical part of musick, in regard that there are introduced all the varieties of points, syncopcs, diversities of measures, and whatever is capable of adorning the composition.

Descant
Descant, double, is when the parts are so contrived, that the treble, or any high part, may be made the bass; and, on the contrary, the bass the treble. See the articles Harmony, Counterpoint, and Melody.

Descendant, in genealogy, a term relative to ascendant, and applied to a person who is born or issued from some other referred to: thus mankind are said to be the descendants of Adam. See the article Descend.

Descension, or descending, in general, signifies much the same with descent. See the article Descend.

Descension, in astronomy, is either right or oblique.

Right DESCENSION is an arch of the equinoctial, intercepted between the next equinoctial point and the intersection of the meridian, passing through the center of the object, at its setting, in a right sphere.

Oblique DESCENSION, an arch of the equinoctial intercepted between the next equinoctial point and the horizon, passing through the center of the object, at its setting, in an oblique sphere.

DESCENSIONAL, something belonging to descent. See Descension.

DESCENSIONAL DIFFERENCE, that between the right and oblique descent of any heavenly body. See Descension.

DESCENT, in general, is the tendency of a body from a higher to a lower place; thus all bodies, unless otherwise determined by a force superior to their gravity, descend towards the center of the earth: the planets too may be said to descend from their aphelion to the perihelion of their orbits, as the moon does from the apogee to the perigee.

Heavy bodies, meeting with no resistance descend with an uniformly accelerated motion, for the laws of which see the article Acceleration.

Laws of the DESCENT of bodies. 1. All bodies near the surface of the earth descend perpendicularly at the rate of fifteen feet one inch in a second of time.

The velocity of a body descending in an inclined plane, at the end of any given time, is to the velocity that it would acquire by descending perpendicularly in the same time, as the altitude of the inclined plane is to its length.

3. The last velocity acquired by the direct descent, is to the last velocity acquired in the same time by the oblique descent, as the absolute gravity is to the relative gravity of the descending body.

4. The line described by the direct descent, is to the line described in the same time by the oblique descent, as the length of the oblique plane is to its height.

5. If the line described by the direct descent be to the line described by the oblique descent, as the height of the inclined plane to its length, then the times of descent shall also be in the same proportion, and the last velocities equal.

6. The last velocities acquired upon several inclined planes of the same height, however different in length, are equal.

7. The time of oblique descent through any chord of a circle, drawn from its lowest point, is equal to the time of a direct descent through the diameter of that circle.

8. The last acquired velocities of a body, descending to the lowest point of a given circle, through different chords, are as those chords.

9. The time of the descent of a body in any arch of a semicycloid, is equal to the time of its descent through any other arch, whether longer or shorter, of the same curve.

10. A body will descend faster along an arch of a cycloid, than along that of any other curve; drawn between the same points.

11. If water runs out through a hole made in the bottom of a parabolic cone, the surface of the water will descend equal spaces in equal times.

12. A body descends in a refilling medium with a force only equal to the excess of its gravity above that of an equal bulk of the medium.

13. If a body be thrown downwards, in a refilling medium, with such a force as shall make the resistance of the medium equal to the acceleration of gravity, it will afterwards descend with an uniform motion.

14. If a body descends through any number of inclined planes, it will acquire the same velocity at the end of its fall, as though it had fallen through a plane equal in height to the whole, and of the same inclination with the last of them.

Descent, or Descend, in law, an order or method whereby lands or tenements are derived to any man from his ancestors.

It is either by the common law, custom, or statute. By the common law, as where a person has lands of inheritance in fee, and dies without having made any disposition thereof: wherefore the land descends and goes in course to the eldest son and heir. By custom, as where the lands sometimes descend to all the sons; or to all the brothers, where one brother dies without issue, as in gavel-kind; &c. And descent
defent by statute is a defent in see-tail, as directed by the manner of the limitation or settlement, pursuant to statute. Westm. 2 and 13 Ed. I.

Defent, at common law, is either lineal or collateral.

Lineal defent is that conveyed down in a right line from the grand-father to the father, from the father to the son, and from the son to the grand-son. Collateral defent is that springing out of the side of the line, or blood, as from a man to his brother, nephew, or the like.

Descent, in genealogy, the order or succession of descendants in a line or family; or their distance from a common progenitor: thus we say, one defent, two defents, &c. See Extraction.

Descent, in heraldry, is used to express the coming down of any thing from above; as, a lion en defcent, is a lion with his head towards the base points, and his heels towards one of the corners of the chief, as if he were leaping down from some high place.

Descents, in fortification, are the holes, vaults, and hollow places made by undermining the ground.

The defent into the moat or ditch is a deep passage made through the esplanade and covert-way, in form of a trench, whereof the upper part is covered with madders and clays, to secure the besiegers from the enemy's fire. In wet ditches this trench is on a level with the surface of the water, but in dry ones it is sunk as deep as the bottom of the ditch.

Descrìbent, in geometry, a line or surface, which, by moving parallel to itself, describes a surface or solid. See the articles Line, Surface, and Solid.

Description, is such a strong and beautiful representation of a thing, as gives the reader a distinct view and satisfactory notion of it.

Descriptions are almost peculiar to poetry: historians indeed describe things, places, and persons; but not so much for the sake of ornament, as of necessity. Orators likewise attempt descriptions when they have a mind to work upon the passions; but neither the one nor the other use them as decorations to their writings, which poets generally do, very successfully, not only with a design to move the passions, but to please the fancy. Great judgment is required in the due exercise of this art. A judicious author will omit low and vulgar circumstances, and chiefly below his pains to complete all the essential and masterly strokes, cutting off all superfluities, and rejecting the most pleasing thought and florid lines, when foreign to his subject: many things must be left to the imagination of the reader, and feaonable silence has its emphasis; thus Virgil tells us, Georg. iv. 457, that Eurydice was killed by a monstrous serpent, lurking in a bank; but says nothing more of that venemous creature. A poet after would probably have spent as many lines in the description of it, as composed that admirable poem. The description of a person is called a character, in drawing which the true proof of art and judgment is to hit a beautiful likeness, and, with a delicate touch, to give those features and colours which are peculiar to the person, and distinguishing him from the rest of mankind. In every good and lively description, a man must come to an enumeration of the chief particulars; for generals are often obscure and faint. A judicious author, by setting everything in full view, makes a strong and lasting impression on the reader.

Deesada, or Desiderada, one of the Caribbee-islands, subject to France, lying eastward of Guardaloupe. See the article Caribbee.

Deserter, in a military sense, a soldier who, by running away from his regiment or company, abandons the service. A deserter is, by the articles of war, punishable by death, and, after conviction, is hanged at the head of the regiment he formerly belonged to, with his crime writ on his breast, and suffered to hang till the army leave that camp, for a terror to others.

Deshache, in heraldry, is where a beast has its limbs separated from its body, so that they still remain on the effigies, with only a small separation from their natural places.

Desideratum is used to signify the desirable perfections in any art or science: thus, it is a desideratum with the blacksmith, to render iron fusible by a gentle heat, and yet preserve it hard enough for ordinary uses; with the glazemaker and looking-glass maker, to render glass malleable; with the clock-maker, to bring pendulums to be useful, where there are irregular motions; with the brazier and coopermith, to make malleable folder; with the shipwright, to build vessels that will fail under water; with the diver, to procure manageable instruments.
DESIGN, in a general sense, the plan, order, representation, or construction of a building, book, painting, &c.

In building, the term ichnography may be used, when by design is only meant the plan of a building, or a flat figure drawn on paper: when some side or face of the building is raised from the ground, we may use the term orthography; and when both front and sides are seen, in perspective, we may call it scenography. See ICHNOGRAPHY, ORTHOGRAPHY, and SCENOGRAPHY.

DESIGN, in the manufactories, expresses the figures wherewith the workman enriches his stuff, or silk, and which he copies after some painter, or eminent draughts-man, as in diaper, damask, and other flowered silk and tapestry, and the like.

In undertaking of such kinds of figured stuffs, it is necessary, says Mon. Savary, that, before the first stroke of the shuttle, the whole design be represented on the threads of the warp; we do not mean in colours, but with an infinite number of little packthreads, which, being disposed so as to raise the threads of the warp, let the workmen see, from time to time, what kind of silk is to be put in the eye of the shuttle, for woof. This method of preparing the work is called reading the design, and reading the figure, which is performed in the following manner: a paper is provided, considerably broader than the stuff, and of a length proportionate to what is intended to be represented thereon. This they divide lengthwise, by as many black lines as there are intended threads in the warp; and cross these lines, by others drawn breadthwise, which, with the former, make little equal squares: on the paper thus squared, the draughts-man designs his figures, and heightens them with colours, as he sees fit. When the design is finished, a workman reads it, while another lays it on the simblot. See the article SIMBLOT.

To read the design, is to tell the person who manages the loom, the number of squares, or threads, comprised in the space he is reading, intimating at the same time whether it is ground or figure. To put what is read on the simblot, is to fasten little strings to the several packthreads, which are to raise the threads named; and thus they continue to do till the whole design is read.

Every piece being composed of several repetitions of the same design, when the whole design is drawn, the drawer, to begin the design afresh, has nothing to do but to raise the little strings, with flip-knots, to the top of the simblot, which he had let down to the bottom: this he is to repeat as often as is necessary till the whole be manufactured.

The ribbon-weavers have likewise a design, but far more simple than that now described. It is drawn on paper with lines and squares, representing the threads of the warp and woof. But instead of lines, whereof the figures of the former consist, these are constituted of points only, or dots, placed in certain of the little squares, formed by the intersection of the lines. These points mark the threads of the warp that are to be raised, and the spaces left blank denote the threads that are for conveying fresh air to the bottom of the sea, sufficient for respiration and the burning of lights; with the assay-master, to melt or copel ores or metals immediately, without the use of bellows or furnaces; and with the carvers and joiners, to fashion wood in moulds like plaiter of paris, or burnt alabaster, &c. And tho', as Mr. Boyle observes, the obtaining of calx, yet it is proper they should be these desiderata may be thought to melt paris, or burnt alabaster, be attainable, yet approaches to it may of the owners of several mines in this kingdom.

All arts have their defects; and it is not at first to be guessed, for how many of these remedies may be found, by means of chemical researches, properly directed. Chemistry itself is greatly defective in many particulars, as in an experimental history of general fermentation, separatory and combinatorial; in subjects of the animal, vegetable, and mineral kingdoms. The schemes for new trades will rise occasionally in prosecuting many of the subjects; thus it is natural for the making of iron malleable with pit-coal was once thought of chemical researches, properly

In an experimental history of general fermentation, separatory and combinatorial; in subjects of the animal, vegetable, and mineral kingdoms. The schemes for new trades will rise occasionally in prosecuting many of the subjects; thus it is natural for the making of iron malleable with pit-coal was once thought impossible, yet it is now put in practice, to the great advantage of the owners of several mines in this kingdom.

are to keep their situation: the rest is managed as in the former.

Design is also used, in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large. The art of painting has been by some of the greatest masters divided into the design, or draught, the proportion, the execution, the clavo-obcuro, the ordonnance, the colouring, and the perspective.

Design, in painting, is the simple contour, or outlines of the figures intended to be represented, or the lines that terminate and circumscribe them; such design is sometimes drawn in crayons, or ink, without any shadows at all; sometimes it is hatched, that is, the shadows are expressed by sensible outlines, usually drawn across each other with the pen, crayon, or graver. Sometimes, again, the shadows are done with the crayon rubbed so as that there do not appear any lines: at other times, the grains or strokes of the crayon appear, as not being rubbed: sometimes the design is washed, that is, the shadows are done with a pencil in Indian ink, or some other liquor; and sometimes the design is coloured, that is, colours are laid on much like those in indigo; if the grum appears, as that there do not appear any lines: at other times, the grains or strokes of the crayon appear, as not being rubbed: sometimes the design is washed, that is, the shadows are done with a pencil in Indian ink, or some other liquor; and sometimes the design is coloured, that is, colours are laid on much like those intended for the grand work. The essential requisite of a design are correctness, good taste, elegance, character, diversity, expression, and perspective. Correctness depends on the justness of the proportions, and knowledge of anatomy. Taste is a certain manner of correctness peculiar to one's self, derived either from nature, masters, or studies, or all of them united. Elegance gives a delicacy that not only strikes persons of judgment, but communicates an agreeableness that pleases universally. The character is what is peculiar to each thing, wherein there must be diversity, inasmuch that every thing has its peculiar character to distinguish it. The expression is the representation of an object, according to the circumstances it is supposed to be in. Perspective is the representation of the parts of a painting, or a figure, according to the situation they are in with regard to the point of sight. See Correctness, &c.

The design or draught, is a part of the greatest import and extent in painting. It is acquired chiefly by genius and application, rules being of less avail here than in any other branches of the art, as colouring, &c. The principal rules that regard design are, that novices accustom themselves to copy good originals at first sight; not to use squares in drawing, left they hint and confine their judgment; to design well from life, before they practice perspective; to learn to adjust the size of their figures to the visual angle, and the distance of the eye from the model or object; to mark out all the parts of their design before they begin to shade; to make their contours in great pieces, without taking notice of the little muscles, and other breaks; to make themselves masters of the rules of perspective; to observe the perpendicular, parallel, and distance of every stroke; to compare and oppose the parts that meet and traverse the perpendicular, so as to form a kind of square in the mind, which is the great and almost the only rule of designing judiciously; to have a regard not only to the model, but to the parts already designed, there being no such thing as designing with strict justice, but by comparing and proportioning every part to the first. All the other rules relate to perspective. See Perspective.

Designation, the act of marking or indicating, and making a thing known. There were designations of the confuls and other magistrates among the Romans some time before their election.

Designator, in Roman antiquity, a sort of petty master of the ceremonies, who assigned every body their places in the theatres, and other public shews. The Romans had officers of this nature attending all their solemn shews and processions, for directing precedencies. The designator was one of the goddess Libitina's principal servants, the shews of the funerals of persons of quality being marshalled by the designator. When he went to raise the corps, he was attended with a train of funeral officers called libitinarii, subdivided into pellinatores, vehipiones, uitores, &c. All these, habited in black, walked before the designator, as mace-bearers before magistrates.

Designing, the art of delineating or drawing the appearance of natural objects, by lines, on a plane. To design according to the rules of mathematics, makes the object of perspective. See the article Perspective. To design by the camera obscura. See the article Camera obscura.

Mechanical method of Designing. There are several methods of designing mechanically. The following is the method of the learned Sir Christopher Wren, and may be put in practice with great ease.
A is a small fight, with a short arm B (plate LXIX. fig. 5.) which may be turned round about, and moved up and down the small cylinder CD, which is screwed into the piece ED, at D; this piece ED moving round about the center E, by which means the fight may be removed either towards E or F.

EF is a ruler fastened on the two rulers GG, which rulers serve both to keep the square frame S S S S perpendicular, and, by their sliding through the square holes TT, they serve to fly the fight, either farther from, or nearer, to the said frame; on which frame is stuck on, with a little wax, the paper O O O O, whereon the picture is to be drawn by the pen I. The pen I is, by a small brass-handle V, so fixed to the ruler H H, that the point I may be kept very firm, so as always to touch the paper. H H is a ruler that is constantly, by means of the small strings a a a, b b b, moved horizontally, or parallel to itself; at the end of which is stuck a small pin, whose head P is the fight, which is to be moved up and down on the out-lines of any object.

The contrivance of the strings is this: the two strings a a a, b b b, are exactly of equal length. Two ends of them are fastened into a small leaden weight, which is employed in a socket on the backside of the frame, and serves exactly to counterpoise the ruler H H, being of an equal weight with it. The other two ends of them are fastened to two small pins H H, after they have rolled about the small pulleys M M, L L, K K; by means of which pulleys, if the pen I be taken hold of, and moved up and down the paper, the string moving very easily, the ruler will always remain in a horizontal position.

The manner of using it is this: set the instrument upon a table, and fix the sight A at what height above the table, and at what distance from the frame S S S S, you please. Then looking through the sight A, holding the pen I in your hand, move the head of the pin P up and down the out-lines of the object, and the point of the pen I will describe on the paper O O O O the shape of the object to traced.

DESIGN, the macedonian name of the month, called by the Athenians anthes-pherion. See the article ANTHESTHERION.

DESISE, a town of France, situated on the river Loire, fifteen miles south-east of Nevers: east long. 3° 32', north lat. 46° 48'.

DESON TORT, a term sometimes used for an absolute prince. See the next article.

Under the emperors of Constantinople, despote was a title of honour given to the emperor's sons, or sons in law; as also to their colleagues, and partners in the imperial dignity, in the same manner as Caesar was at Rome. See Caesar.

DESOPHILIC, in general, denotes any thing that is uncontrollable and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turkey, Peru, and most of the eastern governments; and even those of Europe, if we except the republics, our own, and the Swedish government.

DESPOTIC, in general, denotes any thing that is uncontrollable and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turkey, Peru, and most of the eastern governments; and even those of Europe, if we except the republics, our own, and the Swedish government.

DESSIPHILIC, in heraldry, the whole cafe, skin, or flough of a beast, with the head, feet, tail, and all appurtenances, so that being filled and fluffed, it looks like the intire creature.

DESPUMATION, a term sometimes used for the clarifying a liquor, by the skimming off its froth. See Clarification.

DESQUAMATION, the name with exfoliation. See Exfoliation.

DESSAW, a city of upper Saxony, in Germany, situated on the river Elbe, sixty miles north-west of Dresden, and subject to the prince of Anhalt Dessow: east long. 12° 40', north lat. 51° 50'.

DESSERT, or Desart, a service of fruits and sweet-meats, usually erved up last to table.

DESSICATIVE, or Desiccative, in pharmacy, an epithet applied to fuch topical medicines as dry up the humours flowing to a wound or ulcer. See the article Wound.

DESTILLATION, or Distillation. See the article Distillation.

DESTINIES, in mythology, the name with parce. See the article Parce.

DESTINY, among philosophers and divines, the name with fate. See Fate.

DESTRUCTION, in general, an alteration of any thing from its natural state to one contrary to nature; whereby it is deemed the name with corruption. See the article Corruption.

A chemical destruction, or corruption, is nothing but a resolution of the whole naturally mixt body into its parts.
DESUDATION, in medicine, a profuse and inordinate sweat, succeeded by an eruption of pustules, called sudamina, or heat-pimples. See the articles Sudamina and Hydroa.

DESLUTOR, in antiquity, a vaulter, or leaper, who, leading one horse by the bridle, and riding another, jumped from the back of one to the other, as the custom was after they had run several courses, or heats.

This practice required great dexterity, being performed before the use of either saddles or stirrups. The custom was practised in the army, when necessity required it; but chiefly among the Numidians, who always carried two horses, at least, with them for that purpose, changing them as they tired. The Greeks and Romans borrowed the practice from them, but only used it at races, games, &c. The Sarmatæ were great masters of this exercise, and Hussars have still some remains of it.

DETACHED PIECES, in fortification, are such out-works as are detached, or at a distance from the body of the place; as demilunes, ravelines, bastions, &c. In painting, the figures are said to be well detached, when they stand free and disengaged from each other.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scour the country.

A detachment of two or three thousand men, is a command for a brigadier; eight hundred, for a colonel; four or five hundred, for a lieutenant-colonel. A captain never marches on a detachment with less than fifty men, a lieutenant, an ensign, and two serjeants. A lieutenant is allowed thirty, and a serjeant; and a serjeant ten or twelve men. Detachments are sometimes made of entire squadrons and battalions.

DETENTS, in clock-work, are those flops, which, by being lifted up or let down, lock or unlock the clock in striking. See the article Clock-work.

DETTENT-WHEEL, or HOOPE-WHEEL, in a clock, that wheel which has a hoop almost round it, wherein there is a vacancy at which the clock locks.

DETERGENTS, detergentia, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abrade, and carry along with them such particles, as they lay hold on in their passage.

Medicines of this kind are supposed to cleanse, and fill up with new flesh, all ulcerations and foulnesses occasioned thereby, whether internal or external. To do this internally, the medicine is supposed to maintain its primary properties, till it arrives at the place of action, where it is intitled to the appellation of a detergent and vulnerary, by its adhesive quality, which conñits in the comparative largeness of its surface, and flexibility of its component parts: for by this it readily adheres to the flough of ulcerous exudations, which are easily carried along with the medicine; and when this is done, what was instrumental in deterging, will afterwards flick to the cutaneous filaments, till, by the protrusion of proper nourishment, the ulcer is healed; and, in like manner, the operation of external substances are accounted for: only this is to be taken notice of, that internally whatsoever mixes with the animal fluids, will be the first separated and left behind; for all those parts which are specifically heaviest, will move nearest the axis of the canals, because their momenta are greatest, and will carry them nearly in a straight line: but the lighter parts will be always jettled to the sides, where they soonest meet with out-lets, or are struck into the eroded cavities, in which they adhere and make part of the substance. Thus it is easy to conceive how an increase of those qualities of activity and adhesion may make a medicine arise to the greatest efficacy in this respect, even so far, as to fetch off the membranes and capillary vessels. Syphny.

DETERIORATION, the impairing or rendering a thing worse; it is the reverse of melioration. See the article Melioration.

DETERMINATE PROBLEM, in geometry, that which has but one, or, at least, a limited number of answers: as the following problem, which has but one only solution, viz. To describe an isosceles triangle on a given line, whole angles at the base shall be double that at the vertex. But the following hath two solutions, viz. To find an isosceles triangle, whole area and perimeter are given.

A determinate problem may be either simple or linear, plain, solid, or surfold.
DETERMINATION, in mechanics, signifies much the same with the tendency or direction of a body in motion. See the articles Direction and Motion.

DETERMINATION, among school-divines, is an act of divine power, limiting the agency of secondary causes, in every instance, to what the deity predestinates concerning them. See Predestination. Such a determination the Thomists, and other predestinarians, maintain necessary to all the actions of natural agents, particularly mankind. The Jesuits, on the other hand, deny such a determination, as supposing it inconsistent with liberty and free-will. See the articles Liberty and Free-will.

DETERMINATION. See the article Barrying of trees.

DETERGIVES, in medicine, the same with detergents. See Detergents.

DETHMOLD, a town of Westphalia, in Germany, fifteen miles north of Paderborn: eaft long. 8° 3', north lat. 52°.

DETINUE, in law, a writ or action that lies against one who has got goods or other things delivered to him to keep, and afterwards refuses to deliver them. In this action the thing detained is generally to be recovered, and not damages; though, if a person cannot recover the thing itself, he shall recover the damages, and also for the detainer. The nature of a thing must continue without any alteration, to intitle this action; besides, it is necessary that the thing detained be known; therefore it does not lie for money out of a bag, corn out of a sack, &c. Where goods are delivered to a person, and he delivers them over to another, action of detinue may be had against the second person; and notwithstanding he delivers the things to a person who has a right to the same, yet he is chargeable. If the person to whom a thing is delivered happen to die, action of detinue lies against his executors, &c. A man may have a general detinue against another that finds his goods; but if before the owner brings his action, the finder sells them, or they are recovered from him on an execution, &c. he cannot have detinue.

DETINUE of charters. An action for detinue lies for deeds and charters which make the title to lands. An heir, in case of difficulty, may have a detinue of charters, though he has not land. If in this action the issue be upon the detinue, and it is found by jury that the defendant hath burnt the charters, the plaintiff shall have judgment to recover the lands in damages.

DETINUE of goods in frank marriage, is had after a divorce between a man and his wife, for her to recover the goods given with her in marriage.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination. See the article Fulmination.

DETRAHENS QUADRATUS, in anatomy, a muscle otherwise called platysma. See the article Platysma.

DETRANCHE', in heraldry, a line in heraldry, a line.

DETTANGER, or Dittander, in botany. See the article Dittander.

DETTINGEN, a village of Germany, about nine miles east of Hanau, in the circle of the upper Rhine: east long. 8° 45', and north lat. 50° 8'.

DEVA, a port-town of Spain, situated on the bay of Biscay, forty miles east of Bilboa: west long. 2° 16', and north lat. 43° 26'.

DEVASTAVIT, or Devastaverunt, bona testatoris, in law, a writ which lies against executors or administrators for waiting the testator's goods, or paying debts upon simple contracts before debts on bonds, and other specialties; also for paying legacies before debts; and, generally, for squandering the effects of the deceased, and not paying his debts.

DEVENERUNT, in law, a writ which lay formerly on the death of the heir of the king's tenant, and directed to the escheator; commanding him to inquire by the oaths of good and lawful men, what lands and tenements came to the king by the death of the tenant.

DEVENSRING, or Denshiring, a term used in many parts of the kingdom for burning of land. See Burning of land.

DEVENGER, a city of the united Provinces, and province of Overeyssel, about eight miles north of Zutphen: east long. 6°, and north lat. 53° 26'.

DEVESTING, in old law-books, the reverse of inveffing or investiture. See the article Investiture.

DEVIATION, in old astronomy, signified the motion of the deferent or eccentric, whereby
whereby it advanced to, or receded from, the ecliptic. *Harris.*

**DEVICE, or DEVISE, among painters.** See the article **DEVISE.**

**DEVIIL, DEVIOL, an evil angel, one of these celestial spirits, cast down from heaven, for pretending to equal himself with God.** The Ethiopians paint the devil white, to be even with the Europeans who paint him black. There is no mention of the word devil in the old Testament, but only of the word Satan and Belial: nor do we meet with it in any heathen authors, in the sense it is taken among Christians, that is, as a creature revolted from God. Their theology went no farther than to evil genii, or demons. See the articles **GENI and DEMONS.** Some of the American idolaters have a notion of two collateral, independent beings, one of whom is good, and the other evil; which last they imagine has the direction and superintendance of this earth, for which reason they chiefly worship him: whence those that give us an account of the religion of these savages give out, with some impropriety, that they worship the devil. The Chaldeans, in like manner, believed both a good principle and an evil one, which last they imagined was an enemy to mankind. Isaiah, speaking, according to some commentators, of the fall of the devil, calls him Lucifer, from his former elevation than to evil genii, or demons. See the articles **LUCIFER and EBLIS.**

**DEVIL-IN-A-BUSH, a plant called by authors nigella.** See the article **NIGELLA.**

**DEVIL'S BII, the same with the scabious of botanists.** See the article **SCABIOUS.**

**DEVIL'S MILK, a species of tithynal, or spurge.** See the article **TITHYNAL.**

**DEVINCTION, in antiquity, a kind of love-charm, described by Virgil in his eighth eclogue: it confisted in tying certain knots, and repeating a formul of words.**

**DEVISE, or DEVICE, in heraldry, painting, and sculpture, any emblem used to represent a certain family, person, action, or quality; with a suitable motto, applied in a figurative sense.** See **MOTTO.**

The essence of a devise consists in the metaphorical similitude between the things representing and represented: thus a young nobleman, of great courage and ambition, is said to have borne for his devise, in the last carousal at the court of France, a rocket mounted in the air, with this motto in Italian, *poco duri; urche m' inalzi*; expressing, that he preferred a short life, provided he might thereby attain to glory and eminence. The Italians have reduced the making devises into an art, some of the principal laws of which are these: 1. That there be nothing monstrous or extravagant in the figures. 2. That figures be never joined which have no relation or affinity to each other; excepting some whimsical unions established in antient fables, which custom has authorized. 3. That the human body be never used. 4. The fewer the figures, the better. 5. The motto should be every way suitable. **DEVISE is frequently also used for cypher.** See the article **CYPHER.**

**DEVISES, in law, the act whereby a person bequeaths his lands or tenements to another, by his last will and testament.** The person who makes this act, is called the devisor, and he in whose favour the act is made, is termed in law the devisee. The law interprets the words of a will in a larger and more favourable sense than those of a deed: for if land be devised to a man to have to him for ever, or to have to him and his assigns, in those cases the devisee shall have a fee-simple; yet if given in the same manner by feoffment, grant, or gift, he shall have but an estate for life: so if one devise land to an infant in his mother's belly, it is a good and valid devise, though it is otherwise by feoffment, grant or gift; for in those cases, there ought to be one of ability to receive prudence, otherwise it is void. See **DEED and WILL.**

**DEVISES, a borough-town in Wiltshire, eighteen miles north-west of Salisbury: west long. 2° 6', and north lat. 51° 25'. It sends two members to parliament.**

**DEUNX, in roman antiquity, eleven ounces, or 3/5 parts of the libra.** See **LIBRA.**

**DEVOLVED, something acquired by right of devolution.**

**DEVOLUTION, in law, a right acquired by succession from one to another.** See the articles **INHERITANCE, HEIR, SUCCESSOR, &c.**

**DEVONSHIRE, a county in the west of England, bounded by the Bristol channel, on the north; by Somersetshire and Dorsetshire, on the east; by the English channel,
DEU [890] DEU

channel, on the soufh; and by Cornwall, on the west. From this county the noble family of Cavendish take the title of duke.

DEVOTION, devo'tio, a sincere ardent worship of the deity. See PRAY'ER, ADORATION, WORSHIP, &c.

Devotion, as defined by Jurieu, is a softening and yielding of the heart, with an internal confusion, which the souls of believers feel in the practice or exercise of piety. By devotion is also understood certain religious practices, which a perfon makes it a rule to discharge regularly, and with reafon, if the exactitude be founded on solid piety, otherwife it is vanity or superflition. That devotion is vain and trifling, which would accommodate itself both to God and to the world. 

Devotion, among the Romans, was a kind of sacrifice, or ceremony, whereby they conferated themfelves to the service of some perfon. The antients had a notion, that the life of one might be ransomed by the death of another, whence thofe devotions became frequent for the lives of the emperors. Devotion to any particular perfon, was unknown among the Romans till the time of Auguftus.

The very day after the title of Auguftus had been conferred upon Octavius, Pa'ceuvis, a tribune of the people, publicly declared, that he would devote himself to Auguftus, and obey him at the expense of his life, as was the practice among barbarous nations, if he was commanded. His example was immediately followed by all the reft, till, at length, it became an efftablifhed custom never to go to salute the emperor, without declaring that they were devoted to him. Before this, the practice of the Romans was that of devoting themselves to their country. The devotion of Decius, who, after devoting himself to his country, threw himself into the hands of his enemies and was killed, is said to have gained the Romans the victory.

DEVIURING, in heraldry, is when effes are borne in an escutcheon in a feeding posture, for they swallow all the meat whole.

DEUS, GOD, among divines and philofophers. See the article GOD.

DEUTERO-CANONICAL, in theology, a term applied to certain books of scripture which were added to the canon after the reft; either because they were not wrote till after the canon was compiled, or because of some debate in regard to their canonicity.

The Jews undoubtedly acknowledge fe'veral books in their canon which were put there later than the reft. They alledge, that under Ediras, a great assembly of their doctors, which, by way of eminence, they term the great synagogue, collected the holy books, which now compose the hebrew old Testament: and they allow, that this assembly put books therein, that had not been in it before the babylonifh captivity. Such are those of Daniel, Ezekiel, Haggai, &c. and the books of Ediras and Nehemiah.

The church of Rome added, since then, others to the canon that were not in the canon of the Jews, nor could be there, by reafon some of them were not composed till after: such are the books of Eccle'sia'tics, with fe'veral of the apocryphal books; as thofe of the Maccabees, Wis'dom, &c. Others were added still later, by reafon their canonicity had not been examined; and till fuch examen and judgment, they might be fet aside at pleafure.

The deuto-canonical books in the modern canon, are the books of Esther, either the whole, or, at leaft, the seven laft chapters of it; the epiftle to the Hebrews, thofe of James and Jude; the feventh of St. Peter, the second and third of St. John, and the Revelations. The deuto-canonical parts of books are the hymn of the three Children, the prayer of Azar'iah, the histories of Sufannah, of Bel and the Dragon, the laft chapter of St. Mark, the bloody sweat and appearance of the angel, related in Luke xxii. and the history of the adulterous woman in John viii.

DEUTERONOMY, a canonical book of the old Testament, and the laft of the pentateuch of Moses. See the articles BIBLE, CANON, and PENTATEUCH.

This book was called Deuteronomy by the seventy greek translators, as being a recapitulation of the laws before delivered at large.

DEUTEROPOTAM, δευτεροποτάμι, in grecian antiquity, a designation given to fuch of the Athenians as had been thought dead, and, after the celebration of the funeral rites, unexpectedly recovered. It was un-lawful for the deuteropotam to enter into the temple of the Eumenides, or to be admitted to the holy rites, till after they were
DEUTEROSIS, the greek name by which the Jews called their mishnah, or second law. See the article MISHNAH.

Eusebius accuses the Jews with corrupting the true sense of Scripture with the trifling explanations of their deuteroris. Epiphanius says, that there were four sorts of these quoted: the first under the name of Moses, the second under that of Akiba, the third under that of Adda, or Judah, and the fourth under the name of the sons of the Asmonnees, or Maccabees. It is not easy to say, whether the present Mishnah is the same with any of these; whether it contains them all, or only some part, or whether it be different from them all. St. Jerom says, that the Hebrews referred their deuteroris to Shammai, and Hillel; he speaks of the deuteroris with the utmost contempt; he looked upon them as a collection of fables, childish stuff, and obscenities.

DEVUIDER, in the manege, is applied to a horse that, upon working upon volt's, makes his shoulders go too fast for the croupe to follow; so that, instead of going upon two heads as he ought, he endeavours to go only upon one. This comes from the resentment he makes in defending against the heels; or from the fault of the horfeman, who is too haftly with his hand.

DEUX PONTS, a city of Germany, in the palatinate of the Rhine, sixty miles north east of Nancy; east long. 7° 15', and north lat. 49° 25'.

DEW, a denfe moist vapour, falling on the earth in form of a milkling rain, while the fun is below the horizon. In the summer-season, when the weather is fair and very dry, and the earth's surface has, for a considerable time, been parched with the great heat of the sun, then, not only the watery, but likewise other fels volatile particles, as the oily and saline, are, by the power of the solar rays, carried up into the air, and fill that part of it which lies nearest to the surface of the earth; and fo long as thefe exhalations are kept in agitation by the heat of the sun, fo long nothing of them appears to the eye: but as soon as the solar heat, which at three in the afternoon is the greatest, begins to remit, the air not long after begins to grow cool, though the earth, which retains the heat communicated to it by the sun a thousand times longer than the air, being still hot, continues to exhale the agitated corpuscles: by which means there is collected a white, denfe, vapour, which is cool above, but still continues warm below. This vapour therefore appears first in ditches, and watery or marshy places, whence differing itself by degrees, it covers the face of the earth, in the evening and night-time, with a cloud, consisting of this kind of particles, which in the morning is again diffipated by the heat of the rising sun. By this it appears, that dew is a very compound liquid, fo that nothing can be affected of its nature, which in every circumstance would hold true. In gravel-pits, for instance, and in high, dry, healthy grounds of a large extent, there is collected but a very small quantity of this vapour, and that almost entirely watery; whilst that which is collected about flanding waters, fens, marshes, and fat bituminous grounds, abounding with putrified fish, and other animals, is of a quite different nature, and very often pernicious to mankind: whence it is no wonder that chemifs, in their analyzing of dew, should find fuch different refults, that scarce any two are agreed about them: some dew, that had been collected in a certain part of the earth, has afforded alqnor, by distillation, which tricked the colours of the rainbow upon glaids, fo strong as not to be effaced by friction, alkaline lixiviums, or aqua regia; it also burnt like spirit of wine; again some distilled dew, having been digefted with a gentle heat for eight days, and then refifted fix times over, till it was exceeding fubtle, is reported to have broke three glafs vefpels successively, though it still remained perfectly infipid: again fome dew is defcribed to be like a yellowifh butter, that melts by being rubbed upon the hand, yet grows hard and dry with a moderate heat, being of a fetid odour, and to be found in pretty large lumps in the night, espeffially in the fpring and winter. The nature of dew also differs furprizingly with the different feafons of the year, and the various fucceffions of meteors: hence, exceedingly small feeds of vegetables, and invisible eggs of minute animals, with numerous other things coming to be digefted, fermentee, or putrified therein, it must afford many very different productions by distillation: whence chemifs.
chemists have formed very odd opinions about it.

DEW-BORN, in country affairs, a distemper in cattle, being a swelling in the body, as much as the skin can hold, so that some beasts are in danger of bursting. This distemper proceeds from the greediness of a beast to feed, when put into a rank pasture: but commonly when the gravis is full of water. In this case the beast should be stirred up and down, and made to purge well: but the proper cure is bleeding in the tail; then take a grated nutmeg, with an egg, and breaking the top of the shell, put out so much of the white as you may have room to slip the nutmeg into the shell; mix them together, and then let shell and all be put down the beast's throat; that done, walk him up and down, and he shall soon mend.

Sun-Dew, ran fèlis, in botany. See the article Ros SOLIS.

DEX, in zoology, the same with thrips. See the article THRIPS.

DEXTANS, in roman antiquity, ten ounces, or $\frac{1}{2}$ of their libra. See the article LIBRA.

DEXTER, in heraldry, an appellation given to whatever belongs to the right side of a shield, or coat of arms: thus we say, bend-dexter, dexter-point, &c. See the articles BEND, POINT, &c.

Ambo-Dexter, or AMBIDEXTER. See the article AMBIDEXTER.

DEXTROCHERE, or DESTROCHERE, in heraldry, is applied to the right arm painted in a shield, sometimes naked, sometimes cloathed, or adorned with a bracelet; and sometimes armed, or holding some moveable, or member used in the arms.

DEY, in matters of government, the sovereign prince of Algiers, answering to the bey of Tunis. See the article BEY.

DEYNSE, a town of Flanders, nine miles south west of Ghent: east long. 5° 30', north lat. 51°.

DIA, the beginning of several terms in medicine, pharmacy, surgery, &c. Where these three letters commence the name of a remedy, unguent, platter, &c. they signify composition and mixture, as diapomna, &c.

DIA is also the beginning of many terms in the other arts, as diameter, dialogue, &c. See the article DIAMETER.

DIAEE, a species of hisrix, or porcupine-fish. See the article HISTRIX.

DIABOLUS, a devil. See the article DEVIL.
DIABOLUS MARINUS, the Sea-devil, a name given by some authors to a species of ray fish, with a blind-fin, and of a very ugly appearance. See the article RAIA.

DIABOLUS METALLORUM, a title given by chemists to Jupiter or tin, because when incorporated with other metals, it renders them uneetable of reduction, or at least very difficult to undergo that operation.

DIABOTANUM, in pharmacy, a plaiter prepared of herbs described by Galen, De C. M. P. G. lib. vi. c. 2. It resolves and discusses wens.

DIABROSIS, in medicine, the fame with anabrosis. See the article Anabrosis.

DIACARTHAMI, in pharmacy, an elecutary composed of some purgatives with the addition of the pulp of the seed of carthamus, formerly mixed in medicines along with other purgatives, but now wholly out of use.

DIACARYON, in pharmacy, the fame with dianacum. See Dianacum.

DIACOCAUSTIC CURVE, a species of the caustic curves formed by refraction. Thus if you imagine an infinite number of rays BA, BM, BD, &c. (plate LXX. fig. 1.) issuing from the fame luminous point B to be refracted in or from the perpendicular MC, by the given curve AMD, and so that CE, the lines of the angles of incidence CME, be always to CG, the lines of the refracted angles CMG, in a given ratio, the curve HFN, which touches all the refracted rays, is called the diacaustic, or caustic by refraction. See the article Caustic-Curve.

DIACELTATESSON, in chemistry, a name given by Van Helmont, to a purging preparation procured from the fixed flowers of antimony. It is said by its author to cure all intermittent and continued fevers. It is to be given without any acid, and if it operate too violently, the violence may be stopped by taking any thing acid. Boerhaave observes, that he had often given it with good succes, but never with those effects which the author ascribes to it, who says, that it radically cures the gout and fevers, heals ulcers of the larynx, celaphogus and bladder, and purges the body when in perfect health, but not otherwise.

DIACENTROS, a term used by Kepler, for the leffer diameter of a planet's orbit.

DIACHALASIS, among antient physi­gians, signifies the receafs of the bones of the cranium, or the opening of its futures, frequently owing to wounds.

DIACHALCITIS, in surgery and pharmacy, a plaiter composed of oil, alexandria, and chalcitis, which formerly ufed to be applied after the amputation of a cancer, and on many other occasions.

DIACHYLON, in pharmacy, an emollient digestive plaiter, composed of mucilages or vicid juices drawn from certain plants. See Mucilage.

There are several plaiters described by dipensatory writers under the name of diachylon, but the following are those ordered by the college of physicians.

1. Simple diachylon, compounded of fine oil, litharge of gold, the mucilages of fengreek, linseeds, and marshmallow roots. 2. Diachylon magnum, the greater diachylon, made of the mucilages of raisins, figs, marshmallow roots, fengreek, and linseeds, birdlime, of the juices of orrice and squills, of cepsus, of the oils of orrice, camomile and dill, of litharge of gold, of turpentine, of rosin of the pine-tree, and of yellow wax. 3. Diachylon magnum cum gummi, the great diachylon with gums, which consists of the former with the addition of strained galbanum, bellow, fagapenum, and ammoniacum.

Compound diachylon or the mucilage plaiter, compounded of yellow wax, the oil of mucilages, gum ammoniac, and common turpentine.

DIACODIUM, in pharmacy, a syrup prepared from poppy heads. It is also called the syrupus de meconio. As it is of consequence that all the circumstances in the directions for compounding this medicine, be exactly followed, we here give the method of preparing it from the London Dipensatory. Take of the heads of dried white poppies without their seeds, three pounds and a half, of water fix gallons. Slice the heads and boil them in the water, often stirring them that they may not burn, till about a third only of the liquor is left, which will be almost all imbied by the poppy heads: then take all from the fire, and press the liquor strongly out from the heads: in the next place, boil the liquor by itself, to about two quarts, and strain it while hot, sift through a sieve, and then through a thin flannel: let it by for a night, that what scapes have passe the strainers, may fiddle, next morning pour off the clear liquor, and boil it with fix pounds of double refined sugar, till
till the whole comes to the weight of nine pounds, or a little more, that it may become a syrup of a just confusion.

This syrup partakes of all the virtues of the poppy. See the article Poppy.

DIACODUS, among ancient writers, a name given to a kind of beryl, or sapphire, of which many fabulous things are related.

DIACONATE, diaconissa, the office of a deacon. See the article Deacon.

DIACONICON, in church history, an apartment answering to our vestry. See the article Vestry.

DIACOPES, in grammar, the same with tmesis. See the article Tmesis.

DIACOUSTICS, called also diaphonic, the consideration of the properties of refracted sound, as it passes through different mediums. See Sound.

DIACRISIS, in grecian antiquity, an appellation given to a faction at Athens, who favoured oligarchy; in opposition to the pediaci, who were for a pure democratical government.

DIACYDONITSES, in pharmacy, a term applied to these remedies where quinces are a principal ingredient.

DIADELAHIA, in the linnaean system of botany, a class of plants, the seventeenth in order; comprehending all those with papilionaceous and hermaphrodite flowers, and leguminous feed-vessels. See Papilionaceous and Legumen. The distinguishing characteristic of this class is, that the stamina adhere together; forming two dissimilar bodies or filaments, the one standing above the pistil, and the other surrounding it. See plate XXX. fig. 17.

The lower part of this class is membranaceous, and of a cylindrical figure, only open above; but towards the top, it is divided into several fibulated bodies, whereof those in the middle are alternately longer and shorter by pairs. The upper filament is fingle, altogether subulated, and covers the slit of the cylindrical part of the under one. Add to this, that the pistil is fingle; its germ oblong, and rounded; its style, fibularto-filiform; and the stigma covered with down, of the length of the style, and lying directly below the anther of the stamina. This is a very natural class, and comprehends peas, beans, vetches, liquorice, and a great many other genera. See the articles Pease, Beans, &c.

DIADEM, in antiquity, a head-band, or fillet, worn by kings, as a badge of their royalty. It was made of silk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was usually white, and quite plain, tho' sometimes embroidered with gold, and set with pearls and precious stones. In latter times, it came to be twisted round crowns, lawrels, &c. and even appears to have been worn on divers parts of the body. See Crown.

DIadem, in heraldry, is applied to certain circles, or rings, serving to inclose the crowns of sovereign princes, and to bear the globe and crofs, or the flower ducles for their creft. The crowns of sovereigns are bound, some with a greater, and some with a less number of diadems. The bandage about the heads of moors on shields is also called diadem, in blazoning.

DIADROME, the same with vibration, or swinging of a pendulum. See the articles Vibration and Pendulum.

DIÆRESIS, in surgery, an operation serving to divide and separate the part when the continuance is a hindrance to the cure. Some profuders divide surgery into fex parts, affigning to each grecian names, of which diæresis is one.

DIÆRESIS, in medicine, is the confinuing of the vefsels of an animal body, when from some corroding caufe certain paffages are made, which naturally ought not to have been; or certain natural paffages are dilated beyond their ordinary dimensions, fo that the humours which ought to have been contained in the vefsels extravafate or run out.

DIÆRESIS, in grammar, the division of one fyllable into two, which is usually noted by two points over a letter, as aulæ instead of aula, disolliienda for dissollevanda.

DIÆRESIS is also the same with what is otherwise called tmesis. See Tmesis.

DIÆTEREÆ, in grecian antiquity, a kind of judges, of which there were two forts, the cleroti and diaislaferii. The former were public arbitrators, chosen by lot to determine all causes exceeding ten drachmas, within their own tribe, and from their sentence an appeal lay to the superior courts.

The diaislaferii, on the contrary, were private arbitrators from whose sentence there lay no appeal, and accordingly they always took an oath to administer justice without partiality.
**DIAGRAM**

In geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c. See the articles **TRIANGLE, SQUARE, &c.**

**DIAGRAM, among antient musicians, the name of a collyrium, recommended by Scribonius Largus, for beginning lippitudes and ophthalmics.** See the composition in the above-mentioned author, No. 22.

**DIAGLYPHICE,** the art of cutting or engraving figures on metals, such as seals, intaglias, matrices of letters, &c. or coins for medals. See the articles **ENGRAVING and SCULPTURE.**

**DIAGNOSTIC,** in medicine, a term given to those signs which indicate the present state of a disease, its nature and cause. There are two principles upon which the diagnosis of diseases is founded: the first depends on a knowledge of the preceding cauces, which are such as appear to have produced the same disease before; and the second is a knowledge of the disease in its own nature, and present effects. To the diagnosis of fevers, belongs the knowledge of their various stages or times, as distinguished into beginning, increase, height and declension.

**DIAGONAL,** in geometry, a right line drawn across a quadrilateral figure, from one angle to another, by some called the diameter, and by others, the diametral of the figure. Thus a b in plate LXX. fig. 2. is called a diagonal.

It is demonstrable, 1. That every diagonal divides a parallelogram into two equal parts. 2. That two diagonals drawn in any parallelogram bisect each other. 3. A line f g, passing through the middle point of the diagonal of a parallelogram, divides the figure into two equal parts. 4. The diagonal of a square is incomensurable with one of its sides. 5. That the sum of the squares of the two diagonals of every parallelogram is equal to the sum of the squares of the four sides. This proposition is of great use in the theory of compound motions; for, in an oblique angled parallelogram, the greater diagonal being the subtenfe of an obtuse, and the leffer of an acute angle which is the compliment of the former, if the obtuse angle be conceived to grow till it be infinitely great with regard to the acute one, the great diagonal becomes the sum of the two sides, and the leffer one, nothing. Now two contiguous sides of a parallelogram being known, together with the angle they include, it is easy to find one of the diagonals in numbers, and then the foregoing proposition gives the other. This second diagonal is the line that would be described by a body impelled at the same time by two forces which should have the same ratio to each other, as the contiguous sides have, and act in those two directions; and the body would describe this diagonal in the same time, as it would have described either of the contiguous sides in, if only impelled by the force corresponding thereto. See the article **COMPUND MOTION.**

**Diagram, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c. See the articles **TRIANGLE, SQUARE, &c.**

**Diagram,** among antient musicians, the name with the scale of the moderns. See the article **SCALE.**

Its utmost extent was only two octaves; the lowest note being to the highest as 1 to 4.

Within this compass, they had eighteen notes or sounds; the names of which, beginning with the lowest, are these:

5 Y x This
This diagram, it is to be observed, represents only the diatonic genus, where the notes or sounds are by no means distinct, the parametric system coinciding with the trite diezeugmenon, and the nete system with the parametric diezeugmenon. It is also observable, that some of the notes stand nearer together than the rest; the interval between the latter being a tone, and between the former only a semitone. See the article INTERVAL.

DIAGRKYDIUM, in pharmacy, a preparation of scammony, invented by Galen: it consists in baking the scammony in a quince, but is at present seldom used, the scammony being found not to need any correction. See the article SCAMMONY.

DIAHEXAPLA, or DIAHEXAPTE, among farriers, a compound medicine, so called from its containing six ingredients, viz. birthwort and gentian roots, juniper-berrvies, bay-berries, myrrh, and ivory shavings. It is recommended for colds, consumptions, purgatives, and many other disorders in horses.

DIAL, or SUN-DIAL, an instrument serving to measure time by means of the shadow of the sun. Sun-dials are differently denominated, according to their different situation, and the figure of the surfaces upon which they are described, as horizontal, vertical, equinoctial, polar, direct, erect, declining, inclining, reclining, cylindrical, &c. We shall here proceed to describe these particular kinds of dials; and explain the philosophical principles on which dialling is founded under the article dialling. See DIALLING.

Dials are distinguished into primary and secondary. The first are either drawn on the plane of the horizon, called horizontal dials; or perpendicular thereto, on the planes either of the meridian, or prime verticle, called vertical dials; to which are added those drawn on the polar and equinoctial planes, though neither horizontal nor vertical.

Equinoctial Dial, is that described on an equinoctial plane, or a plane representing that of the equinoctial. They are usually distinguished into upper, which look towards the zenith, and lower which respect the nadir. Now as the sun only illuminates the upper surface of an equinoctial plane, while he is in our hemisphere, or on the northern side of the equator, an upper equinoctial dial will only shew the hour during the spring and summer season. And again, as the sun only illuminates the lower surface of an equinoctial plane, while he is in the southern hemisphere, or on the other side of the equator, a lower equinoctial dial will only shew the hour in autumn and winter. To have an equinoctial dial therefore that shall serve all the year round, the upper and lower must be joined together; that is, it must be drawn on each side of the plane.

To describe an upper equinoctial Dial. From a center C (plate LXX. fig. 3. n. 1.) describe a circle ABDE, and by two diameters AD and BE, intersecting each other at right angles, divide it into quadrants AB, BD, DE and EA. Subdivide each quadrant into six equal parts by the right lines. C I, C II, C III, &c. which lines will be hour lines, and thro' the center C drive a fyle or pin perpendicular to the plane ABDE. The dial thus described being raised so as to be in the plane of the equator, the line C XII, in the plane of the meridian, and the point A looking towards the south; the shadow of the fyle will shew the hours both of the forenoon and afternoon.

A lower equinoctial Dial is described in the same manner, with this exception, that no hour lines are to be drawn beyond that of six o'clock.

To describe an universal equinoctial Dial: join two metal planes ABCD and CDEF. (ibid. n. 2.) so as to be moveable at the joint. On the upper surface of the plane ABCD describe an upper equinoctial dial; and upon the lower, a lower, as already directed, and through the center I, drive a fyle. In the plane DEF C cut a box, and put a magnetic needle G therein; fit on the same plane a brass quadrant LH, nicely graduated, and passing through a hole H cut in the plane ABCD. Now since this may be so placed by means of the needle, as that the line I is shall be in the plane of the meridian, and by means of the quadrant so raised, as that the angle BCF shall be equal to the elevation of the equator, it will serve as a dial in any part of the world. On this dial may be drawn several concentric circles, which will shew the time's place and declination. Thus divide the fyle into 100 parts, which being the radius of a circle, take the complement of the declination 5°, 10°, 15°, &c. and with the
the tangent of these degrees describe concentric circles, and when the end of the shadow of the style comes into one of them, it shews the declination and the sun's place, which may be marked on the circles.

**Horizontal Dial**, that described on a plane parallel to the horizon.

To draw the hour lines upon an horizontal Dial, geometrically, draw a right line NS (ibid. n° 3.) for the meridian and hour line of 12, and cross it with another E W. for the hour line of 6 at right angles in Z: and upon Z as a center describe a circle ENWS. representing the horizon, of London for example, whose latitude is 51° 32', and likewise this dial plane. Within this circle project the sphere according to your latitude: then shall the several hour circles touching the plane of the horizon give you points to draw the hour lines upon your dial plane. If a ruler therefore is laid to Z, and every one of the points 1, 2, 3, &c. 11, 10, 9, &c. and straight lines drawn, these lines shall be the true hour lines for your horizontal dial. There is nothing required to compleat this dial but to make the height of the style equal to the latitude of the place. Wherefore for the latitude of London take 51° 32' from your scale of chords, and set them upon the horizon from S to A, and draw a line Z A for the style. The substyle, upon which the style stands in all horizontal dials, is the meridian, or hour line of 12.

In large dials, where great accuracy is required, it is best to determine the lines of the dial by trigonometrical calculation, in which the elevation of the pole of the place being given, the angles which the hour lines make with the meridian in the center of the dial are found by the following canon. As the line of 90°, is to the line of the elevation of the pole or latitude of the place; so is the tangent of each hour's equinoctial distance from the meridian, to the tangent of the angle required.

**Vertical Dial**, that drawn on the plane of a vertical circle. The verticals chiefly used are the prime vertical and the meridian, whence arise south, north, east, and west dials. If the dial respects the cardinal points of the horizon, it is called direct, but if any other vertical be chosen, it is said to decline. Again, if the circle whole plane is used be perpendicular to the horizon, the dial is denominated erect; but if the plane be oblique to the horizon, it is laid to incline or recline.

Erect, direct, south or north Dial, is that described on the surface of the prime vertical circle, looking southward or northward.

To describe the hour lines upon a vertical erect, direct, south or north Dial. Having drawn a right line N S. (ibid. n° 4. and 5.) for the meridian, or line of 12, and another at right angles E W. for the horizontal line of the plane, crossing in the point Z; upon Z as a center, describe a circle N E S W representing the horizon, and thereon project the sphere. Then draw a line upon your projection to represent your plane. Now an erect direct plane, which beholds the south, must needs be in the azimuth circle of east and west, and therefore a right line drawn from east to west shall represent your plane. Having drawn the plane upon the projection, you must find its pole. Now, this plane E W lying in the azimuth of east and west, its poles must lie in the azimuth of north and south, so that N is the pole of the north face of this plane, and S of the south face, either of which poles are removed 90 degrees from the plane, and a line drawn from the one pole to the other, will cut the plane at right angles in Z. The next thing to be found is the elevation of the pole of the world above the plane. Now P the pole of the world is elevated above this plane E W the quantity of the arch of the meridian Z P. To find the quantity of which, take the distance Z P in your compasses, and measure it upon the scale of half tangents, and you will find it to be equal to the complement of the latitude. Then as for the hour distances upon the plane, they are found thus. Lay a ruler to N, the pole of the plane, and to the several points 1, 2, 3, &c. 11, 10, 9, &c. where the hour circles of the projection cut the plane, and where the ruler cuts the primitive circle make small **:** and lines drawn from the center Z, through these stars, shall be the true hour lines upon the dial plane. The height of the pole above the plane being equal to the complement of the latitude, take that in degrees from a scale of chords and set them from S to B, and draw a line Z B for the style, which must stand upon the meridian, and on the south face must point downwards to the south pole.
DIAL

pole, and on the north face upwards to the north pole, as in n° 5.

To draw this dial trigonometrically, EU, as the radius to the co-line of the latitude, SO is the tangent of 15° the first hour's equinoctial distance, to the tangent of the first hour's distance on the plane.

Erect, direct, east or west DIAL, that described on the plane of the meridian, looking to the east or to the west.

To describe an erect, direct, east or west DIAL. Let A B C D, plate LXX. LXXI. n° 6 and 7. be the dial plane. 1. Upon the point C at the lowermost corner, if it be an east dial, or upon the point D, at the other lowermost corner, if it be a west dial, with 60 degrees of a line of chords, describe an obscure arch of a circle E F. Then from the same line of chords take the complement of the latitude of the place, which is also the elevation of the equinoctial above the horizon; and set that distance upon the arch from E to F, and draw the line C F A quite through the plane. This line will represent the equinoctial circle. 2. That you may the better proportion your style to your plane, and that all the hours may come on, and be at a convenient distance from one another, assume two points in the equinoctial line, one towards the end of C for the hour of XI, in the east dial, or of I in the west dial, as the point G; and another towards the other end thereof, for the hour of VI, as the point H; and through these two points G and H, draw two lines at right angles to the equinoctial for the hour lines of XI and VI o'clock. 3. Upon the point G with 60 degrees of the line of chords, describe an obscure arch of a circle, below the equinoctial line, as IK, setting thereon 15° of your line of chords from I to K, and draw the obsolete line G K L extending it till it cut the hour line of VI in the point L; so shall the distance L H be the height of the perpendicular style proportioned to this plane. 4. Open your compasses to 60° of your line of chords, and setting one foot in the point L with the other, describe an obscure arch of a circle M N between the hour line of VI and the line G L. 5. Divide the arch M N into five equal parts, at the points ⊙ ⊙ ⊙ ⊙ ⊙, and lay a ruler from L to each of these points, and the ruler will cut the equinoctial line C H in the points ***, through which points draw right lines parallel to the hour line of VI, as the lines VII * VII, VIII * VIII, IX * IX, X * X, and they will be the true hour lines of an east dial from six in the morning to eleven before noon. 6. For the hour lines before VI, namely, of IV and V in the morning, you may put them on by transferring the same distances upon the equinoctial line before VI, as there is between VI, and the hour lines of VII and VIII, after VI. and through these points draw lines parallel to the hour line of VI, and they will be the hour lines of IV and V in the morning. 7. For the style of east or west dials it may be either a straight pointed pin or wire exactly of the length of the line H L, fixed in the point H, or some other part of the line of VI, perpendicularly to the plane, which will show the true hour only by the shadow of the very top, as in the west dial n° 7; or, which is better, it may be a plate of brafs of the same breadth with the distance between the hour lines of VI and IX upon the equinoctial, as in the east dial n° 6, which plate being let perpendicularly upon the hour line of VI, will show the hour by the shadow of the upper edge. 8. If you would insert the halves and quarters of hours, divide each space between ⊙ and ⊙ on the arc M N into four equal parts, and to transfer them to the equinoctial circle, as you did the whole hours. In an east and west dial every thing is the same, with this difference only, that whereas the arch E F in the east dial, through which the equinoctial passes, was described on the right hand of the plane upon the center C; in the west dial it must be described on the left hand on the center D; and the hour lines of IV, V, VI, VII, VIII, IX, X, XI in the forenoon on the east dial, must be VIII, VII, VI, V, IV, III, II, I in the afternoon on the west dial.

Polar DIAL, that described on a plane passing through the poles of the world, and the east and west points of the horizon, denominated upper or lower, according as it looks up towards the zenith, or down towards the nadir. It is therefore inclined to the horizon in an angle equal to the elevation of the pole.

To draw an upper polar DIAL. Draw a right line A B (n° 10) parallel to the horizon; and if the plane be immovable,
able, find the meridian line CE. Divide CE into two equal parts, and thro' C draw a right line FG parallel to AB. Then from the center D, with the interval DE, describe a quadrant, which divide into six equal parts; and from the center D, through the several points of division, draw right lines D 1, D 2, D 3, D 4, D 5, and set off the intervals E 1, E 2, E 3, E 4, E 5, contrary way, viz. E 11, E 10, E 9, E 8, E 7. From the points 5, 4, 3, 2, 1, raise perpendiculars, meeting the line FG in the correspondent points. Lastly, in D erect a perpendicular style equal to DE, or on two equal pieces, E, C, fix a cross iron rod, then will 12, 11; 1, 2, 2; 3, 3, &c. be hour lines to be pointed out at the proper times by the shadow of the indices. A lower polar dial is made by putting out the hours of the forenoon 9, 10, 11, and those of the afternoon 12, 1, 2, 3, with the noon-hour 12 itself, and only leaving the hours 4 and 5 in the morning and 7 and 8 in the afternoon.

Secondary Dial, that drawn on the plane of other circles than the horizon, prime vertical, equinoctial, and polar circles; or that which either declines, inclines, reclines, or delineines.

Declining Dials are erect or vertical dials, which cut either the plane of the prime vertical, or of the horizon at oblique angles. They are of very great use, as the walls of houses, upon which dials are frequently drawn, commonly deviate from the cardinal points.

To describe a vertical Dial, declining from the south to the east, or west, trigonometrically. In order to do this, 1. The height of the pole or style above the plane must be found. 2. The deflexion or style's distance from the meridian. And 3. The plane's difference of longitude. All which are parts of the spherical triangle PZR. (n° 8.) right angled at R, in which are given the side PZ, equal to the complement of the latitude of the place; the angle PZR, the complement of the plane's declination; and the right angle at R. From these three data are found, 1. The height of the style above the plane by this canon, As the line of 90° is to the fine complement of the latitude, So is the fine complement of the plane's declination To the fine of the height of the style.

2. The distance of the substyle from the meridian by this canon. As the line of 90° To the fine of the plane's declination, So is the tangent of the complement of the latitude of the place To the tangent of the substyle's distance from the meridian.

3. To find the plane's difference of longitude, say, As the fine of the complement of latitude To the line of 90°, So is the fine of the substyle's distance from the meridian To the fine of the plane's difference of longitude.

4. To find the angle that each hour makes with the substyle, say, As the line of 90° To the line of the hour above the plane, So is the tangent of the difference of the sun's distance from the meridian and the difference of longitudes To the tangent of the angle required.

An example of a north dial declining east, which is only a south dial inverted, may be seen in (n° 9.)

Inclined Dials are those delineated on planes inclining towards the southern side of the horizon in an angle either greater or less than the equinoctial plane.

To draw an inclined Dial. The inclination of the plane, as DC, (n° 11) being found by a declinator, as taught under the article Declinator, if it fall between the equinoctial plane CE, and the vertical one CB, so as that the angle of inclination DCA be greater than the elevation of the equator ECA, on the upper side draw a north dial, and on the lower a south dial to an elevation of the equator, which is equal to the aggregate of the elevation of the equator of the given place, and the complement of the inclination to a quadrant. If the inclined plane CF fall between the horizontal one CA, and the equinoctial one CE, so as that the angle of inclination FCA is less than the elevation of the equator ECA, describe an horizontal dial to an elevation of the pole equal to the aggregate of the elevation of the pole of the given place, and the inclination of the plane. See the article Hor.

Inclined
Inclined dials are drawn after the same manner as primary dials, except that the index in the former case must be fitted under the angle $ADC$, and in the latter, under the angle $DFC$, and that the distance of the center of the dial from the line of contingency is in the former case $DC$, and in the latter $FC$.

Reclining Dials, those delineated on planes, reclining backwards from the zenith towards the north, in an angle greater or less than the polar plane.

To describe a reclining Dial. If the reclined plane $HC$, (no. 11.) fall between the vertical plane $BC$, and the polar plane $IC$, so as that the angle of reclination $BCH$ is less than the distance of the pole from the zenith $BCI$, describe two vertical south and north dials to an elevation of the equator equal to the difference between the elevation of the equator of the given place, and the angle of reclination. See vertical, south and north Dial.

If the reclined, as $KC$, fall between the polar plane $IC$, and the horizontal one $CL$, so as that the angle of reclination $BCK$ is greater than the distance of the pole from the zenith $ICB$, describe an horizontal dial thereon to an elevation of the pole equal to the difference between the angle of reclination, and the elevation of the equator of the given place. See Horizontal Dial.

Declined Dials are those which both decline and incline, or recline. The use of these being very rare, we shall not trouble the reader with a description of them.

Construction of an universal inclined, horizontal and equinoctial Dial. This instrument consists of two plates of brass, or other solid matter, whereof the under one $A$ (no. 12.) is hollowed about the middle, to receive a compass fastened underneath with screws. The plate $B$ is moveable by means of a strong joint at $C$. Upon this plate is drawn a horizontal dial for some latitude greater than any of those the dial is to be used in, with a style $E$ proportionable to that latitude. For when the plane $B$ is raised by means of the quadrant $D$, the horizontal plane must always have a less latitude than that the dial is made for, otherwise the axis of the style will have an elevation too little. Instead of the quadrant $D$ is generally placed, an arch from the equator to $60^\circ$ numbered down-wards, $60^\circ$ being at the bottom, and for this latitude of $60^\circ$, the horizontal dial is commonly drawn. The arch of $60^\circ$ is fastened by two small tenons, and may be laid down upon the plate $A$, as likewise may the style upon the plate $B$, and both of these are kept upright by means of little springs underneath the plates.

The use of the inclined horizontal Dial. Raise the upper plate $B$ to the degree of latitude of the place where you are, by means of the graduations on the quadrant $D$. Then if the plane $A$ be set horizontal, so that the needle of the compass settles over its line of declination, the shadow of the axis will shew the hour of the day.

Use of the equinoctial Dial. You must place the edge of the equinoctial circle $HBI$ to the degree of the elevation of the pole by means of the quadrant, and if the dial be set north and south by means of the compass, the shadow of the style will shew the hour of the day at all times of the year, even when the sun is in the equinoctial, because the circle is hollowed.

Ring-Dial, a kind of dial, consisting of a brass ring, seldom exceeding two inches in diameter, and one third of an inch in breadth. In a point of this ring there is a hole, through which the sun beams being received, make a lucid speck on the concavity of the opposite semicircle, which gives the hour of the day in the division marked therein. But it only holds good about the times of the equinox, unless the hole is made moveable, and the days of the month are marked on the convex side of the ring. In this case the dial can be refixed for any time, and will shew the hour of the day throughout the year.

To use it, put the moveable hole to the day of the month, then suspending it by the little ring, turn it towards the sun till his rays point out the hour among the divisions on the inside.

Universal or Astronomical ring-Dial, a dial serving to shew the hour of the day in any part of the earth; whereas the former is confined to a certain latitude. It is composed of two rings, or flat circles, from two to six inches in diameter, and their breadth proportional. The outward ring $H R E P$ (plate LXXI. fig. 13.) represents the meridian of the place of the observer, and contains two divisions of
of 90° each, as HR and EP diametrically opposite to each other, the one serving from the equator to the north pole, and the other from the equator to the south. The inner ring BC represents the equator, and turns exactly within the outward ring, by means of two pivots at the points of the hours of 12. A cursor N composed of two little pieces, slides along an aperture, in the middle of the bridge I, which cursor has a small hole to admit the rays of the sun. The middle of this bridge represents the axis of the world, and its two extremities the two poles; on one side of it are drawn the signs of the zodiac, and on the other, the days of the month. On the edge of the meridian slides a piece b a, with a ring I, fitted to it, by which the instrument is to be turned during the observation. This ring represents the zenith.

Use of the universal ring-Dial. Place the line on the middle of the sliding piece, immediately below the ring, to the latitude of the place, and fix the line crossing the hole of the cursor to the day of the month, or degree of the sign in which the sun then is. Open the instrument so that the two rings be at right angles to each other, and suspend it by the ring I: turn the flat side of the bridge towards the sun, so that his rays coming through the little hole in the middle of the cursor fall exactly on a line drawn round the middle of the concave surface of the interior ring, where it will point out the hour. Let it be observed, however, that this dial will not shew the hour of 12, because the outer circle being then in the plane of the meridian, hinders the sun's rays from falling on the inner. Neither will it shew the hour when the sun is in the equinoctial, for then his rays fall parallel to the plane of the inner circle.

Quadrantal Dial. See the article HORODICTIC QUADRANT.

Reflecting Dial, a sort of dial shewing the hour of the day by means of a thin piece of looking-glass plate, so placed, as to reflect the sun's rays on the top of a ceiling, where the hour-lines are drawn.

Nocturnal Dial, that which shews the hours of the night, of which there are two kinds, lunar and sidereal.

Lunar, or moon-Dial, shews the hour of the night by means of the shadow of the moon, projected from an index.

To describe a horizontal moon-Dial. Draw first a horizontal sun-dial. 2. Erect two lines A B, C D. (plate LXXI. fig. 1.) perpendicular to the line of 12 o'clock; and dividing the interval GF into twelve equal parts, draw lines parallel through the several points of division. 3. If the first line CD be appropriated to the day of the new moon, and the second line to the day when the moon comes later to the meridian than the sun by one hour, and so the last line AB correspond with the day of full-moon, the intersecions of these lines with the hour-lines will give points, through which to draw a curve line, 12, 12, for the meridian line of the moon. 4. In the same manner determine the other hour lines, 1; 2; 2 3; 3; &c. which the shadow of the moon projected from the style of the dial, intercets at the respective hours. 5. Blot out the hour lines of the fun-dial, together with the perpendiculars, by means of which the lunar hours were drawn, and divide the interval GF by other parallel lines into fifteen equal parts, because there are nearly fifteen days between new moon and full moon. Lastly, to these lines write the several days of the moon's age. Now the moon's age being learnt from the calendar, the intersection of the line of the moon's age, with the lunar horary lines, will give the hour of the night.

We may likewise find the hour of the night by a sun-dial. Thus, observe the hour which the shadow of the index points at by moon-light: find the moon's age in the calendar; multiply the number of days by $\frac{12}{12}$ and the product is the number of hours to be added to the hour shewn by the shadow, to give the hour required. But if this number exceed 12, then twelve hours are to be subtracted, and the remainder will be the hour required.

Dials without centers, those whose hour-lines converge so slowly, that the center they converge towards cannot be expressed on the given plane. Horizontal dials of this kind are to be made for places, the elevation of whose pole is either very great or very small; and vertical dials without centres are for places, which have the pole very much elevated.

Furniture of Dials. See Furniture.
so far as it differs from that of the whole kingdom. The term, however, is more particularly used in speaking of the ancient greek, whereas there were four dialects, the attic; Ionic, Aeolic, and Doric, each of which was a perfect language in its kind, that took place in certain countries, and had peculiar beauties.

In Great Britain, besides the grand diversity of English and Scotch, almost every county has a dialect of its own, all differing considerably in pronunciation, accent, and tone, although one and the same language.

The way of the Gileadites proving the Ephraimites, by the pronunciation of 

[chibboleth, or fabbaleth, with [ch]in, or [je]meth, is well known. So the Flemings are said to prove whether a man be a native of France, or not, by bidding him pronounce ach ten tachentick, which they pronounce alt en tallentick, as being unable to articulate the aspirate ch.

DIALECTICS, dialec'tica, in the literary history of the antients, that branch of logic which taught the rules and modes of reasoning. See the article Logic.

DIALIA, and FLAMEN DIALIS, in Roman antiquity. See Flamen.

DIALLING, the art of constructing all manner of dials. See Dial.

Having described the most useful dials under the word Dial, we now proceed to explain the philosophic principles of the art of dialling. In order to this, therefore, we are to consider, that as the time which passes between any meridian's leaving the sun, and returning to it again, is divided into 24 hours, so if we conceive a sphere to be constructed with 24 of these meridians, the fun will orderly come upon one of them at the beginning of every hour.

Such a sphere may be represented by the figure PDSB (plate LXXII. fig. 2. n° 1.) where the several meridians are represented by P S, P' S, P" S, and so on to P 24 in all; since these meridians divide the equinoctial into 24 equal parts, each part will contain just 15°, because 35×24=860, the whole circle; and since all the meridians pass through the poles of the world, the planes of those meridians all intersect each other in one common line PS, which is the axis of the sphere, therefore the said axis PS is in the plane of each of the 12 meridians. Suppose Z to be the zenith of any place, and DBE the plane of the horizon fixed within the sphere, constructed with the 12 meridians, 1, 1; 2, 2; 3, 3; 4, 4; &c. then will the axis of the sphere PS pass through the center of the plane at N; so that one half NP will be above the plane, and the other half NS below it.

Suppose now this dialling sphere to be suspended by the point Z, and moved about so as to have the points D and B exactly in the south and north points of the horizon, and E and W in the east and west points, then will the sphere have a situation every way similar to that of the earth and heavens with respect to the given place, and the axis of the sphere to that of the earth. The sun, therefore, shining on such a sphere, will be attended with all the same incidents, and produce all the same effects as would happen if the said sphere were at the center of the earth, or the center N of the sphere coincided with the center of the earth, because the distance between the surface and center of the earth is insensible at the distance of the sun. Now it is evident, as the sun revolves about such a sphere, it will every hour be upon one half or other of the 12 hour circles, viz. from midnight to noon, it will be on those parts of the circles which are in the eastern hemisphere; and from noon to midnight, it will pass over all those in the western. It is also farther evident, that while the sun is in the eastern hemisphere, it will be first below and then above the plane of the horizon, and vice versa on the other side. Again, when the sun is upon any of these hour circles, by shining upon the axis it causes it to cast a shadow on the contrary side, on the plane of the horizon, on the lower or upper surface, as it is below or above the said plane. This shadow of the axis will be precisely in the line in which the plane of the hour-circle would intersect the plane of the horizon; if, therefore, lines were drawn through the center N, joining the points on each side the plane where the hour-circles touch it, as 4 N 4, 5 N 5, 6 N 6, &c. the shadow of the axis will fall on those lines at the beginning of each respective hour, and thereby indicate the hour-circle the sun is in for every hour of the day. These lines are properly called hour-lines, and among the rest that which represents the hour of 12 at noon is NB, half the meridian line DB; whence it appears that the hour-lines N 1, N 2, N 3, &c. which serve for the afternoon, lie on the east side of the plane, and are numbered from the north to the east; and on the contrary.
It also appears, that as the sun's altitude above the plane is greater or less, the number of hour-circles the sun will poise above the horizontal plane will be also greater or less. Thus when the sun is at $S$ in the equinoctial, its diurnal path for that day being the equinoctial circle itself $\triangle E E Q W$, it is plain, since the arch $\triangle E E Q$, the sun will apply to fix hour-circles below the horizon, and to fix above it, in each half of the day; and consequently that on this day the shadow will occupy but 12 of the hour-lines on each surface of the plane, beginning and ending at fix. But when the sun is in the tropic of cancer, its diurnal path for that day being the tropic itself, $\triangle C R F$, it is manifest the sun in the forenoon ascends above the plane in passing between the hour-circles of 3 and 4 in the morning, and descends below it in the afternoon between the hours of 8 and 9; therefore on the summer tropic the shadow will pass over 16 of those hourlines. On the contrary, when the sun is in the winter tropic at $O$, its path being then $O G I H$, it rises above the plane between 8 and 9, and leaves it between 3 and 4.

From what has been said, it is evident that if the circles be supposed removed, and only the horizontal plane remain, with the half of the axis $NP$ (ibid. n° 2.) above it in the same position as before, then should we have constituted a horizontal dial, every way the same with those in common use, with only the addition of a substyle $PO$, to render the style $NP$ very firm. Hence appears the reason why the gnomon or style $NP$, in those dials in our latitude, is always directed to the north pole, and always contains such an angle $P N O$, with the hour of 15 line, $NB$, as is equal to the latitude of the place. Lastly, the reason appears why the number of hour-lines on these dials exceeds not 16, and are all drawn from 6 to 15 and 6 again, on the northern part, the rest on the southern; and why the hour-line of 6 lies directly east and west, as that of 12 does north and south. If a plane be fixed within the same sphere in a vertical position, or perpendicular to the horizon, and coinciding with the plane of the prime vertical, that is, facing full south and north; then will the axis $PS$ (ibid. n° 3.) fall pass through the center of the plane $N$; and the lower semi-axis $NS$ will by its shadow mark out the hour-lines on the southern surface, and the upper semi-axis $NP$ will do the same on the northern. These hour-lines are determined in the same manner as those on the horizontal dial; and it is plain the sun cannot come on the southern face of this plane before fix in the morning, nor shine on it after fix in the evening. It is also evident, that all the hours before 6 in the morning, and after 6 at night, will be shewn on the northern face or side of this plane, for the time of the sun's being above the horizon in any place. Hence the reason of a direct south and north vertical dial easily appears, both which are represented in fig. 3, n° 4 and 5 of plate LXX.

The gnomon $NS$ (pl. LXXII, fig. 2, n° 3.) contains an angle $SNF=Z NP$ with the meridian or hour-line of 12, viz. $Z F$, which is exactly the compliment of $PNB$ to 90°; hence the elevation of the gnomon in vertical dials is equal to the compliment of the latitude of the place. The principles of a direct south dial being understood, it will be easy to understand those of a dial which does not face the south or north directly, but declines therefrom any number of degrees from east to west. But we refer the reader, who requires more ample instruction on this head, to the authors who have treated professedly of dialling; the most remarkable of these, besides Wolfius, to whom we are indebted for a great part of the article DIAL, are Clavius; Comandine, De Horologiorum descriptione; Joann. Bapt. Benedictius, De Gnomonum Us, brarumque solarium ufu; Geo. Schomberg, Exegetis fundamentorum Gnomonicorum; Solomon de Caus, Traite des Horologes solaires; Desargues, Maniere universelle pour pofer l'effieu, & placer les heures, & autres choses, aux cadans solaires; Kircher'sArs magna Lucis & Umbrae; Leybourn's Art of Dialling; Ozanam'sDialling; and M. De la Hire's Gnomonique, ou l'art de tracer les cadans, avec les demonstrations.

Dialling-globe, an instrument of brass or wood, with a plane fitted to the horizon, and an index, so contrived as to give a clear illustration of the principles on which dials are made. See the preceding article.

Dialling-lines, or scales, are graduated lines placed on rulers, or the edges of quadrants and other instruments, to expedite the construction of dials. These...
are, 1. A scale of six hours, which is only a double tangent, or two lines of tangents each of 45°, set together in the middle, and equal to the whole line of lines, with the declination set against the meridian altitudes in the latitude of the place. 2. A line of latitudes, which is fitted to the hour-scale, and is made by this canon. As the radius: to the chord of 90°: so are the tangents of each respective degree of the line of latitudes: to the tangents of other arcs. And then the natural lines of these arcs are the numbers, which taken from a diagonal scale of equal parts, shall graduate the divisions of the line of latitudes to any radius. The lines of hours and latitudes are general, for pricking down all dials with centers.

The other scales are particular, and give the several requires for all upright declining dials by inspection. They are, 1. A line of chords. 2. A line for the sun's distance from the meridian. 3. A line for the fyle's height. 4. A line of the angle of 12 and 6. 5. A line of inclination of meridians.

Dialoging-sphere, an instrument made of brass, with several semi-circles stiling over each other upon a moveable horizon; serving to demonstrate the nature of spherical triangles, as well as to give the true idea of drawing dials on all sorts of planes. See the article Dialoging.

Dialoging, among miners, the same with plumming. See Plumming.

Dialogism, dia
gogos, in rhetoric, is used for the foliloquy of persons deliberating with themselves, as the following of Juno, in the first Enide of Virgil:

mene incipio desiptere veniam?

Nec poie Italia Teurowum avertere genet?

quippe aeror facti? &c. In this sense, it is distinguished from dialogue. See the article Dialogue.

Dialogism is also, in a more extensive sense, taken for discourse in general, whether held by a person alone, or in company.

Dialogue, in matters of literature, a conversation between two or more persons, either by writing or by word of mouth. Dialogue appears to be the most ancient form of writing, and is greatly recommended by several authors. The archbishop of Cambrai, at the head of his Natural Institution, gives an account of the advantages of dialogue. The Holy Spirit has thought proper to teach us in dialogue, viz. patience, in the book of Job; and love of God, in the Canticles. The Dies Canonicae of Simon Maiolus, concerning various subjects of nature, is by the way of dialogue. That learned philosopher Claud Berirgardus, a man of most profound judgment and ingenuity, wrote his Circulus Piatanus, wherein he lays open the most impenetrable secrets of all natural philosophy, by way of dialogue between Charilæus, as defender of the peripatetics, and Arifteæus, as maintaining the principles of Anaximander. Also Joh. Bodinus, in his Physics, as well as in all the rest of his writings, treats, in his Theatrum universæ naturæ, of the various subjects of nature, in the form of a dialogue: and indeed under this appearance, and in this method of styie, he has better opportunities, by way of objections, to introduce his own paradoxes, and the rest of his monstrous opinions. We have also several writers of travels, &c. in this way, both in the French and German languages; and not a few medical and chemical authors, who have chose to instruct by way of dialogue.

Among religious writers, Justin Martyr opened this way in his controversy against the Jews. Minutius Felix followed it, in his against the idolators. It is in this form that Origen judged he could best refute the error of Marcian. Many others might be mentioned who thought it no diminution to the majesty of the mysteries of faith, to maintain them by the familiarity of dialogue.

Dialogue, in music, a composition for at least two voices, or two instruments, which answer one another, and which frequently uniting at the close, make a trio with the thorough bass.

These are very much used by the Italians in their operas, oratorios, serenatas, &c.

Dialthæa, in pharmacy, an unguent much used as a relolvent, so called from althæa, or marsh-mallows, which is the principal ingredient in it. See the article Althæa.

This ointment consists also of linseed and fenugreek feed; the other ingredients are common oil, wax, resin, and turpentine. It is applied by rubbing it on the part affected.

Dialysis, in grammar, a mark or character, consisting of two points, placed over
over two vowels of a word, in order to separate them, because otherwise they would make a diphthong, as mosaic, &c. See the article DIÆRESIS.

DIAMARGARITON, in pharmacy, the name of an antidote in Myreplius, § i. cap. 37. in which pearls are a principal ingredient.

There are two kinds of the diamargariton, the hot and the cold, but neither of them are at present used.

The hot diamargariton, is a powder composed of pearls, pellitory, ginger, cinnamon, and several other hot ingredients.

Cold diamargariton is a solid electuary, composed of pearls ground fine, and white sugar dissolved in roe-water, or that of buglos, and boiled to a consistence.

Compound cold diamargariton is a powder made of pearls, red roses, flowers of nenuphar and violet, lignum aloes, red and citron santal, tormentil root, &c.

DIAMASTIGOSIS, διαμαστιγωσις, in grecian antiquity, a solemnity at Sparta, in honour of Diana Orthia, wherein the children of the most distinguished families were wont to flay and tear each others bodies with rods, before the altar of the goddess: the parents of the children being always present, used to animate and excite them not to give the least sign of pain or concern; and indeed so great was the bravery and resolution of the boys, that seldom or ever any cry or groan was heard to proceed from any of them, though they frequently whipped one another to death. The design of this custom was, no doubt, to fortify the children betimes, and harden them against wounds, bruises, &c.

DIAMETER, in geometry, a right line passing through the center of a circle, and terminated at each side by the circumference thereof. See the article CIRCLE.

The chief properties of the diameter are, that it divides the circumference of a circle into two equal parts: hence we have a method of describing a semicircle upon any line, affuming its middle point for the center. The diameter is the greatest of all chords.

For finding the ratio of the diameter to the circumference. See CIRCLE.

DIAMETER of a curve is a right line AC (plate LXXII. fig. 3.) bisecting the right lines DE, DL, drawn parallel to one another; and are either of a finite or infinite lengths. Though a right line, bisecting all parallel lines drawn from one point of a curve to another, is taken in a strict sense only for the diameter of a curve line, yet it may not be amiss, more generally, to define a diameter in saying that it is that line, whether right or curve, which bisects all parallels drawn from one point of a curve to another, so that, according to this, every curve will have a diameter: and hence for Isaac Newton's curves of the second order have all either a right-lined diameter, or else the curves of some one of the conic sections for diameters; and many geometrical curves of the higher orders may also have for diameter curves of more inferior ones, and that ad infinitum. See the article CURVE and CONIC SECTION.

DIAMETER conjugate. See the article CONJUGATE DIAMETER.

DIAMETER of a sphere is the diameter of the semicircle, by whose rotation the sphere is generated; in which sense it is the fame with axis. See the article AXIS.

DIAMETER of gravity, in any surface or solid, is that line in which the center of gravity is placed. See CENTER.

DIAMETER, in astronomy. The diameter of the planets are either apparent or real; the apparent diameters are such as they appear to the eye; and being measured by a micrometer, are found different in different circumstances and parts of their orbit. See the article PLANET.

The real diameters of the planets are such as they are in themselves, as expressed in the following table.

A Table of the real Diameters of the Sun and primary Planets in British Miles.

<table>

</table>

For the real diameters of the secondary planets, see MOON and SATELLITE. The apparent diameters of the planets measured with a micrometer, are found different in different circumstances and parts of their orbits, as expressed in the following table.

Apparent
The least apparent diameter of the planets, according to Huygens, are as follows: Saturn 36", his ring 1'8", Jupiter 1°4", Mars 30", Venus 1°23".

**Diameter of a column, in architecture, is its thickness just above the base. See Column.**

From this the module is taken, which measures all the other parts of a column. See the article Module.

**Diameter of the diminution of columns, that taken from the top of the shaft. See the article Diminution.**

**Diameter of the swelling, that taken at the height of one third from the base.**

**Diamond, adamant, in natural history, a genus of precious stones, of a fine pellucid substance, of great hardness, never fouled by any admixture of earthy or any other coarse matter, susceptible of elegant tinges from metallic particles, giving fire with feel, not fermenting with acid menstruums, scarcely calculable by any degree of fire, and of oneimple and permanent appearance in all lights.**

This is the most valuable and hardest of all gems, and, though found of different shapes, and sometimes accidentally tinged to several colours; yet ever carries the same distinguishing characters, and is very evidently in all those states the same body. It is, when pure, perfectly clear and pellucid as the purest water, and is eminently distinguished from all other substances, by its vivid splendor, and the brightness of its reflections. It is extremely various in shape and size, being found in the greatest quantity very small, and the larger ones extremely seldom met with; the largest diamond certainly known ever to have been found is that in the possession of the Great Mogul, which weighs 279 carats, and is computed to be worth 779,444.

The diamond has certainly one proper and determinate figure, into which it naturally mucf concretes, when in a state of reft, and impeded by no other accident in its formation: the true figure then is an inequilateral obtuse-hedron; and wherever it has concreted in a perfect manner, and without any interrupting accidents, it has always formed itself into this figure; and often in this its several surfaces are as bright as if polished by art: but, as in common falt, though its figure be pyramidal, yet very easy accidents can determine it into cubes and parallelopipeds; so the diamond has often, in the state of formation, been thrown into two other figures, both also seeming regular ones; the one a prismatic columnar one, of six angles somewhat emulating the figure of crystal; the other an oblong quadrilateral column with two truncated ends: these seem the only regular figures of this gem; but besides these it is every day found in numberless other mis-shapen forms, often roundish, emulating the shape of pebbles, but full of small flat planes or faces; frequently oblong, very often flat, and as often tapering, either from one end to the other, or else from the middle to both ends. A diamond bears the force of the strength fire, except the concentrated solar rays, without hurt, and even that infinitely aercft of all fires does it no injury, unless directed to its weaker parts.

It is a common thing for diamonds to be too thick or deep for the extent of their surface, and there is a certain proportion of depth, beyond which the gem should not be allowed: in this case two diamonds are often made, by the regularly dividing one: this, when the mafs is of an angular figure, is done by cutting it through with a wire, wetted with oil, and covered with diamond-powder; but in the flat or more common masses, it is done much more expeditiously by finding the grain of the stone, and introducing the point of a fine flat chisel between them. This is not the only use of the splitting, for when a diamond has a flaw or blemish in it, which greatly debases its value, the plates may be separated at a proper breadth, and the flaw removed; in which case the thinner cut, struck off, is of value in proportion to its size, and the remainder, being now freed from its flaw,
is of much more value than it was at first.
The places whence we have the diamonds are the East-Indies, in the island of Borneo, and in the kingdoms of Vifapour, Golconda, Bengal; and the Brafs in the West-Indies. They are not unfrequently found yellowish, blueish, and reddish, but more rarely greenish.

There have not been wanting people who have attributed to the diamond great virtues as a cordial; but we are apt to believe no body ever did, or will, try whether this has been said with any sort of foundation.

**Valuation of Diamonds, among jewellers, is thus calculated:** they suppose the value of a rough diamond to be 21 per caratt; then to find the value of those of greater weight, they multiply the square of their weight by 2, and this last product is the value of the diamonds in their rough state: thus, the value of a rough diamond weighing 4 carats, is equal $4 \times 2 = 8$.

**Cornish Diamond, in natural history, a name given to a kind of crysftals, from their being found in Cornwall. See the article Crystal.**

**Rough Diamond is the stone as nature produces it in the mines.**

**Rope-Diamond is that quiteflat underneath, with its upper part cut in divers little faces, usefully triangles, the uppermost of which terminate in a point.**

**Table-Diamond is that which has a large square face at top, encompassed with four leffer.**

**Brilliant Diamond is that cut in faces both at top and bottom; and whose table, or principal face at top, is flat.**

**Diamond, in the glafs-trade, an instrument used for squaring the large plates or pieces; and, among glaziers, for cutting their glasses.**

These sort of diamonds are differently fitted up; that used for large pieces, as looking-glasses, &c. is set in an iron ferril, about two inches long, and a quarter of an inch in diameter; the cavity of the ferril being filled up with lead, to keep the diamond firm: there is also a handle of box, or ebony, fitted to the ferril, for holding it by.

**DIAMOND, in heraldry, a term use for expressing the black colour in the achievements of peerage.**

Guillim does not approve of blazoning the coats of peers by precious stones instead of metals and colours; but the English practice allows it. Morgan says the diamond is the emblem of fortitude.

**DIAMOND-CUTTER. See Lapidary.**

**DIAMORUM, in pharmacy, a preparation of mulberries and honey, used against diseases of the throat, and for stopping dysenteries, &c.**

**DIANAE ARBOR, or ARBOR LUNAE; in chemistry, the beautiful crystallizations of silver, dissolved in aqua fortis, to which some quicksilver is added; and so called from their resembling the trunk, branches, leaves, &c. of a tree.**

This elegant arrangement, however, of the particles of silver is not peculiar to this state ormenstruum, since copper filings dropped into the solution of silver in aqua fortis, is found to have the same effect, when viewed by the microscope: nay, the silver-ores are frequently found ramified in the same manner.

**DIANDRIA, in the linnaean system of botany, a class of plants comprehending all those with hermaphrodite flowers, and only two stamens in each; such are sage, olive, phillea, jaffamin, rosemary, &c.**

**DIANS, a town of the Genoese, about three miles from the sea. The country about produces great numbers of olives.**

**DIANTHERA, in botany, a genus of the diandria-monogynia class of plants, whose corolla consists of a single ringent petal; the tube is patulous, of the length of the limb; the upper lip is of an ovated figure; the lower lip is divided into three oblong and equal segments.**

**DIANTHUS, in botany, a genus of the decandria-digynia class of plants, whose corolla consists of five petals, the unguies of which are of the length of the cup; they are narrow, and inducted into the receptacle; the limb is plane; and the bracteae of the petals broad at the extremity, and crenated; the fruit is a cylindric covered capsule, consisting of one cell, and opening four ways at the top; the seeds are numerous, compressed, and roundish. See plate LXXII, fig. 4, which represents the pink.**

This genus comprehends the clove-jully-flowers or carnations, the pinks, and sweet-williams; all beautiful flowers, which may be propagated by seeds or layers.

**DIAPASMA,**
DIA [908] DIA

DIAPASMA, in pharmacy, a name for all powders sprinkled on the body, whether as perfumes or otherwise. See the article CATAPASMA.

DIAPASON, in music, a musical interval, by which most authors, who have wrote upon the theory of music, use to express the octave of the Greeks. See OCTAVE. The diapason is the first and most perfect of the concords; if considered simply, it is but one harmonical interval; though, if considered diatonically, by tones and semitones, it contains seven degrees, viz. the three greater tones, two leffer tones, and two greater semitones.

The interval of a diapason, that is the proportion of its grave sounds to its acute is duplicate, i.e. as 2 : 1. See the articles INTERVAL.

DIAPASON, among the musical instrument makers, a kind of rule or scale, whereby they adjust the pipes of their organs, and cut the holes in their flutes, hautboys, &c. in due proportion, for performing the tones, semitones, and concords just.

A square being divided into eight parallelograms, the points wherein a diagonal line intercets all these parallelograms, express all the usual intervals in music: and on this principle it is that the diapason is founded. There is a particular kind of diapason for trumpets serving as a standard of the different magnitudes they must have to perform the four parts of music. See the article TRUMPET.

There is another for sackbuts, shewing how far they are to be lengthened and shortened, to raise or fall from one tone to another.

The bell-founders have likewise a diapason, serving to regulate the size, thickness, weight, &c. of their bells.

DIAPASON DIAEX, in music, a kind of compound concord, whereof there are two sorts; the greater, which is in the proportion of 10 : 3 ; and the leffer, in that of 16 : 5.

DIAPASON DIAPENTE, in music, a compound consonance in a triple ratio, as 3 : 9. This interval, says Martianus Capella, consists of nine tones and a semitone; nineteen semitones, and thirty-eight dieës. It is a symphony made when the voice proceeds from the first to the twelfth sound.

DIAPASON DIATESSARON, in music, a compound concord, founded on the proportion of 8 : 5. To this interval Martianus Capella allows eight tones and a semitone, seventeen semitones, and thirty-four dieës.

This is when the voice proceeds from its first to its eleventh sound. The moderns would rather call it the eleventh.

DIAPASON DITONE, in music, a compound concord, whose terms are as 10 : 4, or 5 : 2.

DIAPASON SEMIDITONE, in music, a compound concord, whose terms are in the proportion of 12 : 5.

DIAPEDESIS, in medicine, a transfusion of the fluids through the sides of the vessels that contain them, occasioned by the blood's becoming too much attenuated, or the pores becoming too patent.

DIAPENIA, in botany, a genus of the pentandria-monogynia class of plants, the flower of which consists of one saucer-like petal, the tube being cylindrical, and the limb divided into five obtuse and plane segments; the fruit is a trilocular roundish capsule, containing a great many roundish seeds.

DIAPENTE, in the antient music, an interval marking the second of the concords; and, with the diatessaron, an octave. See the article DIATESSARON.

This is what in the modern music is called a fifth. See the article FIFTH.

The diapente is a simple concord; yet, if considered diatonically, it contains four terms; two greater tones, a less tone, and a greater semitone. The diapente is the greatest part of the octave harmonically divided. It is produced when the voice passes from its first to its fifth found.

DIAPENTE COL DITANO, in music, is, by Zarlino, and many others, used for what we call the seventh major. See the article SEVENTH.

DIAPENTE COL SEMIDITANO, in music, is the seventh minor. See the articles MINOR and MAJOR.

DIAPENTE, in pharmacy, is used for a medicine compounded of five several drugs or ingredients.

DIAPERED, or DIAFRE, in heraldry, the dividing of a field in planes, like fretwork, and filling the same with variety of figures. This chiefly obtains on bordures, which are diapered or fretted over, and the frets charged with things proper for bordures. Baron renders it varia\-tus, which is not sufficient to express the several things of which it is variated.

DIAPHANOUS, an appellation given to all transparent bodies, or such as transmit the rays of light; a quality which, according to the cartesians, is owing to the rectitude or straightness of their pores; but,
but, according to Sir Isaac Newton, to
the homogeneity of the substance of these
bodies, and of the medium which occup-
ies their pores.
DIAPHONICUM, in pharmacy, a sort
of medicine or electuary chiefly made of
dates. It purges featories, and excites
the menfe. It is also used in drophes,
lethargies, apoplexies, and palfies.
DIAPOROSIS, in medicine,
an elimination of the humors in any part
of the body through the pores of the skin.
See the article PERSPIRATION.
DIAPORETICs, among physicians, all
medicines which promote perspiration.
See the article ALEXIPHARMIC.
DIAPHRAGM, in anatomy, a large, ro-
bust, mucous membrane or skin, plac-
ed transversely in the trunk, and divid-
ing the thorax from the abdomen, whence
the latin writers call it septum tran-
versum.
Its situation is not exactly even, but some-
what oblique, so that the anterior part is
higher, the posterior lower; its upper
superficies convex, and its lower concave.
It is connected with the sternum, the flpu-
rious ribs, the pericardium, the medi-
astinum, and the vertebras of the loins.
Its figure, taken transversely, is somewhat
oblong and eilliptic. There are in the
diaphragm two large foramina; the first
is in the left side of it, and gives passage
to the gula, and the par vagum; the
second is in the right side of it, and the
lower trunk of the vena cava passes thro' it
: there is also an interstice between the
four heads of the lower part, through
which passes the aorta, the vena asyzgos,
and the ductus thoracicus. The dia-
phragm is covered with a membrane on
the upper part from the pleura ; on the
lower, from the peritonem. Its sub-
stance is mucular: the upper part, which
is large and elliptic, arises from the flpu-
rious ribs, the transverse muscles of the
abdomen, and the cartilago xiphoides;
and, with its tendon, renders the nervous
center of the diaphragm almost triangu-
lar: the lower arises from a double bafe,
from the vertebrae of the loins on each
side, and is inserted nearly into the cen-
ter of the superior.
The ules of the diaphragm are, first, to
affift in respiration; for, in taking in the
breath, it is pressed downwards, and, in
expiration, it rises upward into the ca-
vity of the thorax: secondly, to affift the
necessary motions of the contents of the
abdomen, viz. of the stomach, inte-
tines, liver, and spleen; and in the pro-
moting the secretions of the chyle, bile,
&c. And, lastly, for affisting the expul-
sion of the facces, the urine, the foetus in
parturition, and of the secundines.
DIAPORESIS, in rhetoric, a figure of or-
tatory, expressing the uncertainty of the
speaker how he shall proceed in his dis-
course: such is that beautiful line of
Homer,

> Ti προτος, τι η απλησσα, τι η εραμων καταβλεγει;

DIAPRE', DIAPERED, in heraldry. See
the article DIAPERED.
DIAPRUM, in pharmacy, the name
of two compositions directed thus in the
London dispensatory.
The diaprum lenitivum: Take of new
and ripe damask prunes, one hundred;
boil them in a sufficient quantity of water,
till they are soft: then remove them from
the fire, and when cold, drive the pulp
through a sieve, and set, by for life.
In the liquor strained from the prunes,
before pulping, boil one ounce of violet
flowers, and after straining again, dif-
solve in it two pounds of figar, and boil
into a syrup; to which add of the before-
mentioned pulp half a pound; of cafea
and tamarinds, dissolved in a little of the
sacred decoction and pulped, of each one
ounce; boil them again over a gentle
heat, and frequently stir the mixture;
after which fit in the following pow-
ders, of coriander-feed, rhubarb, liquor-
ice, and marsh-mallow roots, of each a
sufficient quantity to make into a foit
electuary.
The diaprum solutivum: Take of the
lenitive composition of prunes, four
pounds; of prepared scammony, two
ounces five drams, and mix them toge-
ther into an electuary.
DIARBEC, or DIARBEC, the capital of
a province of the same name, answering
to the antient Mesopotamia: it is situat-
ed on the river Tigris, near its source, in
42° east long., and 35° 30' north lat.
DIARRHODON, in pharmacy, a name
given to divers compositions in which
roles are the principal ingredient. In the
old college dispensatory, one of these
is directed diarrhodon abbatia; but it is
omitted in the last. There are also the tro-
chitii diarrhodon, compos'd of red roes,
shavings of ivory, the saunders, liquo-
ice, mutlic, fafron, camphor, and rose-
water: they are good to fortify the heart,
fromach, and liver, and to stop dysente-
ries, and other fluxes of the belly.
Pulule diarrhodon are compos'd of aloe,
&c; trochitii
DIARRHOEA, or Looseness, in medicine, is a frequent and copious evacuation of liquid excrement, by stool; and may proceed from aliments or humours of various kinds, derived from different parts into the intestines.

The cause is a stimulus, which irritates the viscéra, occasioning the expulsion of their fluids; and may, therefore, proceed from the vessels of the liver, pancreas, mesentery, and intestines; whence, at the same time, the mouths of the mesenteric veins, and of the lacteals, are obstructed; or there may be an extraordinary laxity of the intestinal fibres: or, lastly, it may arise from a stoppage of other excretions.

It is frequently attended with gripings; the patient is weak, makes but little urine, has a depressed pulse, a depraved appetite, and is sometimes feverish. In a diarrhoea arising from sharp, fermenting juices in the prime viscus, which accelerate the peristaltic motion of the intestines, the first indication is to discharge the stimulating matter, which may be perfected by a dose or two of rhubarb in the morning; at night the patient may take fifteen drops of the expressed oil of nutmeg, impregnated with thin emulsions of almonds and white poppy seeds, with the addition of diacodium. When a diarrhoea is very obstinate, after toasted rhubarb has been given for some days, a sweat should be promoted, with a dram of new venetian treacle, and twelve grains of burnt hartshorn, calx of antimony and purified nitre. The patient’s common drink may be decocted with solution of gum arabic; rice boiled in water, with a little cinnamon; or a decoction of the cori. granat. These may be made palatable with syrup of orange-peel. Clysters are likewise often serviceable.

An obstinate diarrhoea, according to Et-muller, is to be cured by a course of vomits of ipecacuanha. An habitual diarrhoea is greatly relieved by wearing a flannel shirt, and keeping the body warm, according to Wainwright.

The diarrhoea of children is not to be stopped, either with astringents, or narcotics; for the astringents turn the flux of sharp humours towards the noble parts, and endanger the life of the child. And though narcotics appease the severity of the gelidulent humours for a time, yet they afterwards break out with greater force. Besides, opiates are too powerful for the tender constitution of infants, and must not be given at all, or with the utmost caution. In flight cases, diazcurdiurn may be ventured on, to five or six grains: but if there is a fever, it cannot be given without danger.

Therefore, the best way is to give chalk, coral, pearls, and the like, of which about half a scruple is a dose: after which the cure may be completed with rhubarb, from six grains to half a scruple in solution of syrup of roces.

In dangerous cases, a few grains of the eleuther bark may be added, or a dram of the extracts of peruvian bark may be dissoluted in half an ounce of mint, or cinnamon water, and given from one to nine drops, every three or four hours. Externally the abdomen may be anointed with expressed oil of nutmegs, impregnated with carminative and stomachic oils. The nurse should shun the cold air, abstain from drinking too much, and use a temperate diet.

DIARTHROSIS, in anatomy, a kind of articulation, or juncture of the bones, in which there is a manifest motion. See the article Articulation.

The diarthrosis comprehends, 1. The enarthrosis, in which the head of one of the bones is received into a deep cavity in the other, as in the articulation of the femur. 2. The arthrodia, in which the head
head of one of the bones is received into a flighther cavity in the other, as in the juncture of the os humeri with the scapula. 3. The ginglymus, in which the bones mutually receive, and are received by one another, as is the case in the articulation of the humerus and cubitus. To thefe, Fallopius adds the trochoides, some of the modern physicians, the fame with what the ancients called interval. Muticicians divide intervals into two kinds; one of them is called syfrem, which is to contain, at leaft, two intervals in the diatomic kind of music; but in the enharmonic, it contains more: the other, which they call diafrem, is a mere simple interval.

DIASCHELVl, DIASCHISVl, DIASCO, {DIUM, head of one of the bones is received into a flighther cavity in the other, as in the juncture of the os humeri with the scapula. 3. The ginglymus, in which the bones mutually receive, and are received by one another, as is the case in the articulation of the humerus and cubitus. To thefe, Fallopius adds the trochoides, some of the modern physicians, the fame with what the ancients called interval. Muticicians divide intervals into two kinds; one of them is called syfrem, which is to contain, at leaft, two intervals in the diatomic kind of music; but in the enharmonic, it contains more: the other, which they call diafrem, is a mere simple interval.

DIASEBESTEN, in pharmacy, a soft purgative electuary, whereof febestens are the principal ingredients. The other ingredients are prunes, tamarinds, juices of iris, anguria and mercurialis, peni­dies, simple diaprunum, violet seeds, and diagrydium. It is good in remitting and continued fevers, &c.

DIASENNA, in pharmacy, the name of a medicine in which fenna is the principal ingredient. The other ingredients are sugar-candy, cinnamon, lapis lazuli, flk, cloves, gal­langa-minor, black pepper, nardus in­dica, feed of basilicum, flowers of cloves, cardamoms, faffron, ginger, ze.ary, &c. This elec­tuary is taken against melancholy and spleen, and against diseases arising from an atrabilis.

DIASIA, in grecian antiquity, a festival kept at Athens in honour of Jupiter the propitious.

DIASIAS, a term used by antient phy­cicians for a diftention of the muscles, or feparation of the bones.

DIASTEM, dia&yia, among antient mu­icians, the fame with what the moderns call interval. See INTERVAL.

Muficians divide intervals into two kinds; one of them is called syfrem, which is to contain, at leaft, two intervals in the diatomic kind of music; but in the enharmonic, it contains more: the other, which they call diafrem, is a mere simple interval.

Take of cinnamon and cafis-wood, of each half an ounce; of true fcorbium, one ounce; of crenat dittany, tormentil, bifort, galbanum, and gum-arabic, of each half an ounce; of terebax, four drams and an half; of opium, and feeds of forcil, of each one dram and an half; of gentian, half an ounce; of american bole, one ounce and an half; of lemnian falted earth, half an ounce; of long pepper and ginger, of each two drams; of clarified honey, two pounds and a half; of fugar of roxes, one pound; of generous canary, eight ounces; make into an elctuary. See the article ELECTUARY. It is excellent in all kinds of fluxes, and a great ftrengthen er both of the fomach and bowels. Nuries frequently give chil­drin this medicine to make them fleep; but the practice is very detrimonial, and generally the caufe of many disorders, as it keeps them too colive. It is alfo used againft the plague, and to prevent purre­faction.
Dia stole, in grammar, a figure of pro-
sody, whereby a syllable naturally short
is made long: such is the first syllable of
Priamides, in the following verse of
Virgil.

\[\text{Diastolē, nilībō tibi, amīce, velītum.}\]

This figure is used either out of mere poetic licence, without any necessity for
so doing, or through necessity, for the
fake of the verse; as when three or more
short syllables follow each other in hexa-
meter verse.

Diatyle, in the ancient architecture,
an edifice, where the columns stand at
such a distance one from another, that
eight modules, or four diameters, are
allowed for the intercolumniation.

Dias yrmus, διασύρμος, in rhetoric, a
kind of hyperbole, being an exaggeration
of some low, ridiculous thing.

Diates saron, διατετσαρος, among an-
tient musicians, a concord, or harmonic-
interval, composed of a greater tone,
a less tone, and one greater semi-tone:
its proportion in numbers is as 4 : 3. See
the article Concord.

Diatessaron, in pharmacy, the name of
a composition so called, from the four
ingredients it comprehends: it is pre-
pared thus.

Take of gentian root, bay-berries, myrrh,
and roots of birthwort, of each two ounces;
of honey, two pounds; mix them into
an electuary. This, with the addition of
the flavings of ivory, two ounces, is en-
titled diapente, or a composition of five
ingredients.

This medicine was at first entered in the
college dispensatories under the name of
therigca. Quincy recommends it as a
medicine of great importance in the dis-
cases of cattle. It is also used against the
fling of venomous beasts, epilepsies, con-
vulsions, &c.

Diatonic, an epithet given to music,
as it proceeds by tones and semi-tones,
both ascending and descending. See the
article Music and Genre.

The Greek authors divide the genera or
kinds of music into diatonic, chromatic,
and enharmonic. See Chromatic and
Enharmonic.

Diatonic music, according to Nicomas-
clus and others, allows of three degrees,
the greater tone, less tone, and semi-tone.
See the article Tone.

Hence diatonic music appears the most
natural, and of consequence the most an-
tient. In the diatonic music, there is a
tone between every two notes in the scale,
except mi, fa, and, as the French term it, fi and sol, where there is only a greater
semi-tone. The diatonic genus was by
the antients divided into two species, the
molé, and the intertunium. The last is in
daily practice. It is commonly said to
consist of two tones and a semi-tone; but
to speak exactly, it consists of a semi-tone
major, a tone minor, and a tone major.

Diatonico-Diatonic, according to
Zarlin, is the pure and natural diato-
nic genus, or when the progress of the
notes is B quadr, or B natural, in which
not one of the sounds is the least altered.
Such is the plain chant of the church.

Diatragacanth, in pharmacy, a
name applied to certain powders, where-
of gum tragacanth is the principal in-
gredient; of which there are two kinds,
the cold and the hot: the cold is directed
thus: take of gum tragacanth, two
ounces; of gum arabic, an ounce and
two drams; of starch, half an ounce;
of liquorice, and the seeds of melons and
white poppies, of each two drams; of
sugar-candy, three ounces; mix them into
a powder. This is frequently prescribed
in hæmatic heats, in choleric constitutions,
in di tempers of the breast, in stranguries,
heat of urine, and the pungency of venu-
real gleet.

Powder of hot diatragacanth is com posed
of gum tragacanth, cinnamon, hyssop,
almonds, linseed, fenugreek, liquorice,
and ginger. It is good against athenas,
to promote expirations, strengthen the
stomach, and assist digestion.

Diaugophragmia, in natural his-
tory, a genus of fossils of the order of
septarian, whose partitions, or septa,
consist of spar with an admixture of crystal.
Of this genus there are three species. 1. A
red kind, with brownish-yellow par-
titions. 2. A brownish-yellow kind,
with whitish partitions. 3. A bluish-
white kind, with straw-coloured parti-
tions.

Dialodromi, διαλοδρομος, in anti-
quity, an appellation given to such racers
as passing round the meta, or goal, re-
turned to the carcer, or place of starting,
before the race was finished.

Diazuectic, or Dizuectic tone,
in the ancient Greek music, a tone which
disjoined two fourths, one of each side of
it; and which, being joined to either
made a fifth: this, in their music, was
from me to parade; that is, from our
A to B: supposing me to stand in B fab
mi,
DICOTYLDON, a genus of plants, the corolla of which consists of five ovato-lanceolated, acuminate, unguiculated, and unequal petals; three of which are turned upwards, and two are placed obliquely at the sides: the fruit is composed of five capsules, growing together by their inside; they are compriest, acuminate, distant at the top, and formed of two valves: the seeds are numerous, and turbinated. See plate LXXII. fig. 5.

The ancients have recorded almost miracles of the virtues of this plant in the cure of wounds, and in the prevention of mischief from venomous bites: they tell us, that even the beasts were informed of its virtues on these occasions, and had recourse to it when hurt: they gave it also to promote the menest, and to affist delivery, in the expelling of the fcundines, and in malignant fevers: with us it is wholly out of use, except as an ingredient in some of the official compositions.

The white dittany-root, which we call fraxinella in the hops, is accounted cardiac, uterine, and alexipharmic.

DICTATEN, dictamen, among schoolmen, a motion, or suggestion of a man’s conscience, contrary to which if any action is performed, it is properly termed a bad one, even if the consequences should prove otherwise. See CONSCIENCE.

DICTATE, dictata, is also used in the schools for the lecture of a master, which the scholars take down in writing: whence this act of the master is termed dictating.

DICTATOR, in the policy of the ancient Romans, a magistrate invested with sovereign and even arbitrary power.

He had power of life and death; also to raise or disband troops, make war or peace, and that without the consent either of the senate or people, or being accountable for his proceedings. He was elected by one of the consuls in the night-time on the frontiers of the commonwealth, and no where else; and the ordinary duration of his office was only for six months, during which time all other magistracies ceased, the tribuneship excepted.
DIC [914] DIC

ceped. Whenever he appeared in public, he was attended by twenty-four lictors, or double the number allowed a consul. However, notwithstanding all this power, he could not go out of Italy, or even ride on horseback during a march, without leave from the people.

This office was accounted the safeguard of the commonwealth for four hundred years together, till Sylla and Cæsar, by assuming the title of perpetual dictators, converted it into tyranny, and rendered the very name odious.

DICTION, the phrase, elocution, or style of a writer, or speaker.

It is required that the diction, or language, of an orator, should be pure, proper to the subject, rich without affectation, strong and close without drudgery, and suitable to the person, time, place, and audience. In tragedy, the diction is accounted the fourth essential part; and though it is of the least importance of any of the other essentials, yet special care must be taken that every passion speak in its peculiar diction. It is observed, that the diction of the Italians abounds too much with shrewd words, quarks, and chibbles; and even the French are charged with the like fault in their diction. Some authors are, again, thought so preposterously fond of jocose and facetious repartees, and ludicrous sentences, that they have indulged this affection to a fault; whence arose that sort of diction commonly called burlesque, of which the French have afforded us a specimen in the works of the celebrated Scarrot.

DICTIONARY, a collection, or catalogue, of all the words of a language, art, science, &c. with their explanations, ranged in alphabetical order.

The most antient dictionaries for the Latin tongue, are that called Papias, compiled by Solomon, abbot of St. Gall, and bishop of Constance, who lived about the year 459; another compiled in 1496, called Gemma Vocabulorum; a third, called Promptorium Parvulorum, five Clericorum, printed in folio, at London, in the year 1499, by Richard Pynson: this work consisted only of one part, which exhibited the English words before the Latin, being destitute both of the Latin and historical parts: but the defects were supplied by a dictionary which was printed at London in quarto in the year 1416, by Wynkyn de Worde, entitled, Ortus Vocabulorum alphabeticorum ordine fere omnia quae in Catholicismo, Brevisloquio, Cornucopia, Gemma Vocabulorum, atque medulla grammaticae ponuntur, cum vernacularis lingus Anglica, et expositione, continent. The most celebrated old Latin dictionary, is that of Ambrofio Calepin, a hermit of St. Augustine, at Bergamo, and son of the count Calepin. The most noted old dictionaries in English and Latin, are those of Cooper, Holyoake, and Gouldman: among the modern ones, Littleton, Cole, &c. but that of Ainsworth merits most consideration, as being agreeable to its title, Thesaurus lingus Latinæ compendiarius. The last editions of this book have been greatly improved by Samuel Patrick, L. L. D.

For the Greek, the most noted dictionaries are those of Stephens, Scapula, Schrivelius, Hedericus, &c. The most celebrated historical dictionary is that of Mr. Bayle, in two volumes folio, entitled, an historical and critical dictionary. The philosophical dictionary of greatest note, is that of Chauvinus; for commerce, that of Savary; for law, those of Calvinus and Jacob; and among the dictionaries of arts and sciences, may be reckoned those of Harris, Chambers, and Barrow.

In the French, the most worthy of notice among works of this nature, are the dictionary of Trevoux, and the Encyclopedic, of which last only three volumes in folio have yet appeared.

A performance of this kind being a digest of the body of learning, or, rather, of general knowledge, is thought capable of being made universally useful and instructive; and as the objects of our knowledge grow daily more numerous, and improvements in arts and sciences are continually made, a work of this kind is continually capable of new improvements. It is farther advanced, that, besides preventing, in some measure, the necessity and expense of a multitude of books, which too frequently retard rather than promote, and bewilder rather than guide in the pursuit of knowledge, there is no form or method of writing so advantageously disposed to propagate knowledge through the body of a people, or that can be made to comprehend so great a part of the circle of learning, and so well answer the purposes of a library, as a dictionary of this nature. The writers of a dictionary of arts and sciences, are exempted from the observation of certain laws concerning property; never pre-tending
DIE, in architecture, the same with dye. See the article Dye.

DIE, in geography, a town of France, in the province of Dauphiny, situated on the river Drome, twenty-two miles south of Grenoble: east long. 5° 20', north lat. 44° 50'.

DIEBEL, in ornithology, a name given to the chub. See the article Chub.

DIEGEM, a town of the Austrian Netherlands, in the province of Brabant, about three miles north of Brussels: east long. 4° 20', and north lat. 51°.

DIEM CLAUSET EXTREMUM, a writ that formerly issued out of the chancery to the exchequer of the county, upon the death of any of the king's tenants in capite, to inquire by a jury of what lands he died seized, of what value, and who was the next heir to him: and on the heir's coming of age, he was to sue livery of his land out of the king's hands.

DIEPE, a port-town of France, situated on the British channel, about thirty miles north of Rouen, and opposite to the port of Rye in England: east long. 1° 15', and north lat. 49° 55'.

DIEPHOLT, a city of Westphalia, in Germany, situated at the north end of the Dummer-lake, thirty-five miles south of Bremen: east long. 5°, north lat. 53°. It is subject to the king of Great Britain, as elector of Hanover.

DIER, or DYER. See the article Dyer.

DIERVILLA, in botany, a genus of the 

DIDACTIC, or DIDACTICAL, in the schools, signifies the manner of speaking, or writing, adapted to teach or explain the nature of things.

DIDAPPER, in ornithology, the same with the dodd-chick, a species of columbus.

DIDELPHIIS, in zoology, a genus of quadrupeds, of the order of the glires, the characters of which are these: there are two obtuse and four conical fore-teeth in the upper jaw; those of the lower jaw are eight, and very small; and the dog-teeth, in each jaw, are three in number.

To this genus belong the opposum, and African rat, called by some hayopolin. See OPOSSUM and HAYOPOLIN.

DIDYNAMIA, abjuration, in the linean system of botany, a very comprehensive class of plants, the fourteenth in order; the essential characteristic of which is, that there are four subulate flaminia, inserted into the tube of the flower, two whereof are shorter than the others, and placed together; the anther being commonly hid under the upper lip of the flower, and connivent in pairs. It has its name from the two longer flaminia being fuppered more efficacious in fecundating the seeds, than the rest; and as the genera belonging to it are very numerous, they have been divided into two series or orders, under the names of gymnopermann and angiopermia; the latter having, and the former wanting a pericarpium, or seed-vessel. See the article Botany.

To this genus belong baum, germander, lavender, thyme, betony, mint, basil, fox-glove, bear's-breech, &c.
DIE [916]  

DIES MARCHJAE, was the day of congress, or meeting of the English and Scotch, annually appointed to be held on the marches, or borders, in order to adjust all differences between them.

DIESIS, in music, is the division of a tone less than a semi-tone; or, an interval consisting of a less or imperfect semi-tone. Diesis is the smallest and softest change or inflexion of the voice imaginable; it is called a faint, expressed thus X, by a St. Andrew's cross, or falter. Aristotle calls diesis the elements of the voice, as letters are those of discourse. It appears, however, that Aristotle's dieses were different from ours; and we find Vitruvius, and all the greek authors, expressly make the dieses a quarter of a tone; but the Pythagoreans, who are held inventors of the name dieses, did not make it so small: they only divided the tone into two unequal parts; and they called the lesser diesis, which we call a lesser semi-tone; and the greater, which we call the greater semi-tone, they called apotome. See the article Apotome.

But in aftertimes, when the tone came to be divided into three or four parts, the name dieses was retained to them all. The harmonical dieses is the difference between a greater and a lesser semi-tone. Dieses are divided into three kinds; the lesser enharmonical dieses, or simple dieses, marked by a single cross, which raifes the note following two commas, or about a quarter of a tone, and is the least interval that is fent; and never more than two are found together in whatever genus; nor are those two of the same kind. The chromatic or double dieses, denoted by a double cross, raifes the note following by a lesser semi-tone, or four commas, which is the common diesis. The greater enharmonical dieses, denoted by a triple cross, raifes the following note six or seven commas, or about three quarters of a tone.

DIEST, a town of the austrian Netherlands, in the province of Brabant, situated on the river Demer, fifteen miles north-east of Louvain; east long. 5°, and north lat. 51° 5'.

DIE, diete, diale, in medicine, according to fome, comprehends the whole regimen, or rule of life, with regard to the fix non-naturals, air, meats and drinks, sleep and watching, motion and reft, passions of the mind, retentions and excreations. See the article Regimen, &c.

The more accurate writers, however, regar-
DIE [917]

Presents the head, generates wind, obstructions, the strangury, asthma, and colic. See Wine, Beer, Cider, Obstruction, Strangury, &c.

Tea promotes perspiration, strengthens and cleans the stomach, and helps digestion. Coffee, taken after dinner, helps digestion, and allays the fumes of wine. Moderately taken, it thins the blood and humours; but its excess agitates the blood, causes watching, and occasions hemorrhages.

From this view of the materials of diet, it appears, that the best way to preserve health, is to live upon plain simple foods, lightly seasoned, and in a quantity agreeable to the age, strength of the stomach, health, is to live upon plain haemorrhages.

Hunger shews the best time of laws, or coming to any resolutions. Hunger has by experience been found to differ. Voice prevents their change their manner of life; and, in representing his state of the spirits and fluid parts the canton of that name. When a person is much fatigued, and his spirits diffipated, it will do nothing to correct them. In summer, when the spirits and fluid parts are apt to evaporate, the diet should be diyet. A term used in old writers for a part of Poland, to deliberate and concert William, who used the motto of the archbishop of Gnesa. The general diet of Poland fits but six weeks, and often breaks up in a tumult much sooner: for one differing voice prevents their passing any laws, or coming to any resolutions on what swiss is proposed to them from the throne. Switzerland has also a general diet, which is usually held every year at Baden, and represents the whole helvetic body: it seldom lasts longer than a month. Besides this general diet, there are diets of the protestant cantons, and diets of the catholic ones; the first assemble at Arau, and are convoked by the canton of Zurich; the second at Lucern, convoked by the canton of that name.

Diet, or Dyet, in matters of policy, is used for the general assembly of the states, or circles of the empire of Germany, and of Poland, to deliberate and concert measures proper to be taken for the good of the public.

The general diet of the empire is usually held at Ratibon: it consists of the emperor, the nine electors, and the ecclesiastical princes; viz. the archbishops, bishops, abbots, and abbeses; the secular princes, who are dukes, marquesses, counts, vicounts, or barons; and the representatives of the imperial cities. It meets on the emperor's summons, and any of the princes may send their deputies thither in their stead. The diet makes laws, raises taxes, determines differences between the several princes and states, and can relieve the subjects from the oppressions of their sovereigns.

The diet of Poland, or the assembly of the states, consists of the senate and deputies, or representatives of every palatinate or county and city, and meet usually every two years, and oftener, upon extraordinary occasions, if summoned by the king, or, in his absence, by the archbishop of Gnesa. The general diet of Poland sits but six weeks, and often breaks up in a tumult much sooner: for one differing voice prevents their passing any laws, or coming to any resolutions on what is proposed to them from the throne. Switzerland has also a general diet, which is usually held every year at Baden, and represents the whole helvetic body: it seldom lasts longer than a month. Besides this general diet, there are diets of the protestant cantons, and diets of the catholic ones; the first assemble at Arau, and are convoked by the canton of Zurich; the second at Lucern, convoked by the canton of that name.

DIET, a term used in old writers for a day's journey.

DIETETIC, denotes something belonging to diet, but particularly that part of physic which treats of this subject. See the article Diet.

DIETS, a town in the circle of the upper Rhine, in Germany, situated on the river Lohn, twenty miles north of Mentz, and subject to the house of Nassau-Orange: exit long. 7° 46', and north lat. 50° 28'.

DIEU ET MON DROIT, i.e. God and my right, the motto of the royal arms of England, first assumed by king Richard I. to intimate that he did not hold his empire in vassalage of any mortal.

It was afterwards taken up by Edward the third, and was continued without interruption to the time of the late king William, who used the motto je maintiendrai, though the former was still retained upon the great seal. After him queen Anne used the motto "femper cadam", which had been before used by queen Elizabeth; but ever since queen Anne, dieu et mon droit continues to be the royal motto. See the article Morro.

DIEU SON ACT, words antiently often used in our law; and to this day, it is a
maxim in law, that the act of God shall prejudice no man: therefore, if a house is blown or beaten down by a tempest, thunder or lightning, the lessor, or tenant for life, or years, shall be quit of an action of waste; and by the law he has likewise a special interest or liberty allowed to take timber, to rebuild the house for his habitation.

**Diexahedria**, in natural history, a genus of pellucid and crystalliform spars, composed of two pyramids, joined base to base, without any intermediate column: the diexahedria are dodecahedral, or composed of two hexagonal pyramids. See the article *spar*.

**Diffamatory**, a term chiefly used in the phrase diffamatory libel, signifying a writing intended to scandalize or discredit a person, &c. See *libel*.

By the Roman law, and the antient ordinations of France, the authors of diffamatory libels were punished with death.

**Diffarreation**, in roman antiquity, a ceremony whereby the divorce of the priests was solemnized, or the dissolving of marriage contracted by confarration. See the article *Confarreation*.

Vigenere will have confarration and disfarreation to be the same thing.

**Difference**, in logic, signifies an essential attribute belonging to any species that is not found in the genus, and is the universal idea of that species: thus, body and spirit are two species of substance, which contain in their ideas something more than is in that of substance. In a body, we find impenetrability and extension; in a spirit, a power of thinking and reasoning; so that the difference of body is impenetrable extension, and the difference of a spirit is cognition.

**Difference**, in mathematics, is the remainder, when one number or quantity is subtracted from another. It was a fundamental principle among the antient geometers, that the difference of any two unequal quantities, by which the greater exceeds the less, may be added to itself till it shall exceed any proposed finite quantity of the same kind. This principle seems inconsistent with the supposition of an infinitely small quantity, or difference, which added to itself by any number of times, is never to be supposed to become equal to any finite quantity whatsoever, which is the foundation of the modern method of infinitesimals: however, this last may, with proper caution, be made useful and accurate.

**Difference of longitude**, of two places on the earth, is an arch of the equator, comprehended between the meridians of these two places.

**Difference of ascension*. See the article *Ascensional difference*.

**Differences**, in heraldry, certain additions to coat armour, whereby something is added or altered to distinguish younger families from the elder. Of these differences Sylvanus Morgan gives us nine; viz. the label, for the first son; the crescent, for the second; the mullet, for the third; the martlet, for the fourth; the annulet, for the fifth; the flower de lis, for the sixth; the rose, for the seventh; the eight-foil, for the eighth; and the cross moline, for the ninth. See *label*, *crescent*, &c.

Again, as the first differences are single for the sons of the first house or descent, the sons of the younger house are differed by combining or putting the said differences upon each other. As the first differences are the label, crescent, &c. for the first house, the difference for the second house is the label on a crescent for the first of that house; for the third brother of the second house, a mullet on a crescent, &c.

The original difference is controverted: Camden will have them to have begun about the time of king Richard: Pandarin assigns differences worn as early as the year 870; wherein he contradicts the opinion of the president Fauchet, who says, arms were not hereditary in the French families, till after the time of Lewis the great, who came to the crown in the year 1100.

**Differential calculus**. See the article *Calculus differentialis*.

**Differential**, *differentials*, in the doctrine of logarithms, a term used by Kepler for the logarithms of tangents, which we call artificial tangents. See the articles *Logarithm* and *Tangent*.

**Differentialis differentialis calculus**, is a method of differencing different quantities.

We have observed, under the word *calculus*, that the differential of a quantity is expressed by the letter *d* prefixed to it, as the differential of *x* is called *dx*; we are to remark, therefore, in this place, that the differential of *dx* is *ddx*; and the differential of *ddx* is *ddddx*; or, as Sir Isaac Newton would express it, *x*, &c. These differentials may be expressed more comprehensively thus, *d²x*, *d³x*, &c. whence
whenevber we have powers or degrees of differentials. The differential of an ordinary quantity, is called a differential of the first degree, as \( dx \). The differential of the second degree, is an infinitesimal of a differential quantity of the first degree, as \( ddx, d^2x, \) or \( dx^2 \), \( dxdy \), &c. The differential of the third degree, is an infinitesimal of a differential quantity of the second degree, as \( d^3x, d^3y \), \( dx^3 \), and \( d^3z \).

The powers of differentials are differentiated after the same manner as the powers of ordinary quantities: and as compound differentials either multiply or divide each other, or are perfect or imperfect powers of differentials of the first degree, the differential-differential calculus is in effect the same with the differential calculus. See the article CALCULUS DIFFERENTIALIS.

For the use of the differential-differential calculus, see Wolfii Elementa Analyticae, par. 2. sect. iv.

DIFFORM, *difformis*, an appellation given to things whose appearance is irregular, in contradifferentiation to uniform. See the article UNIFORM.

It is much used in the description of plants of the **fungus** clas, or those with compound flowers, when the partial flowers, or smaller florescules, happen to be of different kinds. See the article FLOWER.

DIFFUSE, an epithet applied to such writings as are wrote in a prolix manner. Among historians, Salut is reckoned sententious, and Livy diffuse. Thus alio among the orators, Demosthenes is close and concise; Cicero, on the other hand, is diffuse.

DIFFUSION, the dispersion of the subtile effluvia of bodies into a kind of atmosphere all round them. Thus the light diffused by the rays of the sun, issue; all round from that amazing body of fire; and thus are the magnetic particles diffused every where round about our earth, and parts adjacent to it.

The schoolmen make three kinds of diffusion. 1. That by which a pure quality is diffused, as light, force, &c. 2. That performed by the motion of bodies, as the diffusion of sound, smell, magnetic and electric bodies, &c. And, 3. That performed partly by the motion of corpuscles, and partly by the motion of a quality. Thus, say they, fire is diffused.

DIGAMMA, a name given to the letter \( \Gamma \). See the article F.

DIGAMY, the same with bigamy. See the article BComput.

DIGASTRICHUS, in anatomy, a muscle of the lower jaw, called also biventer. See the article BIVENTER.

Mr. Monro affur'd us, that the digastriac muscles not only pull down the lower jaw, but serve to draw up the os hyoides, and parts annexed to it, in deglutition. See the Medical Essays, vol. I. art. 2.

DIGEST, *digestum*, in matters of literature, a collection of the decisions of the roman lawyers properly digested, or arranged under distinct heads, by order of the emperor Justinian. It constitutes the first part or volume of the civil law.

DIGESTER, or DIGESTOR. See the article DIGESTOR.

DIGESTION, in medicine, is the dissolution of the aliment into such minute parts as are fit to enter the laceral vessels, and circulate with the mass of blood. Various are the systems and hypotheses framed by physicians and philosophers to account for digestion. Some contend that it is done by a kind of elixation of the solid and groffer parts of the food in the liquid by the heat of the stomach, and of the adjacent parts, the liver, spleen, &c. Others will have it done by attrition, as if the stomach, by those repeated motions, which are the effects of respiration, rubbed off the minuter particles from the groffer matters, and agitating the rest against each other, attenuated and dissolved them. See TRITURATION. Others think the bilious juice, others the spirits, chiefly concerned in digestion.

Others will have the food dissolved by a menstruum; but then they are greatly divided as to the nature and origin of this menstruum; some supposing it an acid furnished by the glanis of the stomach; others, a nitro- aerial spirit, which by penetrating the mass of food, breaks the connection of the molt solid parts; and others, a saline juice, which divides and volatilizes the parts of the food. Others, again, suppose digestion to be performed by means of a ferment or leaven, which mixing with the aliment, excites an intestine motion in the parts thereof, by which means the parts are attenuated and dissolved. But these likewise differ in their opinion of this ferment; some taking it to be the remains of the food last digested, which by its continuance in the stomach, has contracted an acid quality and become a ferment others take the principles of fermentation to be contained in the aliment.
ment itself, which, when inclosed in the stomach, heated there, and put in motion, enters on its office of fermentation: others suppose the matter of the ferment supplied by the glands of the stomach; and lastly, others contend for the saliva, and make that the ferment serving principally for the digestion of the food. See the article Fermentation.

Some suppose digestion owing to gentle heat and motion. By this heat and motion, say they, the texture of the nourishment is changed in the bodies of animals; and then the constituent solid parts are induced with peculiar attractive powers of certain magnitudes, by which they draw out of the fluids moving through them, like parts in certain quantities, and thereby preserve their forms and just magnitudes. And, to mention no more, Boerhaave very justly, in our opinion, ascribes digestion to the joint action of several of the above-mentioned causes, aided by the expansion of the air contained in the aliment. See the articles Chyle, Chylification, Blood, &c. Mastication, Nutrition, &c.

Part of Digestion, a disease attended with pain, and a sense of weight with eructations and copious flatulences from corrupt humours in the stomach. See Apepsy. It generally arises from a bad diet, particularly from eating too plentifully, especially fat and oily aliments, with a sedentary life and idleness. When the humours are corrupt, after a vomit, laxatives should be used: afterwards with a spice diet, stomachics and strengtheners, with exercise, and abstinence from studies. The use of spaw, or chalybeate waters, is very efficacious for the cure of this disease. In almost all weaknesses of the stomach, chawing of rhubarb is convenient, especially in those that are collyve.

Digestion, in chemistry, pharmacy, &c. the subjeeting bodies, included in proper vessels, to the action of a gentle and continued heat.

The application of this operation, in regard to its end, is very various. In some cases, it is used with a view of producing a change in some one single body, as in the instance of the preparation called mercurius precip. per se; in others, to promote solutions, or other combinations; but most frequently for extraction or separation, by means of fluids, of the required parts of some solid bodies, whose texture, impeding the quicker access and effect of menstrua, renders a long infusion, and the relaxation of a gentle heat, necessary, in order to their being penetrated; or for accelerating the solution of bodies by menstrua, whose action when cold is not sufficiently vigorous.

The vessels generally used to contain the matter to be digested, are matraffes, or bolt-heads, and sometimes glasses; but where the heat is so gentle as to make no evaporation, the structure is indifferent. In cases where an evaporation does happen, and the exhaling fluid is of any value, the vessels are to be constructed so as to confine the vapour, and return it in a condensed state. This is called circulation, and is commonly executed by inverting the neck of a smaller matraff into that of a larger, in which case the conjoined glasses are called a pelican. There are several other kinds of pelicans of a more complex structure, but the flask used for Florence wine, diversified of the straw-work, and inverted into a matraff with a very long neck, will conveniently answer all the purposes. See Circulation.

This operation is most generally performed in a fair heat, and no greater adjustment of the degrees of heat is necessary for the purposes of pharmacy, than can be there effected; but formerly when the more mysterious and operose methods were followed, the heat of dung-hills has been employed.

The degree of heat requisite in digestion, differs according to the nature of the subject: in tinctures, made with strong spirit of wine, or volatile salts, and in solutions where a great effervescence is apt to arise, a very gentle one should never be exceeded. In aqueous solutions, and most other cases, a greater may be allowed; but it must always be understood to be, lest than will make the matter boil, otherwise the operation comes not within the proper meaning of the word digestion, which is a distinction from coction.

The time which digestion ought to be continued, differs so greatly, according to the different application of the operation, that no other rule for it can be laid down, than that it should be continued till the intention to which it is made subservient be completed.

In circulatory digestions, it is proper to lute the vessels, to prevent the escape of the vapours through the junctures, but in many cases this following precaution
caution is extremely necessary, viz. that a small aperture, or vent, be left, otherwise an incondensible vapour, which arises, will, if it cannot force the lute, inevitably burst the glabella. The instances in which this precaution is necessary, are all mixtures of acid spirits, with earths, metals, or alkaline salts; or of such salts of those substances which can be acted on by them. But in solution of salts in water, and in extracts of gums, or refinings, made with volatile salts, wine, or spirits of wine, it may be safely omitted. The college of London have, in their dispensatory, as well according to the last edition as the former, used the word digestion in a sense different from the above definition, meaning by it only the suffering the ingredients of certain mixtures to be continued together without applying the use of heat; which they expressly order on each occasion to be applied or omitted, by laying, digest with heat, or digest without heat: this is confounding the sense of the word digest, with that of the word infuse. See the article Infusion.

Digestion, among physicians, is used for maturation, or that state of a disease, when the morbid matter is so changed in bulk, figure, cohesion, mobility, &c. by the use of proper medicines, or even by the force of nature, as to be less noxious and hurtful, and consequently to abate the violence of the distemper. See the article Digestive.

Digestion, in surgery, is the dispoing of an ulcer or wound to suppurate, or to discharge good pus, by the application of proper medicines. See the next article.

Digestive, in medicine, such remedies as strengthen and increase the tone of the stomoch, and afford in the digestion of foods. See the article Digestion. To this class belong all stomachics and strengtheners, or corroborants.

Digestive, in surgery, such medicines as are applied to wounds, &c., in order to promote a good maturation and laudable suppuration of matter. Lentin, anodyne, and balsamic digestives, are to be applied to a gangrene. Digestives of turpentine, and the yolks of eggs, are useful in abscesses, wounds, and ulcers. See the article Suppuratives.

Digestor, in chemistry, a strong vessel made of copper, or iron, and fitted with a close cover and screws; so as to remain perfectly tight in a considerable degree of heat, whilst water, common air, and the subject of the operation are contained therein. See the article Digestion.

The cover of the digester should always be provided with a valve to let out the steam, otherwise the vessel will certainly burst, whereby it may prove fatal to the by-standers.

Of all chemical vessels hitherto invented, the digester seems best calculated for increasing the action of menstrua. Water, confined in a digester, is susceptible of so much heat, as to melt lead; and it is frequently found to melt the folder of lead and tin, wherewith the copper vessel was held together: here appears the necessity of using hard folder, made of spelter, or silver and brass, for this purpose; otherwise, the digester cannot contain the water, when much heated, without melting in the joints.

In this vessel, a fresh ox-bone will be digested in the space of a quarter of an hour, as to become soft and tender, and capable of being cut with a knife; and the water, in which it was boiled, turned into a hard jelly, and a large cake of fat on its surface, when all is properly cooled.

Diggmg, among miners, is appropriated to the operation of freeing any kind of ore from the bed or stratum in which it lies, where every stroke of their tools turns to account: in contradistinction to the openings made in search of such ore, which are called hatches or essay-hatches, and the operation itself, tracing of mines; or hatching. See the article Tracing of Mines.

When a bed of ore is discovered, the beetle-men, so called from the instrument they use, which is a kind of pick-axe, free the ore from the fossils around it, and the shovel-men throw it up from one shamble to another, till it reaches the mouth of the hatch. See the article Beetle, Hatch, &c.

In some mines, to save the expense as well as fatigue of the shovel-men, they raise the ore by means of a windcr, and two buckets, one of which goes up as the other comes down.

Diggmg a Badger, among hunters, is dislodging or raising him out of the earth.

Digit, digitis, in astronomy, the twelfth part of the diameter of the sun or moon, is used to express the quantity of an eclipse. Thus an eclipse is said to be of six digits, when six of these parts are hid.
DIGITS, or MONADES, in arithmetic, signify any integer under 10, as 1, 2, 3, 4, 5, 6, 7, 8, 9.

DIGIT is also a measure taken from the breadth of the finger. It is properly 1/4 of an inch, and contains the measure of four barley-corns laid breadth-wise.

DIGITALIS, FOX-GLOVE; in botany, a genus of the didynamia angiofermoria class of plants, with a monopetalous and campanulated, or bell-fashioned flower, quadrifid at the edge; the fruit is an oval, acuminate, and bilocular capsule, containing a great number of small seeds. See plate LXXII. fig. 6.

The leaves and flowers of this plant, the only parts used in medicine, are reputed emetic and vulnerary.

DIGITATED, among botanists, an appellation given to compound leaves, each of which is composed of a number of simple foliolas, placed regularly on a common petiole; though, strictly speaking, there must be more than four foliolas to make a digitated leaf. See plate LXXIII. fig. 7.

DIGITUS, FINGER; in anatomy. See the article FINGER.

DIGITUS VENERIS, in botany, a name used by some for the nymphaea, or water lily. See Nymphaea.

DIGLYPH, in architecture, a kind of imperfect triglyph, confiole, or the like, with two channels or engravings, either circular or angular. See the article Triglyph.

DIGNE, a title and bishop's see of Provence, in France, fifty-five miles north of Toulon: east long. 6° 5', and north lat. 44° 6'.

DIGNITARY, in the canon law, a person who holds a dignity, that is, a benefice which gives him some precedence over mere priests and canons: such is a bishop, dean, arch-deacon, prebendary, &c. See the article Bishop, Dean, &c.

DIGNITY, as applied to the titles of noblemen, signifies honour and authority. As the omission of a name of dignity may be pleaded in abatement of a writ; so may it be where a peer or nobleman, who has more than one name of dignity, is not named by that which is most noble.

DIGNITY, in the ecclesiastical sense, is defined by canonists, an administration joined with jurisdiction and some power. Simple prebendaries, therefore, without jurisdiction, are not dignities.

Dignities are sometimes simple, sometimes with cure of souls, and sometimes with jurisdiction and administration of sacred things. Camden reckons in England, including prebends, 544 ecclesiastical dignities. See the article DIGNITARY.

DIHELIOS, in aetymology, a name given by Kepler to that ordinate of the ellipse which passes through the focus, where the sun is supposed to be placed.

DIJAMBUS, in ancient poetry, a double jambus. See the article JAMBUS.

DIJON, the capital of the province of Burgundy, in France, situated on the river Ouche, 140 miles south east of Paris: east long. 5° 5', and north lat. 47° 15'.

DIKE, a ditch, or drain, made for the paffage of waters. See Ditch, &c.

Dike also signifies a work of stone, timber, earth, falines, &c., raised to oppose the entrance of the waters of the sea, a river, lake, &c.

The most stupendous works of this kind are the Dikes of Holland.

DIKE-REEVE, an officer who takes care of the dikes and drains in Lincolnshire.

DILAPIDATION, in law, a wanton destroying or letting buildings, especially parsonage-houses, &c. run to decay; for want of necessary repair: if the clergy neglect to repair the houses belonging to their benefices, the bishop may seize the profits thereof for that purpose. And in these cases, a prosecution may be brought either in the spirituul court, or at common law, against the incumbent himself, or against his executor or administrator.

DILATATION, in physics, a motion of the parts of any body, by which it is fo expanded as to occupy a greater space. This expansive motion depends upon the elastic power of the body, whence it appears that dilatation is different from rarefaction, this last being produced by the means of heat. See RAREFACTION.

Gassendus and his followers affirm, that dilatation, by whatever cause it is produced, cannot happen without vacancies interposed in the parts of the expanded body; on the other hand, the Cartesians teach that dilatation is performed by the intrusion or intromission of some subtile matter into the pores of the dilated body.

The moderns observe, that bodies, being compressed, and afterwards left at liberty to restore themselves perfectly, endeavour
endeavour to dilate themselves with the same force, whereby they were compressed, and accordingly they sustain a force, and raise a weight equal to that by which they were compressed. They likewise remark, that bodies in dilating by their elastic power, exert a greater force at the beginning of their dilatation than towards the end, as being at first more compressed: and the greater the compression, the greater the elastic power and energy of dilatation. Wherefore these three, the compressing power, the compression, and the elastic power, are always equal. Again, the motion whereby compressed bodies restore themselves is for the most part accelerated. Thus an arrow shot from a bow does not quit the firing till after it be perfectly restored to its natural state; nor does the arrow move swifter than the firing: and if the firing before it hath perfectly restored itself be stopped, the arrow will not go its full length; a proof that it is continually acquiring a new impetus from the firing.

It may however happen, that where the compression is only partial, the motion of dilatation shall not be accelerated, but retarded, as appears in the compression of soft bread, sponge, gauze, &c.

DILATATION in surgery and anatomy, denotes the widening of the orifice of a wound; or the distension of any vessel, or the like.

DILATATORES, in anatomy, a name given to several muscles in the human body; as, 1. Dilatores alae nae, a pair of muscles which serve to elevate the nose, and are very various in different subjects. In general, however, they are two on each side, though even in this they vary extremely, and sometimes are so thin and fine as scarce to be perceptible. They are also called the pyramidalis and myrtiformis. See the article PYRAMIDALIS, &c.

2. Dilatatores urethrae, of which the transversi arise from the tubercle of the os ischium on each side, and are inserted into the posterior part of the bulb of the urethra: they are not quite determinate and certain, however, either in their origin or insertion, and sometimes they are wholly wanting. When they act they dilate the urethra in its posterior part. The dilator politicus arises from the anterior part of the sphincter of the anus, and is inserted into the posterior and lower part of the acceleratores; or else into the lower part of the bulb of the urethra. Some have taken this muscle for a part of the sphincter ani. See the article SPHINCTER.

DILEMMA, in logic, an argument consisting of two or more propositions, which divides the whole into all its parts, or members, by a disjunctive proposition, and then infers something concerning each part, which is finally referred to concerning the whole.

Inferences of this are frequent, as, "In this life we must either obey our vicious inclinations, or resist them: to obey them will bring sin and sorrow; to resist them is laborious and painful: therefore, we cannot be perfectly free from sorrow and pain in this life." A dilemma becomes faulty, or ineffectual three ways. First when the members of the division are not well opposed, or not fully enumerated: for then the major is false. Secondly, when what is asserted concerning each part is not just, then the minor is not true. Thirdly, when it may be retorted with equal force upon him who utters it. There was a famous ancient inference of this case, wherein a dilemma was retorted. Euathlus promised Protagoras a reward when he had taught him the art of pleading: and it was to be paid the first day he gained any cause in court. After a considerable time, Protagoras goes to law with Euathlus for the reward, and uses this dilemma. "Either the cause will "go on my side, or on yours: if the "cause goes on my side, you must pay "me according to the sentence of the "judge: if the cause goes on your "side, you must pay me according to "your bargain. Therefore, whether the "cause goes for me, or against me, you "must pay the reward." But Euathlus retorted the dilemma thus. "Either I "shall gain the cause, or lose it. If I "gain the cause, then nothing will be "due to you according to the sentence of "the judge: but if I lose the cause, "nothing will be due to you according "to my bargain. Therefore, whether "I lose or gain the cause, I will not pay "you, for nothing will be your due." A dilemma is usually described, as the it always proved the absurdity, inconvenience, or unreasonable of some opinion or practice, and this is the most common design of it. But it is plain, that
that it may be used to prove the truth or advantage of any thing proposed. As, "In heaven we shall either have de-
"fires, or not: if we have no desires, then we have full satisfaction: if we have desires, they shall be satisfied as
"faith as they arise; therefore, in heaven we shall be completely satisfied."
This sort of argument may be composed of three or more members, and may be called trilemma. It is also called
*fyllogismus cornutus*, a horned *fyllogism*; its horns being so disposed, that if you avoid the one, you run against the other. It is also called *crocodilinus*, by reason that as the crocodile leads such as follow it, into the Nile, and pursues them as fly it, to destroy them; so, whatever the adversary either affirms or denies in this kind of *fyllogism*, is turned to his advantage.

**DILIGENZA**, in music, is used for a
dill,
**Dillingen**, a city of Swabia, in Germany, situate on the Danube, about twenty miles north of Ulm: it is a good carminative.

The *Dill*, *Anethum*, in botany, a genus of the *pentandria digynia* class of plants, the compound *flora* of which is uniform; the particular ones all consisting of five lanceolated petals, bending inwards: the fruit is naked, ovated, compressed, and separable into two parts; and the seeds are two in number, sub-
equal, convex, and striated on one side, and plane on the other.

To this genus Linusus likewise refers fennel, which differs only from dill, in that its seeds are not membranaceous at the edge, like those of dill.

The seeds of dill are recommended as good carminatives.

**Dillenburg**, a city of the circle of the Upper Rhine, in Germany, about forty miles north of Frankfort, and subject to the house of Nassau: east long. 8° 8', and north lat. 50° 45'.

**Dillingen**, a city of Swabia, in Germany, situated on the Danube, about twenty miles north east of Ulm: east long. 10° 20', and north lat. 48° 40'.

**Dillenia**, in botany, a genus of *polypodium-polygynia* class of plants; the corolla of which consists of five cori-
aceous, large, roundish, and hollow petals: the fruit is roundish, and externally covered with a number of capsules, which are oblong, and divided by a furrow; within, there is a large column or pulpy receptacle: the seeds are numerous, and very small; and nidulated underneath the capsules.

**Dilute.** To dilute a body is to render it liquid; or, if it were liquid before, to render it more fluid, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors. It is requisite for a diluent, that it be fluid, that it be more fluid than the liquor to be diluted; and finally, that it retain its fluidity after a mixture. It is observed, that there is no body endued with these three properties besides water. Wine indeed is said to dilute; but its diluent power depends on its quality, joined with its stimulating force. Water, if it be made warm, dilutes the more.

**Dimachæs**, in antiquity, a kind of horsemens, anfwering to the dragoons of the moderns. See the article *Dragoons*.

**Dimachærus**, in antiquity, a gla-
dator who fought with two swords.

**Dimension**, in geometry, is either length, breadth, or thickness; hence a line hath one dimension, *vex.* length; a superficies two, *viz.* length and breadth; and a body, or solid, has three, to wit, length, breadth and thickness.

**Dimension** is also used with regard to the power of the roots of an equation, which are called the dimensions of that root; as in a cubic equation, the high-
eft power has three dimensions, &c.

**Dimensiven**, a term used by some for diameter. See the article *Diameter*.

**Diminished column**, in architecture. See the article *Column*.

**Diminished interval**, in music, is a defective interval, or an interval that is short of its just quantity, by a lesser *femitone*, &c. See *Interval*.

**Diminution**, in architecture, a con-
traction of the upper part of a column, by which its diameter is made less than that of the lower part.

It generally commences from one third of the height of the column. Vitruvius would have the diminution of columns different according to their height, and not according to their diameter. But this rule is not found to have been observed in the antique. Mr. Perrault observes, that a difference of orders does not infer a difference in diminished, and Mr. Le Clerc says, all diminutions of columns ought to be more or less sensible accordingly as the orders are more or less delicate. For instance, in the Tuscan order, where the column is fifteen modules high, the diminution under the astragal may be five minutes
DIM [925] DIN

minutes and a half. In the Doric order, where the column is sixteen modules, the diminuation may be but five minutes. In the Ionic, where the column is eighteen modules, the diminuation may be but four minutes and a half; and in the Corinthian, no more than four. Diminutions are as differently adjusted in antique buildings, as in different modern authors.

**DIMINUTION**, in heraldry, a term used for what the French call brises, and we denominate differences. See the article **DIFFERENCE**.

**DIMINUTION**, in law, is where the plaintiff or defendant in a writ of error alleges to the court, that part of the record remains in the inferior court not certified, and therefore prays, that it may be certified by certiorari. Diminution cannot be alleged of what is fully certified, but of something that is wanting, as the want of an original, or a warrant of attorney.

**DIMINUTION**, in music, is when there are several words which are to make tones, and several quick motions in a cadence, several quavers, semi-quavers, &c. corresponding to a crotchet or minim, as when a semi-breve is divided into two minims, four crotchets, &c. Of this there are several kinds, and if done in conjoint degrees, it is called trilli, tremoli, cincoli mezzi, group, tirate, and if in disjoint degrees, it is said to be done per saltum. See the articles **TRILLI**, **TREMOLI**, **SALTO**, &c.

**DIMINUTIVE**, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus cellulæ is a diminutive of cella, globule of globe, killock of hill. The Italians abound in diminutives: the French are a good deal more refined: in English we have very few. The Latins, and especially Catullus, use them as expressions of blandishment, and in that language, as well as in the Italian, French and English, they are generally formed from primitives by the addition of a few letters or syllables. They have a very pretty effect in that celebrated address of Adrian to his departing soul, which begins, *Animula, vagula, blandula, Hoppes comesque corporis, &c.*

**DIMISSORY LETTERS**, in the ancient Christian church, were letters granted to the clergy, when they were to remove from their own diocese, and settle in another, to testify that they had the bishop's leave to depart. In the canon-law, dimissory letters are such as are used when a candidate for holy orders has a title in one diocese, and is to be ordained in another: in which case the proper diocesan sends his letters directed to the ordaining bishop, giving leave that the bearer may be ordained to such a cure within his diocret. Perions inferior to bishops cannot grant these letters, unless by special commission; or unless the bishop be at a great distance, in which case the vicar general may grant such licence; as the chapter may do, *fede vacante*.

**DIMORPHEITÆ**, in church-history, a name given to the Apollinarians, from their separating the understanding from the human soul of Christ.

**DIMNESS OF SIGHT**, a disorder in horses, proceeding from blood-shot eyes. If the ball of the eye be found, the cure is effected by keeping the horse warm, with a hood of linen cloth fitted to his head; and anointing the eyelids twice a day, with a composition of sugars, candy, honey, and white rose-water. In two or three days, the eyes will be well again, after which the creature should be blooded.

In this disorder, you ought by no means to clip or meddle with the bladders on any part of the eye.

**DIMORPHOTHECA**, in botany, a name used by Vaillant, for the calendula of Linnæus. See the article **CALENDULA**.

**DINANT**, a town of France, situated on the river Mele, about twelve miles south of Namur: east long. 4° 50', and north lat. 59° 18'.

**DINANT** is also the name of a town of Brittany, in France, about ten miles south of St. Malo: west long. 2° 5', and north lat. 48° 30'.

**DINGELFING**, a town of Bavaria, in Germany, situated on the river Iler, twenty miles south of Landshut: east long. 12° 40', and north lat. 48° 30'.

**DINGLE**, a port town of Ireland, in the county of Derry, and province of Munster, situated on Dingle-bay, 74 miles west of Limmerick: west long. 10° 18', and north lat. 52°.

6 C **DINGWEL**
DINGWEL, or DINGWAL, a parliament-town of Scotland, situated on the west of the Cromarty-bay, in the county of Ross; well long. 4° 15', north lat. 57° 56'.

It classes with Dornoch, Wick, and Kirkwall.

DINKELSPIEL, a city of Swabia, about forty miles north of Ulm. east long. 10° 12', and north lat. 49°.

DINNER, the meal taken about the middle of the day.

It is generally agreed to be the most substantial to make a plentiful dinner, and to eat sparingly at supper. This is the general practice among us. The French, however, in imitation of the antient Romans, defer their good cheer to the evening, and Bernardinus Paternus, an eminent Italian physician, maintains it to be the most wholesome method, in a treatise expressly on the subject.

The grand Tartar emperor of China, after he has dined, makes publication by his heralds, that he gives leave for all the other kings and potentates of the earth to go to dinner, as if they waited for his leave.

DINUS, a name used by some physicians for a vertigo. See the article Vertigo.

DIOCALLIA, in botany, a name sometimes used for chamæmile. See the article Chamæmile.

DIOCESE, denotes a particular district, or division, under the direction and government of a bishop.

It is the general opinion, that the Christian church, in the modelling her own external polity, followed the state and division of the Roman empire, and that the ecclesiastical magistracy was originally formed upon the plan of the civil. As the empire therefore was divided into provinces and dioceses, (a diocese, according to Constantine’s distribution, comprehending several provinces under the direction of a general magistrate) so the church set up her metropolitical and patriarchal power, the metropolitan bishops answering to the civil magistrates of provinces, and the patriarchs to the civil magistrates of dioceses. This is to be understood of the state of the church, after the empire became Christian. See the articles Metropolitain, Patriarch, Province, &c.

Some pretend that a diocese, during the three first centuries, was never more than such a number of people as could meet, and ordinarily did meet, in a single congregation; others extend the limits of the antient dioceses, so as to include a whole city, and the region about it. And this is the plain reason of that great difference we find in the extent of antient dioceses, some being very large, others very small, according as each city happened to have a larger or lesser territory under its jurisdiction. Dioceses were originally called parishes, parishes, by which name is to be understood the episcopal city, with the country places and villages round it. The name diocese began first to be used in the fourth century, when the exterior polity of the church began to be formed upon the model of the Roman empire.

England in regard to its ecclesiastical state, is divided into two Provinces, viz. Canterbury and York, and each Province into subordinate dioceses, of which there are twenty-two in England, and four in Wales.

DIOCLESIAN EPOCHA, in chronology. See the article Epocha.

DIOCLIA, διοκλία, in grecian antiquity, a festival kept in honour of Diocles, who died in defence of a youth he loved.

DIOCTAHEDRIA, in natural history, a genus of Pellucid crystalliform spars, composed of two octagonal pyramids, joined base to base, without any intermediate column. Of these fome have long pyramids, others short and sharp-pointed ones, and others short and obtuse-pointed ones; the two former species being found in the hartz-forest, and the last in the mines of Cornwall.

DIODIA, in botany, a genus of the dynamia-angiospermia class of plants, the corolla of which consists of a single petal, of the ringent kind. The tube is slender and longer than the cup, the upper lip is erect and bifid, the lower lip is patent, and divided into two lanceolated segments. The fruit is an oval quadrangular capsule, coronated, formed of two valves, and containing two seeds; the seeds are finge, of an ovato-oblong figure, smooth and flat on one side, and convex on the other.

DIOECESIS, διοικία, a diocese. See the article Dioecese.

DIONYSIA, in grecian antiquity, solemnities in honour of θυσία, or Bacchus, sometimes called by the general name of orgia; and by the Romans, bacchanalia, and liberalia. See Bacchanalia, &c.

There were divers, Dionysia observed, over all Greece: but those celebrated at Athens
Athens had more splendor and ceremonious superition than in any other part; for the years were numbered by them: the chief archon had a share in the management of them, and the priests that officiated therein, were honoured with the first seat at public shows. But at first, they were without splendor and ornaments, being days set apart for public mirth, and observed only with the following ceremonies: first a veil of wine, adorned with a vine branch, was brought forth, after that followed a goat; then was carried a basket of figs; and after all the phalli. At some of them, it was usual for the worshippers in their garments and actions to imitate the poetical fictions concerning Bacchus. They put on lawn skins, fine linen and mitres, carried thyrsi, drums, pipes, flutes, and rattles, and crowned themselves with garlands of trees, sacred to Bacchus, such were the ivy, vine, fir, &c. Some imitated Silenus, Pan, and the Satyrs; exposing themselves in comical dreeses, and antic motions: some rode upon asses, others drove goats to the slaughter. In this manner, perrons of both sexes ran about the hills, deserts, and other places, waggling their heads, dancing in ridiculous postures, filling the air with hideous noises and yells, perforating people distracted, and crying aloud Ecce Caen, 6' o Bacchi, or o Bacchi, or Be Bacchi, or Io Bacchi.

In some of the festivals, a company of men called περιφακεῖς, carried long poles, at the end of which were fixed things in form of a man's privities. The λιαστός, or mythical fan of Bacchus, was a thing essential to all his feasts.

DIONYSIACA, in grecian antiquity, an appellation given to all manner of theatrical entertainments, from their being sacred to Dionysius, or Bacchus.

DIONYSIAN PERIOD, in chronology. See the article PERIOD.

DIOECIA, in the Linnean system of botany, the twenty-second class of plants, comprehending all those which have the male and female parts of fructification, or the staminia and pistil, on distinct plants of the same kind; in which respect, they bear some analogy to quadrupeds, whose males and females are likewise distinct. See BOTANY.

To this class belong the willow, hemp, poplar, juniper, pittacchia, yew, &c. in all which, the female plants alone produce seeds; but even their prove barren, unless planted near the male plants, so as to be within the reach of the farina fcecundans. See FARINA.

DIOMEDIS AVES, in ornithology, a bird of the duck-kind, about the size of the common hen, and of a dusky brown colour, said to be peculiar to the island Diomedia, or Tremiti, in the gulf of Venice.

DIPHTER, DIOPTERA, a name sometimes used for the hole pierced in sights of mathematical instruments. See SIGHTS.

DIOPTERA, among surgeons, the same with speculum. See SPECULUM.

DIOPTRICS, the science of refractive vision, or that part of optics which considers the different refractions of light in its passing through different mediums, as air, water, glass, &c. and especially lenses. See the articles REFRACTION, LENS, &c.

DIOSCOREA, in botany, a genus of the dioecia-hexandria class of plants, having no corolla in either the male or female flowers: the fruit is a compressed large capsule, of a triangular form, containing three valves, and divided into three cells: the seeds are two, compressed, and surrounded, with a large membraneous margin.

DIOCURIA, Diocuria, in grecian antiquity, a festival kept in honour of the Dioscuri, or Castor and Pollux, wherein the assistants shared plentifully of the gifts of Bacchus.

DIOSMA, in botany, a genus of the pentandria monogynia class of plants, the flower of which consists of five obtusely ovated, sessile, and erecto-patent petals, of the length of the cup: the fruit is composed of five capsules, adhering together by their inner sides, and containing each a single, oblong, and sharp-pointed oval seed.

DIOSPOROS, a name antiently used for litholapis or beryllium, or gromwell.

DIOSPYROS, in botany, a genus of the octandria digynia class of plants, called by Turnefort, guaiacana, the flower of which is monopetalous, very small, and of an oval campanulated figure: the fruit is a large globose and multilocular berry, containing a few sharp-pointed oval seeds. See plate LXXIII. fig. 1.

DIOTA, a name used by some chemists for a circulating or double vessel.

DIOTOTHECA, in botany, the same with the morina of Linnaeus. See the article MORINA.
DIPHRYGES, in antient pharmacy, the floriz, sediment, or calx of melted copper, gathered in the furnace, when the metal was run out.

There are suppos'd to be three species of diphryges, one made of a clay, or bole dried in the sun; another made of marcasite, or pyrites burnt; and a third, that of the faces of copper. See the article COPPER.

The last diphryges, which taste of copper, is æruginous, affrigent, and vehemently drying upon the tongue, qualities of which burnt aker, though told for diphryges, is deftitute. It is an affringent, a potent cleanser, abetter and drier, repreffes excreffences of fleshy, induces malignant and spreading ulcers to cicatrize, and mixed with turpentine, or cerate, difficultes an abfcess.

DIPHTHONG, διφθογγον, in grammar, a double vowel, or the mixture of two vowels pronounced together, so as to make one syllable. See the article VOWEL. The Latins pronounced the two vowels in their diphthongs, æe or ææ, ee or ee, much as we do, only that the one was heard much weaker than the other, though the division was made with all the delicacy imaginable. Diphthongs, with regard to the eyes, are distinguished from those with regard to the ears: in the former, either the particular sound of each vowel is heard in the pronunciation, or the sound of one of them is drowned; or, lastly, a new sound, different from either, results from both: the fift of these only are real diphthongs, as being such both to the eye and the ear. Diphthongs with regard to the ear are either formed of two vowels, meeting in the same syllable, or whole sounds are severally heard; or of three vowels in the same syllable, which only afford two sounds in the pronunciation. English diphthongs, with regard to the eye and ear, are æi, æu, ea, ee, ei, oo, ou. Improper English diphthongs, with regard to the eye only, are æa, ea, eo, eu, ie, ei, oa, oe, ue, ui. Steele's Eng. Gr.

DIPHYGES, among natural historians, an appellation given to fomes resembling the male and female parts of generation in mankind.

DIPLOASIAMUS, in medicine, a reduplication of diseases.

DIPLOASIAMUS is also used for two muscles of the arm, which serve to turn it round.

DIPLOE, in anatomy, the soft medullilium, or medullary substance, which lies betwixt the two laminae of the bones of the cranium. See the article CRANII.

DIPLOMA, an instrument or license given by colleges, societies, &c. to a clergyman to exercise the ministerial function, or to a physician to practice the profession, &c. after passing examination, or admitting him to a degree.

DIPLOMA, in chemistry, &c. a double vessel. To boil in diplomate, is to set one vessel, containing the ingredients intended to be acted upon, in another larger vessel, full of water, and to this last the fire is to be applied.

DIPONDIUS, in the scripture-language, is used by St. Luke to signify a certain coin, which was of very little value: our translation of the passage is, Are not two sparrows fold for two farthings? In St. Matthew, who relates the same thing, we read, Are not two sparrows fold for a farthing? The greek reads affairion instead of as. See AS.

Dr. Arbuthnot says that this coin was at first libralis, or of a pound weight, and that even when diminished, it retained the name libella: so that dipondius denoted two ales.

DIPPING, among miners, signifies the interraption, or breaking off, of the veins of ore; an accident that gives them a great deal of trouble before they can discover the ore again.

DIPPING NEEDLE, or INCLINATORY NEEDLE. See the article NEEDLE.

DIPSACUS, TEASEL, in botany, a genus of the tetrandria-monogynia class of plants, the flower of which consists of only one tubular eretic petal, divided into four segments at the mouth; its fruit is a common receptacle, of a conical figure, bent with long scales, and containing a single columnar fead with a marginaceous rim. See plate LXIII. fig. 2. The leaves of wild tease1 are recommended against flatulencies, and crudities of the fomach. See TEASEL.

DIPSACUS, in medicine, a term used by some for a diabetes. See DIABETES.

DIPSAS, in zoology, a species of serpent, so called from its bite creating a thirst that proved mortal. See SERPENT.

DIPTERE, or DIPTERON, in the antient architecture, signified a temple surround- ed with two rows of columns, which form a sort of porticos, called wings, or ifles. Pseudo-diptere is the same, except that instead of the double row of columns, this was only encompassed with a row of single ones.

DIPTOTES,
DIPTOTES, in grammar, are such nouns as have only two cases, as ήπτετας, ήπτεται, &c.

DIPTYCHS, διπτυχ, in antiquity, a public register, in which were written the names of the confuls and other magistrates among the heathens; and among the christians, they were a sort of tablets, on one of which were written the names of the deceased, and on the other those of the one of which were written the names of living who had done any service to the church, for whom prayers were offered, the deacon reading the names at mass.

It is certain there were prophane diptycha in the greek empire, as well as sacred ones in the greek church. The prophane diptycha were frequently lent as a present to princes, &c. on which occasion they were finely gilt and embellished, and usually of ivory. Carrión supposes that such presents were at first made to persons who had been nominated quaestors, to whom they were useful. Hence arose the custom of diptycha in the antient christian church; where some distinguishing three sorts of diptycha, one wherein the names of bishops only were written, such especially as had been governors of that particular church; a second, in which the names of the living were written, such in particular as were eminent for any office or dignity, or some benefaction or good work, in which rank were bishops, emperors, and magistrates; lastly, a third, containing the names of such as were deceased in catholic communion. To erase a person's name out of these books, was the same thing as declaring him a heretic, or some way deviating from the faith.

DIRECT, in arithmetic. The rule of three direct, is opposite to the rule of three inverse. See the articles Rule of Three and Proportion.

DIRECT, in astronony. A planet is said to be direct, when it appears to an observer on the earth to go forward in the zodiac, or according to the succession of the signs. See the article Planet.

DIRECT, in matters of genealogy, is understood of the principal line, or the line of ascendants and descendants; in contradistinction to the collateral line. The heirs in the direct lines always precede those in the collateral lines.

DIRECT ray, in optics, is a ray flowing from a point of a visible object directly to the eye, thro' one and the same medium.

DIRECT east and west dials, dials drawn upon planes that directly face the east and west points of the horizon, or parallel to the meridian. See Dial.

DIRECT north and south dials, are those which face directly the north and south points of the horizon, or parallel to the prime vertical circle. See the articles Dial and Dialling.

DIRECT sphere. See Sphere.

DIRECTION, in mechanics, signifies the line or path of a body's motion, along which it endeavours to proceed, according to the force impressed upon it. See the articles Line and Motion.

Angle of Direction, that formed by the lines of direction of two conspiring powers.

Quantity of Direction, a term used by some mathematicians for the product of the velocity of the common center of gravity of a system of bodies, by the sum of their quantities of matter: this is nowise altered by any collisions among the bodies themselves.

Magnetical Direction denotes the tendency of the load-stone, and other magnetic bodies, to certain points called their poles; thus, a magnetical needle always presents one of its ends towards the north pole of the world, and the other towards the south pole.

DIRECTLY. See DIRECT.

DIRECTOR, in commercial polity, a person who has the management of the affairs of a trading company: thus we say the directors of the India-company, South-sea-company, &c. See the article Company.

The directors are considerable proprietors in the stocks of their respective companies, being chosen by plurality of votes from among the body of proprietors. The dutch East-india company have sixty such directors; that of France, twenty-one; the british East-india company has twenty-four, including the chair-man, who may be re-elected for four years successively. These last have fallaries of 150 l. a year each, and the chair-man 200 l. They meet at least once a week, and commonly oftener, being summoned as occasion requires.

But besides these directors, who reside in Europe, and there superintend the general economy of the trading companies, there are also officers belonging to them in Asia, Africa, and America, under the title of directors-general, and, by an honourable abbreviation, generals. The English give these the title of presidents, whereof there used to be two in the East-indies.
D I S  [930] D I S

ladies, one at Surat, and the other at Bantam. They have the absolute dispo-
sal of all the company's effects, regulate their trade, establish new compting-houses, and command all the merchants, and even captains of ships; make presents to princes, treat with them, make peace and war with them, &c. It is true, they have a council, but one entirely subse-
vient to their pleasure.

DIRECTOR, in surgery, a grooved probe, to direct the edge of the knife or scissors, in opening sinews, or fistula, that by this means the subjacent veins, nerves, and tendons may remain unhurt. The first fig. at the side of the figure is prefixed to give them. Dantzic and Ghnief. 

Frufil., &c.

AB

folid figure: thus, if the line AB (plate LXXIII. fig. 4.) move along the line

AB C D, will be formed, where the surface AD is the describent, and the line AC, fo that the point A always keeps in the line AC, a parallelogram, as A B C D, will be formed, of which the side AB is the deficient, and the line AC the dirigent; fo also, if the surface A B C D be supposed to be carried along CE, in a position always parallel to it-

self, in its first situation, the folid AD FH, will be formed, where the surface AD is the describent, and the line CE the dirigent.

DIRITTA, in music, a term intimating that the piece is to be played or sung in conjoint degrees: thus, contrapunto alla diritta, according to Angelo Berardi, is when one is obliged to raise or fall the voice by the same degree, i.e. by an equal number ascending or descending, without making a leap, even of the in-
terval of a third.

DIRSCHAW, or Dirschau, a town of Prussia, in the palatinate of Culm, situa-

ated upon the Viftula, half way between Dantzic and Ghnief.

DIS, an inseparable article prefixed to di-

vers words, the effect whereof is either to give them a signification contrary to what the simple words have, as disjohice, disjober, &c. or to signify a separation, detachment, &c. as disposing, distribut-
ing, &c.

DISABILITY, in law, is when a person is rendered incapable of inheriting lands, or taking that benefit which otherwise he might have done. 

Disability may happen four ways, viz. by the act of an ancestor, by the act of the party himself, by the act of God, or by the act of the law.

Disability by the act of an ancestor is where a man being attained by treason or felony, his blood becomes corrupted, and thereby his children are rendered in-
capable to inherit.

Disability by the act of the party, is when one binds himself by obligation, that, upon the surrender of a lease, he will grant a new estate of the same premises to the leasor, and afterwards he grants over the reversion to another, whereby he is disabled to perform his obligation.

Disability by the act of God, is where a person is not fame memorie, not of sound memory, which incapacitates him to make any grant, &c. and in all cases where he gives or passes an estate from him, after his death, it may be disan-
nulled and made void; though it is a maxim in our law, that a man of full age shall never be received to disable his own peron.

Disability by the act of the law, is where one, by the sole act of law, without any thing done by him, is rendered incapable of the benefit of the law, as an alien born, &c.

There are also, by the common law, other disabilities, as idiocy, infancy, and co-

verture, in respect to the making of grants, &c. and by statute in many cases; for papists are disabled to make any presentation to a church, or to purchase or take lands, &c. Officers not taking the oaths, to hold offices, &c.

DISAFFORESTED, the same with de-

afforested. See Deafforested.

DISARMING, in law, the prohibiting people to wear arms. See Arms.

It is an offence, by the common law of England, for persons to go or ride armed with dangerous and uncommon wea-

ons; though gentlemen may wear com-

mon armour, according to their quality. It is also ordained by statute, that no perons shall come before the king's juries with force of arms, on pain of imprison-

ment, &c.

DISARMING,
DISARMING the lips of a horse, in the manage, is the preventing them from taking off the true prehure or appui of the mouth, when they happen to be so large as to cover the bars.

DISBUDDING, the same with affart. See the article ASSART.

DISBUDDING of trees signifies the taking away such branches or sprigs, newly put forth, as are ill placed.

DISBURDING of trees, the taking off part of the leaves and fruit, when too numerous, that those left may grow the larger.

DISC, discus, in antiquity, a quoit made of stone, iron, or copper, five or six fingers broad, and more than a foot long, inclining to an oval figure, which they hurled in the manner of a bowl, to a vast distance, by the help of a leathern thong tied round the person's hand who threw it, and put through a hole in the middle. Homer has made Ajax and Ulysses great artificers at this sport; and Ovid, when he brings in Apollo and Hyacinth playing at it, gives an elegant description of this exercitium, lib. x. ver. 175.

DISC, in botany, is an aggregate of flores forming, as it were, a plane surface.

DISC, in optics, is the width of the aperture of telescopic glases, whatever their form be, whether plain, convex, concave, &c.

DISC, in the liturgy of the Greek church, is nearly the fame with the patena in the Latin church. See PATENA.

DISCEIT, or DECEIT. See DECEIT and Deception.

DISCERNING, or DISCERNMENT, among logicians, a faculty of the mind, whereby it distinguishes between ideas. See JUDGMENT and INTUITION.

On this depends the evidence and certainty of several, even general, propositions, which pass for innate truths; that, in reality, proceed from this clear discerning faculty of the mind, whereby it perceives two ideas to be the same, or different. In being able nicely to distinguish one thing from another, confists, in a great measure, that exactness of judgment, and clearness of reason, which is observable in one man above another. To the well distinguishing our ideas it chiefly contributes that they be clear and determinate; and when they are so, it will not breed any confusion or mistake about them, though the senses should convey them from the same object differently on different occasions. Locke.

DISCIPLE, one who learns anything from another: thus, the followers of any teacher, philosopher, &c. are called disciples. In the Christian sense they were followers of Jesus Christ; in general; but in a more restrained sense, the disciples denote those alone who were the immediate followers and attendants on his person, of which there were seventy or seventy-two. The names disciplo and apostol are often synonymously used in the gospel-history, but sometimes the apostles are distinguished from disciples as persons selected out of the number of disciples, to be the principal ministers of his religion; of these there were only twelve. The Latins kept the
DISCLOSED, a term used to signify birds' or flowers just blown; also chickens newly hatched. See the articles Bud; Flower and Hatching.

DISCOIDES TRIBULA, a genus of the echini-marini, or sea hedge-hogs. See the article ECHINITES.

DISCONTINUANCE, in law, signifies an interruption or cessation of the course of a thing, and is of two kinds. 1. Discontinuance of estate or possession, which has this effect, that a person may not enter upon his own land, &c. aliened, whatever his right be to it, of his own authority, but must bring his writ, and seek to recover possession by law. A discontinuance may be by foeman, fine, recovery, leaf, and confirmation with warranty; but grants of land without livery, or if made in feu without any warranty, are not discontinuances: 2. Discontinuance of process, where the opportunity to prosecute a suit is loit, or the plaintiff is, put sine die, and dismissed the court. After a verdict in a cause, no discontinuance is allowed without leave of the court, and costs are usually given the defendant on discontinuing suits. As discontinuance of process is helped by appearance at common law, so all discontinuances and miscontinuances of the plaintiff or defendant, are cured after verdict by statute.

DISCONTINUANCE of plea, is when divers things should be pleaded to in a suit or action, and some thereof are omitted in the pleading. Where a defendant's plea answers to part only, it is a discontinuance as to the part not answered, and the plaintiff may take judgment by nil dictum for that. But if the plaintiff pleads over thereto, the whole action is discontinued.

DISCORD, in music, the relation of two sounds which are always and of themselves disagreeable, whether applied in succession or consonance. Thus the second, fourth, and seventh, with their octaves, and, in general, all intervals, except those few which precisely terminate the concords, are called discords. Discords are distinguished into concinuous and inconcinuous intervals. See the article INTERVAL.

Concinnous DISCords, called by the antients emelli, are such as are fit for music, next to and in combination with concords. These are relations which in themselves are neither very agreeable nor disagreeable, and have only a good effect in music, as by their mixture and combination.

the festival of the seventy or seventy-two disciples on July 15, and the Greeks on January 4.

DISCIPLINE, in a general sense, denotes instruction and government, as military discipline, ecclesiastical discipline, &c. Ecclesiastical discipline consists in putting those laws in execution by which the church is governed, and inflicting the penalties enjoined by them against the several sorts of offenders that professe the religion of Jesus: the primitive church never pretended to exercise discipline upon any but such as were within her pale, in the largest sense, by some act of their own profession; and even upon these he never pretended to exercise her discipline so far as to cancel or disannul their baptism: all that she pretended to, was to deprive men of the benefits of external communion, such as public prayer, receiving the eucharist, and other acts of divine worship. The church discipline was only confined to the admonition of the party, and to the lesser and greater excommunication.

As to the objects of ecclesiastical discipline, they were all such delinquents as fell into great and scandalous crimes after baptism. Discipline, in a more peculiar sense, is used for the chastisements, or bodily punishments inflicted, on a religious of the romish church who has been found a delinquent; or even for that which the religious voluntarily undergo or inflict on themselves, by way of mortification.

DISCLAIMER, in law, is a plea wherein answerers to part only, the largest: a pleader, church union, penalties enjoined by profession; and even upon these he pretended to exercise discipline upon any that professe the religion of Jesus: the primitive church never pretended to exercise discipline upon any but such as were within her pale, in the largest sense, by some act of their own profession; and even upon these he never pretended to exercise her discipline so far as to cancel or disannul their baptism: all that she pretended to, was to deprive men of the benefits of external communion, such as public prayer, receiving the eucharist, and other acts of divine worship. The church discipline was only confined to the admonition of the party, and to the lesser and greater excommunication.

As to the objects of ecclesiastical discipline, they were all such delinquents as fell into great and scandalous crimes after baptism. Discipline, in a more peculiar sense, is used for the chastisements, or bodily punishments inflicted, on a religious of the romish church who has been found a delinquent; or even for that which the religious voluntarily undergo or inflict on themselves, by way of mortification.
tion with the more natural and essential principles, they produce a variety necessary to our being better pleased.

**Discords** by the antients called ecmelis, are such as are never chosen in music, as having too great a harshness in them, though even the greatest discord is not without its use. The essential principles of harmony, harmonical intervals, or concords, are in number only eight: the indefinite numbers of other ratios are all discords. Hence Mr. Malcolm shews the necessity of taking some of the less untoward of these discords into the system of music. In order to this, he considers the effect of having none but harmonical intervals in the system of music.

1. With respect to a single voice. If that should move always from one degree to another, so as every note or sound to the next were in the ratio of some concord, not only the variety, which is the life of music, would be soon exhausted, but the very perfection of such relation of sounds would clog the ear, in the same manner as sweet and luscious things do the taste.

2. With respect to music in parts, that is, where two or more voices join in concordance, the general rule is, that the successive sounds of each be so ordered, that the several voices shall be all concords. Now there ought to be a variety in the choice of those successive concords, and also in the method of their succession; all which depends on the movement of the single parts. So that if these could only move in an agreeable manner by harmonical distances, there are but few different ways wherein they could move from concord to concord, and hereby we should lose much of the ravishment of sounds in concordance. A variety, therefore, is requisite, by which each single voice, or more in concordance, may move agreeably in the successive sounds, so as to pass from concord to concord, and meet at every note in the same or a different concord, from what they stood in at the last note. From these two considerations, it appears how imperfect music would be without any other intervals than concords; but in what cases, and for what reasons discords are allowed, the rules of composition must teach. See Harmony.

Besides the concinnous discords used designedly in music, there are several other discord relations which happen unavoidably in an accidental and indirect manner. Thus in the succession of several notes, there are to be considered not only the relations of those which succeed others immediately, but also of those, betwixt which others intervene. Now the immediate succession may be conducted so as to produce melody; and yet among the distant notes there may be very gross discords, that would not be tolerable in mediate succession, and far less in concordance. Thus taking any one species, for example, that with the greater third, and marking the degrees between each term and the next, though the progression be melodious, as the terms refer to one common fundamental, yet there are several discords among the mutual relations of the terms, e.g. from the fourth to the seventh greater is 32:45, and from the second greater to the sixth greater is 27:40, and from the second greater to the fourth is 27:52, all discords.

Discords may transiently pass upon the unaccented part of a measure, without great offence to the ear. This is called supposition. See Supposition.

The harmony of discords, is that wherein the discords are made use of as the solid and substantial part of the harmony. For by a proper interposition of a discord, the succeeding concords receive an additional grace. Thus the discords are in music, what strong shades are in painting. See the article Harmony.

The discords are the fifth when joined with the sixth, the fourth with the fifth. The ninth of its own nature is a discord; so is the seventh. The discords are introduced into harmony with due preparations, and must be succeeded by concords, which is the resolution of discords. The discord is prepared by substituting it first in the harmony, in quality of a concord; that is, the same note which becomes a discord, is first a concord to the bass note immediately preceding that to which it is a discord. Again, a discord is resolved by being immediately succeeded by a discord, descending from it only by the distance of a greater or lesser second.

**Discovery**, in dramatic poetry, a manner of unravelling a plot, or fable, in tragedies, comedies, and romances, wherein, by some unforeseen accident, a discovery is made of the name, fortune, quality, &c. of a principal person, which were before unknown. See Catastrophe.

A discovery ought never to be in vain, by leaving those who remember one another in the same sentiments they were in before:
DISCOURSE, or DISJUNCT PROPORTION, is when the ratio of two or more pairs of numbers or quantities is the same, but there is not the same proportion between all the four numbers. Thus if the numbers 3:6::8:16 be considered, the ratio between 3:6, is the same as that between 8:16, and therefore the numbers are proportional; but it is only discretely or discontinuously, for is not to 6 as 6 to 8; that is, the proportion is broken off between 8 and 3, and is not continued as in the following continual proportions, 3:6::12:24. See PROPORTION.

DISCRETE QUANTITY, such as is not continuous and joined together. Such is a number whole parts being distinct units, cannot be united into one continuum; for in a continuum, there are no actual determinate parts before division, but they are potentially infinite.

DISCRETIONE, in music, intimates to play or sing with attention and care.

DISCRETE PROPOSITIONS, are those where various judgments are made and denoted by the particles but, notwithstanding, &c. either expressed or understood. Thus, fortune may deprive me of my wealth, but not of my virtue, is a disjunctive proposition.

DISCUS, in antiquity, an instrument used by the ancients in their public games. It is certain it was used in the gymnastic art.
DISCUSSION, in matters of literature, signifies the clear treating or handling of any particular point, or problem, so as to shake off the difficulties with which it is embarrassed: thus we say, such a point was well discussed, when it was well treated of, and cleared up.

DISCUSSION, in a medicinal sense, the same with diaphoresis. See DIAPHORESES.

DISCUSSION, or diapason, in music, a compound concord, described by F. Farran, in the quadruple ratio of 4:1, or 8:2.

The didiapiason is produced when the voice goes diatonically from its first to its fifteenth found, and may be called a fifteenth. The voice ordinarily does not go farther than from its first found to the didiapiason; i.e., it does not go beyond the compound, or double octave; for the didiapiason is an octave doubled. The voice sometimes rises several degrees above the didiapiason, but the effort or struggle disfigures it, and makes it fale. In reality, the ancient scale or diagram extended only to a didiapiason.

DIDIAPASON-DIAPENTE, a concord in a sexuple ratio of 1:6.

DIDIAPASON-SEMI-DIAPENTE, a compound concord in the proportion of 16:3.

DIDIAPASON-DITONE, a compound concord in the proportion of 10:2.

DIDIAPASON-SEMI-DITONE, a compound concord in the proportion of 24:5.

DISEASE, in medicine, that state of a living body, wherein it is deprived of the exercise of any of its functions, whether vital, natural, or animal.

Some authors have given us compendious theories of diseases: Bontekoe deduces all human diseases from the scorbutus: Mutgrave, from the arthritis; Dr. Woodward, from the bile; some from the vernal virus, which has lurked in the seed ever since the sin of Adam; some from extraneous fermenta, formed in or out of us; and some from worms. As the aitions or conditions of the body, so also the diseases or defects thereof may be reduced to three general heads, viz., those of the solids and fluids, and those compounded of both.

The solids, i.e., the bones and flesh, may disordered in five ways, viz., rendered ruddy by tumors, cut by wounds, corroded by ulcers, &c., removed out of their places, or discontinued by fractions and contusions.

Diseases of the fluids are in the blood or spirits. Those of the blood are two, such as thicken and retard its motion, or such as attenuate and impede some of its functions, and make it false. In the last kind, the fever and feverish affections only belong: all other diseases of the blood belong to the former.

The diseases of the animal spirits arise either from an intermission or retardation of their motion; or a diminution of their quantity; or disorder in their quality. Lastly, diseases of the fluids, whether those of the blood or spirits, are seldom long confined thereto, but presently come to disturb and impede some of the functions of the solid parts, and at last corrupt the substance of the solids themselves: hence aris compound or complicated diseases, which are infinitely various. The learned Boerhaave furnishes us with an accurate and scientific division of diseases into those of the solids and fluids, to which we refer the reader.

All diseases are owing to the bad regulation of our lives, either from too much or too little sleep, too much or too little exercise, &c. Sometimes they are caused by things without, and very often by an abuse of food; that is, by our intemperance in eating and drinking, which is so much the more injurious to us, because it affects us inwardly. See REGIMEN.

Mr. Hacquet rejects the system of the materialists, who considered all diseases as...
entia nova, or new productions, and endeavours to account for all new modifications on a destruction of proportions, or a change in the structure of parts: he supposes the pressure, structure, and convulsion of the nerves affecting the fluids, to be the principal cause of distemper; and undertakes to prove, that the first operations of poisons and infections is on the spirits, and from them communicated to the blood.

To attain a complete history of diseases, such enquiries are to be made, and circumstances known, which show the genius and state of the disease; and the operations and effects of the medicines are to be carefully observed. A particular regard must be had to the symptoms which differ strangely in all different subjects, on account of the various constitutions of different bodies. It will therefore be necessary to inquire into the age, sex, structure, and habit of the body; or the acquired habit and strength of the patient; and whether he has an hereditary disposition to this or that disease. From the different constitution of the parts, arise the different state and mechanism of the solids and fluids, and a proneness to certain diseases; as also, the variety of manners and inclinations. In childhood, there is a remarkable softness of the fibres, a lax and thin habit, with an abundance of serum; young persons have tense and contractile fibres, with more hot blood, which is more apt for motion: those that are old have a great rigidity of the solids, and a straitness of the piaffeys, vessels, and canals, with a fallo-sulphureous dyscrasy of the humours. Likewise, regard must be had to the female sex, for they are not only obnoxious to distinct diseases, which arise from disorders of the menfes and child-bearing, but the system of their nerves is likewise more weak: whence they are more liable to spastic and convulsive disorders, and are more easily restored to health than men. See MENSES, PREGNANCY, &c.

It is likewise proper to know whether the patient be of a lax or tense habit of body, whether the vessels are slender and numerous, or large and few; because in narrow and slender canals, the progressive motion of the fluids is more difficult, as well as the secretions and excretions: for these are more quick and ready when the fibres are tense, and the vessels pretty large. Whence we may observe, that they are more liable to disorders, and grow well with more difficulty, whose fibres are more strong, and whose circulation of the fluids is more quick. The same may be said of lean and fat persons. Regard must also be had to the colour of the face and skin. A fair, florid, and clear complexion, show the purity of the lymphatic fluids; if it be livid, lurid, and yellow, they discover a fallo-ulphureous impurity of the same, and a disordered secretion in the proper organs, especially in the liver. It appears from daily observation, that the debility, defects, and faults of the vuccera and fibres, as well as diseases proceeding from thence, often descend to children; and the practitioner should be informed hereof: for hereditary imbecilities and weaknesses are more difficult to be cured, more readily return, and tire the physician's patience. It is likewise necessary to know the strength; whether the patient's spirits are low, especially in the beginning of an acute disease, for weaknesses and lownesses are then bad signs; but if the person is in strength and vigour, which appear from the motion and impulse of the fluids, there are great hopes of recovering health.

We are not only to examine the condition of the body, but the state of the mind, and what disorders it is liable to, because there is a wonderful connection between the mind and the body. For a greater tenfity and mobility of the fibres and solids, dispose the mind to anger; whereas a laxity and defect of the vis. mo- trix, shows the person to be dispirited, timid, and fearful. On the other hand, anger increases the tone and contractions of the solids, and renders the fluids more impetuous; but timidity dissolves and de- jefts the strength, whence the circulation of the fluids is more flow. Terror greatly contrinhes the surface and extreme parts of the body, and drives the blood to the interior and noble parts; that is, the precordia and head; whence proceed grievous disorders, especially of the genus nerval. The same may be said of sad- nes, which often proceeds from a defect of the vuccera, and a faulty circulation of the fluids, as in the hypochondriac passion: but when its hurtful influence attacks the solid parts, it wonderfully de- jefts the strength of the whole body, and hurts its functions, relaxing and lessening the strength of the fibres. See the articles ANGER, TIMIDITY, TERROR, &c.
If the mind is not composed, and at eafe, but subje& to various passions and com-
motions, diseases are cured with greater
difficulty; therefore, enquiry is to be
made whether the patient is not addicted
to hard study, and to profound and fa-
tiguing meditation: for it can hardly be
imagined what a content there is between
the brain and its membranes, as well as
between the stomach and the adjoining
intestines. See Consent of parts.
Besides, it is necessary to consider the
place where the patient lives, the nature
of the air, and his usual diet. See the
articles Air and Diet.
Enquiry must be made into the kind of
life: whether it be laborious or unactive,
requiring exercife or fedentary; whether
the person be a courtier, or a soldier; a
student, or a tradesman; whether he be
convertant among metals or minerals,
or work at the fire: for evety kind of
life produces particular diseases; thus
brassiers are subject to diseases of the eyes;
husbandmen, to those of the breath; makers
of starch, to coughs and asthmas; por-
ters, to asthmas, ruptures, and burfting
of the vesfels in the breath; tallow-chand-
lers, to diseases of the head and stomach;
workers in tow, hemp, and flilk, to short-
ness of breath; leather-drelfers are gen-
erally cacheftic and hydropical; run-
ers of races are often troubled with a
shortness of breath, and spit blood; car-
penters are subject to fore eyes; night-
men are apt to be blind; plafkters are sub-
ject to shortness of breath, and con-
fumptions; washerwomen are liable to
difficulties of breathing, and dropfies;
makers of oil are cacheftic and asthma-
tic; plumbers are subject to palpies;
hotch-potch painters are generally valetudina-
rans, cacheftic, and paralytic; fisher-
men have ulcers in their legs; bakers
are subject to coughs, hoarifenes, and
lippitude, as well as a conflipation of the
pores; cutters of tobacco are subject to
the vertigo; and the like.
Another thing to be examined is the ex-
cretions, for unless these are regular,
health cannot be maintained; and there-
fore, if they are too plentiful, or defeotive
and fupprefed, they will cause various
disorders. Regard is also to be had to
perspiration, which carries off more ma-
ter than all emunctories besides. See
Excretion and Perspiration.
The practitioner should likewise enquire
what diseases the patient has been subject
to, at what time, and how cured; for
it often happens in the rash and impru-
dent cure of diseases, that terrible and
dangerous symptoms are produced, and
that the driving away one disease is pro-
ductive of a much worse.
Sometimes diseases are strangely compli-
cated, infomuch, that if the patient was
affected with the hypocondriac passion, or
a cacheftic, scurvy, debility of the head,
spitting of blood, consumption, pilers,
gravel, or gout, another difternper super-
vvenes, which requires the utmost pru-
dence, and a different method of cure.
It is likewise necessary to inquire wheth-
er the patient is plethoric, or cachexy-
ic; what is the state of the stomach,
and intestines; what is the condition of
the liver, whether the circulation through
it is impeded; whether the bile be duly
secreted; what is the state of the lungs;
and, lastly, the temperies of the brain,
and nervous fytem, are to be considered.
These things being mutually confluted,
we must proceed to the disease itself, as
whether it be common, or epidemic;
whether the virulence appears on the skin
in pufles, or otherwise. As there is no
fear or other difeafe which has not fen-
tible remifions and intermiffions of the
symptoms, the phifician ought to know
the state of the natural, vital, and animal
functions, as well in, as out of the par-
roxyms.
In acute difeases, we may know the ge-
nius and force of the disorder, from the
respiration, nature, and condition of the
pulse; besides, as no patient dies with-
owt an inflammation and internal morti-
fication, and as the inflammation of
the stomach and membranes are produced
eafily in acute difeases, and in the cho-
nic the mortifications of the viscera put
a period to human life, the phifician
should carefully attend to these fatal
symptoms, in order to manage the dif-
ease with greater certainty.
Likewise, the state of the prime vise is
carefully to be examined, as whether they
are replete with fordes; whether the body
is colitive, or otherwise, &c.
It is likewise necessary to obferve the
operations of the medicines, and what
changes they produce, whether the force
and vehemence of the symptoms mitigate
or inceafes; or whether nothing of this
kind happens. See Medicine.
Many difeases, and especially fevers of
all kinds, attack the patient all at once,
and are attended with particular symp-
toms, requiring sometimes one kind of
management,
management, and sometimes another: therefore, the causes of these diseases can be nothing else but such as are common to many men, and equally affect them all. The most common of which is the unhealthy state of the air: but this alone is not sufficient for the generation of epidemic diseases; for it is evident from observation, that, in the same climate, and the same constitution of the heavens, a disease shall infest the inhabitants of one place, and not another, as appears from the small-pox, dyerentaries, and military fevers: wherefore, recourse must be had to the nature of exhalations from pools and marshy places, which are replete with sulphureous, vitriolic, aluminous, bituminous, saline, and other particles. Regard must likewise be had to the different way of living, and kinds of aliments, from whence the causes of epidemic diseases differ in their nature, matter, texture, power, and virtue; and affect the structure and motion of the body in a preternatural manner: these causes and concurrent circumstances being known, an epidemic disease may be predicted, and the best methods of cure advised.

The method of distinguishing the various kinds of diseases, is affixed to our account of these diseases, as they occur under their several names, and is therefore omitted here.

Endemic Diseases. See the article ENDEMIC DISEASES.

Epidemic Diseases. See the article EPIDEMIC DISEASES.

Disembogue, in the sea-language, is said of a ship that passes out of a gulf or bay into the open sea: a river is also said to disembogue or discharge itself into the sea.

Disergot, in the mange. See the article Ergot.

Disfranchising, among civilians, signifies the depriving a person of the rights and privileges of a free citizen or subject. See Franchise.

Disgoring, in the mange, the discharging an inflammation or swelling. See the article Dispersion.

Disguise, a counterfeit habit. Persons doing unlawful acts in disguise, are by our statutes sometimes subjected to great penalties, and even declared felons. Thus by an act, commonly called the black act, persons appearing disguised and armed in a forest, or grounds inclosed, or hunting deer, or robbing a warren or a fish-pond, are declared felons.

Dish, among miners, denotes a wooden measure, wherein they are obliged to measure their ore: it is kept by the barmaster, and contains about 672 solid inches. See Ore.

Disherison, a term used in old writers for disinheriting.

Disjunct proportion, the same with that otherwise called discrete. See the article Discrete.

Disjunctive, something that separates or disjoins. Thus, or, neither, &c. which in connecting a discourse yet separates the parts of it, are called disjunctive conjunctions.

Disjunctive proposition, in logic, is that whereof several predicates we affirm one necessarily to belong to the subject to the exclusion of all the rest, but leave that particular one undetermined. Such is the major of the following disjunctive syllogism.

The world is either self-existent, or the work of some finite, or of some infinite being.

But it is not self-existent, nor the work of a finite being.

Therefore it is the work of an infinite being.

Dish, or Disc. See the article Disc.

Dislocation, in surgery, the same with luxation. See Luxation.

Disma, a town of Japan, separated from Nanquefaque only by a narrow canal. The Dutch have a very fine magazine there.

Dismembered, in heraldry, is applied to birds that have neither feet nor legs, and also to lions and other animals whose members are separated. See Membered.

Dismes, decaes, a term formerly used for tithes. See the article Tithe.

Dismounting, in the military art, the act of unhorsing. Thus to dismount the cavalry, dragoons, &c. is to make them alight.

Dismounting cannon, is the breaking their carriages, wheels, axletrees, or any thing else, so as to render them unfit for service.

Disorientated, a term chiefly used in speaking of dials, which have been some how altered from the situation of directly facing the east or any other of the cardinal points. See the articles Dial and Dialing.

Disparagement, in our law, is properly used for the matching an heir in marriage under his degree, or against decency.
DISPART, in gunnery, is the setting a mark upon the muzzle ring, or thereabouts, of a piece of ordnance, so that a sight-line taken upon the top of the bafe-ring against the touch-hole, by the mark set on or near the muzzle, may be parallel to the axis of the concave cylinder. The common way of doing this, is to take the two diameters of the bafe-ring, and of the place where the dispar is to stand, and divide the difference between them into two equal parts, one of which will be the length of the dispar which is set on the gun with wax or pitch, or fastened there with a piece of twine or marlin. By means of an instrument it may be done with all possible nicety.

DISPATCH, a letter sent abroad by a courier on some affair of state, or other matter of importance. The business of dispatches lies upon the ministers of state and their clerks.

DISPAYER also signifies the packet or mail containing such letters.

DISPENSARY, or DISPENSATORY, denotes a book containing the method of preparing the various kinds of medicines used in pharmacy. Such are those of Bauderon, Quercetan, Zwefher, Charas, Bates, Mefue, Salmon, Lemery, Quincy, &c. but the latest and most esteemed are the Edinburgh and London Dispensatories. In compiling this laft, the chief care of the college of physicians was to expunge the medicines no longer made use of in general practice, and to insert such as have come lately into use; and also to examine the articles they have retained or given admission to, both in regard to their pharmaceutic composition, and upon the genuine principles of medicine. The apothecaries in and about London are obliged to make up their compound medicines according to the formulas preferred in the college dispensary, and are enjoined to keep always ready in their shops all the medicines there enumerated. See the article PHARMACOPOEIA.

DISPENSARY, or DISPENSATORY, is likewise a magazine or office for selling medicines at prime cost to the poor. The college of physicians maintain three of these in London, one at the college itself in Warwick-lane; another in St. Peter's alley, Cornhill; and a third in St. Martin's-lane.

DISPENSATION, in law, the granting a license of doing some certain action that otherwise is not permitted. The greatest dealer in dispensions is the pope, who claims the office Jure Divino, and extends it to every thing. The more moderate of the romanists themselves deny that he can give a dispensation for any thing contrary to the divine law, or the law of nature; and confine him to what is contrary to positive laws, or to things relating to faults, marriages, holding several benefices, &c. and they limit him even in these things.

The archbishop of Canterbury has a power, by statute, of dispensing in any cause wherein dispensions were formerly granted by the see of Rome; and as well to the king as his subjects; and during the vacancy of the archbishop's see, the guardian of the spiritualities may grant dispensions. Every bishop of common right has the power of instituting into benefices, and of dispensing in common cases, &c. A dispensation of the kind, makes a thing prohibited lawful to be done by the person that has it, though a thing evil in itself will not admit of a dispensation. And where the subject has an immediate interest in an act of parliament, the king cannot dispense with it; but may, if the fiute be the king's own only, for the breach of a penal law that is not to the damage of a third person.

There is a dispensation by non obstante, which is where a statute tends to restrain some prerogative incident to the person of the king, as the right of pardoning, or commanding the service of the subjects for the benefit of the public, &c. each of which prerogatives are inseparable from the king, and therefore, by a clause non obstante, such a statute may be dispensed with. See the article NON OBSTANTE.

DISPENSATORY, or DISPENSARY. See the article DISPENSARY.

DISPERSION, in optics, signifies the scattering or dissipating something. Hence, Dispersion, in optics, the same with the divergency of the rays of light.

Point of Dispersion, in dioptics, the point from which refracted rays begin to diverge, where their refraction renders them divergent. See REFRACTION.

Dispersion of Inflammations, in medicine and surgery, is the removing the inflamm-
inflammation, and restoring the inflamed part to its natural state.

Though the methods used to cure inflammations be various, according to the several causes and supervening symptoms, with other various circumstances, yet as the inflammation contantly arises from an infpiration of the blood in its smallest vessels, the grand intention of each of these methods should be, to open such small vessels as are thus obstructed, and to restore the blood to its natural consistence and free circulation.

If the cause of the inflammation is found to be external, and obvious to the sense, as thorns, splinters, the point of a sword, or any other foreign body stuck into the part, nothing can be more serviceable than speedily and carefully to remove whatever is lodged there; if it can be done with safety. So also, when the inflammation proceeds from too strait a bandage in wounds, &c. or from a luxation or fracture, the first and principal business is speedily to remove the bandage, or else set the fracture, or reduce the luxation.

When the external causes are once removed, and when the inflammation is great, and proceeds from internal causes, it is in both cases very useful to open a vein, either in the arm or foot, and to draw off a large quantity of blood proportionable to the strength and habit of the patient; giving afterwards a brisk purge, not one that heats the body, but judiciously accommodated to the age and constitution of the patient; and if the symptoms do not remit and grow milder, they must be repeated at discretion.

To resolve and attenuate the inflipated blood in the small vessels, benefit may arise from internal medicines, which are watry, diluent, cooling, and attenuating; but aliments which are of a difficult digestion, such as pickled or salted meats, with all spices and fermented liquors, or any thing elè that may heat the blood, are to be altogether avoided. With regard to the regimen and diet, the most proper aliments seems to be broths and drinks, made with barley, oats, or flour; also vipers’s grafts, ficcor’s chervil, forrel, endive, apples, and vegetables of the like nature.

With regard to external medicines, it must be generally observed never to apply hot remedies to hot constitutions, nor the contrary. Among the domestic medicines cow’s dung, fresh and warm, mixt with warm vinegar, is an application of no small efficacy: the external medicines should always be applied hot, and the disordered limb first well rubbed with a cloth dipped in some warm diluent fomentation, before any fresh castaplasm be laid on. Of the cooling external medicines proper in this case, are the li targhe vinegar, applied warm on linen rags folded together; or hot vinegar mixt with red-lead, or with bore-armoniac, and applied in the same manner. Among the hot remedies for cold constitutions, are spirit of wine alone; or camphorated spirit; or either of these, with an admixture of a small quantity of Venice-treacle applied on a linen cloth; also spirit of wine mixed with lime-water, or even lime-water alone; or hungary-water with lapis calaminaris, cerus, fal armoniac; or a mixture of a pint of rectified spirit of wine with two ounces of castile soap.

DISPLAYED, in heraldry, is underfoot of the position of an eagle, or any other bird, when it is erect, with its wings expanded or spread forth. See plate LXXIII. fig. 5.

DISPONDEE, dispandens, in the greek and latin poetry, a double spondee or foot, consisting of four long syllables, as βαμαζοιος, mæcènates, conclùdentes.

DISPOSITION, in architecture, the just placing the several parts of an edifice, according to their proper nature and office. See the article BUILDING.

DISPOSITION, in rhetoric, the placing words in such an order as contributes most to the beauty and sometimes even to the strength of a discourse. Nature formed man with a taste which makes him sensible of harmony and cadence: for this we need only consult nature, study the genius of the language and sound, and, as it were, interrogate our ears: for let a thought be ever so beautiful in itself, if the words which express it are ill placed, the delicacy of the ear is shocked at it; a harsh and unharmonious composition grates it, whereas it is generally flattered with that which is soft and flowing. There are no expressions, however harsh they may appear in themselves, but may contribute to the harmony of a discourse, when judiciously ranged. Iocrates was the first among the Greeks that made them sensible of the beauty of disposition, as Cicero did the Romans.
DISPROPORTION, a general term for any kind of irregularity, or want of proportion in the parts of a thing. See the article Proportion.

DISPROVING, in rhetoric and logic, the same with refutation. See the article Refutation.

DISPUTATION, in the schools, a contest, either by word or writing, on some point of learning for a degree, prize, or for an exercise. See Degree and Thesis.

DISQUISITION, a serious and exact examination into the circumstances of any affair, in order to discourse clearly about it. See Reasoning.

DISSEISIN, a market-town of Norfolk, on the river Waveney, sixteen miles south of Norwich.

DISSECTION, in anatomy, the cutting up a body, with a view of examining the structure and use of the parts. See the article Anatomy.

Le Gendre observes, that the dissection of a human body, even dead, was held a sacrilege till the time of Francis I. and the same author affures us, he has seen a confutation held by the divines of Salamanca, at the request of Charles V. to settle the question whether or no it were lawful in point of conscience to dissect a human body in order to learn the structure thereof.

It is easily perceived that surgery and physic must improve in a country, according to the opportunities of enquiring into the structure of the animal economy; for which reason we could wish that students in anatomy were furnished with subjects for dissection in this country, in as great abundance, and with as little inconvenience, as in France.

DISSEISIN, in law, an unlawful dispossession of a person of his lands or tenements. It is of two sorts, either single disaffin, which is committed without force of arms, or disaffin by force of arms, more properly termed defacement. See the article Defacement.

The disturbing a person from entering on his land, or hindering him from tilling it, are both disaffins of land; and denial of rent, when lawfully demanded, is a disaffin of the rent.

If a disaffor, after he has expelled the right owner, gains peaceable possession of the lands five years without claim, and continues in possession so as to disafford, and the land descends to his heirs, they will have a right to the possession till the owner recovers at law; and here the owner shall lose his estate for ever, if he do not prosecute his suit within the time limited by the statute of limitations.

DISSIPOR, a person who is guilty of dissipation. See the preceding article.

DISSENTERS, separatists from the service and worship of the church of England. At the revolution a law was enacted, that the statutes of queen Elizabeth and king James I. concerning the discipline of the church, should not extend to the protestant dissenters. Persons dissenting, however, are to subscribe the declaration of 30 Car. II. cap. 1. and take the oaths of fidelity, &c. Besides, they are not to hold their meetings till their place of worship is certified to the bishop, or to the justices of the quarter sessions, and registered. Also they are not to keep the doors of their meeting-houses locked during the time of divine service. And to secure to them the free exercise of their religion, whoever disturbs or molests them in the performance of divine worship, on conviction at the sessions is to forfeit twenty pounds by the statute 1 William and Mary. Unless dissenters conform and receive the sacrament as administered by the church of England, they are excluded from holding any public places under the government.

The dissenters tolerated by law, may be reduced to four classes, viz. presbyterians, independants, anabaptists, and quakers; to which may be added another sect, which some years ago obtained a toleration in this country, namely, the unitas fratrum, or moravians. See the articles Presbyterian, Anabaptists, &c.

DISSIMILAR, in general, an appellation given to things which are unlike: thus the seminal or first leaves of plants, are called dissimilar, as being generally of a different figure from those of the grown plants.

DISSIMILAR PARTS, in anatomy, those compounded of parts of various structure, such are all the limbs of the body.

DISSIMILITUDE, in general, denotes whatever constitutes the difference between two dissimilar things. See the articles Dissimilar and Similitude.

DISSIMILITUDE, in rhetoric, an argument wherein from dissimilar or unlike things, other dissimilars are deduced, as in the following argument from Catullus.

6 &

Sedes
Suo.s occidere 8 redire posseunt.
Nobis cam semen ocdit brevis lux,
Nox eft perpetua una dormienta.

Dissipation, in physics, an inefible
lois or consumpion of the minute parts
of the body; or, that flux whereby they
fly off, and are lost. See Effluvia.

Circle of Dissipation, in optics, is ufed
for that circular space upon the retina,
which is taken up by one of the extreme
pencils or rays issuing from an object.
To understand this, it is to be observed,
that when the distance of an object from
the eye is too small or too great for per-
fect or distinct vision, the rays of each
pencil, issuing from the object, cannot be
united at a point on the retina, but be-
yond it, or before they
unite at a point on the retina, and this circle is called the circle
of dissipation, because the rays of a pen-
cil, instead of being collected into a cen-
tral point, are difpelled all over this
circle.
The consideration of the circles of dif-
pation, formed by the rays coming from
the extremities of objects, is of use to ac-
count for several curious phenomena of
vision. Smith's optics.

Dissolvent, in general, whatever dif-
solves or reduces a folid body into fuch
minute parts as to be futfained in a
fluid.
The principal dissolvents for metals, are
aqua-regia and aqua-fortis; for fards,
earth, and gums, water; for coral, and
other alcaline fubfiances, diftilled vinegar
or fpirits of wine. See the article A quo-
Regia, &c.

Dissolvents are the fame with what the
chemifs call menftruums. See the article
Menftruum.

Universal Dissolvent. See the article
Alkahef.

Dissolution, in chemiftry, the fame
with solution. See the articles Solution
and Menftruum.

Dissolution, in music, is when a found
in the enharmonic genus is lowered three
diètes; for thereby that genus is diffo-
ced, and the music, or that interval at
leat, is chromatic.

Dissonance, in music, the fame with
discord. See the article Discord.

Dissyllable, among grammarians, a
word confliting only of two syllables:
such are nature, fience, &c.

Distaff, an instrument about which ilax
is tied in order to be fpun.

Distance, in general, an interval be-
tween two things, either with regard to
time or place.

Accessible Distances, in geometry, are
fuch as may be measured by the chain,
&c. See Chain, Thedolite, &c.

Inaccessible Distances, are fuch as cannot
be measured by the chain, &c. by reason
of some river, or the like, which obftrufes
our paffing from one object to another.
Inaccessible distances may be measured in
the following manner: fuppose it were
required to measure the distance between
the ftation A (plate LXXIII. fig. 6. n. 1.)
and the object at C. Assume another ftation
as B, from whence the object may be
feen. Then, with any proper instrument,
take the angles C A B, and C B A,
and measure the distance A B. Then,
in the triangle A B C are given three
angles, and the distance A B, whence the
distance A C required may be easily
found, thus: as the line of the angle C:
the distance A B: : the line of the angle
B: A C required.

But fmal'l inaccessible distances may be
measured from one ftation, in the fol-
lowing manner. Let A B (ibid. n. 2.)
represent an inaccessible distance to be
measured; fet up perpendicular a ftick
C A, of a known length, place the cen-
ter of your quadrant C, on the top of
the ftick; and look through the fights of
it till the vertical ray points to the object
at B. Then in the right angled trian-
gle B A C, are given the perpendicular
A C, and the angle A C B, and there-
fore, if A C be the radius, the
required side will be the tangent to the
given angle A C B; whence to find A B
it will be as the radius to A C, fo is the
tangent of the angle A C B, to A B re-
quired.

Distance, in navigation, the number of
minutes or leagues a ship has failed from
any given place or point.

Distance, in astronomy. The distance
of the fun, planets, and comets, is only
found from their parallaxes, as it cannot
be found either by eclipses or their dif-. .
ferent phases: for from the theory of the
motions of the earth and planets we
know, at any time, the proportion of the
distances of the fun and planets from us;
and the horizontal parallaxes are in a re-
ciprocal proportion to these distances.
See the article Parallax.

The
The mean distances of the planets from the sun, in British miles, are as follow.

Mercury 32,000,000
Venus 59,000,000
The Earth 81,000,000
Mars 123,000,000
Jupiter 424,000,000
Saturn 777,000,000

The distance of the fixed stars, as having no sensible parallax, can be little more than guessed at.

The distances of the secondary planets, from their respective primary ones, are as follow.

The moon is distant from the earth 60 semi-diameters and a half of the earth, from its center, or 240,000 miles.

The first moon of Jupiter is at the distance of 5 5/8 semi-diameters of Jupiter's body from his center, as measured with a micrometer.

The second at the distance of 9 semi-diameters.

The third at the distance of 14 1/8 semi-diameters.

The fourth at the distance of 25 7/8 semi-diameters.

The first Saturnian moon is at the distance of near 2 semi-diameters of Saturn's ring from its center.

The second at the distance of 2 7/8 semi-diameters of the ring.

The third at the distance of 3 7/8 semi-diameters.

The fourth at the distance of 8 semi-diameters.

The fifth at the distance of 23 7/8 semi-diameters. See DIAMETER.

Curtate Distance, the distance of the planet's place, reduced to the ecliptic, from the sun. See the article CURTATE.

Distance of the eye, in perspective, is a line drawn from the eye to the principal point. See PERSPECTIVE.

Distance of the baptism, in fortification, is the side of the exterior polygon. See the article POLYGON.

DITASTE properly signifies an aversion or dislike to certain foods, and may be either constitutional, or owing to some disorder of the stomach; in which last case emetics are recommended.

DISTEMPER, among physicians, the same with difeafe. See the article DISEASE.

DISTEMPER, in painting, a term used for the working up of colours with something besides water or oil. If the colours are prepared with water, that kind of painting is called limning; and if with oil, it is called painting in oil, and simply painting. If the colours are mixed with fire, whites of eggs, or any such proper glutinous, or unctuous matter, and not with oil, then they say it is done in distemper. In this manner the admirable cartoons at Hampton-court are painted. The greatest disadvantage of distemper is, that it has no glittering, and all its colours look dead, by which means they appear alike in all sorts of lights, which oil colours, or even colours in distemper, when varnished, do not.

DISTEMPER, or DISTEMPERATURE of trees. See the article TREE.

DISTENSION, in general, signifies the stretching or extending a thing to its full length or breadth.

DISTENSION, division, among ancient musicians, is used in a synonymous sense with Interval. See INTERVAL.

DISTICH, διϊςτηχον, a couplet of verses making a complete sentence. Thus hexameter and pentameter verses are disposed in distichs.

There are excellent morals in Cato's Distichs.

DISTICHIASIS, in surgery, a disease of the eye-lids, when under the ordinary eye-lashes there grows another extraordinary row of hair, which frequently eradicates the former, and prickling the membrane of the eye, excites pain, and brings on a defluxion.

It is cured by pulling out the second row of hairs with nippers, and cauterizing the pores out of which they issued.

DISTILLATION, in chemistry, the act of drawing off the spirituous, aqueous, oleaginous, or saline parts of a mixed body from the groffer and more terrestrial parts by means of fire, and collecting and condensing them again by cold. The end of distillation is of two kinds: the first, and by far the most general, is for the separation of some acquired bodies, from others with which they were mixed, as in the case of vinous and volatile spirits, and effential oils; the other is for the quicker and more effectual combination of such bodies, whose mixture is affisted by a boiling heat, as in the case of spirit of nitre, dule.

Distillation is performed by several kinds of apparatus, for all which the general name is an alembic; to form each kind whereof, two or more vessels are conjoined, viz. a proper resevoir to contain the matter while the heat acts upon it, a refrigerant to condense the vapour as it

6 E 2

ris
DIS [944] DIS

rites, and a receiver to contain it when condensed. See Alembic, Retort, and Receiver.

Distillation is usually performed by means of fire, raised to a greater or less degree of heat, as circumstances require. And the fire is either applied immediately to the vessels in which the matters are to be distilled; or it is applied mediately by means of water, sand, iron-flings, &c. Hence these different methods are called bulbenum maris, balneum arenorum, &c. See the article Balneum.

Distillation is either per officium, by ascent, or per defcentum, by descent. In the former, the matter to be distilled is above the fire, and the spirit or other principle is raised from it. In the latter, the matter to be distilled is below the fire, and the vapour drawn from it is precipitated to the bottom of the vessel.

Distillation by ascent is either right, performed with a common alembic, wherein the liquor is raised perpendicularly, and descends again in form of drops into a receiver, being chiefly used when the texture of the body allows of an easy ascent, as in vegetables; or oblique, performed laterally, as in distillation by the retort; the use of this is for bodies, as almost all minerals and metals, which cannot be raised without a strong impulse, nor even by the strongest, so high as the top of the alembic.

The processes and measures of distillation are very different, according to the different subjects to be distilled. Acid spirits are usually drawn in a reverberatory furnace, and with a vehement fire: ponderous woods, as guaiacum, box, &c. are distilled in a retort after the same manner. Odorous plants, as baum, wormwood, fenn, hyssop, &c. are distilled by the cucurbit, or velica, first pouring a strong decoction of the same plant hot upon the plant itself bruised, or adding common water to the plant, whether dry or fresh, cut into small pieces, and letting the whole digest in a close vessel for two days. In distilling plants that are not odoriferous, pound the plant, and then fill two thirds of the velica or alembic with it; after which pour a good quantity of the expressed juice of the same plant upon it, so as the bruised matter may float therein, without sticking any where to the vessel; then draw off about half as much water as there was juice, which is the distilled water of the plant: if what remains be strained or put in a cloth, and the settled juice be filtrated and evaporated to two thirds, then letting it in a cool place, the essential falt floats into crystals.

The precautions to be used in regard to distillation, are, 1. To leave sufficient room in the containing vessel for the expansion and ebullition of the matter to be distilled, otherwise it is very apt to overflow in the neck, and break the vessels if of glass, hazard the firing of the building in case of vinous spirits, and frustrate the operation in all. 2. To take care that the condensing surface be sufficiently large, and the heat accommodated to it; for if an error of this kind occur in the case of the worm-still, the head will be blown off, and the vapour dissipated with considerable loss; and in that of vinous spirits, whoever may happen to be in the place will be in very great danger. 3. It is necessary in distillation, as well as in digestion, to avoid luting the vessels too closely with any tenacious substance; for if a sufficient vent be not left for the escape of the air which is generated during the distillation of some substances, as also for the expansion which attends the increase of heat of that air which is included in the vessels at the time of their junction, the vessels will be in extreme danger of being burst with great violence.

The method of distilling malt-wash, or a fermented mixture of meal and malt, for spirit. Fill two thirds of a still, first moistened by the steam of boiling water, with malt-wash, immediately clap on the head, and let it down, there will soon run a spirituous inflammable liquor. Thus is obtained what the malt-distillers call a malt low-wine; what comes over after the spirit falls off from being proof, is called fains. This experiment may be rendered general, with slight variation; for if any wine, beer, or fermented liquor from sugar, treacle, or fruits, &c. be thus treated, it affords a spirit differing only according to the nature of the subject: but none of them will afford the least inflammable spirit without a previous fermentation. The requisite cautions for success, are, 1. That the fermentation be well performed. 2. That it be gently distilled, with a soft well regulated fire. 3. That the groffer oil, apt to rise along with the spirit, be let out by flannel under the nose of the worm. These cautions observed, the low-wines will be pure and vinous.

The method of distilling the lower wines into proc spiris for sale. The lower wines of
of the last process, distilled in a bath-heat, give a higher rectified spirit than before, which being let down with fair water to a certain size or standard, called proof, is what the malt-distillers understand by proof-goods, or their rectified malt-spirit.

The inconveniences of this art, on account of the many large vessels required, which increase the labour and price of the commodity, might perhaps be remedied by the introduction of a new art, subservient to the malt-distillers, and confined to the boiling down the malt-wort to a rob; wherefore it were to be wished that those who were skilled in this branch of distillation would try whether a spirit superior to that of treacle may not be procured from the rob of malt, prudently prepared and fermented. See the article Rectification.

Combinatory Distillation, a term used by Dr. Shaw, to express that sort of rectification of distilled spirits, which is done with additions, and which he otherwise calls improper rectification, by way of distinction from that called proper rectification which is only the method of reducing a spirit to its utmost degree of purity and perfection. Malt-spirit is the general subject of combinatory distillation, and the means to rectify it on this plan may be reduced to three heads: 1. That by fixed alkaline salts alone. 2. That by fixed alkaline salts and acid spirits. And, 3. That by saline bodies and flavouring additions. The effect of this operation, when carefully performed, is to attenuate and thin the spirit, and to keep back a part of its gross and letid oil, and so far to alter the part of the oil which comes over, as scarce to leave the spirit distinguishable from a malt spirit. The salts used on this occasion are either the fixed alkalies, as potash and calcined tartar, or de creeping common salt, or calcined vitriol, alum, or landider. The most common flavourers are mace, orrice-root, parsnips, artichokes, rhodium, rassin-falts, damask roses, wine lees, rape or grape huks, and the oil of wine, which is infinitely preferable to all the others, but is not so well known. The ultimate perfection aimed at in all the processes of combinatory distillation, is the depurating the English malt-spirit at one operation, so as to render it tallowless and inodorous and yet vinous; or else to make it resemble the French brandy, arrack, or some other low-flavoured vinous spirits.

DISTILLED, something that has undergone the action of distillation; thus we say distilled water, distilled vinegar, &c. See the preceding article.

DISTILLER, he who makes distillations, and commonly denotes a tradesman who makes spirits from malt, &c. Distillers are to make an entry of all warehouses for keeping brandy, on pain of 201. and forfeiture of the liquor; and no brandy shall be sold but in places entered, under penalty of 40s. a gallon.

By Stat. 24 Geo. II. distillers who shall knowingly sell spirituous liquors to be unlawfully retailed, or to any unlicensed retailer, forfeit 101. and treble the value of the liquors so sold and delivered; and such unlawful retailer, discovering and convicting the distiller, is entitled to his share of the penalty, and indemnified against the penalties incurred by himself. The same act further provides, that no person whatsoever shall recover, either in law or equity, any debt for spirituous liquors under 20 s. contracted at one time; nor shall any article in any account for such be allowed, where the value of such item shall not amount to 20 s. at the least. Distillers are also to give notice to the gauger, before they receive any fermented wassell of the quantity, &c. under penalty of 50 l. They are also to make entry of all vessels for distillation, under the same penalty of 50 l. and forfeit 20 l. for defacing the guager's mark.

DISTILLERY, the art of distilling brandies, and other spirits. See the article Distillation.

To this art likewise belong the peculiar processes of brewing and fermentation, the knowledge of proper additions, and the rectification of spirits. See the articles Brewing, Fermentation, Additions, and Rectification.

DISTINCT NOTION, or IDEA, is that wherein the mind perceives a difference from all other ideas.

It will be useful, says Mr. Locke, to distinguish ideas as they are perceptions in our minds, from what they are in the bodies that cause such perceptions in us; for we are not to think the former exact images and resemblances of something inherent in the subject, most of those sensations being in the mind no more the likenesses of something existing without us, than the names that stand for them are the likenesses of our ideas, which yet upon hearing they are apt to excite in us.

DISTINCT BASE, in optics, is that distance from
DISTRACTION, in medicine, sometimes denotes the act of pulling a fibre, membrane, or the like, beyond its natural extent, DISTRAINING, in law, the same with attaching. See the article Attaching. DISTRESS, in law, the seizing or distraining any thing for rent in arrear, or other duty unperformed. The effect of this distress is to compel the party either to replye the things distrained, and contest the taking, in an action of trespass against the distrainer; or rather to oblige him to compound and pay the debt or duty, for which he was so distrained. There are likewise compulsory distresses in actions, to cauze a person appear in court; of which kind there is a distress personal of one's moveable goods, and the profits of his lands, for contempt in not appearing after summons: there is likewise distress real, of a person's immoveable goods. In these cases none shall be distrained to answer for anything touching their freeholds, but by the king's writ. Distresses may be either finite or infinite: Finite distresses is that which is limited by law, in regard to the number of times it shall be made, in order to bring the party to a trial of the action. Infinite distresses is that which is without any limitation, being made till the person appears: it is farther applied to jurors that do not appear, as upon a certificate of affize, the process is venire facias, habeas corpus, and distresses infinite. It is also divided into grand distresses and ordinary distresses; of these the former extends to all the goods and chattels that the party has within the county. A person, of common right, may distrain for rents and all manner of services; and where a rent is referred on a gift in tail, lease for life, or years, &c. though there be no clause of distresses in the grant or lease, so as that he has the revission; but on a cession made in fee, a distress may not be taken, unless it be expressly referred in the deed. DISTRIBUTION, in a general sense, the act of dividing a thing into several parts, in order to the disposing each in its proper place. DISTRIBUTION, in architecture, the dividing and disposing the several parts and pieces which compose a building, as the plan directs.
DISTRIBUTION of ornaments, is an equal orderly placing of the ornaments in any member of architecture.

DISTRIBUTION, in logic, is a kind of division which distinguishes an universal whole into its several kinds of species; as division is to distinguish an integral whole into its several parts.

The rules of a good distribution are much the same as those of division. See the article DIVISION.

DISTRIBUTION, in rhetoric, a kind of description, whereby an orderly division and enumeration is made of the principal qualities of the subject. David supplies us with an example of this kind, when in the heat of his indignation against sinners, he gives a description of their iniquity, "Their throat is an open sepulchre; they flatter with their tongues; the poison of asps is under their lips; their mouth is full of cursing and lies; and their feet are swift to shed blood." See PRINTING.

DISTRIBUTIVE JUSTICE, is that whereby we give every person what properly belongs to him.

DISTRIBUTIVES, in grammar. See the article NUMERALS.

DISTRICT, in geography, a part of a province, distinguished by peculiar magistrates, or certain privileges; in which sense it is synonymous with hundred. See the article HUNDRED.

It is also used to denote the territory belonging to a city, town, or borough; or the extent of a judge's jurisdiction. See TERRITORY and JURISDICTION.

DISTRINGAS, in law, a writ commanding the sheriff, or other officer, that he distrain a person for debt to the king, &c. or for his appearance at a certain day. There is a great diversity of this writ.

DISTRINGAS JURATORES, a writ directed to the sheriff, whereby he is commanded to distrain upon a jury, to appear, and to return issues on their lands, &c. for non appearance. This writ of discharging jurors issues for the sheriff to have their bodies in court, &c. at the return of the writ.

DISVELLOPED, in heraldry, is said much in the same sense with displayed, as flying colours are said to be displayed.

DISUNITE, in the manege, is said of a horse that drags his haunches in galloping.

DITCH, in country affairs, a narrow channel or trench made for draining marshy grounds, the conveyance of water, or enclosing fields.

Ditches for draining must be more or less deep and wide, according as there is more or less water to be carried off. Ditches used about inclosures are five or six feet wide, and proportionably deep, where there is no quick-set hedges; but where these are set on the banks, they are only three feet wide at the top, one at the bottom, and two deep: the slope is of great advantage, as by means of it the sides of the ditch are prevented from being washed down. See DRAIN and INCLOSURE.

DITCH, in fortification, the same with moat. See the article MOAT.

DITHYRAMBIC, somthing belonging to the dithyrambus, as a dithyrambic verse, a dithyrambic poet, &c. See the next article.

The dithyrambic poetry was very bold and irregular, for the poets not only took the liberty to forge new words for the purpose, but made double and compound words, which contributed very much to the magnificence of this sort of poetry.

DITHYRAMBUS, in ancient poetry, a hymn in honour of Bacchus, full of transport and poetical rage.

This poetry owes its birth to Greece, and to the transports of wine; and yet art is not quite exploded, but delicately applied to guide and restrain the dithyrambic impetuosity, which is indulged only in pleasing flights. Horace and Aristotle tell us, that the ancients gave the name of dithyrambus to those verses wherein none of the common rules or measures were observed. As we have now no remains of the dithyrambus of the ancients, we cannot say exactly what their measure was.

DITMARSH, a territory in the duchy of Holstein. See HOLSTEIN.

DITONE, in music, an interval comprehending two tones. The proportion of the sounds that form the ditone is 4:5, and that of the semiditone is 5:6. F. Parren makes the ditone the fourth kind of simple concord, 48 comprehending two tones, according to Aristotle, a greater and a less. Others make it the first discord, dividing the ditone into eighteen equal parts, or commas; the nine on the acute side making the greater tone, as affected by Salomon de Caux.

DITRIGLIPH, in architecture, the space between two triglyphs. See TRIGLYPH.

DITRHEDRIA,
DIVIHEDRIA, in mineralogy, a genus of spars with twice three sides, or fix planes, being formed of two trigonal pyramids joined base to base, without any intermediate column. See Spar.

The species of ditrihedria are distinguished by the different figures of these pyramids.

DITTANY, ditannus, in botany, &c. See the article DICTAMNUS.

DITTO, usually written Do, in books of accounts, an Italian word, signifying the aforementioned.

DIVAL, in heraldry, the herb nightshade, used by such as blazon flowers and herbs, instead of colours and metals, for fable, or black.

DIVALE, in botany, a name sometimes used for the folanum lethale, or deadly nightshade. See SOLANUM.

DIVALA, the same with angeronalia. See the article ANGERONALIA.

This feast was instituted on occasion of a divine which destroyed man and beast. It was held on December 21, when the pontiffs performed a sacrifice in the temple of Volupia, or the goddes of joy and pleasure, and was the same with Angeronia, supplanted to drive away all forrows and chagrins in life.

DIU, a little island and town on the coast of Guzurat, in the hither India, and subject to Portugal: east long. 69°, north lat. 21° 15'.

DIU is also a town of Bulgaria, upon the Danube.

DIVAN, a council chamber, or court of justice, among the eastern nations, particularly the Turks.

DIVAN-BEGHI, the superintendant of justice in Persia, whose place is the last of the six ministers of the second rank, who are all under the athemaduclare, or first minister. To this tribunal of the divan-beghi he appeals from sentences passed by the governors: he has a fixed stipend of 50,000 crowns for administering justice: all the serjeants, uffers, &c. of the court, are in his service: he takes cognizance of the criminal causes of the chiefs, governors, and other great lords of Persia, when accused of any fault. There are divan-beghis not only at court, and in the capital, but also in the provinces, and other cities of the empire. The alcoran is the sole rule of his administration of justice, which also he interprets at pleasure. He takes no cognizance of civil causes, but all differences arising between the officers of the king's household, and between foreign ministers, are determined by him.

DIVANDUROW, the name of seven islands which lye a league north of the Maldives, and twenty-four from the coast of Malabar, almost opposite to Cananar.

DIVAR, an island in the indian sea, situated north of Goa. It belongs to the Portuguese.

DIVER, colymbus, in ornithology, the English name of a genus of birds, for the characters of which see COLOMBUS. Of this genus there are a great many beautiful species. The speckled diver, about the size of a tame duck, is represented in plate LXXIV. fig. 1. n° 1. The hinder part of the neck is of an aht colour; the back and wings are black, spotted with white; the throat is black, and belly white. This is thought to be the cock of the red-throated duck, or loon, represented ibid. n° 2. The upper part of the body of this bird is of a dark grey colour, the quill feathers of the wings approaching to black: the legs and feet of both are of a blackish colour.

DIVERGENT, or DIVERGING LINES, in geometry, are those which constantly recede from each other.

DIVERGENT RAYS, in optics, are those which going from a point of the visible object, are dispersed, and continually depart one from another, in proportion as they are removed from the object: in which sense it is opposed to convergent. See the article CONVERGENT.

Concave glaftes render the rays divergent, and convex ones convergent.

Concave mirrors make the rays converge, and convex ones make them diverge. See CONCAVE and CONVEX.

DIVERGENT, or DIVERGENT HYPERBOLA, one whose legs turn their convexities towards one another, and run outwards quite contrary ways. See HYPERBOLA.

DIVERGING SERIES. See SERIES.

Point of Divergency. See the article VIRTUAL FOCUS.

DIVERSIFYING, among orators, is the handling a subject different ways, in order to throw new light on it, and enforce it the stronger on the hearers. According to Vossius, there are six ways of doing this: 1. By enlarging on what was said before. 2. By recapitulating. 3. By adding something new. 4. By repeating the principal heads. 5. By urging the same arguments, only in a different order. 6. By imitating them.
DIVERSION, in military affairs, is, when an enemy is attacked in one place where they are weak and unprovided, in order to draw off their forces from another place, where they have made, or intend to make, an irruption. Thus the Romans had no other way in their power of driving Hannibal out of Italy, but by making a diversion, in attacking Carthage.

DIVERSION, in physic, is when by means of medicines, an attempt is made to give a different turn to the flux of humours: thus blood-letting makes a great diversion.

DIVERSITY, in logic, stands in opposition to identity. See IDENTITY.

DIVERSITY, in painting, consists in giving every part or figure in a piece, its proper air and attitude.

The skilful painter has the penetration to discern the character of nature, which varies in all men: whence the countenances and gestures of the persons he paints continually vary.

DIVESTING, or DIVESTITURE, in law, is used for the act of surrendering one's effects. By a contract of donation, or sale, the donor, or seller, is said to be divested and invested of his property, in such a commodity. In this sense it stands contrasted with investiture, where the donee or purchaser becomes invested with the property of the donor or seller. See the articles INVESTITURE and DISEISIN.

DIVIDEND, in arithmetic, the number proposed to be divided into equal parts. It must always be greater than the divisor. See the articles DIVISOR and DIVISION.

DIVIDEND, in the Exchequer, is one part of an indenture, as used in the Stat. 10 Ed. I. c. 11.

DIVIDEND, in law proceedings, is taken for a dividing of fees and perquisites between officers of courts, arising from writs, &c.

DIVIDEND of stocks, is a share, or proportion of the interest of stocks erected on public funds, as the south-fea, &c. divided among, and paid to the adventurers half yearly.

Stealing of any dividend warrants of the Bank, South-fea company, East-india company, or of any other corporation, is made felony with or without benefit of clergy, in the same manner as if the offender had stolen, or taken by robbery, goods to the value of the money due on such dividend warrants. Stat. 2 Geo. II. c. 25. S. 3.

DIVIDEND, in the university, signifies that part or share which every one of the fellows equally divide among themselves of their yearly stipend. See the articles FELLOW and UNIVERSITY.

DIVINATION, the knowledge of things obscure, or future, which cannot be attained by any natural means.

It was a received opinion among the heathens, that the Gods were wont to converse familiarly with some men, whom they endowed with extraordinary powers, and admitted to the knowledge of their councils and designs. Plato, Aristotle, Plutarch, Cicero, and others, divide divination into two sorts, or species, viz. natural and artificial. The former was so called, because not attained by any rules or precepts of art, but infused or inspired into the diviner without his taking any further care about it, than to purify and prepare himself for the reception of the divine afflatus. Of this kind were all those who delivered oracles, and foretold future events by inspiration, without observing external signs or accidents. The second species of divination was called artificial, because it was not obtained by immediate inspiration, but was the effect of experience and observation. Such was soothsaying, as depending upon human art and invention, which however was supposed not to be altogether delusive of divine direction and concurrence, and such was divination by lots. Of this sort there were various kinds, as by sacrifices, entrails, flame, cakes, flour, wine, water, augury, birds, lots, omens, &c. The several sorts of divination are alec­tryomancy, alphitomancy, arithmomancy, axinomancy, bellomancy, catoptromancy, ceromancy, chiromancy, claromancy, daechromancy, galtramancy, geomancy, hydromancy, lithomancy, necromancy, onerocritics, &c. See the article ALECTROYOMANCY, &c.

DIVINE, something relating to God. See the article GOD.

DIVINE STONE, in natural history, a species of the jasper. See JASPER.

The indians attribute great medicinal virtues to this stone: they wear it externally as a cure for the gravel; they say it promotes urine extremely, and seldom fails to bring away large quantities of gravel with it, when there has been
DIVING, the art of descending under water, to considerable depths, and abiding there a competent time; the uses of which are considerable, particularly in fishing for pearls, corals, sponges, wrecks of ships, &c.

There have been various engines contrived to render the business of diving safe and easy; the great point is to furnish the diver with fresh air, without which he must either make but a short stay, or perish. Those who dive for sponges in the Mediterranean, carry down sponges dipp’d in oil in their mouths, but considering the small quantity of air that can be contained in the pores of a sponge, and how much that little will be contracted by the prehure of the incumbent air, such a supply cannot sustain a diver long, since a gallon of air is not fit for respiration above a minute.

See the next article.

DIVING-BELL, a machine contrived for the safe conveyance of a diver to any reasonable depth, and whereby he may stay more or less time under water, as the bell is greater or less.

That the reader may have a just idea of the diving-bell, according to the latest improvements by Dr. Halley, and Mr. Triewald of Stockholm, we have here exhibited two figures of the same. The first (plate LXXV. fig. i. n° 1.) is that of Dr. Halley’s form, which was three feet wide at top, five at bottom, and eight feet high, and contained about sixty-three cubic feet, or near eight hogheads in its concavity.

This was coated with lead, so heavy, that it would sink empty, and the weight was distributed about the bottom IX, so that it would go down in a perpendicular position, and no other. In the top was fixed a strong but clear glass D, to let in the light from above; and likewise a cock, as at B, to let out the hot air that had been breathed; and below, was fixed a circular seat, L M, for the divers to sit on; and lastly, from the bottom was hung, by three ropes, a flag for the divers to stand on, to do their business. This machine was suspended from the mast of a ship by a spur, which was sufficiently secured by flays to go the mast-head, and was directed by braces to carry it over-board, clear of the side of the ship, and to bring it in again.

To supply the bell with air under water, two barrels, such as C, of about sixty-three gallons each, were made, and cafed with lead, so that they might sink empty, each having a hole in its lowest part, to let in the water, as the air in them is condensed in their defcent, and to let it out again when they were drawn up full from below. And to a hole in the top of the barrel was fixed a hose, or hollow pipe, well prepared with beeswax and oil, which was long enough to fall below the hole at the bottom, being sunk with a weight appended, so that the air in the upper part of the barrels could not escape, unless the lower end of these pipes were first lifted up.

These air barrels were fitted with tackle proper to make them rise and fall alternately, like two buckets in a well. In their descent, they were directed by lines fastened at the under edge of the bell to the man standing on the flag to receive them, who, by taking up the ends of the pipes above the surface of the water in the bell, gave occasion for the water in the barrels to force all the air in the upper parts into the bell, while it entered below, and filled the barrels; and as soon as one was discharged by a signal given, it was drawn up, and the other descended to be ready for use.

As the cold air rushed into the bell from the barrel below, it expelled the hot air (which was lighter) through the cock B, at the top of the bell, which was then opened for that purpose. By this method air is communicated so quick, and in such plenty, that the doctor tells us, he himself was one of the five who was at the bottom in nine or ten fathom water, for above an hour and a half at a time, without any sort of ill consequence; and he might continue there so long as he pleased, for any thing that appeared to the contrary.

In going down, it is necessary it should be very gentle at first, that the dense air may be inspired to keep up, by its spring, a balance to the prehure of the air in the bell: upon each twelve feet descent, the bell is loft, and the water that enters is driven out by letting in three or four barrels of fresh air.

By the glass above, so much light was transmitted, when the sun shone, that he could see perfectly well to write and read, and
and by the return of the air-barrels, he could send up orders, written with an iron pen, on small pieces of lead, directing, that they were to be moved from place to place: but in dark weather, when the sea was rough and troubled, it would be as dark as night, in the bell; but then the doctor perceived he could keep a candle burning in the bell, as long as he pleased, it being found, by experiment, that one candle consumes much about the same quantity of confined air, as one man does, viz. about a gallon per minute. The only inconvenience the doctor complained of, was, that upon first going down, they felt a small pain in their ears, as if the end of a quill were forcibly thrust into the hole of the ear. This may proceed from its being some time before the air can get from the mouth, through the small canal of the eustachian tube, which leads to the inner cavity of the ear, where, when it comes, it makes an equilibrium with the outward air, pressing on the tympanum, and thus the pain, for a short time, ceases: then descending lower, the pain of the ear returns, and is again abated; and so on, till you come down to the bottom, where the air is of the same density continually. This bell was so improved by the doctor, that he could detach one of his divers to the distance of fifty, or a hundred yards from it, by a contrivance of a cap, or head-piece, somewhat like an inverted hand-basket, as at F, with a glass in the fore-part, for him to see his way through. This cap was of lead, and made to fit quite close about his shoulders; in the top of it was fixed a flexible pipe, communicating with the bell, and by which he had air, when he wanted, by turning a stop cock near his head-piece. There was also another cock at the end in the bell, to prevent any accident happening from the perfon without. This person was always well clothed with thick flannel, which were warmed upon him, before he left the bell, and would not suffer the cold water to penetrate. His cap contained air enough to serve him a minute or two: then by raising himself above the bell, and turning the cock F, he could replenish it with fresh air. This pipe he coiled round his arm, which served him as a clue to find his way to the bell again.

This diving bell received its last improvement from Mr. Martin Triewald, F. R. S. and military architect to his Swedish majesty. The manner and form whereof is shewn in a figure of his own drawing. (ibid. n. 2.) A B is the bell, which fills with leaden weights D, D, appended at the bottom: the substance of the bell is copper, and tinned within all over: the bell is illuminated with three strong convex lenses G, G, G, with copper lids H, H, H, to defend them. The iron ring, or plate E, serves the diver to stand on, when he is at work, and it is suspended at such a distance from the bottom of the bell, by the chains F, F, F, that when the diver stands upright, his head is just above the water in the bell, where it is much better than higher up in it, because the air is colder, and consequently more fresh, and fit for respiration: but as there is occasion for the diver to be wholly in the bell, and his head of course in the upper part, Mr. Triewald has contrived that, even there, when he has breathed the hot air as long as he well can, by means of a spiral copper tube b, placed close to the inside of the bell, he may draw the cooler and fresher air from the lowermost parts; to which end, a flexible leather tube, about two feet long, is fixed to the upper end of the tube at b; and to the other end of this tube is fixed an ivory mouth-piece for the diver to hold in his mouth, by which to respire the air from below.

DIVING-BLADDER, a term used by Borelli, for a machine which he contrived for diving under water to great depths. The vesica, or bladder, as it is called, is to be of brass or copper, and about two feet diameter. This is to contain the diver's head, and is to be fixed to a goat's skin exactly fitted to the body of the diver. Within the vesica are pipes, by means of which, a circulation of air is contrived, and the person carries an air pump by his side, in order to make himself heavier and lighter, as the fishes do by contracting or dilating their air-bladder.

DIVINITY, properly signifies the nature, quality, and essence of the true God. See the article God.

The heathen divinities may be reduced to three classes. 1. Theological, representing the divine nature under divers attributes. Thus Jupiter is the absolute power of God, Juno his justice, &c. 2. Physical. Thus Eolus is that power in nature which collects vapours and exhalations.
DIV [952] DIV

halations in order to form winds. 3. Moral. For example, the furies are only the secret reproaches and flings of con-
science.
DIVINITY is also used in the same fene with theology. See THEOLOGY.
DIVISIBILITY, that property by which the particles of matter in all bodies are capable of a separation, or diffusion from each other.
The Peripatetics and Cartesians hold divisibility to be an affection of all matter. The Epicureans again, allow it to agree to every physical continuum, but they deny that this affection agrees to all bodies, for the primary corpuscles or atoms they maintain to be perfectly in-
seable and indivisible. See ATOM.
As it is evident that body is extended, so it is no less evident that it is divisible; for since no two particles of matter can exi$t in the same place, it follows, that they are really different from each other, which is all that is meant by being di-
visible. In this sense the least conceivable particle must still be divisible, since it will consist of parts which will be really different. To illustrate this by a familiar instance, let the least imaginable piece of matter be conceived lying on a smooth plane surface, it is evident the surface will not touch it every where: those parts therefore which it does not touch, may be supposed separable from the others, and so on, as far as we please; and this is all that is meant when we say matter is infinitely divisible.
The infinite divisibility of mathematical quantity is demonstrated thus geometri-
cally. Suppose the line A D (plate LXXV. fig. 2.) perpendicular to B F, and another, as G H, at a small distance from it, also perpendicular to the fame line: with the centers C C C, &c. de-
scribe circles cutting the line G H in the points e e e, &c. Now the greater the ra-
dius A C is, the less is the part e H. But the radius may be augmented in infinitum, so long therefore, the part e H may be divided into still less por-
tions, consequently it may be divided in infinitum.
All that is supposed in strict geometry, (says Mr. Maclaurin) concerning the divisibility of magnitude amounts to no more than that a given magnitude may be conceived to be divided into a number of parts, equal to any given or pro-
posed number. It is true, that the number of parts into which a given
magnitude may be conceived to be di-
vided, is not to be fixed or limited, be-
cause no given number is so great but a greater may be conceived and asigned: but there is not, therefore, any necessity of supposing the number of parts actu-
ally infinite; and if some have drawn very abstruse consequences from such a supposition, yet geometry ought not to be loaded with them.
How far matter may actually be divided, may in some measure be conceived from hence, that a piece of wire gilt with so small a quantity as eight grains of gold, may be drawn out to a length of thirteen thousand feet, the whole surface of it still remaining covered with gold. We have also a surprising instance of the mi-
nuteness of some parts of matter from the nature of light and vision. Let a candle be lighted, and placed in an open plane, it will then be visible two miles round, and consequently was it placed two miles above the surface of the earth, it would fill with luminous particles a sphere whose diameter was four miles, and that before it had lost any sensible part of its weight. A quantity of vi-
troil being dissolved, and mixed with
nine thousand times as much water, will tinge the whole, consequently will be divided into as many parts as there are visible portions of matter in that quan-
tity of water. There are perfumes which without a sensible diminution of
their quantity, shall fill a very large space with their odoriferous particles, which must therefore be of an incon-
ceivable smallness, since there will be a sufficient number in every part of that space, sensibly to affect the organ of smel1ing. Dr. Keill demonstrates that any particle of matter how small ever being given, it is possible for that small particle of matter to be diffused through all that space, and to fill it in such a manner, as that there shall be no pore in it whose diameter shall exceed any given line. See EFPLUVIA.
The chief objections against the divi-
sibility of matter in infinitum are, that an infinite cannot be contained by a finite, and that it follows from a di-
visibility in infinitum either that all bodies are equal, or that one infinite is greater than another. But the anwer to-
these is easy, for the properties of a de-
termined quantity are not to be attri-
buted to an infinite considered in a ge-

eral
DIVISION, in general, is the separating a thing into two or more parts.

DIVISION, in arithmetic, one of the four fundamental rules, whereby we find how often a less number, called the divisor, is contained in a greater, called the dividend; the number of times which the divisor is contained in the dividend being termed the quotient.

In effect, division is only a compendious subtracring: for since the divisor is so many times contained in the dividend as there are units in the quotient, if we subtrac the former from the latter as many times as possible, the sum of these subtractions will be equal to the quotient.

To perform this operation with expedition, one ought to be previously well acquainted with the table of multiplication; thus, if I know that $5 \times 5 = 25$, it will be easy for me to say how many times $5$ is contained in $25$; and so in other instances, where the dividend does not exceed the square of the divisor. But where this is the case, we must follow a different method, which is this: set down the divisor first, and then the dividend, both in the same line, but with a stroke of your pen between them, as in the example in the margin; then beginning from the left hand, set a dot under that part of the dividend in which the divisor can be found; which is the figure 7, wherein the divisor 6 is found 1: place this 1 after the dividend, only with a stroke between them, and it will make the first figure of the quotient: you must next multiply the divisor by this number, viz. $6 \times 1$, and subtrac the product from 7, and there will remain 1; after which place the next figure of the dividend, viz. 2, marking it with a dot, that you may know how many figures of the dividend are taken down. Find how many times the divisor is contained in these two figures, viz. 12, which is twice exactly: place this 2 in the quotient after the former 1; and then multiplying and subtracring, you will find no remainder.

However, taking down and dotting the next figure of the dividend, viz. 8, you will find 6 only once in it: place this 6 in the quotient, and multiplying and subtracring as formerly, there will remain 2; after which place the last figure of the dividend, which is also to be dotted, and you will have 24, wherein 6 is contained just 4 times; place this 4 in the quotient, and the operation is finished. Hence it appears, that the divisor 6 is contained in the dividend 7284 just 1214 times, as expressed in the quotient.

The method is much the same, when there are several figures in the divisor; thus, in the example annexed, as 54 is 54) 24084 (446

not contained once in 2 or 24, we must take down three figures, viz. 240, and the first dot is to be placed under the 0. We then proceed, and find 54 contained in 240 four times; this 4 we place in the quotient, and multiplying the divisor 54 by it, and subtracring the product, viz. 216 from 240, there remains 24. After this place the next figure of the dividend, viz. 8, and the sum is 248, in which 54 is found 4 times. Multiply and subtrac as formerly, and there will remain 32; after which placing the last figure of the quotient, viz. 4, you will have the sum 324, in which 54 is found just 6 times. So that the divisor 54 is contained in the dividend 24084 exactly 446 times, as expressed in the quotient.

DIVISION of fractions. See the articles DECIMAL and FRACTION.

DIVISION, in algebra, is performed by placing the dividend above a small line, and the divisor under it; expunging any letters that may be found in all the quantities of the dividend and divisor, and dividing the co-efficients of all the terms by any common measure.

Thus, if $10ab + 15ac$ is to be divided by $20ad$, they are first placed in this manner, $\frac{10ab + 15ac}{20ad}$; which after expunging the letter $a$ out of all the terms, and dividing all the co-efficients by 5, is reduced to $\frac{2b + \frac{3}{4}c}{4d}$. In the same man-
DIVISION

\[ \text{Example I. without any remainder.} \]
\[ 3a - b \]
\[ \frac{6a^2 - 9b^2}{2a^3 + 4a^2 + 8a + 16} \]
\[ \frac{12a^3 - 9b^2}{2a^3 + 2a^2} \]
\[ \frac{24a^2 - 96}{24a^2 - 96} \]
\[ \frac{45a - 96}{48a - 96} \]
\[ \frac{0}{0} \]

\[ \text{Example II. with a remainder.} \]
\[ a + x \]
\[ a^2 + x^2 \]
\[ (a - x + \frac{2x^2}{a}) \]
\[ \frac{a^2 + ax}{a - x - x^2} \]
\[ \frac{-ax + x^2}{a} \]
\[ \frac{+ 2x^2 + \frac{2x^3}{a}}{a} \]
\[ \frac{-2x^3}{a} \]
\[ \frac{-2x^3 + 2x^4}{a} \]
\[ \frac{a + x}{a^2} \]
\[ \frac{+ 2x^4}{a^2 + \&c.} \]

In this last example the signs are alternately + and –, the co-efficient is constantly 2, after the two first terms, and the letters are powers of \( x \) and \( a \); so that the quotient may be continued as far as you please, without any farther division. But in common examples of division, after you come to a remainder of one term, as \( 2x^2 \), it is usually set down in the quotient, with the divisor under it, after the other terms; and the quotient in the last example will stand thus, \( a - x + \frac{2x^2}{a + x} \).

As for the other signs of division, see the article Character.

DIVISION, among logicians, is the explanation of a complex idea, by enumerating the simple ideas whereof it is composed; in which sense it is nearly allied to definition, only that this last regards names and things, whereas division is employed wholly about ideas.

When the parts of an idea are divided, in order to a clearer exposition of the whole, this is called a subdivision: thus, a year is divided into twelve months, a month is subdivided into weeks, weeks into days, days into hours, and so on. The rules for a good division are these, that the members entirely exhaust the whole;
DIVISION, in natural philosophy, is the taking a thing to pieces, that we may have a more complete conception of the whole; this is frequently necessary in examining very complex beings, the several parts of which cannot be surveyed at one view. Thus, to learn the nature of a watch, the workman takes it to pieces, and shews us the spring, wheels, axles, pinions, balances, dial-plate, pointer, and figures of the whole machine.

DIVISION, in music, the dividing the interval of an octave into a number of less intervals. See OCTAVE.

The fourth and fifth divide the octave perfectly, though differently: when the fifth is below, and serves as a base to the fourth, the division is called harmonical; but when the fourth is below, it is called arithmetical.

To run a division, is to play, or sing, fourth, the division is called harmonical; fifth, but when the arithmetical.

DIVISION, in rhetoric, the arrangement of a discourse under several heads, each of which is to be separately spoken to.

DIVISION of proportion, among mathematicians. See the article PROPORTION.

DIVISION of a battalion, are the several parcels into which a battalion is divided in marching. The lieutenants and ensigns march before the divisions.

DIVISION, in the sea-language, the third part of a fleet of men of war, and sometimes the ninth part; which last happens when the fleet is divided into three squadrons: for then each squadron is distributed into three divisions. In a sea engagement, the order of battle is to place all the squadrons, and all the divisions of each side, in one line. This order is kept as long as the wind, and other circumstances will permit.

DIVISOR, in arithmetic, the number that divides another, called the dividend; or, which shews into how many parts the dividend is to be divided. See the article DIVISION.
DIURESIS, in medicine, an excretion of urine: whence,

DIURETICS, in pharmacy, such simples as increase the discharge of urine; or which are supposed to have a power of removing obstructions in the urinary passages. DIuretics must increase the liquor to be secreted in the proper glands, and are of the five following kinds: the first contains all relaxing and emollient decoctions, emulsions, &c., which do not stimulate, but only remove obstructions, by relaxing the vessels. The second comprehends all those which dissolve and dilute the blood. The third contains three kinds of medicines, 1. All acids which stimulate the vessels. 2. All alkaline bodies. 3. All fixed and volatile fluids. The fourth takes in all that prefer a moderate heat of the body, without sweat. The fifth class contains those whose effects discover themselves about the kidneys and bladder; also all acrid and solvent diuretics.

DIURNAL, in astronomy, something relating to the day, in opposition to nocturnal, which regards the night.

DIURNAL ARCH, the arch or number of degrees that the sun, moon, or stars describe between their rising and setting.

DIURNAL CIRCLE. See Circle.

DIURNAL motion of a planet, is so many degrees and minutes as any planet moves in twenty-four hours. Hence the motion of the earth about its axis, is called its diurnal motion. See EARTH.

DIURNAL is also used in speaking of what belongs to the nyct-hemeron, or natural day of twenty-four hours, in opposition to annual, menstrual, &c. The diurnal phenomena of the heavenly bodies, arise from the motion of the earth round its axis. For since the earth turns round its own axis from west to east, every spectator on its surface must necessarily be carried round the same way; and consequently those parts of the heavens which lie hid towards the east, will by and by come into his sight, and those which are visible to him, will depart out of it towards the west. From hence it is that the spectator not being sensible of his own motion (the reason of which is, because all things about him move along with him) imagines the whole heavens to turn round the contrary way, viz. from east to west every twenty-four hours, which is nearly the time in which the earth performs one revolution about its axis. This may be illustrated in the following manner.

Let the circle STV (Plate LXXV. fig. 3.) represent the earth; S, the place of the spectator; ABC, so much of the heavens as is visible to him in that situation; and let A be the place of the sun, or any other of the heavenly bodies. When S, the place of the spectator, is carried by the rotation of the earth about its axis to T, the visible part of the heavens will become B A D; and the point A, which before was just at one edge of the visible portion of the heavens, is now in the midst of it, or directly over the spectator’s head. Again, when the spectator is got to V, the visible part of the heavens
heavens is become A.D.X, and the point A is got to the other extremity of it, and just ready to disappear; after which it is seen no more till the spectator returns to the point S again. From this motion of the earth arises that apparent revolution of the planets and fixed stars once in twenty-four hours, as also that of the sun, and therewith the succession of day and night. See Earth.

Diurnal parallax. See Parallax.

Diurnal, diurnarius, an officer in the greek empire, who wrote down in a book, kept for that purpose, whatever the prince did, or ordered, &c. every day.

Diurnarity, in chronology, the length of duration, or long continuance of any thing. See the article Duration.

Divus and Diva, in antiquity, appellations given to men and women who had been deified. See Deification.

We find this title on medals struck for the consecration of an emperor or empress, thus, Divus Iulius, Diva Favstina AVG. &c.

Dixmude, a town of Flanders, situated on the river Ypres, about eleven miles north of the city of Ypres, and thirty-three miles west of Ghent: east long. 2° 45', and north lat. 51°.

Dizier, or St. Dizier, a city of Champagne in France, situated on the river Marne, about forty-five miles north-east of Troyes: east long. 5°, and north lat. 48° 32'.

Dizostos, in botany, a name used by the Greeks for the tuberose rooted thorny, comprehended by Linneus among the euphorbia. See the article Euphorbia.

Dizziness, in medicine, a disease of the head, called by physicians vertigo. See the article Vertigo.

Doe, in music, a note of the Italian scale, corresponding to ut of the common gamut. See the article Gamut.

Dol, the name with make law. See the article Make.

Dob-chick, in ornithology, the English name of the columbus minor. See the article Columbus.

It is a pretty little bird, smaller than the common teal; and, as is seen swimming, appears like the young of some of the duck-kind; not yet fledged or feathered.

But what is most singular in it, is, its having absolutely no tail. See plate LXXV. fig. 4. 11°. 1.

There are several other species of this bird, one of the most elegant of which is the cored dob-chick, of a blackish brown on the upper part of the back, except the ridge thereof, which is white; the ears are formed of a tuft of loose, long, and reddish feathers. Ibid. n° 2.

Doblac, a town of the Tyrolese, in Germany, situated at the foot of the Alps, about two miles north of the frontiers of the state of Venice.

Dobula, in ichthyology, a name used by some for the club. See Chub.

Docimasia, in Greek antiquity, a probation of the magistrates and perions employed in public business at Athens. It was performed publicly in the forum, where they were obliged to give account of themselves and their past life before certain judges. Among several questions proposed to them, we find the following, whether they had been dutiful to their parents, had served in the wars, and had a competent estate.

Dock, lapathum, in botany and medicine. See Lapathum.

Dock, or Docking, in law, an expedient for cutting off an estate-tail in lands or tenements, that the owner may be enabled to sell, give, or bequeath the same.

Dock, in maritime affairs, is a pit, great pond, or creek, by the side of an harbour, made convenient either for the building or repairing of ships. It is of two forts, 1. Dry-dock, where the water is kept out by great flood-gates, till the ship is built or repaired, when the gates are opened, and the water let in to float and launch her. 2. Wet-dock, a place where the ship may be hauled into, out of the tide's way, and so dock herself, or sink herself a place to lie in.

Dock, in the manage, called by the French troufqueune, is a large cafe of leather, as long as the dock of a horse's tail, which covers the tails of leaping horses. It is made fast by straps to the crupper, and has leathern thongs that pass between his thighs, and along the flanks to the saddle-straps, in order to keep the tail tight, and to hinder it to whisk about, or make the horse appear broader at the croupe.

Dock, among sportsmen, the fleshly part of a boar's chin, between the middle and the buttocks.

Dock-Yards, in ship-building, are magazines of all sorts of naval stores. The principal ones in England are those of Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace, ships of war are laid up in these docks; those of the first rates mostly at Chatham,
Chatlham, where, and at other yards, they receive from time to time such repairs as are necessary. These yards are generally supplied from the northern crown with hemp, pitch, tar, rosin, &c. but as for malt, particularly those of the larger size, they are brought from New England.

How much it imports the good of the public to keep these magazines constantly in our English plantations, might meet the before-mentioned commodities, with all time or other, it may prove difficult to get them goods.

A brief in writing, made on a small piece of paper, or parchment, containing the purport and writing. The title of a faculty, and is created in the XIIth century, the scholastic degrees of bachelors and licentiates, by Peter Lombard and Gilbert Porrens, the human sciences, and the scholastic sciences depending on revelation and imitation of Lombard’s Sentences, not necessary. Thefe yards are necessary. Thefe yards, particularly those of the larger size, they are brought from New England.

To pass doctor in divinity, the candidate must have been five years batchelor of laws, or seven years master of arts. To pass doctor in phyfic, he must have been batchelor in phyfic five years, or seven years master of arts. It is remarkable, that by a statute of 37 Hen. VIII. a doctor of civil law may exercise ecclesiastical jurisdiction, though a layman.

Doctor, is also an appellation adjoined to several specific epithets, expressing the merit of some of the schoolmen: thus Alexander Hales is called the irrefragable doctor; Thomas Aquinas, the angelic doctor; St. Bonaventure, the seraphic doctor; John Duns Scotus, the subtle doctor; Raimond Lully, the illuminated doctor; Roger Bacon, the admirable doctor, &c.

Doctor of the church, a title given to certain of the fathers, whose doctrines have been most generally received: of these are usually reckoned four in the Greek church, viz. St. Athanasius, St. Basil, St. Gregory Nazianzen, and St. Chrysoptom; and three in the Latin church, namely St. Jerom, St. Augustin, and Gregory the great.

Doctor, διάκοιτας, in the Greek church, is a particular officer appointed to interpret part of the scripture. He who explains the gospels is called doctor of the gospels; he who explains St. Paul’s Epistles, doctor of the apostle; and he who interprets the Psalms, doctor of the psalter. The grecian bishops still confer those sorts of offices by imposition of hands, as it is practised in ordinations.

Doctor of the law, a title of honour among the Jews. The investiture, if we may so fay, of this order was performed by putting a key and a table-book in their hands, which is what some authors imagine our Saviour had in view, Luke xi. 52. when speaking of the doctors of the law, he says, “Woe unto you, doctors of the law, for you have taken away
away the key of knowledge, you entered not in yourselves, and them that were entering you hindered.” The greek text of St. Luke calls them υψίκοι, and the vulgate legis periti: agreeably to which our english translators call them lawyers. The word υψίκοι, however, in St. Matt. is rendered by the vulgate legis dòctor, though the english version still retains the word lawyer.

These jewifh doctors are otherwise called rabbins. See the article RABBI.

DOCTORS-COMMONS. See College of civilians.

DOCUMENT, in law, some written monument produced in proof of any thing affer ted.

DODARTIA, in botany, a genus of the didymnia-angioafrica class of plants, the flower of which consists of one ringed petal, with the upper lip erect, and apicifid; and the lower lip patent, twice broader than long, and trifid: the fruit is a globose bilocular capsule, containing a great number of very small seeds. See plate LXXVI. fig. 1.

DODDER, the english name of a plant, called by authors cuscuta. See the article CUSCUTA.

DODECACTIS, in zoology, a species of star-fish with twelve rays.

DODECADACTYLON, in anatomy, the name with the duodenum. See the article DUODENUM.

DODECAGON, in geometry, a regular polygon consisting of twelve equal sides and angles.

DODECAGON, in fortification, is a place surrounded by twelve bastions.

DODECAHEDRON, in geometry, one of the platonic bodies, or regular solids, contained under twelve equal and regular pentagons. Its solidity is found by multiplying the area of one of the pentagons by 12, and then this product by $\frac{3}{2}$ of the distance of the face from the center of the dodecahedron, which is the same with the center of the circumferibing sphere. The side of a dodecahedron, inscribed in a sphere, is the greater part of the side of a cube, inscribed in the same sphere, cut into extreme and mean proportion. If the diameter of the sphere be 1.0000, the side of the dodecahedron, inscribed in it, will be .5528 nearly. All dodecahedrons are similar, and are to one another as the cubes of their sides; their surfaces are also similar, and therefore they are as the squares of their sides; whence as .50928 is to 10.34.59, so is the square of the side of any dodecahedron to the superficies thereof; and as .7637 is to 2.78276, so is the cube of the side of any dodecahedron to the solidity of it.

DODECANDRIA, in the linean system of botany, a class of plants, the eleventh in order, comprehending all those with hermaphroditic flowers, and only twelve stamens in each: such are agrimony, astra rum, rhizophora, &c.

DODECATEMORY, an appellation given to the twelve signs of the zodiac, because each of them contains a twelfth part of the whole. See Sign.

It is also applied to the twelve houses or parts of the zodiac of the primum mobile, to distinguish them from the twelve signs. See the article HOUSE.

DODECUPULA DI CROME, in the italian music, a name given to the triple $\frac{7}{2}$, in four of which twelve notes are required, instead of four in common time.

DODECUPULA DI SEMI CROME, is our triple $\frac{7}{2}$, wherein there are twelve notes instead of sixteen, in a bar of duple time.

DODO, in ornithology, a large exotic bird, supposed to belong to the javan-kind, only some-what bigger than the common swans: add to this, that its head is covered with a membrane resembling a hood. See plate LXXXVI. fig. 2.

DODONÆA, in botany, a genus of plants, of the olsandria-monogynia class: it has no corolla; the fruit is a roundish trilocular capsule, with prominent inflated angles, containing solitary seeds.

DODONÆA is also a name given by Plu nier to the ilex. See ILEX.

DODONIAN, dodonæus, in antiquity, an epithet given to Jupiter, because he was worshiped in a temple built in the forest of Dodona, where was the most famous and it is said the most antient oracle of all Greece. It is reported that the pigeons and the very oaks of the forest of Dodona spoke and delivered oracles. In the temple was a fountain, which the antient naturalists affir me we had a property of re-kindling torches when newly extinguished. It is also said to have extinguished lighted torches, which is no great miracle, since plunging them into a place where the air was too dense, or into the water, must necessarily have that effect.

DODRANS, in antiquity, three fourths of the as. See the article AS.

DOESBURG,
the fruit is composed of oblong, acuminate follicles, each formed of two valves and containing one cell; the seeds are numerous, very small, and coronated with long down.

Dog-berry-tree, a name sometimes used for the cornel-tree. See Cornus.

Dog-days, the name with those called canicular. See Canicular.

Dog-draw, a term in the forest-law, used when a man is found drawing after a deer, by the scent of a hound which he leads in his hand.

Dog's fen nel, in botany, a name by which the cotula is sometimes called. See the article Cotula.

Dog-fly, a kind of fly so called from its being particularly troublesome to dogs: it is not unlike that species which infests cattle.

Dog's grass. See the article Grass.

Dog's mercury, in botany, the name of a species of mercury. See Mercury.

Dog's rose, a name sometimes given to the common briar, or hip-bush, a species of wild rose. See the article Rose.

Dog's stones, a species of orchis, said to be a great provoking to venery.

Dog's tail, in botany, the name with the cyno phorus. See Cynosurus.

Dog's tongue, dens canis, a plant called by Linnaeus, erythronium. See the article Erythronium.

Dog's tooth shell, the same with the dentalium. See Dentalium.

Dog-wood, the same with the dog- berry-tree, supra.

Dog-wood of Jamaica, the robinia of botanical writers. See Robinia.

Dog-wood of Virginia, a species of bay-tree. See the article Laurus.

Dogado, a duchy of Italy, of which Venice is the capital. See Venice.

Dogge, the chief magistrate in the republics of Venice and Genoa.

This dignity is elective in both places; at Venice it continues for life, at Genoa it is only for two years. His title is serenity: he is chief of the council, and mouth of the republic, he being to answer for her. The Venetians do not go into mourning at his death, being only the phantom of majesty, as all the authority is vested in the republic; the dogge only lends his name to the senate; the power is diffused through the whole body though answer to foreign ambassadors, &c. are made in the name of the doge.

The
The money is struck in his name, but does not bear his arms. All the magistrates rise and salute him when he comes into the council; but he rises to none but foreign ambassadors. He must not stir out of Venice, without leave of the councilors, &c.

Doggers, in the alum-works, a poor kind of alum-ore. See ALUM.

Doggers is also a name used for fisher vessels; whence, in some of our old statutes, we meet with dogger-men, denoting the fishermen of those vessels.

Doggis denote iron machines for burning wood on; also hooks fixed in large timbers, for drawing them with horses.

Dogma, a principle, maxim, tenet, or settled opinion, particularly with regard to matters of faith and philosophy.

Dogmatical, something belonging to a doctrine or opinion. A dogmatical philosopher is one who afferts things positively; in opposition to a sceptic, who doubts of every thing.

Dogmatists, dogmatici, a sect of antient physicians, of which Hippocrates was the first author. They are also called logici, logicians, from their using the rules of logic in subjects of their profession. They laid down definitions and divisions, reducing diseases to certain genera, and those genera to species, and furnishing remedies for them all; supposing principles, drawing conclusions, and applying those principles and conclusions to particular diseases under consideration: in which sense the dogmatists fland contradistinguished from empirics and methodists. They reject all medicinal virtues that they think not reducible to manifest qualities; but Galen hath long ago observed of such men, that they must either deny plain matter of fact, or assert but very poor reasons and causes of many effects they pretend to explain.

Dole, in our antient customs, signified a part, or portion, most commonly, of a meadow, where several persons have share. It also signifies a distribution or dealing of alms, or a liberal gift made by a great man to the people.

Dole-fish seems to be that fish which the fishermen, yearly employed in the north seas, do, of custom, receive for their allowance or shares.

Dole, in the law of Scotland, is used for malevolent intention.

Dole, in the law of Scotland, as well as dolum in the civil law, from whence it is taken, is an essential ingredient to constitute an action criminal. In crimes where, in the will, not the event, must be regarded, no negligence can equal dole, unless the negligence be so extremely Fortune, as not to be conceivable without im- plying dole.

Under dole are comprehended the vices and errors of the will, which are immediately productive of the criminal fact, though not premeditated, but the effect of sudden passion. In this respect dole differs from what the English law calls malice. See the article MALICE.

Dolet, a term sometimes used for red vitriol, or colchothar of vitriol.

Dolg-bote, in our old writers, signifies a recompense for a fear or wound.

Dolichos, in botany, a genus of the diadelphs-decandria class of plants, the corolla of which is papilionaceous; the vexillum is roundish, large, emarginated, and wholly reflected; the fruit is a large, acuminate, oblong pod, composed of two valves, and containing two cells; the seeds are numerous, elliptical, and frequently compressed.

Doliman, a kind of long caslock, worn by the Turks, hanging down to the feet, with narrow sleeves buttoned at the wrist.

Dolium, in natural history, the name of a genus of shells, called by some concha-globosae.

The dolium is a simple shell, without any hinge, formed of one continuous piece, which makes a body of a figure approaching to round, distended, and, as it were, inflated. The animal inhabiting this shell is a limax. See the article LIMAX.

Some of these have the mouth dentated; others smooth; in some the clavicle is moderately long, though in most it is depressed; and the columella is in some species smooth, in others wrinkled; these shells are found on the shores of many parts of the East-indies, and are also frequently brought from America. See plate LXXVI. fig. 3.

Dollar, a silver coin current in several parts of Germany and Holland. There are various species of dollars, as the rix-dollar, the semi-dollar, the quarter-dollar, &c. for each of which see COIN.

Dolphin, in ichthyology, the English name of the delphinus, with an oblong rounded body, and a long acute rostrum. It is considerably longer than the por-puffe: the opening of the mouth is vastly wide, reaching on each side to the breast; and
DOM, or DON, DOLPHIN, DOLPHIN is in archit:ecture, DOMAIN, DOMESDAY; or DOOMS-DAY-BOOK, DOME, or DOOM, lignifies; in old chuters, signifies sir, or lord. This title, it seems, was of the king, since it is looked upon as a mark of honour and nobility. In France, it is sometimes used among the religious. It is an abridgment of domus, from dominus.

DOM AND SOM, in old charters, signifies full property and jurifdiction.

DOMAIN, the inheritance, estate, or pol:le:ion of any one. See Domesnes.

DOME, in architecture, a spherical roof, or a roof of a spherical form, raised over the middle of a building, as a church, hall, pavilion, vestibule, stair-case, &c. by way of crowning. Domes are the same with what the Italians call cupolas, and we cuppolas: Vitruvius calls them that. See the article CUPOLA, &c.

They are generally made round, or resembling the bell of a great clock; but there are some instances of square ones, as those of the Louvre. Some of them also are in the form of polygons, as that of the jefuit's church in the Rue St. Antoine, at Paris. Domes have commonly columns ranged around their outsides, both for the sake of ornament and support to the work.

DOME, or DOOM, signifies also a sentence, judgment, or decree.

DOMEA, a great river of Tonquin, in Asia, sometimes called Chaulieu.

DOMESDAY, or DOOMS-DAY-BOOK, a very antient record made in the time of William the Conqueror, which now remains in the exchequer, and consists of two volumes, a greater and a less; the greater contains a survey of all the lands in most of the counties in England, and the less comprehends some counties that were not then surveyed. The book of domes-day was begun by five justices, assigned for that purpose in each county, in the year 1081, and finished in 1086. It was of that authority, that the Conqueror himself submitted, in some cases wherein he was concerned, to be determined by it. Camden calls this book the Tax-book of king William; and it was farther called Magna rolla.

There is likewise a third book of Domes-day, made by command of the Conqueror; and also a fourth, being an abridgment of the other books.

Domes-men, judges or perions appointed to determine suits and controversies between parties. See Day's man.

DOMESTIC, any man who afts under another, serving to compose his family; in which he lives, or is supposed to live, as a chaplain, secretary, &c. Sometimes domestic is applied to the wife and children, but very seldom to servants, such as footmen, lacquies, porters, &c.

DOMESTIC, domestic, in antiquity, was a particular officer in the court of Constantinople.

According to some, this officer was one intrusted to manage affairs of importance; others say, the greek domestici were the same with the roman comites; and that they began first to be used when court became a dignity; domestics therefore were such as served the prince in the administration of affairs, as well those of the family, as the affairs of justice and the church.

The grand domestici, or Megadomesticus, was a sort of dapifer, or major domo. See the articles DAPIFER and MAJOR DO MO.

DOMESTICUS MENSE, officiated as grand seneschal, or steward.

DOMESTICUS REGIO: DOMESTICUS, did the office of matter of the household.

DOMESTICUS SCHOLARUM, or LEGIONUM, commanded the referred forces, called schola palatina, whose office it was to put the immediate orders of the emperor in execution.

DOMESTICUS MURORUM had the superintendance of all the fortifications.

DOMESTICUS REGIONUM was a sort of attorney, or solicitor-general, of the east and west.

DOMESTICUS ICANATORUM commanded the military cohorts. There were several other officers of the army, who were called by the name Domesticus, which meant no more than their commander. There were also two domestici chorii, or chantors, called also protephytai, belonging to the church at Constantinople; one of them was on the right side of the church, and the other on the left.
DOMESTICI, was also a body of forces in the Roman empire.

Pancirollus takes them to be the same with those called protectores, who had the chief guard of the emperor's person, in a degree above the praetorians, and who, under the Christian emperors, had the privilege to bear the grand standard of the court. They are supposed to have been 2500 before Justinian's time, who added 2000 more to the number. They were divided into several companies, or bands, called schola. Some whereof are said to have been instituted by Gordian: some of them were cavalry, and others infantry. Their commander was called comes domesticorum.

DOMESTIC NAVIGATION, coasting, or sailing along the shore, in which the lead and compass are the chief instruments.

DOMIFYING, in astrology, the dividing or distributing the heavens into twelve houses, in order to erect a theme, or horoscope, by means of six great circles, called circles of position.

There are various ways of domifying: that of Regiomontanus, which is the most common, makes the circles of position pass through the intersections of the meridian and the horizon: others make them pass through the poles of the zodiac.

DOMINANT of a mode, in music, that sound which makes a perfect fifth to the final in authentic modes; and a third to the final or sixth, to the lowest chord of a plagal mode. See the articles Mode and Final.

DOMINATION, in theology, the fourth order of angels, or blessed spirits, in the hierarchy, reckoning from the seraphim.

DOMINGO, or St. Domingo, the capital of the island of Hispaniola, the seat of an archbishop, and the most ancient royal audience in America: west long. 70° north lat. 18° 20'.

DOMINI, or ANNO DOMINI. See the article ANNO.

Bull in Ceno Domini. See the article BULL.

DOMINICA, one of the Caribbean-islands, subject to Britain: west long. 61° 20' north lat. 16°.

DOMINICAL LETTER, in chronology, is that letter of the alphabet which points out in the calendar the Sundays throughout the year, thence also called Sunday-Letter. See Calendar and Bisextile. The distribution of days into weeks is made by the seven first letters of the alphabet A, B, C, D, E, F, G, beginning, at the first of January, to place the letter A; to the second of January B is joined; to the third C; and so on to the seventh, where G is figured: and then again beginning with A, which is placed at the eighth day, B will be at the ninth, C, at the tenth, and so continually repeating the series of these seven letters, each day of the year has one of them in the calendar. By this means the last of December has the letter A joined to it, for if the 366 days, which are in a year, be divided by seven, we shall have fifty-two weeks, and one day over. If there had been no day over, all the years would constantly begin on the same day of the week, and each day of a month would constantly have fallen on the same day of the week; but now, on account, that besides the fifty-two weeks in the year, there is one day more, it happens, that on whatever day of the week the year begins, it ends upon the same day, and the next year begins with the following day.

The letters being ranked in this order, that letter which answers to the first Sunday of January, in a common year, will shew all the Sundays throughout the year, and to whatever days in the rest of the months, that letter is put, these days are all Sundays. If the first day of January be on a Sunday, the next year will begin on Monday, and the Sunday will fall on the seventh day, to which is annexed the letter G, which therefore will be the Sunday letter for that year: the next year beginning on Tuesday, the first Sunday will fall on the sixth of January, to which is joined the letter F, which is the Sunday letter for that year; and in the same manner, for the next following, the dominical letter will be E; and so on. By this means the Sunday letters will go on in a retrograde order, viz. G, F, E, D, C, B, A. But because every fourth year consists of 366 days, the series of letters will be interrupted, and the order will not return till twenty-eight years, or four times seven; and hence arises the cycle of twenty-eight years. See the article CYCLE OF THE SUN. Thus, if in a leap year, the first of January be Sunday, and consequently the dominical letter A, the twenty-fourth day of February will fall on a Friday, and the twenty-fifth on a Saturday; and
DOM [964]

This question, by the above rule, will be solved in the following manner, 18 ÷ 4 = 4 from which subtracting 1; and the remainder 3 taken from 18, gives 15, which being subtracted from 21, the nearest evens gives 6, the number to be added. Then to the given year 1842, add its fourth part 460, and the number found 6, the sum is 2308; which being divided by 7, gives 329 for the quotient, and the remainder is 5; which taken from 7; leaves 2, the index of the letter B, the dominical letter required.

DOMINICANS, an order of religious, called in France, jacobihs, and in England, black fryers, or preaching fryars. This order, founded by St. Dominic, a native of Spain, was approved of Innocent III. in 1215, and confirmed by a bull of Honorius III. in 1216. The design of their institution was, to preach the gospel, convert heretics, defend the faith, and propagate christianity. They embraced the rule of St. Augustine, to which they added statutes and constitutions, which had formerly been observed either by the Carthusians or Premonstratensians. The principal articles enjoined perpetual silence, abstinence from flesh at all times, wearing of woollen, rigorous poverty, and several other austerities. This order has spread into all the parts of the world. It has produced a great number of martyrs, confessors, bishops; and they reckoned three popes, sixty cardinals, 150 archbishops, and 800 bishops of their order, besides the masters of the sacred palace, who have always been dominicans. They are inquisitors in many places. The nuns or sisters of this order, owe their foundation to St. Dominic himself, who built a monastery at Prouilles, where poor maids might be brought up and supplied with all necessaries for their subsistence. The habit of these religious was a white robe, a tawney mantle, and a black veil. Their founder obliged them to work at certain hours of the day, and particularly to spin yarn and flax to make their own linnen. The nuns of this order have 150 houses in Italy, forty-five in France, fifty in Spain, fifteen in Portugal, forty in Germany, and many in Poland, Ruffia, and other countries. They lie on straw beds, and never eat flesh excepting in sickness; but many monasteries have mitigated this austerlity.
DOMINION, dominium, in the civil law signifies the power to use or dispose of a thing as we please. Dominium plenum, is when the property is united with the possession. Dominium nudum, when there is the property without the possession. Dominium is again divided into that which is acquired by the law of nations, and that which is acquired by the civil law. The former can never be got without possession, the latter may.

Another distinction of dominium is, into natural and civil. Natural is that which is common to all nations, or that which is acquired by the means which all nations use in acquiring estates. Civil is peculiar to the roman citizens, and consists of these three methods. Sale, prescription, cession of right. DirecIum dominium, is the right alone of dominion. Dominium utile, the profit redounding from it. Thus the wife retains the dominium directum of her jointure, and the dominium utile passes to her husband.

DOMINUS, domain, in our ancient customs.

See the article DOMAIN.

DOMINUS, in the civil law, he who possessest any thing by right of purchase, gift, loan, legacy, inheritance, payment, contract, or sentence.

DOMINUS, in the feudal law, he who grants a part of his estate in fee to be enjoyed by another.

DOMINUS, in the antient times, a title prefixed to a name, usually to denote the person either a knight or a clergyman.

Recto quando Dominus remittit. See the article RECTO.

Domo reparando, in law, is a writ which lies for a person against his neighbour, whose house he fears will fall to the damage of his own.

DON, the name of two rivers; one very large, which after dividing Asia from Europe, falls into the Palus Moetis; the other, in the county of Aberdeen in Scotland.

DONATION, an act whereby a person transfers to another either the property or the use of some thing, as a free gift. In order to be valid, it supposes a capacity both in the donor and donee, and requires consent, acceptance, and delivery; and, by the French law, also regiftary. Civilians distinguish donation into pure and conditional. Donatio pura is when one gives a thing with an intention that it become immediately the property of the donee, never to revert to the donor; and this from no other motive, than his generosity. Donatio conditioni is when one gives a thing with an intention that it become the property of the donee, upon performing some condition stipulated.

DONATISTS, christian schismatics in Africa, who took their name from their leader Donatus. A secret hatred against Cacilian, elected bishop of Carthage about the year 311, excited Donatus to form this sect. He accused Cacilian of having delivered up the sacred books to the pagans, and pretended that his election was void, and all his adherents heretics. He taught that baptism administered by heretics was null, that every church but the African became prostituted, and that he was to be the reformer of religion. Some accufe the donatists of arianism. Constantius and Honorius made laws for their banishment, and Theodolius and Honorius condemned them to grievous mullets.

DONATIVE, a gratuity, or present made to any person.

Donative among the Romans was properly a gift made to the fiolders, as cong iarum was that made to the people. See the article CONG IAR IUM.

Salmatus says, the common and legitimate rate of a donative, was three pieces of gold per head; and Caflaubon observes, that the legal donative was 20,000 denaries; and that it was not customary to give less, especially to the prætorian fiorders; that the centurions had double, and the tribunes, &c. more in proportion.

Donative, in the canon-law, is a bene- fice given by the patron to a priest, without presentation to the ordinary, and without institution or induction. The king may found a church or chapel, and exempt it from the jurisdiction of the ordinary. He may also by his letters patent grant licence to a common person to found such a church, and ordain it to be made donative. The resignation of a donative must be to the donor or patron, nor may the ordinary visit the same, but the patron by commissiurers appointed by him. There can be no lape of this benefice, though the bishop may compel such patron to nominate a clerk by ecclesiastical censures; and the clerk must be qualified as other clergies of churches are.
DONAWERT, a city of Bavaria in Germany, forty miles north-west of Ulm: east long. 10° 40' north lat. 48° 40'.

DONAX, in ichthyology, a name used by some for the siren. See the article SOLEN.

DONAX, in botany, the great reed. See the article REED.

DONCASTER, a market town of York-shire, thirty miles south of York. See the article YORK.

DONEE. See the article DONOR.

DONJON, in fortification, signifies a strong tower, or redoubt of a fortress, whether the garrison may retreat, in case of necessity, and capitulate with greater advantage.

DONOR, in law, the person who gives lands or tenements to another in tail, &c., as he to whom such lands, &c., are given is the donee. See DONCASTER, _a town of France in the province of Guienne,

DONZY, a town of France in the Orléannoise east long. 3° 16', north lat. 47° 17'.

DOOR, in architecture, an aperture in a wall, to give entrance and exit into and out of a building, or any apartment thereof.

It is laid down as a rule, that the doors of an house be as few in number, and as moderate in dimensions, as possible; as all openings are weakenings. Secondly, that they do not approach too near the angles of the walls, it being a very great solecism to weaken that part which strengthens all the rest.

Thirdly, that the doors, if possible, be placed over one another, that void may be over void, and full over full, which circumstance will greatly strengthen the whole fabric.

Fourthly, that, if possible, they may be opposite to each other, in such a manner, that one may see from one end of the house to the other, which will not only be very graceful, but most convenient, in respect that it affords means of cooling the house in summer, by letting the air through it, and by keeping out the wind in winter, which way ever it fit.

Fifthly, 'tis not only ornamental, but very secure, to turn arches over doors, which will discharge them in great measure from the superincumbent weight. The proportions of doors are adjusted by those of a man. In large buildings, they must be always larger than in smaller: but should not be less than six feet high in any, to admit a man of a just stature erect; and as the breadth of a man, with his arms placed akimbo, is nearly subduple his height, the width ought never to be less than three feet. Some architects give us these dimensions following: in small buildings, the breadth of the door four feet, or four and a half; in middling buildings five, or six; in large ones seven, or eight: in chambers of the first story three and a half, three and three-fourths, or four; of the second, four, or four and a half; and of the third, five, or six; in churches seven or eight; in gates, nine, ten, or twelve: hence their height is easily determined, except for the gates of cities, which should only be four-fifths of their breadth.

In plate LXXVI., fig. 5, are represented two doors, of which that marked N is two diameters high; and that marked O, 2 5/6 diameters. Here the architrave being divided into three parts, two is for the breadth of the pilaster, as at P; and on these pilasters are placed the trusses, spires, or corbels, as in Q; whose shape is almost at pleasure. If either of these be used as frontispieces of external doors, the pediment ought not to be broken, or opened, and the architrave should stand on a plinth, equal to two thirds thereof, or to the height of the step, by which one ascends into the house.

DORADO, in ichthyology, the same with guaracapema. See GUARACAPEMA.

DORCHESTER, the capital of Dorsetshire, situated on the river Frome, six miles north of Weymouth; well long. 2° 35', and north lat. 50° 40'. It gives the title of marquis to the noble family of Pierpoint, dukes of Kingston, and fends two members to parliament.

DORDONNE, a river of France, which runs through the province of Guisene, and falls into the Garonne, twelve miles below Bourdeaux.

DORDRECHT, in geography. See DORT.

DOREAS LYBICA, in zoology, the same with the gazella. See GAZELLA.

DOREE, or JOHN DOREE, a fish called by authors faber. See the article FABER.

DORIA, in botany, the name by which some call a species of solidago. See the article SOLIDAGO.

DORIC, in general, any thing belonging to the Dorians, an ancient people of Greece, inhabiting near mount Parnassus.

DORIC ORDER, in architecture, the second of the five orders, being that between the tuscann and ionic. See the articles ORDER, TUSCAN, and IONIC.
This order seems the most natural and best proportioned of all the orders, the several parts of it being founded on the natural position of solid bodies. Accordingly, the doric is the first, and most ancient of the orders of architecture, and is that which gave the first idea or notion of regular building. See plate LXXVII, fig. 1.

It was indeed more simple at its first invention, than it is at present; and when they came in after times to adorn and enrich it more, the appellation of Doric was restrained to this richer manner; and then they called the primitive, simple manner; by the new name of Tuscan.

Some time after its invention, it was reduced to the proportions, strength and beauty of the body of a man: hence as the foot of a man was judged the sixth part of his height, they made the doric column six diameters high. After that, they added another diameter to it, and made it seven; which augmentation seemed to bring it nearer to the proportion of a man; the human foot, at least in our days, not being a sixth but nearly a seventh part of the body.

The characters of the doric order, as they are now managed, are, the height of its column, which is eight diameters; the frieze which is adorned with triglyphs, drops, and metopes; its capital, which is without volutes, and its admitting of cymatiums.

It has been already observed, that the ancients had two dorics; the first of which was the more simple and massive, and was chiefly used in temples; the second, which was the more light and delicate, they used in porticoes and theatres.

The doric is used by the moderns, on account of its solidity, in large, strong buildings, as in the gates of cities and citadels, the outsides of churches, and other mazy works, in which delicacy of ornaments would not be suitable.

The most considerable ancient monuments of this order is the theatre of Marcellus at Rome, the capital, the height of the frieze, and projection of which are much smaller than in the modern architecture.

Vignola adjusts the proportion of the doric order as follows: he divides the whole height of the order without the pedestal into twenty parts, or modules, one of which he allows to the base; fourteen to the frieze, or fust; one to the capital, and four to the entablature; the several parts and members may be seen under their respective heads. See the articles COLUMN, CORNICHE, BASE, FRIEZE, &c.

The DORIC order delineated by equal parts, instead of modules and minutes. The height of the pedestal being two diameters, and \( \frac{2}{7} \), is divided into 4, giving one to the base, whose plinth is \( \frac{2}{7} \) thereof; the other part is divided into seven, giving four to the torus, one to the fillet, and two to the hollow. The breadth of the dye is a diameter and one third. The projection of the base is equal to its height, and the fillet has \( \frac{4}{7} \) of these parts. The height of the coriniche is half the base, being \( \frac{3}{7} \) of the whole height; and is divided into nine, giving two to the hollow, one to the fillet, five to the corona, and one to the fillet: the projection of the hollow is three of these parts, of the corona six, and of the whole seven.

BASE of the column. The height is half a diameter, and is divided into six, giving two to the plinth, \( \frac{1}{3} \) and \( \frac{1}{7} \) to the lower torus, \( \frac{1}{6} \) to the fillet, one to the scotia, \( \frac{2}{7} \) to the fillet, and one to the upper torus. The fillet above the torus is equal to the others, and is part of the column. The projection is two of these parts, and one third thereof is for the upper fillet, and \( \frac{3}{7} \) to the upper torus, and the fillet, under it, is perpendicular to the center. For forming the scotia, divide its height into 3, and on the line that separates the one part above from the other two parts below, and perpendicular to the fillet, is the center for the first quarter sweep; and the same distance forwards, in the line, is the center for the other quarter, and is also the projection of the lower fillet.

The diminishing of this column is \( \frac{1}{6} \) of the diameter. The height of the capital is half a diameter, and is divided into 9, giving three to the frieze of the capital, one to the fillets, which are three, and are equal; two to the ovolo, two to the abacus, and one to the ogee and fillet which is \( \frac{2}{7} \). For the projections, the fillets have one of these parts, the abacus three, and the whole four.

The height of the architrave is \( \frac{1}{4} \) a diameter, and is divided into six parts, giving two to the first face, two to the second, one to the bells and fillet, which is one third, and one to the band at top; the projection is equal to the band.
The frieze is in height $\frac{3}{4}$ of the diameter, and the triglyphs are in breadth $\frac{1}{4}$ a diameter, which are divided into 6, giving 1 to each of the channels, and 1 to the spaces between the channels.

The projection from the naked of the frieze is $\frac{1}{2}$ of a part; and the spaces, or metopes, between the triglyphs, ought to be equal to the height of the frieze.

The height of the cornice is $\frac{1}{4}$ of the diameter, and is divided into 9, giving 1 to the cap of the triglyph, 1 to the hollow and fillet, which is $\frac{1}{3}$, 1 to the ovolo, 1 to the mutule and fillet under it, which is equal to the other; $\frac{1}{4}$ part to the cap of the mutule and fillet, which is $\frac{1}{3}$, 1 and $\frac{1}{3}$ to the corona, $\frac{1}{2}$ to the fillet, 1 and $\frac{1}{2}$ to the cima reversa, $\frac{1}{2}$ to the fillet, 1 and $\frac{1}{2}$ to the cima recta, and $\frac{1}{4}$ part to the fillet.

For the projections, the cap of the triglyph hath 1 of these parts, the hollow 1 and $\frac{1}{3}$, the ovolo 2 and $\frac{1}{3}$, the mutule $\frac{3}{4}$, the corona $\frac{3}{4}$, and the cima reversa 10 and $\frac{1}{3}$, and the whole 12 parts.

Doric dialect, in grammar, one of the five dialects, or manners of speaking which were principally used in the Greek.

It was first used by the Lacedemonians, particularly those of Argos; afterwards it passed into Epirus, Lybia, Sicily, and the islands of Rhodes, Crete, &c.

According to the doric dialect, the vowels $\alpha$, $\epsilon$, $\omicron$, $\upsilon$, are changed into $\epsilon$, the diphthong $\varepsilon$ into $\alpha$ or $\alpha\iota$; and the consonants $b$ into $p$, $\zeta$ into $\epsilon$, $\mu$ into $\tau$, and $\rho$ into $\rho$, $\lambda$, and $\nu$ into $\nu$. Thus for $\phi$ $\nu$, $\theta$ $\chi$, $\kappa$ $\iota$ $\lambda$ $\nu$ $\alpha$, $\beta$ $\rho$ $\alpha$, &c. they say $\phi$ $\nu$, $\theta$ $\chi$, $\kappa$ $\iota$ $\lambda$ $\nu$ $\alpha$, &c. They likewise change $\epsilon$ into $\alpha$, as $\lambda\nu$ for $\lambda\nu\omicron$; also $\epsilon$ $\iota$ into $\epsilon$, as $\beta$ $\alpha$ $\iota$ $\nu$ $\omicron$ for $\beta$ $\alpha$ $\iota$ $\nu$ $\omicron$; $\epsilon$ $\epsilon$ $\iota$ $\nu$ $\omicron$ for $\epsilon$ $\epsilon$ $\iota$ $\nu$ $\omicron$, and $\epsilon$ $\iota$ $\nu$ $\omicron$ for $\epsilon$ $\iota$ $\nu$ $\omicron$, with other transmutations of the like nature.

Doric mode, in music, the first of the authentic modes of the antients; its character is to be severe, tempered with gravity and joy; and is proper upon religious occasions, as also to be used in war. It begins $D$, $la$, $sol$, $re$. Plato admires the music of the doric mode, and judges it proper to preserve good manners, as being masculine; and on this account allows it in his commonwealth. The antients had likewise their sub-doric or hypodoric mode, which was one of the plagal modes. Its character was to be very grave and solemn: it began with $re$, a fourth lower than the doric.

DORING, or DARING, among sportmen, a term used to express a method of taking larks by means of a clap-net and a looking-glass. See CLAP-NET.

DORMANT, in heraldry, is used for the posture of a lion, or any other beast, lying along in a sleeping attitude, with the head on the fore-paws; by which it is distinguished from the crouchant, where though the beast be lying, yet he holds up his head.

DORMANT-TREE, in architecture, is a name given by workmen to a great beam lying across a house, commonly called a summer.

DORMANT-TYLES. See TYLE.

DORMER, in architecture, signifies a window made in the roof of an house, or above the entablature, being raised upon the rafters.

DORMITORY, a gallery in convents or religious houses, divided into several cells, in which the religious sleep or lodge.

DORMITORY is sometimes used for a burying place.

DORONICUS AFFINIS, a name given by Plukenet to a plant called by Linnaeus Gerbera. See the article GERBERA.

DORONICUM, LEOPARD'S BANE, in botany, a genus of the synge, or Palynia, species of plants, the compound flower of which is radiated: the proper flower is funnel-formed; there is no pericarpium, but the cup, being slightly convolvulus, contains a solitary seed, vertically ovated, compressed, falcate, and crowned with a downy pap. The root of the doronicum officinarum is said to be an alexipharmac, but it is not used in the present practice.

DORPT, or DORPAT, a city of Livonia, about fifty miles south of Narva: east lon. 27° 25', and north lat. 58°.

DORSAL, an appellation given to whatever belongs to the back. See DORSUM.

DORSAL MUSCLES, the muscles of the back and loins, which are for the most part common: there are of the extensors usually reckoned three on each side, viz. the facio-lumbaris, the longissimus dorsi, and the semispinosus: the flexors are three also, viz. the quadratus lumborum, the psoas parvus, and the intertransversales lumborum. See each under its proper head.

DORSAL NERVES. See NERVE.

DORSIFEROUS PLANTS, among botanists, such as are of the capillary kind, without
without flsks, and which bear their seeds on the backside of their leaves.

DORSTENIA, in botany, a genus of the tetrandria-monogynia class of plants, which have no flower-petals, only a great many collections of the male and female parts on the disc; each collection, or partial flower, being surrounded by its proper perianthium, as the whole are by a common involucrum or cup; the seeds, which are roundish and solitary, are contained, in a common pulpy receptacle. See the article CONTRAYRVA.

DORSUM, back, in anatomy, comprehends all the posterior part of the trunk of the body, from the neck to the buttocks. The back is furnished with several muscles, which are common to it with the loins, as the longissimus dorfi, the facro-lumbaris, and semispinosus; these are called extensors. See EXTENSOR.

To the back likewise belong the intertransversales lumborum, the quadratus lumborum, and the psoas. See the article INTERTRANSVERSALIS, &c.

Its bones are the spina dorsi, ribs, and os sacrum. See SPINE, RIB, &c.

DORSUM is also used to denote the upper side of the hand and foot, in contradistinction to the lower side, called the palm and sole. See HAND AND FOOT.

DORSUM NASI, the ridge of the nose. See the article NOSE.

DORT, a city of the United Provinces, situated in that of Holland, on an island in the river Maes, about 12 miles east of Rotterdam: east lon. 4° 40', and north lat. 51° 47'.

DORTMUND, a city of Westphalia in Germany, about thirty miles north-east of Duffeldorp: east lon. 6° 50', and north lat. 51° 25'.

It is an imperial city, and constitutes a sovereign state.

DORTERNA, the name of a plant comprehended by Linnaeus among the lobelia. See the article LOBELIA.

DORYCNIUM, in botany, a genus of the diadelphus-decandria class of plants, the corolla of which is papilionaceous; the vexillum is vertically cordated and reflex; the alae are oblong, of the length of the carina, which is short and straight; the fruit is a roundish, acuminated, bivalve, and unilocular pod, almost covered; the seed is either one or two.

DORYPHORI, in antiquity, an appellation given to the life-guard men of the Roman emperors: they were held in such great estimation, as frequently to have the command of armies conferred on them. It was likewise usual for the chief commanders, to have their doryphori to attend them.

DOSE, in medicine and pharmacy, the quantity of a medicine given at one time; or the proportion of which the several ingredients of a compound medicine bear to each other.

It is the business of the physician to adjust the doses of medicines to the cases of his patients; in doing which he cannot use too much caution, since the same dose that would prove highly beneficial to one, may be fatal to another. See MEDICINE, PHARMACOPOEIA, &c.

DOSTITEANS, dothihei, in church-history, a sect among the Hebrews, being one of the branches of the Samaritans. See the article SAMARITANS.

They abstained from eating any creature that had life, and were so superstitious in keeping the sabbath, that they remained in the same place and posture wherein that day surprised them, without stirring till the next day. They married but once, and a great number never married. Dothiteans, their founder, being dissatisfied among the Jews, retired to the Samaritans, who were reputed heretics, and invented another sect; and to make it more authentic, he went into a cave, where, by too long abstinence, he killed himself. The name of dothiteans was also given to some of the disciples of Simon Magus.

DOSSER, in military matters, a sort of basket, carried on the shoulders of men, used in carrying the overplus earth from one part of a fortification to another, where it is wanted.

DOSSIL, in surgery, lint made into a cylindrical form, or resembling the shape of dates, or olive-foles, the size of which is very different. Dossils are used in dressing a disordered part; and are sometimes secured by a thread, tied round their middle. See plate LXXVII. fig. 2.

It requires a good deal of time and experience to acquire a proper expertness in making up these forms.

These different forms of scraped lint are used, 1. To stop the bleeding of fresh wounds; and in large wounds they should first be dipped in some styptic liquor, or sprinkled with a styptic powder. 2. To agglutinate and heal wounds, especially if spread with some digestive ointment, or dipped in some vulnerary liquor. 3. In drying up wounds and ulcers. 4. In
DOUBLE EXCENTRICITY. See the article EXCENTRICITY.

DOUBLE FEAST. See FEAST.

DOUBLE FEVER. See the article FEVER.

DOUBLE FICHY, or FICHY, in heraldry, the denomination of a croc, when the extremity has two points, in contradistinction to fiché, where the extremity is sharpened away to one point. See Plate LXXVII. fig. 3.

DOUBLE FINE, in law. See FINE.

DOUBLE FUGUE, in music. See FUGUE.

DOUBLE LETTER, in grammar, a letter which has the force and effect of two. The Greeks have three of these, viz. ζ, ξ, ω; the Latins have two X and Z; and most of the modern languages have the same.

DOUBLE MEASURE. See MEASURE.

DOUBLE PEDESTAL. See PEDESTAL.

DOUBLE PLEA, in law, is where the defendant in a suit alleges two or more matters in bar of the plaintiff’s action, when one of them is sufficient. This is not admitted in common law. Thus when a person pleads several things, the one having no dependence upon the other, such plea is accounted double, and will not be admitted; but where the things pleaded mutually depend on each other, and the party cannot have the last plea without the first, there the whole shall be received.

DOUBLE PLOUGH. See PLOUGH.

DOUBLE POINT, in the higher geometry. See CURVES of the second order.

DOUBLE POSITION. See POSITION.

DOUBLE QUARREL, a complaint made by any clerk, or other, to the archbishop of a province, against an inferior ordinary, for delaying justice in some spiritual cause, as to give sentence, instituted a clerk, or the like. It seems to be termed double quarrel, because the complaint is usually made both against the judge, and the party at whose fuit justice is delayed.

DOUBLE RATIO.

DOUBLE DESCANT, in music. See the article DESCANT.

DOUBLE DISSIS. See DISSIS.

DOUBLE Gnomon, one of which points out the hour on the outward circle, and the other shews the hour upon the stereographic projection drawn upon it. This dial not only finds the meridian, hour, &c. but shews the sun's place, rising and setting, declination, amplitude, altitude, and azimuth, with many other useful propositions. See the article DIAL.

DOUBLE DANCETTE, in heraldry. See the article DANCETTE.
DOUBLETS, a game on dice, within

tables: the men, which are only fifteen,

being placed thus; upon the first, fifth,

and quater points, stand three

men a-piece; and upon the trey, dace,

and ace, only two. He that throws

the highest hath the benefit of throwing first;

and what he throws lays down, and

so doth the other: what the one throws,

and hath not, the other lays down for

him, but to his own account; and thus

they do till all the men are down, and

then they bear. He that is down first:

bears first, and will doubtless win the
game, if the other throws not doublets to

overtake him; which he is sure to do,
since he advances or bears as many as

the doublets make, viz. eight for two

fours.

DOUBLING, in the military art, is the

putting two ranks or files of soldiers into

one. Thus, when the word of command

is, double your ranks, the second, fourth,

and sixth ranks march into the first, third,

and fifth, so that the six ranks are reduced
to three, and the intervals between the

ranks become double what they were be-

fore. To double by half files, is when the

fourth, fifth, and sixth ranks march up
to double the first, second, and third, or

the contrary. To double the files to the

right, is when every other file faces to the

right, and marches into the next file to it,
so that the six ranks are turned into
twelve, and every file is twelve deep. To
double the files to the left, is when every

other file faces to the left, and marches

into the next. In doubling the files, the

distance between the files becomes
double.

DOUBLING, among hunters, who say that

a hare doubles, when he keeps in plain

fields, and winds about to deceive the

hounds.

DOUBLING, in the manege, a term used

of a horse, who is laid to double his reins,

when he leaps several times together, to

throw his rider; thus we say, the ra-

mingue doubles his reins, and makes

pontlevi. See the articles RAMINGUE

and PONTLEVIS.

DOUBLING a cape or point, in navigation,
signifies the coming up with it, passing by

it, and leaving it behind the ship.

DOUBLINGS, in heraldry, the linings of

robes and mantles of state, or of the

manusings in achievements.

DOUBLON, or DUBLAIN, a Spanish and

Portuguese coin, being the double of a

pistole. See COIN and PISTOLE.

DOUBTING, dubitatio, the act of with-

holding our affent from any proposition,
on fulpicion that we are not thoroughly

appried of the merits thereof; or from

not being able peremptorily to decide be-
tween the reasons for and against it.

Doubting is distinguished by the school-

men into two kinds, dubitatio tertulis, and

dubitatio effeex: the former is that where

no determination ensues; in this manner

the sceptics and academicians doubt, who

with-hold their assent from every thing.

See the articles SCEPTICS, &c.

The latter is followed by judgment, which

distinguishes truth from falsity: such is

the doubting of the peripatetics and car-
teians; the last in particular are perpetu-

ally incalculating the deceitfulness of our

senes, and tell us that we are to doubt

of every one of their reports, till they

have been examined and confirmed by

reason. On the other hand, the epicure-

ans teach that our senes always tell truth,

and that, if you go ever so little from

them, you come within the province of
doubting. See the articles CARTESIANS,

EPICUREANS, &c.

DOUBTING in rhetoric, signifies the debate

of the mind with itself, upon a prefixing
difficulty. It is, for the most, part ex-

pressed by interrogation, though that is

not necessary. Thus Cicero for Roscius:

"Quid primum quar? aut unde po-

tilimum, judices, order? aut quod? aut a quibus, auxilium petam? decorum

immortalum? popularis romain?"

&c. This figure keeps us in eager at-

tention.

DOUCINE, in architecture, a moulding

conceave above and convex below, serv-
ing commonly as a cymatium to a dedi-
cate cornice. It is likewise called guila.

See CYMATIUM and GULA.

DOUCKER, or DUCKER. See DUCKER.

DOVE, columba, in ornithology. See the

article COLUMBA.

DOVE, in geography, the name of a river

dividing Derbyshire from Staffordshire:

also of a town of the Orleansis, in

France, about twenty miles south-east of

Angers.

DOVE-TAILING, in carpentry, is the

manner of fastening boards together by let-
ing one piece into another, in the form of

the tail of a dove. The dove-tail is the

strongest of the assemblages or jointings,
always reduced into writing, as soon as the son was married. 5. Dower de la plus belle, which was where the wife was endowed with the fairest part of the husband’s estate. Of these five the two first only of these writs of dower are now in use.

Admeasurement of Dower. See the article ADMEASUREMENT.

Assignment of Dower, the setting out a woman’s marriage-portion by the heir.

Tenant in Dower. See Tenant.

DOWLE-STONES, in our old writers, the same with land-marks.

DOWN, in geography, the capital of a county of the same name in the province of Ulster, in Ireland: west longit. 5° 50', and north lat. 54° 23’.

DOWNETON, or DUNKTON, a borough-town of Wiltshire, five miles south of Salisbury.

It sends two members to parliament.

DOWNHAM, a market-town of Norfolk, ten miles south of Lynn, famous for its good butter; there being a thousand, and sometimes two thousand firkins bought here every Monday, and sent up the river Ouse to Cambridge, from whence it is conveyed to London, in the Cambridge waggons.

DOWNS, a famous road near Deal, in Kent, where both the outward and homeward bound ships frequently make some stay; and squadrons of men of war rendezvous in time of war.

It affords excellent anchorage, and is defended by the castles of Deal, Dover, and Sandwich.

DOWRY, das, is properly the money or fortune which the wife brings her husband in marriage: it is otherwise called maritum, marriage-goods, and differs from dower. See the article Dower.

Among the Germans it was customary, in former times, for the husband to bring a dowry to his wife.

DOWRY is also used, in a monastic sense, for a sum of money given along with a maid, upon entering her in some religious order.

In France, the dowry of persons entering a monastery, to make profession of a religious life, is limited by law. That given upon entering a monastery of carmelites, urfedines, and others not regularly founded, but established since the year 1600, by letters patent, must not exceed the sum of 8000 livres in towns where parliaments are held; nor 6000, in other places.
DOXOLOGY, an hymn used in praise of the Almighty, distinguished by the title of greater and lesser.

The lesser doxology was antiently only a single sentence, without response, running in these words, glory be to the Father, and to the Son, and to the Holy Ghost, world without end, amen. Part of the latter clause as it was in the beginning, is now, and ever shall be, was inserted some time after the first composition. Some read this antient hymn, glory be to the Father, and to the Son with the Holy Ghost. Others, glory be to the Father in or by the Son, and by the Holy Ghost. This difference of expression occasioned no disputes in the church, till the rise of the arian heresy; but when the followers of Arius began to make use of the latter, as a distinguishing character of their party, it was entirely laid aside by the catholics, and the use of it was enough to bring any one under suspicion of heterodoxy.

The doxology was used at the close of every solemn office. The western church repeated it at the end of every psalm, and the eastern church at the end of the last psalm. Many of their prayers were also concluded with it, particularly the solemn thanksgiving, or consecration prayer at the eucharist. It was also the ordinary conclusion of their sermons.

The greater doxology, or angelical hymn, was likewise of great note in the antient church. It began with these words, which the angels sung at our Saviour's birth, glory be to God on high, &c. It was chiefly used in the communion service, and in men's private devotions. In the Mozarabic liturgy, it is appointed to be sung before the lessons on Christmas day; and St. Chrysostom observes, that the ascetics met together daily to sing this hymn. Both the doxologies have a place in the church of England, the former being repeated after every psalm, and the latter used in the communion service.

DOZENERS. See Decenniers.

DRABA, ARABIAN MUSTARD, or TURKY CRESSES, in botany, a genus of the tetra-dynamia-fuscula class of plants, the flower of which consists of four oblong petals, and is cruciform: it has fix stamina, four whereof are longer than the other two: the fruit is a bicocular, elliptico-oblong, compressed, containing a number of small roundish seeds, and wanting a style.

DRABLER, in the sea-language, a small fish, being the same to a bonnet that a bonnet is to a cap, and is only used when the cap and bonnet are too small to cloath the head. See Course and Bonnet.

DRABS, in the falt-works, a kind of wooden boxes for holding the salt when taken out of the boiling pan, the bottoms of which are made shelving or inclining forwards, that the briny moisture of the salt may drain off. See the article Salt.

DRACHM, a grecian coin of the value of seven-pence three-farthings. See Coin.

DRACO, the DRAGON, in zoology. See the article DRAGON.

DRACO MARINUS, the SEA-DRAGON, in ichthyology, the same with the araneus of Pliny: it is a species of trachinus, growing to six or eight inches in length, and called by some the weaver. See plate LXXIX. fig. 1.

DRACO VOLANS, in meteorology, a fiery exhalation, frequent in marshy and cold countries.

It is most common in summer, and th'o' principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders; its appearance being that of an oblong, sometimes roundish, fiery body, with a long tail. It is entirely harmless, frequently flicking to the hands and cloaths of people without injuring them in the least.

DRACO, in astronomy, a constellation of the northern hemisphere, said by different authors to contain 31, 32, 33, or even 40 stars.

DRACOCEPHALUM, DRAGON'S HEAD, in botany, a genus of the didynamia-pym-nuspermia class of plants, the corolla of which consists of a single stigmatic petal; the tube is of the length of the cup; the upper lip is fornicated and obtuse, the lower is lightly divided into three segments; there is no pericarpium, but the cup cherishes the seeds, which are four ovato-oblong, and three fided ones. See plate LXXIX. fig. 3.

DRACOCEPHALUS, the same with draconcephalus. See the preceding article.

DRACONIUS, in antiquity, the person who carried the standards called dragons, from the figures of these animal's painted on them. These were in use among the Persians, Parthians, Scythians, Romans, &c.

DRACONIS CAPUT, CAUDA, &c. See the article DRAGON.
DRACONTEAS, a name used by the patients for two distinct plants, dracunculus and arum. See DRACUNCULUS and ARUM.

DRACONTIC MONTH, the time of one revolution of the moon, from her ascending node, called caput draconis, to her return thither.

DRACONTIUM, DRAGONS, in botany, a genus of the gynandria-polyandria class of plants, the corolla of which consists of five concave, ovated, obtuse, and almost equal petals; the fruit is a single roundish berry; and the seeds are numerous.

Its root is esteemed a good alexipharmac and sudorific, and accordingly prescribed in the plague and malignant fevers, and for the bites of serpents.

This defensive is very common in Guinea, and principally among the natives: Kempfer found it so alo atOrmuz, upon the perian gulf, and likewise in Tartary. Dr. Tawne, in his treatise of the diseases of the West-Indies, informs us, that this defensive is not so frequent any where as on the Gold coast, at Anamboe, and Cormantyn.

The worm is white, round, and uniform, very much resembling white, round tape, or bobbing. It is lodged between the interfaces and membranes of the muscles, where it feed and instructs itself sometimes exceeding five ells in length. It occasions no great pain at the beginning, but at such times as it is ready to make its exit, the part adjoining to the extremity of the worm, when it attempts its exclusion, begins to swell, throbb, and be inflamed: this generally happens about the ankle, leg, or thigh, and rarely higher.

The countries where this defensive is observed, are very hot and sultry, liable to great droughts, and the inhabitants make use of flaggating and corrupted water, in which it is very probable that the ova of these animalcula may be contained; for the white people who drink this water, are obnoxious to the disease as well as the negroes.

The surgeons seldom attempt to extract this worm by making an incision; but as soon as they perceive the tumor rise to a competent bulk, they endeavour to bring it to a suppuration, with all convenient expedition; and then the head of the worm disloits itself, which they secure, by tying it to a bit of flock, or cotton, that it may not draw itself up again: thus they continue to roll it round the fick, sometimes one inch, sometimes two or more, each day, taking great care not to break the worm, else it will be very difficult to recover the end of it again; and an abeice will be formed, not only at the suppurred part, but likewise through the whole winding of the muscles, where the dead putrifying worm remains, which generally occasions very obdurate ulcers. During the extraction of the worm, the patient should be plied with bitter aloetic and other anthelmintic medicines, in order to dilodge the worm the sooner from his tenement. When the worm is totally extricated, the remaining ulcer may be treated in the same manner as other common ulcers; nor does any further inconvenience remain in the parts of which it had possession. This disease, simply considered, very rarely, it ever, proves mortal.

DRACUNCULUS is also used for a disease in children, arising from little worms called by that name. See the article WORMS.

DRACUNCULIODES, in botany, the name by which Boerhaave calls the hæmatus of Linneus.

DRACUNCULUS, DRAGONs, in botany, is comprehended by Linneus among the arums. See the article ARUM.

DRACUNCULUS is also the name of the linear-leaved artemisia, called in English tarragon. See the article TARRAGON.

DRACUNCULUS, the little sea-dragon, in ichthyology, a species of cottus, with the second back-fin white. See the article COTUS.

The dracunculus is a very singular fish, growing to five or six inches in length. See plate LXXXIX. fig. 2.

DRAGANT, the same with tragacanth. See the article TRAGACANTH.

DRAGOMAN, DROGMAN, or DRUG-GERMAN, a name given in the Levant to the interpreters kept by the ambassadours of christian nations, residing at the Porte, to assist them in treating of their master’s affairs.

DRAGON, draco, in zoology, an animal called allo the flying lizard, being furnished with two lateral, membraneous, and radiated wings: it is a true lizard, with a naked and four-legged body, and a long tail; though there are not wanting some who deny the existence of any such animal. See plate LXXX. fig. 2.

Sea-DRAGON. See DRACO MARinus, and DRACUNCULUS, sipra. DRAGON’s
DRAGON'S BELLY, in astronomy. See the article VENTER DRACONIS.

DRAGON'S BLOOD, fanguis draconis, in pharmacy, a moderately heavy resin, of which there are two kinds: the one firm and compact, brought to us in lumps, of an inch long, or more, and about half an inch in diameter: these are wrapped up in certain long and narrow leaves, and are called the drops, or tears, of dragon's blood. The other is brought to us in larger masses or cakes, of an irregular figure. This is less compact than the former, and less pure: it is called the common dragon's blood, and is greatly inferior to the former in value. Besides these two common kinds, we sometimes meet with a third, which is soft, and will take an impression from the finger; but we are to avoid a counterfeit fort of dragon's blood that is sometimes offered to sale, and is made up of several different resinous matters, coloured with the dragon's blood, or with balsam-wood: this is of no value. The dragon's blood in drops, is to be preferred to any other: the genuine dragon's blood is the fruit of a tall tree of the palm-kind, common in the island of Java, and some other parts of the East-Indies. It is a very powerful astringent, incrustant, and drier. It is given in diarrhœas, dysenteries, and hemorrhages of all kinds; and, externally, in drying and healing ulcers. Its dose is from five grains to twenty-five.

DRAGON-FLY, the English name of the libella. See the article LIBELLA.

DRAGON'S HEAD and TAIL, the two nodes of the moon. See the article NODE.

DRAGON-SHELL, the English name of a species of concamerated patella, with its rostrum very much bent. See the article PATELLA.

DRAGON-TREE, a term used by some for the palm-tree.

DRAGONS, in botany. See the article DRACUNCULUS, Fagara.

WILD DRAGONS, the same with tarragon. See the article TARRAGON.

DRAGONNEE, in heraldry; a lion dragonnee is where the upper half resembles a lion, the other half going off like the hinder part of a dragon. The same may be said of any other beast as well as a lion.

DRAGOON, in military affairs, a musqueteer, mounted on horsecback, who sometimes fights or marches on foot, as occasion requires.

Dragoons are divided into brigades, as the cavalry, and each regiment into troops; each troop having a captain, lieutenant, cornet, quarter-master, two sergeants, three corporals, and two drums. Some regiments have haubboys: they are very useful on any expedition that requires dispatch, for they can keep pace with the cavalry, and do the duty of infantry: they encamp generally on the wings of the army, or at the paffes leading to the camp; and sometimes they are brought to cover the general's quarters: they do duty on the generals of horse and dragoons, and march in the front and rear of the army.

DRAGOON, in ornithology, the name of a small kind of carrier-pigeon, called columbia tabellaria minima, by Moore. It is a bastard breed between the two species of pigeons called the horfeman and the tumbler. They are very good breeders, and as they are lighter than the horfeman, they are supposed more expeditious in flight, for a few miles: but the horfeman outdoes them at greater lengths.

DRAGS, in the sea-language, are whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats, when towed, or whatever else that, after this manner, may hinder the ship's way when the sails are called drags.

DRAINING of lands, the freeing them from an over abundance of water, by means of drains. See the next article.

DRAINS, a name given, in the fen-countries, to certain large cuts or ditches, of twenty, thirty, nay, sometimes forty foot wide, carried, through the nearthy ground, to some river, or other place, capable of discharging the water they carry out of the fen-lands.

The best way is to begin the drain at the lowest place, and so to carry it into the bog towards the spring-head; where it will be proper to make cross trenches, in order to drain it thoroughly. If the drains are deep, so that there is danger of cattle falling into them, they may be partly filled with stones, brick-bats, and the like; and covered with wood, flags, turf, &c. and the water will drain away through the stones. When the drains are left open, the earth should not be laid in heaps by their sides, as is too often done; but spread over the low places near them, or even carried off in carts. See the articles DITCH and FEN.

Most of these drains are made in our fen-countries by a body of men called the undertakers, whose reward is one third of
of the ground they drain: they erect sluices also at a great expence, often not less than two thousand pounds each; yet these, with all the care they employ in erecting them, are subject to be blown up by the vast weight of water that lies on them when the lands are overflowed: some of these sluices have two or more pair of doors, of six, eight, or ten feet high, which shut, when the water in the river is higher than in the drain, by the weight and force of it, and so, e contra, throw out a body of eight feet square of water, for about six or seven hours, during the ebb. The real use of these drains is very evident from the visible improvement of the lands where they have been cut. The inhabitants of Essex have a particular way of draining lands in such grounds as lie below the high-water and something above the low-water mark, and have land floods or fleets running through them, which make a kind of small creek. When these grounds are first enclosed from the sea, it is done with a bank raised from one side of the land designed to be taken in to the other, except a space left where the creek or land-floods run into the sea. When they begin to fill this, it is done at once, with a strong firm head; only according to the quantity of water to be vented, they lay therein several square troughs, composed of four large planks, of the same length that they design the thickness of the head to be; and towards the sea is fitted a small door, which opens when the fresh water bears out on it, and shuts when the salt water rises, as already described. 

**DRAKE**, in ornithology, the male of the duck-kind. See **ANAS** and **DUCK**.

**DRAM**s are accounted a kind of cordials. See **CORDIALS**, **BRANDY**, **RUM**, &c.

**DRAM**, or **DRACHM**, in commerce, a small weight. See **DRACHM** and **WEIGHT**.

**DRAMA**, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind. The principal species of the drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See the articles **TRAGEDY**, **COMEDY**, &c. The primary parts of the drama, as divided by the antients, are the protasis, epistasis, catafalsis, and catastrophe. The secondary parts are the acts and scenes. The accessory parts are the prologue, chorus, mimus, and epilogue, which pointed out the use of the piece, or conveyed some other notice to the audience in the poet’s name. See **PROTASIS**, **PROLOGUE**, **CHORUS**, &c.

The drama, says Voifius, owes its rise to the days of festivity; for in antient times, it was usual for men, when they gathered in the fruits of the earth, to meet together that they might sacrifice to the deity, and unbend their minds from the fatigue of the harvest. Hence arose two sorts of poetry, the one grave, in praise of the gods, the other jocose and full of lampoon, against one another. Thus, from the former arose tragedy, and from the latter, satire, comedy, and mimicry.

The drama, in some circumstances, is superior to epic poetry, particularly in action; for in the drama, the persons themselves are introduced, every thing is transferred in our sight, and our eyes and ears at once are gratified. Besides, the action in the drama, is much more commendable than in the epic; it takes up less time, and therefore requires more art to conduct it. It excites in the mind more rapid commotions, and consequent makes the pleasure and admiration more intense. For which reasons, Ariosto gives the preference to the drama; not that he reckons it more noble in general than the epic, for that would be contrary to truth and reason, but only as far as its sphere extends. According to the Abbe du Bos, tragic poets ought to place their scenes in times remote from that in which they live; but that comedy, on the contrary, ought to be fixed in the very places and times in which it is represented; its design being to make us laugh at the expence of ridiculous persons, in order to purge us of those faults it exposes. Now we cannot distinguish nature so easily, when the appears in strange customs, manners, and apparel, as when it is clad, as it were, after our own fashion; whereas we always distinguish human nature in the heroes of tragedies, whether their scenes be at Rome or Sparta, by reason only great virtues or great vices are there represented. The dramatic poetry of the Romans, was at first divided into three sorts, tragedy, satire, and comedy; which were afterwards subdivided into several species. They had two species of tragedies, viz. the tragediae palliatae, in which the personages, manners, and dress were entirely Greek; and the tragediae praetextatae, or praetextae, wherein the personages...
Dramatic, in poetry, an epithet given to plays; the Roman, or Palliata; and the Roman, or Togata, by reason of the introducing plain citizens into the latter, whose dress was called toga. The Roman comedy was divided into two species, viz. the Greek, or Palliata; and the Roman, or Togata, properly so called, the Tabernaria, the attellana, and the minus. Pieces of the first sort were very serious, and admitted even of persons of distinction, for which reason they were sometimes called pretextate. The second were comedies of a less serious nature, and took their name from Taberna; which chiefly signified a place of rendezvous, proper for assembling persons of different conditions, whose characters were played off in those pieces. The attellana was a kind of piece very like the Italian comedies; that is, those whose dialogues are not written. The actor, therefore, of the attellana, performed his part just as he pleased. The minus resembled our farces, and the actors thereof performed always bare-foot: whereas, in tragedy, they wore a sort of shoe, or boot, called cothurnus; and, in the other species of comedy, another kind called focusus. For the laws of the drama, see the articles Unity, Action, Character, Fable, &c.

Dramatic, in poetry, an epithet given to pieces written for the stage. See the article Drama.

Style-Dramatico, in the Italian music. See the article Style.

Drank, among farmers, a term used to denote wild oats, which never fail to infest worn-out lands; so that when plowed lands run to these weeds and thistles, the farmer knows it is high time to fallow them, or else to sow them with hay-feed, and make pasture of them. Some, indeed, destroy the drank, by fowing the lands with beans, and letting loose sheep upon them when young. This must be done in dry weather, and the sheep eat up the drank and other weeds, without touching the beans.

Drapery, in sculpture and painting, signifies the representation of the clothing of human figures, and also hangings, tapestry, curtains, and most other things that are not carnations or landscapes.

The art of drapery consists, 1. In the order of the folds or plaits, which ought to be so managed, that you may easily perceive what it is they cover, and distinguish it from any thing else. Again, the folds ought to be large, as breaking and dividing the light the less; and there should be a contrast between them, otherwise the drapery will be stiff. 2. In the quality of the stuffs; for some make their folds abrupt and harsh, others more soft and easy; the surface of some have a lustre, others are flat and dead; some are fine and transparent, others firm and solid. 3. In the variety of colours, which, when well managed, makes the greatest beauty of painting; all not being equally amicable and friendly with respect to each other, and some never to be placed near certain others.

M. de Piles observes, that drapery must never be made to adhere to the parts of the body; that a great motion and lightness of the drapery are only proper in figures in great agitation, or exposed to the wind; and that the nudities of the figures should always be designed, before the painter proceeds to the draperies.

Observe the following directions. Draw the out-lines of garments lightly, beginning with the great folds, which you may afterwards stroke into leffer; but be sure they cross not one another. Make the drapery bend with the body, according as it stands in or out, straight or crooked, or turns one way or another; observing that the closer the garment fits on the body, the narrower and smaller must the folds be. All the folds must consist of two lines, and no more, which you may turn with the garment at pleasure, shadowing the inner deep, and the outermost more light; and if the folds, be never so curiously contrived, spare not to shadow them, if they fall inward from the light, with a double or triple shadow, as the occasion requires. The out-lines must be continued through the whole garment; the leffer you may break off and shorten as you please. The shades in silk and fine linnen, require little folds, and a light and rare shadow; and so also fine drapery requires more and sharper folds than coarse. Observe the motion of the wind and air for drawing loose apparel all one way; and examine the nature and disposition of light, especially as it has relation to the sun or any bright body. Moreover, the plaits and folds
DRAUGHT, in medicine. A draught, called also CLOFF or CLOUGH, is a small allowance on weighable goods, made by the king to the importer, or by the seller to the buyer, that the weight may hold out when the goods are weighed again.

The king allows 1 lb draught for goods weighing no less than 1 Cwt. 2 lb for goods weighing between 1 and 2 Cwt. 3 lb for goods weighing between 2 and 3 Cwt. 4 lb from 3 to 10 Cwt. 7 lb from 10 to 18 Cwt. 9 lb from 18 to 30, or upwards.

DRAUGHT-HOOKS, are large hooks of iron, fixed on the cheeks of a cannon-carriage, two on each side, one near the trunnion hole, and the other at the train, distinguished by the name of fore and hind draught-hooks. Large guns have draught-hooks near the middle trunnion, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forwards, by men with strong ropes, called draught-ropes, fixed to these hooks.

DRAUGHT-HORSE, in farming, a sort of coarse-made horse, destined for the service of the cart or plough. In the choice of these horses, for what is called the flow draught, they are to be chosen of an ordinary height; for otherwise, when put into the cart, one draws unequally with the other, and the tall ones hang upon the low ones. The draught horse should be large bodied, and strong joined, and of such a disposition as rather to be too dull than too brisk; and rather to crave the whip, than to draw more than is needful. Mares are the fittest for this use for the farmer, as they will be kept cheap, and not only do the work, but be kept breeding, and give yearly increase of a foal of the same kind, and fit to be bred to the same purposes. They should have a good head, neck, breast, and shoulders: for the rest of the shape, it is not of much consequence, only for breeding; the mare should have a large belly; for the more room a foal has in the dam, the more fit he will be for that employ. See the article FOAL.

DRAUGHT, in the sea-language. A ship is said to draw so much water, according to the number of feet the sinks into it; so that if a ship sink into the water eighteen feet perpendicularly, she is said to draw eighteen feet water; and according as she draws more or less, she is said to be of more or less draught.

DRAUGHT-COMPASSES, are such as have moveable points, to draw fine draughts in architecture. See COMPASSES.

DRAUGHT, in medicine. See POTION.

DRAUGHT, in painting. See the articles DESIGN and DRAWING.
DRAW, or Dog-draw, in the forest-law.
See the article Dog-draw.

DRAW-BACK, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandize, that have paid duty on importation.
The oaths of the merchants importing and exporting, are required to obtain the draw-back of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties; and these may be made by the agent or husband of any corporation or company, or by the known servant of any merchant usually employed in making his entries, and paying his customs. In regard to foreign goods entered outwards, if less quantity or value be fraudulently shipped out than is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no draw-back to be allowed for the same.

Foreign goods exported by certificate, in order to obtain the draw-back, not shipped or exported, or re-landed in Great Britain, unless in case of distress, to save them from perilling, are to lose the benefit of the draw-back, and are forfeited, or their value, with the vessels, horses, carriages, &c. employed in the re-landing thereof; and the persons employed in the re-landing them, or by whose privilege they are re-landed, or into whose hands they shall knowingly come, are to forfeit double the amount of the draw-back. Officers of the customs conniving at, or assisting in any fraud relating to certificate-goods, besides other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail or main-prize; as are also masters, or persons belonging to the ships employed therein. Bonds given for the exportation of certificate-goods to Ireland, must not be delivered up, nor draw-back allowed for any goods, till a certificate under the hands and seals of the collector or comptroller, &c. of the customs be produced, testifying the landing.
The computation of what is to be drawn back upon the exportation of foreign goods, may be seen under their respective heads.

DRAW-BRIDGE, a bridge made after the manner of a floor, to draw up, or let down, as occasion serves, before the gate of a town or castle. See Bridge.

A draw-bridge may be made after several different ways, but the most common are made with pliers, twice the length of the gate, and a foot in diameter. The inner square is traversed with a cross, which serves for a counterpoise; and the chains which hang from the extremities of the pliers to lift up or let down the bridge, are of iron or braits. In navigable rivers it is sometimes necessary to make the middle arch of bridges with two moveable platforms, to be raised occasionally, in order to let the ships and rigging of vessels pass through. This kind of draw-bridge is represented in plate LXXXVIII, where A B is the width of the middle arch; A L and B L, the two piers that support the draw-bridge N O; one of the platforms of which is raised and the other let down, having the beam P Q for its plier. To N O are suspended two moveable braces E H, E H, which refting on the support E, press against the bracket M, and thereby strengthen the draw-bridge. These braces are conducted to the rent by means of the weight S, pulling the chain S L E.

DRAW-GEAR, denotes any kind of harness for draught horses.

DRAW-NET. See the article NET.

DRAWER of a bill of exchange, the person who draws the bill upon his correspontent. See Bill and Exchange.

DRAWING, in general, denotes the action of pulling out, or halting along; thus we read of tooth-drawing, wire-drawing, &c. See Tooth and Wire.

DRAWING, the art of representing the appearances of objects by imitation, or copying without the assistance of mathematical rules.
The general precepts for drawing, are as follow. 1. Begin with plain, geometrical figures, as lines, angles, triangles, polygons, arches, circles, ovals, cones, cylinders, and the like, being the foundation of all other proportions. The circle is of use in the several orbicular forms, as the sun, moon, globes, &c. the oval in giving a just proportion to the face and mouth, and the square confines a picture you are to copy, &c. the triangle is of use in drawing a side or half face; angles and arches in perspective, and the polygon in ground plots, fortifications, &c. the cone, in spires, fleeples, tops of towers, &c. the cylinder, in columns, pillars, pilasters, &c. See the article Perspective.

2. Having brought your hand to be fit and ready in general proportions, accustom yourself to give every object its due shade,
Particular observations with regard to drawing, are as follow. 1. If you draw after a print or picture, place it in such a light, that the gloss of the colours may not interrupt your light, and that the light and your eye may equally and obliquely fall upon the piece, which should be placed at such a distance, that, upon opening your eye, you may view it at once: the larger the picture is, the greater distance off it should be placed: it should also be right before you, and a little reclining.

draw, according to its concavity or convexity, and to elevate or depress the fame, as the object appears either nearer or farther off the light. See the articles Proportion, Design, and Shade.

2. The second practice of drawing, consists in forming fruits, as apples, pears, cherries, &c. with their leaves; the imitation of flowers, as roses, tulips, carnations, &c. herbs, trees, &c. of different kinds.

3. The second practice of drawing consists in the imitation of the body of man, with all its lineaments, as head, nose, eyes, ears, cheeks, arms, and shadows, all exactly proportioned, both to the whole, and to one another.

4. The third, in the imitation of beasts, fowls, fishes, &c.

5. The fourth practice of drawing consists in the imitation of the body of man, with all its lineaments, as head, nose, eyes, ears, cheeks, arms, and shadows, all exactly proportioned, both to the whole, and to one another.

6. The fifth is in the drapery, in the imitation of the body, or linen, artificial or linear, in their natural and proper folds. See Drapery.

7. In drawing of all the forms before-mentioned, it is requisite to be first perfect in the laying down the exact proportion; secondly, in the general or outward lines, before you proceed to shadowing, or trimming the work within.

8. In mixed and uncertain forms, where the circle, square, &c. will be of no use, but only in the idea thereof in your own fancy, as bores, oxen, and the like, you must do it by judgment, and to gain the true proportions by assiduous practice: thus, having the shape of the thing in your mind, first draw it rudely with a coal; then, with more exactness, with a lead or pencil; then perfect it well, and mend it in those parts you have erred in, according to the idea you carry in your mind. When it is mended by your own judgment, compare it with some good pattern of the same kind, and amend it by that.

9. Having good copies to draw after, learn to reduce them to other proportions, either larger or smaller; and thus by frequent practice.

10. Let a perfection in drawing be attained by diligent exercise, and the instruction of a good master, before there be any attempts as to colouring and painting; for the former being attained, the rest will be easily understood, and gained by frequent practice.
INK, &c., drawing them with more exactness, and by imitating all the hatches with their exact distances one from another, their croffings, turnings and windings, with more boldness and freedom perfect your design.

6. In drawing after a naked body, all the muscles are not to be so plainly expressed as in anatomical figures; but that side whose parts are most apparent, and of signification in the performance of any action, must be made to appear more or less, according to the force of that action.

7. In drawing young persons, the muscles must not appear manifestly so hard, as in elder and full grown persons: the same is to be observed as to fat and fleshy persons, and such as are very delicate and beautiful; and in women, scarce any muscles at all are to be expressed, or but very little, unless it be in some very terrible action, and then too they are to be represented very faintly; the like is also to be observed as to little children.

8. The motion of the whole body must be considered in drawing of the muscles; as in the rising and falling of the arms, the muscles of the breast do appear more or less; the hips do the like according as they are bent outward or inward; and it is the same chiefly in the shoulders, arms, and neck, according to the several actions of the body.

9. The proportion of the figure ought to be multiplied by degrees, in proportion of one to two, three, four, &c., for herein the chief skill consists: the diameter of the biggest place, between the knee and the foot, is double to the least, and the largest part of the thigh, triple.

DRA W I N G ME D I C I N E S, those more usually called epispastics and ripeners. See the articles Epispastics and Ripeners.

D R A W I N G, a bill of e xchange. See the articles D r a w e r and B i l l.

D R A W I N G, among sportsmen, the beating the hutes after a fox. Drawing amidst, is said of the hounds or beagles, when they hit the scent of their chase contrary, so as to pursue it up the wind, when they should have done it down.

Drawing on the shot, is when the hounds touch the scent, and draw on till they hit on the same scent.

D R A W I N G a ca t f, among bowlers, is winning the end, without flirring the bowl or block.

D F E N E - D R A W I N G, among tailors, the art of sewing up button-holes, or any rents in cloth, in so nice a manner, as that they cannot be discovered from the entire part of the cloth.

D R A Y, a kind of cart used by brewers, for carrying barrels of beer or ale; also a fledge drawn without wheels.

D R A Y, among sportsmen, denotes squirrel-nefs, built in the tops of trees.

D R A Y-P L O U G H. See the article P l o u g h.

D R A Y T O N, a market-town of Shropshire, fourteen miles north-east of Shrewbury.

D R E D G E, or D R E C, among farmers, denotes oats and barley mingled together.

D R E D G E R S, the term used in the admiralty-court for the oiler-fishers.

D R E I N, in the military art, a trench made to draw the water out of a moat, which is afterwards filled with hurdles and earth, or with fascines, or bundles of rushes and planks, to facilitate the passage over the mud. See the article Trench.

D R E N C H, among farriers, a physical potion for horses. The ingredients for this purpose are to be beat coarsely, and either mingled with a decocation, or with wine. Then let all infirue about a quarter of an hour, and give it to the horse with a horn, after he has been tied up two hours to the rack.

D R E S D E N, the capital of upper Saxony, in Germany, situated on the river Elbe, sixty-five miles north-west of Prague, and eighty-five south of Berlin: east long. 13° 36', north lat. 51°.

It is one of the largest and strongest towns in Germany, and is the usual residence of the elector of Saxony.

D R E S S I N G of h e m p and f l a x. See the articles Hemp and Flax.

D R E S S I N G of h o p s. See the article Hops.

D R E S S I N G of m e a t s, that part of cookery which regards animal foods, whether flesh or fih. See the article Cookery.

D R E S S I N G of o r e s, the breaking and powdering them in the stamping-mill, and afterwards washing them in a wooden trough. See the articles Stamping-mill and Washing.

D R E S S I N G, in surgery, the treatment of a wound or any disordered part. The apparatus of dressing consists of dressings, tents, plasters, compresses, bandages, bands, ligatures, and ftrings. See the articles Wound, Dressing, Tent, Plaster, &c.

D R E U X,
DREUX, a town of Orleanois, in France, seventeen miles north of Chartres, and thirty-five west of Paris.

DRÉE, the name with dry. See DRY.

DRIFT of the forest, is an exact view and examination taken at certain times to know whatbeasts are there; in order that none may come on the forest but such as have right; and that the forest be not overcharged with beasts.

DRIFT, in mining, a passage cut out under the earth, betwixt shaft and shaft, or turn and turn; or a passage or way, wrought under the earth, to the end of a meer of ground, or part of a meer.

DRIFT, a term used at sea. Thus any thing that floats upon the water, is said to run a-drift.

DRIFT-SAIL, a sail used under water, veered out right a head by sheets, as other sails are. It serves to keep the ship's head right upon the sea in a storm, and to hinder her driving too fast, in a current.

DRILL, in mechanics, a small instrument for making such holes as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners.

DRILL, or DRILL-BOX, a name given to an instrument for sowing land in the new method of horse-hoeing husbandry. It plants the corn in rows, makes the channels, sows the seeds in them, and covers them with earth when sown; and all this at the same time, and with great expedition. The principal parts are the feed-box, the hopper, the plough and its harrow, of all which the feed-box is the chief. It measures, or rather numbers, out the seeds which it receives from the hopper, and is for this purpose as an artificial hand; but it delivers out the seed much more equally than can be done by a natural hand. See the article Plough.

Whoever is desirous of knowing more intimately the whole apparatus for this method of sowing, may see it fully described, and illustrated with figures, by Tull, in his Horse-hoeing husbandry.

DRINK, a part of our ordinary food in a liquid form, serving to dilute and moisten the dry meat. See the article Diet.

The drinks in different countries are different. The common drink in England is either water, malt-liquor, wine, or mixtures of these.

The first drinks of mankind were certainly water and milk, but the love of luxury and debauchery soon introduced the art of preparing intoxicating and inert-briating drinks out of vegetables. The vine gave the first of these liquors; after this, wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after those the juices drained from the pine, fycamore, and maple, were brought to this use: in latter times, roots, berries, and the pith of the sugar-cane, have been employed for the same purposes. Honey also is in some repute, and before the use of the things above-mentioned, the vinous liquor made of honey and water, was in the very highest estimation.

It is acknowledged by many physicians, that among the strong drinks, wine is the most pernicious; and that good water, milk, beer, and cider, are greatly preferable to it; none of them bringing on the variety of disorders to which inconsiderate wine-drinkers are subject, such as decay of sight, trembling of the limbs, & c.

Of all drinks, water is the least flatulent, because the unelastic air lodged in it, cannot be extricated by the heat of the body, so as to become elastic. The most flatulent of all drinks, are those taken in the act of fermentation; as for example, the ale which is close shut up in very strong vessels, and flies out with the greatest force upon opening them; for by an imprudent use of such, the most severe colic, ills passion, and cholera morbus, frequently ensue. Next to these come such drinks as have not yet fermented, but are soon set to work by the heat of the body; as for example, must, new wine, or ale, wherein no bitter herbs, such as hops, wormwood, & c. have been boiled as a preservative.

Dr. Bryan Robinson thinks that the proportion of meat to drink, ought to be such as shall make perspiration and urine nearly equal at all seasons of the year.

DRINKING-GLASSES. See GLASSES.

DRIPS, in architecture. See the article LARMIER.

Drips are used in building for a certain kind of stops made on flat roofs to walk upon, a way of building much used in Italy, where the roof is not made quite flat, but a little raised in the middle, with drips or stops lying a little inclined to the horizon. See the article Roof.

DRIVERS, among sportsmen, a machine for driving pheasant-powts, consisting of good strong ozier-wands, such as the basket-makers use; these are to be set in
Fig. 1. *Draco Marinus*, the *Sea-Dragon*.

Fig. 2. *Dracunculus*, the Little *Sea-Dragon*.

Fig. 3. *Dracocephalum*, *Dragon's Head*.

Fig. 4. *Dromedary*. 
in a handle, and twisted or bound with small oizers in two or three places.

With this instrument, the sportman drives whole eyes of young pows into his nets. See the next article.

DRIVING, among sportmen, a method of taking pheasant-pows. It is thus: the sportman finds out the haunts of these birds; and having fixed his nets there, he calls them together by a pheasant-call, imitating the voice of the dam: after this he makes a noile with his driver, which will make them run a little way forward in a cluster; and this he is to repeat till he has made lure of them, which an expert sportman never fails to do, by driving them into his nets.

DRIVING, in metallurgy, is said of silver, when in the operation of refining, the lead being burnt away, the remaining copper riles upon its surface in red fiery bubbles. See the article SILVER.

DRIVING, in the sea-language, is said of a ship when an anchor being let fall will not hold her faw, nor prevent her falling away with the tide or wind. The best help in this case is to let fall more anchors, or to veer out more cable; for the more cable she has out, the faver she rides. When a ship is a-hull or a-try, do, by driving them into her sides pitch and wax, admits pepper, fails to work her, ing heavy loads.

DRIVE-BOLTS, in ship-building. See the article BOLT.

DROCK, in husbandry, the upright piece of timber on the right side of a plough's tail, to which is fixed the earth-board. See the article PLOUGH.

DROGHEDA, a port-town of Ireland, twenty-three miles north of Dublin.

DROGMAN, the same with dragoman. See the article DRAGOMAN.

DROIT, jus, signifies right or law, of which some distinguish six kinds. 1. Jus recuperandi, right of recovery. 2. Jus entrandi, right of entering. 3. Jus hability, right of having. 4. Jus retinendi, right of retaining. 5. Jus percipienda, right of receiving. 6. Jus possidendi, right of possession. See the articles ENTRY, POSSESSION, and RECOVERY.

DROIT is also the highest writ of all other real writs, and takes its name of a writ of right, from the greatest regard being shewn to it; and as it has the most al- fured and final judgment. There are several forts of these writs ufed in our law, as droit de avowfon, droit de dowar, droit de garde, droit patent, droit rationalblie parte, and droit fur disclaimier. See the article RECTO.

DROITWICH, a borough six miles north of Worcester, which sends two members to parliament.

DROMEDARY, dromedarius, a large animal of the camel-kind, with only one bunch on its back; it is taller than the horfe, and has a much longer and flen- derer neck: its ears are short, and the upper lip is divided in the manner of that of the hare: it is a native of Asia, and more ufed for riding on, than for carrying heavy loads. See plate LXXIX. fig. 4.

DROMEUS, a name given by the antients to two very diftinct animals, the flag and dromedary.

DRONE, in the history of insects, a kind of bee, larger than the common working or honey-bees; it is so called from its idleness, as never going abroad to collect either honey or wax. See BEE.

The number of these drones in a hive is more or less, according to the feron and age of the swarm. In a full hive, they sometimes amount to five or six hundred, or even a thousand.

DRONE-FLY, a two-winged insect, extremely like the common drone-bee, whence also the name.

DRONTE, a name ufed by some for the dodo. See the article DODO.

DROPAX, an external medicine ufed by the antients for inducing a redneft upon a part, and also for taking off the hairs from the body. It was either simple or compound. The simple consists of pitch and wax. The compound dropax, besides pitch and wax, admits pepper, bitemen, rotemary-feed, and euphorbium. It was ufed in the form of a platter, or cataplasm.

DROPPING, or DRIPPING, among fal- coners, is said of a hawk which mates directly downwards in fevefal drops, not yerking her dung frighte forwards.

DROPS, in architecture, an ornament in the doric entablature reprenting drops, or little bells immediately under the tri- glyphs.

DROPS, in meteorology, small spherical bodies which the particles of fluids spontaneoufly form themselves into, when let fall from any height. This spherical figure, the newtonian philosophers demontrate to be the effect of corpufcular attraction; for considering that the attractive force of one fingle particle of a fluid is equally exerted to an equal distance, it must follow that other fluid particles are on every side drawn to it, and will therefore take their places at an equal distance.
DROPS; in medicine, a liquid remedy, the dose of which is estimated by a certain number of drops.

Drops of life, gutta vitae, a tincture produced from opium, English saffron, russia-cateor, cochinchal, and Virginia-snake-root, nutmegs, zedoary and camphire, with the tincture of antimony. This medicine, though not commonly met with, is accounted one of the best preparations of the kind. It promotes sweat very much, and is wonderfully carminative. The dose is from ten to forty, fifty, or sixty drops.

English drops, gutta anglica, a name given to a chemical preparation esteemed of great virtue against vapours, and lethargic affections, and purchased at 1000 L. by King Charles II. from the Inventor Dr. Goddard. The medicine appeared to be only a spirit drawn by the retort from raw silk, and afterwards rectified with oil of cinnamon, or any other essential oil, and was in reality no better than the common fial volatile oleaum, or any of the volatile spirits impregnated with an essential oil, except that it was less disagreeable than any of them to the taste.

DROPSY; in medicine, an unnatural collection of watry humours in any part of the body. Droples are of various kinds, but those most common are the anaesarca, afectes, and tympanites. See the article ANASARCA, &c.

Among the causes of these diseases may be reckoned a family or constitutional disposition thereto; a hasty drinking cold water in too large quantities; a stoppage of the natural discharges of perspiration and urine; a lientenous disorder of long continuance; all oblitinate obstructions of the viscera; the jaundice, diarrhoea, dysentery, coeliac passion, and gout; drinking sharp, fermented, and spirituous liquors; and the like.

As to the symptoms, the feet and legs first swell; and when these are distended to the utmost, the waters rush into the abdomen, and cause it to swell by little and little; till at length the more noble viscera are affected thereby, and the patient is soon overwhelmed with the deluge. In proportion as the diseased parts increase in bulk, the rest fall away; and at the same time, the difficulty of breathing, and other symptoms grow more intolerable.

When the abdomen is swelled, it will resound when struck, if the disease be a tympany; and if an ascites, the noife of the fluctuating waters is heard. Besides these symptoms, the patient is also afflicted with a heaviness, stupor, coltivelines, and at length with a flow fever. The waters too, after being long pent up in a close place, grow acrimonious; and hence ulcers, gangrenes, bleeding at the nofe, a mortification of the viscera, and death.

In the anaesarca, as well as in the more advanced stages of a dropisy, the chief indications of cure, are to restore the humours to their natural fluidity, invigorate the languid circulation, brace up and strengthen the relaxed solids, promote the secretions, and carry off the redundant stagnating juices. To this purpose, drastic purges,栈el-medicines, abiorbents, detergents, and florinachs are recommended. A brisk purge should be taken early every morning, or every other day, according to the strength of the patient, till the swelling of the parts affected abate.

Elaterium, and antimonial wine, are said to be excellent for drophical patients, who are not easily purged; two grains of the former being a proper dose for most constitutions; and of the latter, or antimonial wine, a dram and a half, or two drams, may be taken every morning: this frees the abdomen from the load of waters. Some greatly recommend Bonniius's pills, the dose of which is from half a scrupule to a scrupule. Mercurius dulcis, and the juice of the root of iris palustris lutea are also recommended: eighty drops of this last may be given every hour in a little syrup of buckthorn.

As to cathartics, the flow ones are rather hurtful than beneficial; and therefore, the purge had better be too strong than too weak, that the waters may be carried off with as much speed as the patient's strength will bear. When the patient is of a very weakly constitution, it is proper to omit all purgatives, and give diuretics and the lixivial salts in their stead, especially nitre. Some also have been cured by a pertinacious abstinence from all liquids, excepting a little rich wine.

When the waters are by these means carried off, the tone of the debilitated viscera...
DRO [985]: DRU

Althea should be restored by the use of wines, steep, and such strengtheners as are greatly astringent; in which case, purging must be omitted, as also during the use of the lixivial salts; but strengtheners may be properly used with these last.

For the operation of tapping, called by surgeons paracentesis. See the article Paracentesis.

DROP-WORT, in botany, the same with Filipendula. See Filipendula.

Water DROP-WORT, the English name of a plant, called by authors Oenanthe. See the article Oenanthe.

DROSERA, sun-dew, in botany, a genus of the pentandra-pentagyna class of plants, with a funnel-shaped flower, consisting of five obtusely-ovated petals: the fruit is an unilocular, fuboval capsule, containing a great many very small seeds.

DROUGHT, in the history of the air, a long continuance of dry weather.

Great droughts are often very prejudicial to the farmer, unless the lands lie very low, and are well supplied with water; or defended from the scorching heat of the sun by tall inclosures. See the articles Inclosure, and Watering of Lands.

DROWNING, the act of suffocating, or being suffocated, by water.

Naturalists and physicians furnish us with divers well attested instances of purifying recoveries of persons drowned. It is certain from repeated dissections made on persons drowned, that they generally have less water in their stomachs than if they had voluntarily drunk a considerable quantity; whence it does not seem expedient to hang the drowned person by the heels, a position that must prove uneafy as soon as the humours of the body should resume their ordinary motion. In order to know whether the person has swallowed too much water; or not; and to make him vomit it up if he has, it is proper to put him in a tun, open at both ends, which is to be rolled in different directions; or the bearded end of a feather should be introduced into the oesophagus. After taking off the cloaths of the drowned person, we ought, with the utmost expedition, to shelter him from the imprefions of the cold air, and begin to warm him by wrapping him up with cloaths, and coverings: to do this more effectually, he is afterwards to be put into a pretty warm bed, applying also to his body hot napkins and cloths. A hot scorching fum, to which drowned persons have been exposed, and hot baths, have produced the same happy effects.

The great intention to be pursed is, to put the solid parts of the machine in action, that thus they may restore the motion of the fluids: in order to this, the drowned person should be agitated in various directions, in a bed, in the arms of persons of sufficient strength.

Spirituous liquors should be poured into his mouth; or warm urine; and some persons prescribe a decoction of pepper and vinegar, as a gargalium; we must also attempt to irritate the internal fibres of the nose, either by volatile spirits, and by the liquors used in apoplectic cases; or by tickling the nerves of the nostrils with a bearded feather, or by blowing through a quill, shuff, or some other more powerful internalatory. One of the means frequently used with success, is to blow warm air, by means of a pipe, into their mouths; or to introduce it by a pair of bellows; or, by injecting warm clysters, to irrate the intestines: the smoke of tobacco conveyed into the intestines, by means of a tobacco-pipe, is much recommended. Vomisation is by no means to be neglected; and perhaps most successfully in the jugular vein; and when all these measures prove unsuccessful, the last recourse is branchotomy. See the article Branchotomy.

DRUG, a general term for goods of the druggist and grocery kinds, especially for those used in medicine and dying.

The principal drugs in medicine make the greatest part of the wholesale trade in the druggist and grocer ways. Some are produced in France, England, &c. but the greatest part is brought from the Levant, and the East Indies. The chief drugs imported into this kingdom, are from the East-Indies, being as follows, alum, china-root, camphor, rhubarb, musk, vermillion, joy of Japan, ketchup, flick-lack, rofam aloes, shell-lack, borax, lapis lazuli, galangal, benjamin, aqula-wood, gamboge, putchuck, or ciffus dulcis, dragonblood, cubebs, cardamoms, obilbanum, chengue, salt-petre, aloe-hepatica, bezoor-fone, lignum aloes, caspia, goat-fone, opium, unicorn's horn, civet, frankincense, tamarindo, turmeric, rock-fall, fatiron, myrrh, manna, rennes, tacamahac, amber-grease, dammer, coy, cowries,
cowries, chank, nux vomica, snake-stone, caffia lignum, assafetida, dry ginger, long pepper, tynca, fago, lapis tuitia, wormseed, galbanum, gum-elemi, ammoniacum, tragacanth. See the articles Alum, China-root, &c.

Drugs for dyeing are of two principal sorts, viz. drugs that do not give any colour of themselves, but prepare the stuff to take the dye, or make the colours more lively and strong, and drugs that colour.

Of the first sort are alum, tartar, arsenic, realgar, falt-petre, nitre, falt, selt of crystal, of tartar, agate, spirit of wine, urine, pewter, bran, asphalt, &c.

Some of the colouring drugs are wood, indigo, scarlet wood, logwood, ironwood, &c. scarlet grain, cochineal, madder, goats hair, greening weed, favoty, chimney-foot, &c.

There are other drugs used in common by both; which colour either faintly, or very much; as the root, bark, and leaf of the walnut-tree, the rind of the nut, gall-nuts, sumach, copperas, &c.

Drug is used to signify things of little value exposed to sale.

Drug, among fan-makers, is a composition of gum arabic, and some other ingredients used in laying gold or silver leaf upon fans; or, in covering them with either of these metals in powder. They use it also to paste together the papers, gawzes, taffeta's, and other like matters, used by them in their fans.

Drug signifies also a salt, or cinder of glas, used by some in bleaching cloth.

The use of this drug is prohibited in France, as being found corrosive, destructive of the linen, and capable of hurting the health of those who use it. See Bleaching.

Drugs of the French dominions pay for every 20 s. value of their respective rates, (a few excepted) on importation, 4 s. 9 t 7 d. and draw back on exportation 4 s. 4 t 8 d. If for dyer's use, they pay 6 s. 7 t 6 d. and draw back 6 s. 1 t 6 d. Drugs of the growth, product, or manufacture of France, for every 20 s. value of their respective rates (some excepted) pay 6 s. 5 t 7 d. and draw back 4 s. 4 t 8 d. but if for dyer's use, they pay 6 s. 7 t 6 d. and draw back 6 s. 1 t 6 d. All drugs imported from the British plantations, in British built shipping, notwithstanding they come from the Spanish West-Indies to ours, shall pay as from the place of growth and no otherwise.

Drugget, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded; but usually plain.

Those that have the woof of wool, and the warp of thread, are called threaded druggets; and those wrought with the shuttle on a loom of four marches, as the ferges of Moul, Beauvois, and other like stuffs, corded, are called corded druggets. As to the plain, they are wrought on a loom of two marches, with the shuttle, in the same manner as cloth, camlets, and other like stuffs, not corded.

Druids, the priests or ministers of religion of the ancient Britons, and Gauls. The druids were 'chose out of the best families; and were held, both by the honours of their birth, and their office, in the greatest veneration. They are said to have underftood astrology, geometry, natural history, politics, and geography: they had the administration of all sacred things, were the interpreters of religion, and the judges of all affairs indifferently.

Whoever refused obedience to them, was declared impious and accursed: they held the immortality of the soul, and the metaphysical; they are divided by some into several classes, as the vaceni, bardi, bubagis, remOldi: they had a chief, or arch-druid, in every nation: he was a sort of high-priest, having an absolute authority over the rest, and was succeeded by the most considerable among his successors. The youth 'used to be instructed by them, retiring with them to caves, and defolate forests, where they were sometimes kept twenty years. They preferred the memory and actions of great men by their verés; but are said to have sacrificed men to Mercury. Cæsar imagined that the druids came from Britain into Gaul, but several among the modern writers are of a different opinion.

Drum, lympatum, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or fastened at pleasure by the means of small cords and folding knots. It is beat upon with sticks. Some drums are made of brafs, but they are commonly of wood.
There are several beats of the drum, as assembly, chamade, reveille, retreat, &c. See Assembly, Chamade, &c.

Kettle-drums, are two forts of large bacons of copper or brass, rounded in the bottom, and covered with vellum or goat-skin, which is kept flat by a circle of iron, and several holes fastened to the body of the drum, and a like number of screws to screw up and down. They are much used among the horses, as also in operas, oratorios, concerts, &c.

Drum, or drummer, he that beats the drum, of whom each company has one, and sometimes two. Every regiment has a drum-major, who has the command over the other drums. They are distinguished from the soldiers, by cloaths of a different fashion: their poft when a battalion is drawn up, is on the flanks, and on a march it is betwixt the divisions.

Drum of the ear, in anatomy. See the article Tympanum.

String of the Drum. See the articles Chorda Tympani.

Drum, in architecture. See Tambour.

Mire-drum, the fame with the bitttern. See the article Bittern.

Drumlaner, a town of Scotland, fifteen miles north of Dumfries.

Drungus, a name given in the latter times of the roman empire to a body of troops, amounting from one thousand to four thousand men. At first it was used to denote the troops of foreigners and enemies, but in the eastern empire to signify the troops of the empire itself.

Drunkenness, ebrietas, physically considered, consists in a preternatural compreffion of the brain, and a discomposure of its fibres, occasioned by the fumes or spirituous parts of liquors.

All liquors will not give drunkenness: Such only as by their sulphur or spirit are dispoled for an effervescence in the stomach and heart to diffuse their subtile parts plentifully to the brain are capable of producing intoxication. Drunkenness appears in different shapes, in different constitutions. Some it makes gay, some full, and some furious.

Hobbes makes voluntary drunkenness a breach of the law of nature, which directs us to preserve the use of our reason.

The law of England does not allow it to be an excuse in any case whatsoever. On the contrary, it is punishable, the penalty being five shillings fine, or the stocks, in case of non-payment.

Drype, among botanists, a kind of pericarpium, consisting of a soft, fleshy, and succulent pulp, with a nucleus, or kernel in its center.

Drusenheiin, a town of Alsace, in Germany, four miles south east of Hagenaus.

Dry baths, See Bath.

Dry confections, See Confection.

Dry dock, See Dock.

Dry cupping in surgery. See the article Cupping.

Dry exchange, cambium circum, a soft appellation for fury.

Dry fish, See Fish.

Dry fruits, See Fruits.

Dry meat, in the manage, is used for corn and hay. After taking the horse from grafs he is houfed, and put to dry meat.

Dry mass, See Mass.

Dry measure, See Measure.

Dry moat, See Moat.

Dry rent, See Rent.

Dry storax, See Storax.

Dry suture, See Suture.

Dry spavin, See Spavin.

Dryadea, in botany, the fame with the dryas. See the article Dryas.

Dryads, dryades, in the heathen theology, a sort of deities, or nymphs, which the antients thought inhabited groves and woods. They differed from the Hamadryades, thefe latter being attached to some particular tree, with which they were born, and with which they died: whereas they Dryades were goddeses of trees and woods in general.

We likewise find mention made of a kind of prophetess, or witches, among the Gauls, called dryades or druids. See the article Druids.

Dryas, in botany, a genus of the jonandra-pentagyna class of plants, the flower of which consists of eight oblong, emarginated, patent petals, inserted into the cup. There is no pericarpium, but the seeds are numerous, of a roundish compressed figure, and furnished with very long hairy styles.

Dryites, a name given by some to half petrifed foffile wood.

Dublin, the capital of the province of Leinster, and of all Ireland, situated at the mouth of the river Liffie, sixty miles west of Holyhead in Wales: west long, 6° 35', north lat. 53° 16'.

It is a large and beautiful city, pleasantly situated; having a view of the sea on one side, and of a fine country on the other.
of exotic or foreign ducks, authors de-
scribe a great many species, as the mul-
covy-duck, with a naked papillose face;
the tufted duck, the brazillian duck, as
large as a goose, St. Cuthbert’s duck, the
forked-tailed duck, the black duck, &c.
See plate LXXX. fig. 1. where n° 1. re-
prents the little black and white duck,
somewhat less than the common kind ;
and n° 2. the summer duck of Mr.
Catesby, likewise less than the common
duck: it has a double plumé or crest,
the uppermoft of a thinning green, and
the under one of a dark, shining purple
colour. Edwards.

DUCKER, or DUCKER, a particular
kind of game-cock, that in fighting runs
about the cloot almost at every blow he
gives.

DUCER, is also a name given to the co-
ylumbus, or dier. See CYLUMBUS.

DUCING, plunging in water, a diver-
ion antiently practised among the Goths;
by way of exercise; but among the Celte,
Franks, and antient Germans, it was a
sort of punishment for perions of scan-
dalous lives.

They were shut up, naked to the shift,
in an iron cage, fastened to the yard of
a shaloop, and ducked several times.

Ducking at the main-yard, among men,
is a way of punishing offenders on
board a ship; and is performed by bind-
ing the malefactor, by a rope, to the
end of the yard, from whence he is
violently let down into the sea, once,
twice, or three times, according to his
offence; and if the offence be very great,
he is drawn underneath the keel of the
ship, which they call keel-haling.

DUCKUP, at sea, is a term used by the
seer’s man, when the mainail, foreail,
or spritail, hinders his seeing to hear by
a land-mark: upon which he calls out,
duck up the clew lines of these fials,
that is, hail the fials out of the way. Also,
when a shot is made by a chace-piece, if
the clew of the sprit-fail hinders the sight,
they call out, duck up, &c.

DUCZ, ductus, in general, denotes any
tube or canal.

It is much used by anatomists, who men-
tion the adipocele ducts, concerning the
reality of which authors are not agreed;
the thoracic, or chyliferous ducts; the
excretory ducts of the glands; the he-
patie duct, or porus bilarius; the sali-
val ducts; the lachrymal ducts; the ductus
communis choledochus, &c. concerning
all which it is to be observed, that their
ulic

other. It is the seat of the courts of
justice, and an archbishop’s see; and has
a noble college, which is an university of
itself.

DUCAL, in general, something belong-
ing to a duke. See the article DUKE.

DUCAL CROWN, or CORONET. See the
article CROWN.

DUCAT, a coin, current in Germany,
and other countries abroad, for the dif-
ferent values of which see COIN.

DUCATOON, a silver coin, likewise fre-
fquent in several parts of Europe. See
the article COIN.

DUCENARIUS, in roman antiquity,
a military officer, who had the command
of two hundred men.

The title ducenarii is also given to cer-
tain procurators of the emperors, so
called either from their having a fallary
of 200 sesterces, or from their being ap-
pointed to raise the tax of the two
hundredth penny.

DUCES TECUM, in law, a writ that com-
sels a perion to appear in the court of
chancery, and bring with them cer-
tain writings, evidences, or other things,
which the court is inclined to view.

DUCES TECUM LICET LANGUIDUS, in law, is a
writ directed to the sheriff on a
return; that he is not able to bring his prifoner DUCKING,
without danger of death, he being
not able

DUCK, anas, in ornithology, is char-
acterized in general under the article
ANAS.

There are two sorts of ducks common
with us, the tame and wild; whereof the
first is very beneficial to the husbandman,
and at the same time requires no charge
to keep, living on loft corn, worms,
snails, &c. Indeed once a year this fowl
is a great layer of eggs, and when the
fits, must be carefully fed with barley or
other grain. As to the ducklings, they
are fed in the same manner as
goslings, and may be fattened in three weeks time,
by giving them any kind of pulse or
grain, and plenty of water.

For preferring wild ducks, a place (with
a pond in it) must be walled in, and
covered a-top with a strong net: the pond
is to be set with tufts of oxiers, and have
many secret holes and creeks, whereby
they will be induced to feed freely,
though imprisioned. Teals, widgeons,
shell-drakes, and green plovers, may
also be ordered in the same manner.
Mr. Boyle examining some leaf-gold, found that a grain and a quarter's weight took up an area of fifty square inches; supposing therefore the leaf divided by parallel lines \( \frac{1}{100} \) of an inch apart, a grain of gold will be divided into five hundred thousand minute squares, all discernible by a good eye: for gold-wire, the same author shows, that an ounce of gold drawn out therein, would reach 155 miles and a half. But Mr. Reaumur has carried the ductility of gold to a still greater length: a gold-wire every body knows is only a silver one gilt. This cylinder of silver, covered with leaf-gold, they draw through the hole of an iron, and the gilding still keeps pace with the wire, stretch it to what length they can. Now Mr. Reaumur shews, that in the common way of drawing gold-wire, a cylinder of silver twenty-two inches long, and fifteen lines in diameter is stretch'd to 1,163,520 feet, or is 634,692 lines longer than before, which amounts to about ninety-seven leagues. To wind this thread on silk for use, they first flatten it, in doing which it stretches at least \( \frac{1}{2} \) farther, so that the twenty-two inches are now 111 leagues: but in the flattening, instead of \( \frac{1}{2} \), they could stretch it \( \frac{1}{3} \), which would bring it to 120 leagues. This appears a prodigious extension, and yet it is nothing to what this gentleman has proved gold to be capable of.

**DUDERSTAT**, a town of Upper Saxony, thirty-five miles north-east of Cassel.

**DUEL**, a single combat, at a time and place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes and Franks, that none were excused from it but women, sick people, cripples, and such as were under twenty-one years of age, or above sixty. Even ecclesiastics, priests, and monks, were obliged to find champions to fight in their stead. The punishment of the vanquished was either death, by hanging or beheading; or, mutilation of members, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil
DUKE, at present, is used for a single, civil one for the maintenance of rights to estates, and the like: in latter times, however, before they were entirely abolished, they were restrained to these four cases: 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must, by common fame, be supposed guilty. 4. The matter not capable of proof by witnesses. In England, though the trial by duel is disdained, the law on which it is founded is still in force. See the article CHAMPION.

DUEL, at present, is used for a single combat on some private quarrel, and must be premeditated, otherwise it is called a rencontre. If a person be killed in a duel, both the principals and seconds are guilty of murder, whether the seconds engage or not. It is also a very high offence to challenge a person, either by word or letter, or to be the messenger of a challenge. The severe edicts made by Lewis XIV. against duels, have in a great measure put an end to duelling in France.

DUERO, or D U R O , a large river, which, rising in Old Castile, in Spain, runs from east to west, croffes the province of Leon, and, after dividing Portugal from Spain by a footherly course, turns westward, croffes Portugal, and falls into the Atlantic ocean at Porto-Port.

LUKE is either the title of a sovereign prince, as the duke of Savoy, Parma, &c. the grand duke of Tuscany, Munich, &c. or it is the title of honour and nobility next below princes. The commanders of armies in time of war, the governors of provinces, and wardens of marches, in time of peace, were called dukes, under the latter emperors. The Goths and Vandals divided all Gaul into dutchies and counties, the governors of which they sometimes called dukes and sometimes comites. In France, under the second race of kings, though they retained the name and form of ducal government, there were scarce any dukes except those of Burgundy, Aquitain, and France. In England, among the Saxons, the commanders of armies, &c. were called dukes, dukes, without any addition, till Edward III. made his son, the black prince, duke of Cornwall; after whom there were more made in the same manner, the title descending to their posterity. Duke, then, at present, is a mere title of dignity, without giving any domain, territory, or jurisdiction over the place from whence the title is taken. A duke is created by patent, cineture of sword, mantle of state, imposition of a cap and coronet of gold on his head, and a verge of gold put into his hand. His title is Grace; and, in the style of the heralds, Most high, potent, high-born, and noble prince. 

DUKE, among hebrew grammarians, an appellation given to a species of accents, anwering to our comma. 

DULCICHNIUM, in botany, a name used by some for the sweet cyperus. See the article CYPERUS.

DULCIFYING, in pharmacy, is the sweetening any matter impregnated with salts, by frequently washing it in pure water. 

DULCIS ASSA, or ASA. See the articles BENZOIN and ASA.

DULEDGE, in gunnery, a peg of wood which joins the ends of the six fellows that form the round of a wheel of a gun-carriage. The plate of iron on the out side of the wheel, which strengthens the joint, is called the duledge-plate.

DULL, in the manage. The marks of a dull horse, called by the French, marquis de ladre, are white spots round the eye, and on the tip of the nose, upon any general colour whatsoever. Though the vulgar take these spots for signs of dullness, it is certain they are great marks of the goodness of a horse; and the horses that have them are very sensible and quick upon the spur.

DULNESS of bearing. See the article DEAFNESS.

DULWICH, a village near London, remarkable for its mineral waters, which are said to contain a bitter cathartic salt, but no iron. See EPSOM-SALT.

DUMBLAIN, a town of Scotland, about five miles north of Stirling.

DUMBNESS, the deprivation of speech. See the article SPEECH.

Dumbness may be owing either to the want, or bad conformation of the tongue. See the article TONGUE.

DUMFRIEMLING, a parliament-town of Scotland, situated in the county of Fife, fifteen miles north-west of Edinburgh: west lon. 3° 20', and north lat. 56° 19'. Here was formerly a magnificent abbey and palace of the kings of Scotland, in which the princes Elizabeth, daughter of King James VI, and mother of the princes Sophia, from whom the present royal family are descended, was born.

DUMFRIES, the capital of a county of the same name, in Scotland, lying northwards
wards of the Solway frith: west lon. 3° 20', and north lat. 54° 45'.

DUM FUIT INFRA AETATEM, is a writ, that an infant, who by feoffment has aliened his lands, may have, when he arrives to full age, for the recovery of what he so aliened: and during his non-age, it is said, he may enter on the land, and take it back again; for, by his entry, he shall be remitted to his ancestor's right.

DUNBAR, a parliament and port-town of Scotland, about twenty-five miles east of Edinburgh.

DUNBARTON, the capital of a county of the same name in Scotland, called by some Lenox: it is a parliament-town, situated at the confluence of the rivers Clyde and Leven; sixteen miles north-west of Glasgow.

DUNCANNON, a town of the county of Wexford, in Ireland, six miles east of Waterford.

DUNDALK, a port town of Ireland eighteen miles north of Drogheda.

DUNDEE, a large parliament town of Angus, in Scotland, situated on the north-side of the frith of Tay, fourteen miles north-west of St. Andrews: west lon. 2° 42', and north lat. 56° 32'.

DUNG, in husbandry, is of several sorts, as that of horses, cows, sheep, hogs, pigeons, geese, hens, &c. for the several properties of which, see HORSE, COW, SHEEP, &c.

All dungs are very enriching to lands; but some, as horse's, sheep's, pigeon's, &c. being hot and light, are fittell for cold lands; as those of cows, hogs, &c. are for hot and dry lands, on account of their cooling qualities; or mixed together in different proportions, they may be made to answer for all sorts of ground. In winter, or rainy weather, it is proper to turn up the dung in large heaps as possible, to prevent the rain's washing away its fatness and nitrous quality; which purpose the dungmeers answer extremely well. See the article DUNG-MEERS.

DUNGANNON, a town of Ireland, eleven miles north of Armagh,

DUNGEON, in fortification. See the article DONJON.

DUNGING of pastures, &c. The best time for dunging pastures and meadows is in the winter season, about January or February, that the rain may wash the fatness of the soil to the roots of the grass before the sun drives it away. The dung may be spread with a bufh, drawn over the ground like a harrow, before the grass is too high: and for roughy cold land, wood-ashes, sea-coal, peat, turf, or the like fuel, is very proper to be laid on. The dung of pigeons, or other fowl, has a better effect here than on any other lands; also all hot and sandy soils are fittell for this sort of ground: but for such land of this kind as is sandy, or hot, lime, chalk, marl, or any cold soils, digged out of the earth, are of singular use, as well as for corn-lands: so is ury in like manner. As for meadows, or grounds of a middle quality between these extremes, the ordinary soil is best. The principal part of good husbandry consists in a proper application of the compost.

DUNFIELD, a town of Perthshire in Scotland, formerly a bishop's see, situated about twelve miles north of Perth.

DUNG-MEERS, in husbandry, places where soils and dungs are mixed and digested together. For this purpose it is usual to dig a pit sufficient to hold the flock of soil the husbandman is capable of making; and to prepare it at the bottom with stone and clay, that it may hold water, or the moisture of the dung; and besides, it should be so situated that the finks and drips of the houses and barns may run into it. Into this pit they cast refuse-fodder, litter, dung, weeds, &c. where they lie and rot together, till the farmer have occasion for it. Where such a pit is wanting, it is proper to cover the dung with turf, or other stuff, to prevent the sun and wind from drawing off its virtues.

DUNKIRK, a port town of the French Netherlands: east lon. 2° 28', and north lat. 51°.

DUNLIN, in ornithology a small species of snipe, with the breast and throat white, the belly black spotted with white, and the upper part of the body red variegated with pretty large black spots.

DUNNEGAL, the capital of a county of the same name in Ireland, situated on a bay, to which it likewise gives name: west lon. 8° 22', and north lat. 54° 35'.
DUODECIMA, in music, is the twelfth, or the fifth doubled. See Fifth.

DUODECIMAL, in music, a tone or composition to be performed in two parts only, one singing, the other played on an instrument, or by two voices.

DUO is also when two voices sing different parts, as accompanied with a third, which is a thorough base. It is seldom that unisons and octaves are used in duos, except at the beginning and end.

DUODECIMA, in music, is the twelfth, or the fifth doubled. See Fifth.

DUODECIMAL, in music, a tone or composition to be performed in two parts only, one singing, the other played on an instrument, or by two voices.

immediately under the cranium: its figure and magnitude correspond exactly to those of the brain. It adheres everywhere to the skull, only more laxly on the upper part than elsewhere: it adheres also, tho' not very firmly, to the parts placed under it. It receives arteries from the carotids, beautifully ramified in the manner of shrubs. Its veins are of two kinds, some as in other parts of the body, and others of a triangular figure, called sinuæ, for carrying off the blood from the brain. It has nerves for sensation, from the fifth and seventh pair of the brain.

The dura mater has a motion, said to be peculiar to itself, and of a muscular kind: but it seems much more natural to suppose it owing to the pulsations of the arteries of the brain.

As to the uses of this membrane, it serves in the place of a perioöteum to the internal parts of the skull; also to defend the brain by its proeèxes, to prevent the compression of its parts; and by its sinuæ to give warmth to the brain.

DURANCE, a river of France, which falls into the Rhone, a little below Avignon.

DURANTA, a genus of plants, the class of which is not yet ascertained: the flower is formed of a single petal, with a cylindrical tube and ringent mouth, the upper limb of which is oval, erect, and hollow; and the lower one divided into three parts: the fruit is a roundish unilocular berry, covered with the cup; the seeds are four, and of an angular figure. Linneas.

DURATION, an idea which we get by attending to the fleeting and perpetually perishing part of succession; the idea of succession being acquired by reflecting on that train of ideas which constantly follow one another in our minds, as long as we are awake. The simple modes of duration are any different lengths of it whereof we have distinct ideas, as hours, days, years, time, eternity, &c.

Duration, as marked by certain periods and measures, is what we most properly call time. See the article TIME.

Duration of action, according to Aristotle, is confined to a natural day in tragedy; but the epopee, according to the fame critic, has no fixed time.

Duration of an eclipse. See ECLIPSE.

DURESSE, in law, is where a person is wrongfully imprisoned, or restrained of his liberty, contrary to law; or is threat-ened to be killed, wounded, or beaten, till he executes a bond, or other writing.

Any bond, deed, or other obligation, obtained by dureffe, will be void in law; and in an action brought on the execution of any such deed, the party may plead that it was brought by dureffe. A deed must be avoided by special pleading, in these cases; for the party cannot plead to it, non est factum, because it is his deed.

DURHAM, a city and county, in the north of England, situated on the river Wear, fourteen miles south of Newcastle: west lon. 1° 12', and north lat. 54° 50'.

Durham is the see of a bishop, and sends two members to parliament.

DURION, an east-indiafruit, much esteemed by the natives, who prefer it to all others, though the Europeans cannot endure its nauseous smell, which is unlike that of rotten onions.

DUSSELDORP, a city of Germany, situated on the eastern shore of the Rhine, twenty miles north of Cologn: east lon. 6° 20', and north lat. 51° 15'.

DUST is nothing else but dry earthy particles, reduced to a fine light powder. Dust and sand will sometimes get into horses mouths, and make them lose their appetites; in which case it is proper to give them bran well moistened with water, to cool, and refresh their mouths and tongues.

The Hebrews, when they mourned, put dust or ashes upon their heads; and in their afflictions they sit down in the dust, and throw themselves upon the ground.

DUTCHY, in geography, an appellation given to the dominions of a duke. See the article DUKE.

DUTCHY-COURT, a court of the dutchy-chamber of Lancaster, held at Westminster, before the chancellor of the same, for matters concerning the lands and franchises of that dutchy. See the article CHANCELLOR.

The proceedings in this court are by English bill, as in chancery. Gwyn says, that this court grew out of the grant of king Edw. III. who gave the dutchy to John of Gaunt, and endowed it with royal rights and privileges: several others of our ancient kings likewise separated this dutchy from the crown, and settled it in the natural persons of themselves and their heirs; though, in succeeding times, it was united to the crown again.

DUTY,
DUTY, in general, denotes any thing that
one is obliged to perform.

Duty, in polity and commerce, signifies
the impos'd laid on merchandizes, at im-
portation or exportation, commonly call-
ed the duties of customs; also the taxes of
excise, stamp-duities, &c. See the ar-
ticle Customs, Excise, &c.

The principles on which all duties and cus-
toms should be laid on foreign merchan-
dizes, which are imported into their king-
doms, are such as tend to cement a mutual
friendship and traffic between one nation
and another; and, therefore, due care
should be taken in the laying of them,
that they may answer so good an end,
and be reciprocal in both countries: they
should be so laid as to make the exports
of this nation at least equal to our im-
ports from those nations whereewith we
trade, so that a balance in money should
not be suffered out of Great Britain, to
pay for the goods and merchandizes of
other countries; to the end that no greater
number of our landholders and
manufacturers should be deprived of their
revenues arising from the produce of the
lands, and the labour of the people, by
foreign importations, than are maintained
by exports to such countries. These
are the national principles on which all
our treaties of commerce with other coun-
tries are to be grounded.

To shew, says the late Sir Matthew Dec-
ker, how excises, customs, and salt-dui-
ties increase the expense of the people,
and consequently ruin our trade, the follow-
ing account may not be improper.

First the duties themselves. The net pro-
duct of the taxes following, was, before
the late war, computed to be, one year
with another, as under:

Excise, about £2,800,000
Customs, about 1,700,000
Salt, about 150,000
4,650,000

The charges of raising those 7
duties are about 10 per cent. $465,000

Net produce 5,115,000

Secondly, the advanced price of those
goods the above duties are laid on. Ex-
perience teaches us that a very small
duty laid on commodities, raises the price
of them considerably to the consumer, be-
yond the grofs duty. By the fees given
to officers; by trademans loss of time in
attending upon excisemen, or at custom-
houses; by taking away a quarter of our
traders stocks for duties; and forcing
them to take as great pains on one quar-
ter of their stock laid out in goods, in
order to live, as they would on the whole
if duty free; by trademans profits on the
duty, and advances in all the hands that
all taxed goods come through, to the
consumer; as for example, suppose there
should be no other tax but that on leather,
let us see how many advances that would
make on the price of shoes.

The grazier lays (1) on the beast he fabs,
his advanced price of shoes; he sells to
the butcher, who takes (2) his profit on
the grazier's advanced price of the beast
and raises (3) on the hide his advanced
price of shoes; he sells to the tanner,
whole journeymen raise (4) their wages,
on account of the advanced price of shoes;
the tanner pays (5) the tax of two pence
per pound on the leather; takes (6) his
profit on the before-mentioned five ad-
ances, and raise (7) his advanced price
of shoes on the tanned hide: he sells to
the leather-cutter, who takes (8) his pro-
fit on the before-mentioned seven advances,
and raises (9) on the hide he cuts, his
advanced price of shoes; he sells to the
shoe-maker, whose journeymen raise (10)
their wages, on account of their advanced
price of shoes, the shoe-maker takes (11)
his profit on the before-mentioned ten ad-
ances, and raise (12) on the shoes he
makes, the advanced price of the shoes he
wears: he sells to the consumer with all
these twelve advances, highly magnified
beyond the bare duty.

So much for the tax on leather only; but
the grazier, butcher, tanner, leather-
cutter, and shoe-maker, use soap: that
soap, like leather, is taxed, and, like that
leather-tax, must be raised: but that cau-
sed twelve advances on our shoes; place
therefore twelve advances more on shoes,
for the soap-tax. These tradem-
men use candles; twelve advances more
for the tax on them; and the same for
every other tax on necessaries. All which
duly considered, might be computed at
above cent. per cent, on the grofs produce
of the duties; but though the large du-
ties cause some farther advance on all the
goods they are laid on, charged with pro-
fit upon profit, through every hand they
pass; yet as they keep not pace with the
small duties, and as all calculations ap-
pear fair when moderate, let us abate in
the advances, and let them down only at
50 per cent. 2,557,500.

The amount of the advanced price of the
goods these duties are laid on, 7,672,500.

Let
Let us see how this 7,672,500 l. circulates through the people, advances the prices of our goods, and consequently ruins our trade. First, this dearth of all necessaries, which raises the first cost of goods, must advance the price of all labour. The Spectator, n° 200. computes, that the people without property, who work for their daily bread, consume two thirds of our customs and excises, and therefore they pay two thirds of them and their consequences. As these people live but from hand to mouth, whatever is laid on them they must, therefore, shift off, or they cannot live; and since these various taxes have been projected, they must earn enough, when they do work, to pay the taxes, the advanced price of taxed goods, and the advanced prices of all other necessaries, viz. meat, bread, clothing, or whatever they can use, not only for the consumption of the days they are employed, but for those also they are not: therefore they are the cause of raising the wages of the working people two thirds of 7,672,500 l. the amount of the advanced price of the goods the above duties are laid on, which makes 5,115,000 l.

Secondly, the dearth of all necessaries forces the master-admen to raise on their customers the taxes and advances on their consumption. The same author allows one third consumption of our customs and excises to people with property; but as those may be divided into two classes, viz. those in trade, and those out of trade, and the proportion consumed by each not being ascertained by any author, they are computed by Sir Matthew at half and half; therefore the master-traders, or people with property in trade, viz. merchants, manufacturers, mechanics, farmers, wholesale dealers, and retailing shopkeepers, must each lay on the goods they consume, whether food, clothing, or utensils, their one sixth consumption of 7,762,500 l. the amount of the advanced price of the goods the above duties are laid on, makes 1,278,750 l.

Thirdly, tradesmen’s paying advanced prices on their goods, must have advanced profits: for whether they lay out their flocks of money in goods that bear their natural value only, or goods that double their value by taxes, still a living profit must be obtained on the flocks they employ. For the wages of the manufacturer, the mechanic, the labourer, and the expence of the master-tradesman, being of necessity raised, the first cost of goods must be so too: and considering the various tradesmen’s hands that goods pass through, from the workman or labourer, to the consumer, charged with profit upon profit by each of them, the advance thereby made, may, at a moderate rate be computed at 50 per cent. to the consumer on the above two articles, which raise the first cost of goods, and makes 3,536,875 l. People with property, out of trade, their sixth of 7,672,500 l. the amount of the advanced price of the goods the above duties are laid on, makes 1,278,750 l. and the total advance is 10,869,375 l.

This is part of the amount of the consequences of raising 4,650,000 l. for the government, by our present manner of taxing goods.

Our other taxes are, the land-tax; the gross produce, at 4s. in the pound, is about 1,960,000 l. The stamps, windows, post office, &c., their computed gross produce about 500,000 l. The poor’s tax is computed, on a middling rate, to equal the land-tax, but must be much more when trade is reduced, and the price of provisions high: however, to reckon it at no more than the land-tax, or 1,960,000 l. General amount of all our taxes, and part of their consequences, before the late war, 15,289,375 l.

Let us now see the amount of our taxes with regard to our expenses: The British Merchant computes our people at seven millions, and their expenses at 71. per head; but as necessaries are grown dearer since the year 1713, when he wrote, and the number of people increased, let us compute the people at eight millions, and their expenses at 81. per head, which makes our total expenses annually 64,000,000 l. of which the people pay for the taxes and their consequences, as above, 15,289,375 l. which being subtracted, their expenses, if untaxed, would be only 48,710,625 l. 15,289,375 l. charged on 48,710,625 l. is a tax of above 31 per cent. on the expenses of the people, which must add a prodigious artificial value to our goods, consequently render them less saleable, and ruin our trade.

If it be admitted that foreigners pay on that consumption a great portion of our taxes, for what goods they take of us; yet if that was originally intended, and expected to continue the same, as at the first laying on our taxes, it will be the strongest argument in the contrary; for
DUTY, in the military art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guards and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy is called going on service.

DUUMVIRATE, the office or dignity of the duumviri. See the next article.

The duumvirate lasted till the year of Rome 388, when it was changed into a decemvirate.

DUUMVIRI, in roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

DUUMVIRI CAPITALES were the judges in criminal causes: from their sentence it was lawful to appeal to the people, who only had the power of condemning a citizen to death. These judges were taken from the body of the decuriones; they had great power and authority, were members of the public council, and had two lictors to walk before them.

DUUMVIRI MUNICIPALES, were two magistrates in some cities of the empire, answering to what the consuls were at Rome: they were chosen out of the body of the decuriones; their office lasted commonly five years, upon which account they were frequently termed quinquinales magistratus. Their jurisdiction was of great extent: they had officers walking before them, carrying a small switch in their hands; and some of them assumed the privilege of having lictors, carrying axes and the fasces, or bundles of rods, before them.

DUUMVIRI NAVALES were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duty of their office consisted in giving orders for the fitting of ships, and giving their commissions to the marine officers.

DUUMVIRI SACRORUM were magistrates created by Tarquinius Superbus, for the performance of the sacrifice, and keeping of the fylibs books. They were chosen from among the patricians, and held their office for life: they were exempted from serving in the wars, and from the offices imposed on the other citizens, and without them the oracles of the fylibs could not be consulted.

DUYVELAND, or DIVELAND, one of the islands of Zealand, in the United Provinces, lying eastward of Schonen, from which it is only separated by a narrow channel.

DWAL, in heraldry, the herb nightshade used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

DWALE, the same with the sleepy or deadly nightshade. See NIGHTSHADE.
DYE [997] DYE

DWARF, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds: thus there are dwarfs of the human species, dwarf-dogs, dwarf-trees, &c.

The Romans were so passionately fond of dwarfs, that they often used artificial methods to prevent the growth of boys designed for dwarfs, by including them in boxes, or by the use of tight bandages. In Italy, even at present, they wash young puppies every day with astringent liquors, in order to prevent their growth by hardening the parts.

Dwarf fruit-trees are propagated by grafting them on a quince-stock, about five inches above the ground; and when the bud is so far as to have four eyes, it must be flopped, to give rise for lateral branches, for which purpose the uppermost eye should always be left outwards. Apple, pear, plum, and cherry-trees are thus formed into dwarfs, but the summer and autumn pears are found to succeed best.

As to the planting of dwarf-trees, they should be set at twenty-five feet square distance; and the ground between town or planted for kitchen use while the trees are young, only keeping at some distance from their roots: stakes also should be fixed all round them, to which the branches may be nailed with lint, and thereby trimmed in an horizontal direction, and prevented from crossing one another.

DWARF-FERN, filicula, in botany. See the article FILICULA.

DWINA, the name of two large rivers, one of which rises in Lithuania, and, dividing Livonia from Courland, falls into the Baltic sea a little below Riga: the other gives name to the province of Dwina, in Russia, discharging itself into the White sea, a little below Archangel.

DYADIC ARITHMETIC, the same with binary. See the article BINARY.

DYE, in architecture, any square body, as the trunk, or notched part of a pediment; or it is the middle of the pediment, or that part included between the base and the cornice, so called because it is often made in the form of a cube or dye. See CORINTHIAN ORDER, DORIC ORDER, &c.

Dye is also used for a cube of stone placed under the feet of a statue, and over its pedestal, to raise it and show it more.

DYES, in the art of dyeing. See the articles COLOURS and DYEING.

DYE, a person who professes the art of dyeing all manner of colours. See DYEING.

All persons occupying the trade of dyeing woollen manufactures within the city of London, or ten miles round it, shall be subject to the inspection of the company of dyers of London; and the master, wardens, and court of assistants of the said company, may appoint searchers within the said limits; and out of these limits, justices, at their quarter-sessions, may appoint such searchers, who taking to their assistance a constable, or other peace-officer, may, at all reasonable times, enter the shop or work-house of any person using the trade of dyeing, and search all cloths or other woollen goods to be dyed black or blue; and any person opposing, forfeits 101.

Every person dyeing cloths, &c. madder-ed, and not woaded, shall, before delivery, fix a seal of lead to them, with the letter M, on forfeiture for every yard, &c. 3s. 4d.

Any person within England, Wales, or Berwick, dying black any bays or other woollen goods, as madder-blacks, not being woaded throughout with woad, indigo, and madder only, or dyeing any cloths, long-ells, &c. for woaded blacks, not being woaded throughout, shall forfeit for every long Bocking-bays, containing seventy yards, 4s. 4d. For every Colchester-bays, containing thirty-five yards, 2s. and so in proportion for other bays. For every cloth dyed black, not being woaded throughout, containing forty four yards, 4os. All woollen goods truly madder black, shall be marked with a red and blue rose; and all woollen goods truly woaded black, with a blue rose; and any person counterfeiting the said marks, or fixing such to any goods falsely dyed, for madderred or woaded blacks, forfeits 4l. for every piece so marked. Any person using logwood in dyeing blue, shall forfeit 43s. for every piece so dyed, containing forty-four yards.

Dyer of leather, is an artificer who colours skins, either on the one side, or on the other, in the cold or hot dye. See the articles COLOURS and LEATHER.

Hat-Dyer is said of master-hatters, who give themselves particularly to the dyeing of hats. Though there be but one freedom in this company, the masters item to be divided into three distinct professions, the one making the hats, the other dyeing them, and a third fitting them up, and selling them. See HATTER.

Dyer's weed, Luteola, in botany. See the article LUTEOLA. 6 M DYEING.
Dyeing, the art of giving a lasting colour to silks, cloths, and other substances, whereby their beauty is much improved, and value enhanced.

This art depends chiefly on three things, viz. 1. Disposing the surface of the stuff to receive and retain the colours, which is performed by washing them in different ies, digelting, beating them, &c. in which human urine putrified, a sharp fall of ashes, divers loaf, and galls of animals, are of principal use; by means whereof the vicious gluten of the silkworms naturally adhering to their threads, is washed and cleaned from them, and thus they become fitted gradually to imbibe the colours. By these also the greasy founness adhering to wool and flax is scourd off. See cloth.

2. So to grind the colours, that they may enter the body duly prepared, and preserve their brightnesse uniminished. See colour and colouring.

3. The third consists in having beautiful colours. According to Sir W. Petty's account of what is done in particular trades by the art of dyeing. 1. There is a whitening of wax, and several sort of linnen and cotton cloths, by the fun, air, and reciprocal effusions of water. 2. Colouring of wood and leather, by lime, salt and liquors, as in stoves, canes, and marble leathers.

3. Colouring of paper, viz. the marbled paper, by disinter tempering the colours with ox-gall, and applying them upon a rifh gummed liquor. 4. Colouring, or rather discolouring, the colours of silks, tiffanies, &c. by brimtone.

5. Colouring of several iron and copper works into black with oil. 6. Colouring of leather into gold-colour, or rather silver-leaves into gold by varnishes, and in other cases by urine and sulphur. 7. Dyeing of marble and alabaster, with heat and coloured oils. 8. Colouring silver into the brass-colour, with brimstone or urine. 9. Colouring the barrels and locks of guns into blue and purple, with the temper of small-coal heat. 10. Colouring of glass (made of sands, flints, &c.) as also of crystalls and earthen ware, with the ruts and solutions of metals. 11. The colouring of live hair, as in Poland, horse and man's hair: as also the colouring of furs. 12. Enameling and annealing. 13. Applying colours, as in the printing of books and pictures, and as in making of playing cards, being each of them performed in a different way.

14. Gilding and tinning with mercury, block-tin, sal ammoniac. 15. Colouring of metals, as copper with calamey, into bras, and with zinc or specman into a golden colour, or into a silver one with arsenic; and of iron into a resemblance of copper with hungarian vitriol. 16. Making painters-colours by preparing of earth, chalk, and plates; as in amber, ochre, cullen-earth, &c. as also out of calces of lead, as cerule and minium; by sublimates of mercury and brimstone, as in vermilion; by tinging whole earths variably, as in verditer, and some of the lakes; by concrete juices, or fusce, as in gambogium, indigo, pinks, sap-green, and lakes; as also by ruts, as in verdigrease, &c. 17. The applying these colours by the adhesion of ox-gall, as in the marble paper aforesaid; or by gum-water, as by limning; or by clammy drying oils, such as the oils of lints, nuts, &c. 18. The watering of tabbies. 19. The colouring of wool, linnen, cotton, filk, hair, feathers, horn, leather, and the threads and webs of them with woods, roots, herbs, seeds, leaves, salts, limes, licviums, waters, heat, fermentations, macerations, and other great variety of management: an account of all which is a short history of dyeing.

The materials used in the art of dyeing, are iron and steel, or what is produced from them, in all true blacks, called spannish blacks, though not in sanders-blacks, viz. they use copperas, steel-filings, and slippe; they also use pewter for Bow-dye scarlet, viz. they dissolve bars of pewter in aquafortis; litharge is also used by some, though acknowledged by few to add weight to dyed silk. Antimony is much used to the fame purpose. Arsenic is used in crimfon upon pretence of giving luftre, although those who pretend not to be wanting in giving lusure to their filks, disown its use. Verdigrasse is also used by linnen-dyers in their yellow and greenish colours; though, of itself, it strikes no deeper colour than that of a pale straw. Of mineral salts used in dyeing, the chief is alum; the true use whereof seems to be in regard to the fixation of colours. The next mineral salt is falt-petre, not used by ancient dyers, and but by few of the modern: nor is it yet used but to brighten colours, by back-boiling of them, for which argol is more commonly used: lime is much used in working blue waters.
DYE [ 999 ]

Of the animal family are used cochineal, urine of labouring men kept till it be stale and thining, honey, yolks of eggs, and ox-gall; the use of the urine is to flour, and help the fermenting and heating of wood; and is used also in blue- vats instead of lime; it dichargeth the yellow, and therefore is used to spend weld withal.

Dyers use two sorts of water, viz. river and well-water; the last, which is hard, they use in reds and other colours wanting refringency, and in dyeing materials of the flacker contextures, as in callicoe, fulfian, and the several species of cotton-works; but is not good for blues, and makes yellows and greens look rufty. River-water is more fat and oily, and is therefore used in most cafes, and must be bad in great quantities for washing and rinsing their cloths after dyeing. Water is called by dyers white liquor; but a mixture of one part bran, and five of to be dyed be as it were firlt covered, must at laft, to increace the weight. will at least give the silk a gloffinefs; and, digo, and woad, by gums may give the silk a confistency; among which urine may be enumerated as a liquid falt.

The liquors are well and river-water, urine, aquavite, vinegar, lemon-juice, aquafortis, honey, and molasses. Ingredients of another clafs are bran, wheaten-flour, yolks of eggs, leaven, cummin-feed, fenugreek-feed, agaric and fenna.

The fineties, or abfofinces, are fuller's earth, soap, linseed-oil, and ox-gall.

The metals and minerals are pewter, verdigrease, antimony, litharge, and arsenic.

The colourings are of three forts, viz. blue, yellow, and red; of which log- wood, old fuffic, indigo, and madder, are the chief.

General observations upon Dyeing.

1. All materials which of themselves do give colour are either red, yellow, or blue; so that out of them, and the primitive fundamental colour white, all that great variety which we see in dyed stuffs doth arise.

2. That few of the colouring materials, as cochineal, foot, wood-waxi wood, &c. are in their outward and first appearance of the fame colour, which by the slightest diftempers and folutions in the weakest menstrua, they dye upon cloth, filk, &c. 3. That many of them will not yield their colours without much grinding, steeping, boiling and fermenting, or corrosion by powerful menstrua, as red- wood, weld, wood, arnotto, &c.

4. That many of them will of themselves give no colouring at all, as copperas or galls, or with much difadvantage, unlefs the cloth or other stuff to be dyed be as it were firt covered, or incrufated with fome other matter, though colourlefs aforeshand, as madder, weld, brazil, with alun.

5. That fome of them, by the help of other colourlefs ingredients, do difcribe different colours from what they would of themselves, as cochineal, brazil, &c.

6. That fome colours, as madder, in- digo, and wood, by reiterated tinctures, will at laft become black.

7. That although green be the moft frequent and moft common of natural col- ours, yet there is no simple ingredient now ufed alone to dye green with upon any material; fap-green being the near- est, which is ufed by country people.

8. There is no black thing in ufe which dyes black, though both the coal and foot of moft things burnt or scorched be of that colour, and the blacker, by how much the matter before being burnt was whiter, as in ivory-black.

9. The tincture of some dyeing stuffs will fade even with lying, or with the air, or will flain with water only, but very much with urine, vinegar, &c.

10. Some of the dyeing materials are used to bind and strengthen a colour; fome to brighten it; fome to give lufure to the stuff; fome to discharge and take off the colour, either in whole or in part; and fome out of fraud, to make the material dyed, if costly, heavier.

11. That fome dyeing ingredients, or drugs, by the coarfcnes of their bodies, make the thread of the dyed stuff feem coarser; and fome, by fhrinking them,
DYE [1000]

smaller; and fome, by smoothing them, finer.

12. Many of the fame colours are dyed upon feveral stuffs with feveral materials, as red-wood is used in cloth, not in filks; anotto in filks, not in cloth, and may be dyed at feveral prices.

13. That scouring and washing of stuffs to be dyed, is done with fpecial materials, as fometimes with ox-galls, fometimes with fuller's-earth, and fometimes soap; this latter being, in fome cafes, pernicious, where pot-aftes will stain, or alter the colour.

14. Where great quantities of stuffs are to be dyed together, or where they are to be done with any speed, and where the pieces are very long, broad, thick, or otherwife, they are to be differently handled, both in refpeét to the vefsels and ingredients.

15. In fome colours and stuffs the tingent liquor must be boiling, in other cafes blood-warm, and in fome it may be cold.

16. Some tingent liquors are fitted for ufe by long keeping, and in fome the virtues wear away by the keeping.

17. Some colours or stuffs are fught dyed by reiterated dippings in the fame liquor, fome by continuing longer, and others a leffer time therein.

18. In fome cafes, the matter of the veffel wherein the liquors are heated, and the tinture prepared, must be regarded, as the kettles muft be pewter for Bow-dye.

19. There is little reckoning made how much liquor is used in proportion to the dyeing drugs, it being rather adjusted to the bulk of the stuffs, as the vefsels are to their breadth; the quantity of dyeing drugs being proportioned both to the colour, higher or lower, and to the stuffs; as likewife the falls are to the dyeing drugs.

Concerning the weight that colours give to filks, (in which it is moft taken notice of, being fold by weight, and a commodity of great price) it is obferved that one pound of raw filk lofeth four ounces by washing out the gums, and the natural fordes. That the fame fourd filk may be raied to above thirty ounces from the remaining twelve, if it be dyed black with fome materials.

Of a thing very ufeful in dyeing, especially of black, nothing increas weight fo much as galls, by which black filks are reforted to as much weight as they loft by washing out their gum: nor is it counted extraordinary that blacks fhould gain about four or fix ounces in the dyeing, upon each pound. Next to galls, old fuccic encreas the weight about 1⁄2 in 15; madder, about one ounce; weld, half an ounce. The blue vats in deep blues of the fifth fault, give no confiderable weight; neither doth logwood, cochineal, nor even copperas, where galls are not: flippe adds much to the weight, and givet a deeper black than copperas itself, which is a good excuse for the dyers that ufe it.

DYEING of wood and woollen manufactures. For black in woollen manufactures, it is begun with a strong decofion of wood and indige, that communicate a deep blue; after which the stuffs being boiled with alum and tartrar, or pot-aft, are to be maddered with common madder, then dyed black with Aleppo-galls, copperas, and fumac, and finifhed by back-boiling in weld. Wools for tapestry are only to be woaded, and then put in black. For fcarlet, wooll and woollen manufactures are dyed with kermes and cochineal, with which may alfo be ufed agaric and arfenic. Crimfon-fcarlet is dyed with cochineal, maffic, aquafortis, fal armoniac, sublimate, and fpirit of wine. Violet-fcarlet, purple, amaranth, and panys-fcarlets, are given with woad, cochineal, indigo, braziletto, brazil, and orchal. Common reds are given with pure madder, without any other ingredient. Crimfon-reds, carnations, flame and peach-colours, are given, according to their feveral hues, with cochineal, maffic, without madder, or the like. Crimfon-red is prepared with roman alum with cochineal. Orange-aurora, brick-colour, and onion-pee colour, are dyed with woad and madder, mixed according to their feveral shades. For blues, the dark are dyed with a strong tinture of woad; the brighter with the fame liquor, as it weakens in working. Dark browns, minims, and tan-colours, are given with woad, weaker in decofion than for black, with alum and pot-aftes, after which they are maddered higher than black; for tan-colours, a little cochineal is added. Pearl-colours are given with galls and copperas; fome are begun with walnut-tree roots, and finifhed with the former; though to make them more ufeful, they generally dip them in a weak tinture of cochineal. Greens are begun with woad, and finifhed with weld. Pale yellows, lemon-colour, and sulphur-colour, are given with weld alone. Olive-colours of all degrees are first put in green, and taken down with foot, more or lefs, according to the shade.
The dyeing

DYEING of silk, is begun by boiling them in soap, &c. then scouring and washing them in water, and steeping them in cold alum-water. For crimson, they are scoured a second time, before they are put into the cochineal-vat. Red crimson is given with pure cochineal, maflic, adding galls, turmeric, arsenic, and tartar, all mixed in a copper of fair water, almost boiling: with these the silk is to be boiled an hour and a half, after which it is allowed to stand in the liquor till next day. Violet-crimson is given with pure cochineal, arsenic, tartar, and galls; but the galls in lesser proportion than in the former: when taken out, it is washed and put in a vat of indigo. Cinnamon-crimson is begun like the violet, but finished by back-boiling, if too bright, with copperas, and if dark, with a dip of indigo. Light blues are given in a back of indigo. Sky-blues are begun with starch, and finished with indigo. For citron-colours, the silk is first alumed, then welded with indigo. Pale yellows, after aluming, are dyed in weld alone. Pale and brown aurora's, after aluming, are welded strongly, then taken down with rocou and dissolved with pot-ashes. Flame-colour is begun with rocou, then alumed, and afterwards dipped in a vat or two of brazil. Carnation and rose-colours are first alumed, then dyed in brazil. Cinnamon-colour, after aluming, is dyed in brazil, and braziletto. Lead-colour is given with fusilic, or with weld braziletto, galls and copperas. Black silks of the coarser fort, are begun by scouring them with soap, as for other colours; after which they are washed out, wrung, and boiled an hour in old galls, where they are suffered to stand a day or two: then they are washed again, with fair water, wrung, and put into another vat of new galls; afterwards washed again, and wrung, and finished in a vat of black. Fine black silks are only put once into galls of the new and fine fort, that has only boiled an hour: then the silks are washed, wrung out, and dipped thrice in black, and afterwards taken down by back-boiling with soap.

The dyeing of thread is begun by scouring it in a lye of good ashes: afterwards it is wrung, rinsed out in river-water, and wrung again. A bright blue is given with braziletto and indigo: bright green is first dyed blue, then back-boiled with braziletto and verdeter, and lastly woaded. A dark green is given like the former, only darkening more before woadning. Lemon and pale yellow is given with weld mixed with rocou. Orange isabella, with fusilic, weld, and rocou. Red, both bright and dark, with flame-colour, &c. are given with brazil, either alone, or with a mixture of rocou. Violet, dry rote, and amaranth, are given with brazil, taken down with indigo. Feulemort and olive-colour are given with galls and copperas, taken down with weld, rocou, or fusilic. Black is given with galls and copperas, taken down and finished with braziletto wood.

DYKE, or DIKE. See the article DIKE.

DYKE-REEVE, in our statutes, an officer who held the oversight of the dykes in the fen-countries.

DYNASTY, among antient historians, signifies a race or succession of kings of the same line or family: such were the dynasties of Egypt. The Egyptians reckon thirty dynasties within the space of 36525 years: but the generality of chronologers look upon them as fabulous. And it is very certain, that these dynasties are not continually succedaneous, but collateral. DYTICHS, or DIPTYchs. See the article DIPTYCHS.

DYSCRACY, among physicians denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

DYSENTERY, DIPTHERIA, in medicine, a diarrhoea or flux, wherein the stools are mixed with blood, and the bowels miserably tormented with gripes. Dyenteries are distinguished into benign and malignant. The former continues longer, but proceeds more gently, and is less dangerous. The latter is not only of a contagious nature, but is also attended with some fatal symptoms, such as a malignant fever, a defect of strength, and exanthematic disorders. It may likewise be observed, that dyenteries are distinguishing into red and white: in the former, the humours evacuated are always bloody; but in the latter, fanguine, and mixed with carnous filaments and ulcerous shreds abraded from the coats of the intestines. The immediate caufe of a dyentery, according to the most received opinion, is seated in the intestines, and is a highly acrid humour, generated by...
DYS [1002]

By summer fruits when unripe, fermenting with other juices, especially those of the bilious kind, and Hellicating, corroding, and excoriating the nervous coats of the intestines. Others think it occasioned by a certain specific kind of miasma, whose particular quality it is to ferment in the intestines, with the bile especially, and then to corrode them. And others think that the genuine and most immediate cause which produces the severe gripes, and all the other train of symptoms in a dysentery, is principally lodged in the blood-vessels which surround the nervous coat of the intestines.

As to the prognostics, dysenteries are dangerous to pregnant women, to old men and boys, to the scorbatic, the consumptive, and the cachectic. When they begin with vomiting, succeeded with a hiccup, there is danger of an inflammation of the stomach. When clysters are immediately returned, or the anus distinctly closed that nothing can be injected, it is a sign of a palsy in the rectum. And when flatulency is attended with a murmuring noise, it shews the approach of a delirium, an inflammation of the fauces, aphthae, or a palsy of the whole cephalagus. The common method of curing a dysentery, is first to bleed, then to vomit with ipecacuanha, after which produces the severe gripes. And when swallowing is attended with a vomiting, succeeded with a hiccup, there is danger of an inflammation of the stomach. When clysters are immediately returned, or the anus distinctly closed that nothing can be injected, it is a sign of a palsy in the rectum. And when flatulency is attended with a murmuring noise, it shews the approach of a delirium, an inflammation of the fauces, aphthae, or a palsy of the whole cephalagus. The common method of curing a dysentery, is first to bleed, then to vomit with ipecacuanha, afterwards to purge with rhubarb, and, last of all, to give astringents. When the bowels are ulcerated, it will be of service to inject clysters, either of fat broth with the addition of venice-treacle, or the elecampane, or Lucatelli's balfam. As to the prognostics, dysenteries are dangerous to pregnant women, to old men and boys, to the scorbatic, the consumptive, and the cachectic. When they begin with vomiting, succeeded with a hiccup, there is danger of an inflammation of the stomach. When clysters are immediately returned, or the anus distinctly closed that nothing can be injected, it is a sign of a palsy in the rectum. And when flatulency is attended with a murmuring noise, it shews the approach of a delirium, an inflammation of the fauces, aphthae, or a palsy of the whole cephalagus. The common method of curing a dysentery, is first to bleed, then to vomit with ipecacuanha, afterwards to purge with rhubarb, and, last of all, to give astringents. When the bowels are ulcerated, it will be of service to inject clysters, either of fat broth with the addition of venice-treacle, or the elecampane, or Lucatelli's balfam. Sydenham, after bleeding, prescribes a paregoric at night, and the next morning a cathartic. Mr. Ray, from the information of Aubrey, says, that the fungous substance between the lobes of a walnut dried and powdered, and given in a moderate quantity of wine, cured the English army of a dysentery, when all other remedies failed. Jussieu says, a thick yellow bark, called sinaruba, has been found successful in the cure of a dysentery; and Kramer assures us, we may depend on the same effect from the decoction of common millet-seed. Another specific is the vitrum antimonii cera-tum, which has been in use for some time, but was kept a secret till it was communicated to the public by Dr. Young, of Edinburgh. The ordinary dose for an adult is ten or twelve grains; and it has been found successful where bleeding and vomits have been premised, and where they have not. It is best, says Dr. Pringle, to with-hold opium till the patient is both vomited and purged, and when it becomes necessary, to begin with small doses. As to the diet, the same author confuses the sick, in the beginning, to rice-gruel, panado, &c. and for drink, to rice or barley-water, or the white decoction. In the convalescent state they are allowed meat, but no small-beer, and never any milk, unless diluted with lime-water, it being observed, that milk by itself was apt to renew the gripes.

DYSERT, a parliament-town of Scotland, in the county of Fife, situated on the northern shore of the frith of Forth, about eleven miles north of Edinburgh.

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach. See APPETITE.

DYSEPSY, a difficulty of digestion, for which physicians prescribe bitters. See the articles Digestion and Bitters.

DYSPNEA, a difficulty of breathing, usually called asthma. See Asthma.

DYSPHAY, a difficulty of making urine, attended with a sensation of heat and pain. It is distinguished from a strangury, as, in the last, the urine is voided by only a drop, as it were, at a time, but, however, with pain; and from an ischury, as, in this disorder, there is an almost total suppression of urine. A dyspneous subject attends a virulent gonorrhoea, accompanies many other distempers as a symptom, and is frequently excited by very acrimonious medicines, and the external application of causticines. In a dyspneus, emollient and mucilaginous medicines, as gum-arabic dissolved in barley-water, emulsions and decoctions, with an addition of nitre, copious draughts of diluted fluids and camphor, are usually prescribed. See Strangury and Ischury.

DYTISCUS, WATER-BEETLE, in zoology, a genus of insects of the order of the coleoptera, the antennae of which are slender and feteaceous, and their feet formed for swimming. See Coleoptera.

Authors enumerate a great many species of this animal, among which is the great water-beetle, the largest of all European beetles, being an inch and a half in length, and all over of a deep and some-what glossy black. See plate LXXX. fig. 3. n. 1. where two other species, marked n. 2. n. 3. are likewise delineated.
Fig. 1. The Golden Eagle.

Fig. 2. The White-Tailed Eagle.
Eagle, Eadish, Greeks have their eta, the at a their C；and their fable; and their e before an m or n, which sounds like our a in the word war; these are all exemplified in the words empechle or enfermée. In English there are three kinds of e, as. the open or long e, as in the words bear, swear; the close or short e, as in sweet, kept; and mute e, which serves to lengthen the syllable, as in love, came, etc.

As a numeral, E stands for 250. In music it denotes the tone e-la-mi. In the calendar it is the fifth of the dominical letters. And in sea-charts it distinguishes all the easterly points: thus, E. alone denotes east, E. by S. and E. by N. east by south and east by north. See the article Character.

Eadish, or Eddish, among farmers. See the article Eddish.

Eagle, aquila, in ornithology, the English name of several species of the falcon-kind. See the article Falcon.

The iron-coloured eagle with a yellow cera, called by authors chryľaétos, is a large and terrible bird of prey, about the size of a turkey, frequent in many parts of Europe; the tongue of which is in shape like that of the human species. The brown or chesnut-coloured eagle, with a blue cera, is likewise a very bold and fierce bird. The chryšaétos, or common eagle, is very rapacious; it will feed on lambs, and, during the time of its having young, scare any thing is safe from it. See plate LXXXI. fig. 1.

The white-tailed eagle, brought from Hudson’s bay, differs from the common kind in the colour of its tail, which is white, only that the tips of the feathers are black, or dark brown; the breast too is spotted with triangular spots. See plate LXXXI. fig. 2.

To these may be added the pygargus and halietus. See the articles Pygargus and Halietus.

In heraldry, the eagle is accounted one of the most noble bearings in armours, and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or for having done singular services to their sovereigns; in which cases they may be allowed a whole eagle, or an eagle naifant, or only the head or other parts thereof, as may be most agreeable to their exploits.

The reason why eagles are generally borne with their wings and tail expanded, is because this posture is best fitted to fill up the escutcheon. However, there are eagles borne in other postures, though not so common; all which will be explained under their respective articles. The arms of the emperor of Germany are, Or, a spread eagle with two heads, fable; diademæd, langued, beaked, and membered, gules. Some authors express the two heads by the term displayed. The kingdom of Poland bears, Gules, an eagle, argent; crowned and membered, or.

Among the antients, the eagle was held sacred to Jupiter, and on that account placed on his scepter. Philostratus, in his Themistocles, says, the Medes and Lacedæmonians took it for their ensign of royalty; and it is well known that the Romans had the greatest respect for it, looking upon it as the talisman of their state, and taking it for their principal ensign. It was either of gold or silver, borne single on the point of a pike, till the time of Constantine, when the empire being divided into the eastern and western, the eagle was afterwards represented with two heads.

Eagle, aquila, in astronomy. See the article Aquila.

Eagle, in architecutre, a figure of that bird antiently used as an attribute of Jupiter, in the capitals and friezes of the columns of the temples consecrated to that god.
EAGLE-FLOWER, a name sometimes given to the balsamina. See BALSAMINA.

EAGLE-OWL, the name with the bubo, or great horned owl. See BUBO.

EAGLE-STONE, ETITIES, in natural history. See the article ETITIES.

Black EAGLE, an order of knighthood, instituted by the elector of Brandenburg, in 1701, on his being crowned king of Prussia.

The knights of this order wear an orange-coloured ribband, suspending a black eagle.

White EAGLE, a like order in Poland, instituted in 1325, by Uladislaus V, on occasion of the marriage of his son Casimir to the daughter of the great duke of Lithuania.

The knights of this order wear a chain of gold, suspending a silver eagle, crowned.

White EAGLE is also a term used by chemists for mercurius dulcis.

Sea-EAGLE, aquila marina, a fifth of the ray kind. See the article RAIA.

EAGLET, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed eaglets.

EALDERMAN, or EALDOMAN, the name with alderman. See ALDERMAN.

EAR, auris, in anatomy, the organ of hearing. See HEARING.

Anatomists divide the ear into three parts, the exterior, the middle, and the interior. The exterior part is called simply the auricle, but more properly auris externa. In this there are a great many prominences and cavities; as, the pinna and lobule; the helix and anthelix; and the tragus and antitragus; the scapha, which is a cavity between the helix and the anthelix behind; and the concha, which is a larger cavity, situated before the meatus auditus, or passage into the internal ear: here are to be observed the glandulae sebaceae of Valsalva, which are mere cutaneous follicles: their substance is composed of the common integuments and a cartilage.

The muscles of the external ear are in human subjects very small, often scarce discernible; however, sometimes two, three, or more of them may be distinguished. These, from their situation, may be called the superior, the posterior, and the anterior. Their use in moving the ear is none at all, or very inconsiderable; their real use, as is supposed, is to render the ear tense, when we would hear more distinctly. The course of the meatus auditus is tortuous and oblique, turning chiefly towards the anterior parts. Its substance is partly bony, and partly cartilaginous: it is covered with an elastic membrane; the membrane investing its internal part is continuous with the cutis. In the convex part of this membrane, about the middle of the passage, are situated certain small glands, of a yellow colour, called glandulae ceruminosae: they serve to secrete the cerumen, which they deposit for various purposes in the passage.

The use of the external ear is to receive and convey sounds in the manner of an acoustic tube, in order to our hearing them more distinctly.

The middle part of the ear is called the tympanum: in this we are to observe the membrana tympani, which is situated at the extremity of the auditory passage: its situation is very oblique inwards; its figure elliptic, and its surface concave. It is connected in its circumference with a ring of a bony substance in infants, which becomes afterwards transformed into the auditory passage, and in the middle it is connected with the little bone, called the malleus. Its substance is membraneous, composed of two or three lamelle, and is furnished with a vast number of blood-vessels.

Some authors mention a natural foramen, very small, and placed in an oblique direction, penetrating this membrane, and letting the smoke of tobacco, taken in at the mouth, find a passage thro' it out at the ears. The bony cavity of the tympanum is much smaller in human subjects than in quadrupeds. In this cavity are to be observed the periosteum, which is very thin, and furnished with a great number of blood-vessels; the chorda tympani, being a little nerve composed by a combination of ramuli, or little branches of the fifth and seventh pairs: this is extended in the manner of a cord, under the membrane of the tympanum. Here may be observed the three officula auditus, covered with the periosteum; these are called the malleus, the incus, and the stapes. The manubrium, or handle of the malleus, adheres to the membrane of the tympanum, and its head is articulated by a ginglymus with the body of the incus; and, finally, the longer leg of this is articulated, by anthrodia, with the head.
The nerves of the inner ear are, 1. from the auditory pair. 2. from the third pair of the vertebrals of the neck, but these are principally sent to the external ear. The arteries are from the carotids, both external and internal; the veins run partly to the juglars, and partly to the sinues of the dura mater.

**EAR-ACH,** a grievous pain in the auditory passage, proceeding from a sharp extravuluted serum, affecting the nervous membrane which covers the meatus auditorius.

When this matter is translated to the external part, then the ear-ach arises, which, unless speedily appeased, may cost the patient his life.

The principal scope is to ease the pain, which may be done with nitrous and cinnabarine powders, and with emulsions of the greater cold feeds: but if these are inefficient, recourse must be had to opiates, such as styrex pills, or the bare tincture. Outwardly lay a plaster to the temple of the affected side, composed of mafic, galbanum, saffron, expressed oil of nutmegs, and opium. Afterwards let the ear be held over the vapour of milk, with the fragrant and emollient spices: the smoke of tobacco, blown into the ear, is of great efficacy; as also an infusion of millepedes in fallad oil.

**Closed meatus auditorius.** Sometimes the meatus auditorius is from the birth closed with a membrane, differing in degrees of thickness; sometimes immediately after the birth, and sometimes a considerable while after. When this membrane closes the external ear, the faculty of hearing may be restored by making a cruciform incision in the occluding membrane, and keeping the passage open for some time with lint, or a tent; but when the said membrane is feated very deep, it is best to divide it by a transferve or longitudinal incision, taking care that you do not at the same time wound the membrane of the tympanum which in infants is not seated so deep in the ear as in adults.

**Tubercles in the meatus auditorius.** Tubercles or fishy excrescences in the auditory passage of the ears give great uneasiness, and do partly, if not wholly, obstruct the hearing. When they are not of long standing, they may be removed with escharotics; or, as these are dangerous when they touch the membrane of the tympanum,
EAR [1006]

tymanum, they may be extirpated by the icillars, or scalp, when they are not feated too low in the ear. Lastly, it appears from the observations of Hildanus, (cent. iii. obf. 1.) and Purmannus, (chirurg. pag. 280.) that these tubercles may be frequently removed with succés by ligature.

For other disorders of the ear, and for the method of extracting extraneous bodies fallen into it, see the articles Deafness, Tinnitus, &c. and the article Extraction.

EAR, among gardeners, a name given to the leaves that first appear from the seed, which differ considerably from other leaves. See the article Leaf.

Ear-pick, an instrument of ivory, silver, or other metal, somewhat in form of a probe, for cleaning the ear. The Chinese have a variety of these instruments, with which they are mighty fond of tickling their ears; but this practice, as Sir Hans Sloane judiciously observes, must be very prejudicial to so delicate an organ, by bringing too great a flow of humours on it.

Ear-shell, auris marina. See the article Auris.

Small pearls are sometimes found in these shells, whereof there are several species. See the article Pearl.

Ear-wig, forficula, in zoology. See the article Forficula.

Earing, in the sea-language, is that part of the bolt-ropo which at the four corners of the sail is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard arms, and so the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are seized or bent at the clew.

Earl, a brith title of nobility, next below a marquis, and above a viscount. Earls were antiently called comites, because they were wont comitari regem to wait upon the king for council and advice. The Germans call them graves, as landgrave, margrave, palgrave, rheiingrave; the Saxons ealdormen, unless that title might be more properly applied to our dukes; the Danes, earlas; and the English, earls. The title, originally, died with the man. William the conqueror first made it hereditary, giving it in fee to his nobles, and allotting them for the support of their state the third penny out of the sheriff's court, issuing out of all pleas of the shire whence they had their title. But now the matter is quite otherwise; for whereas heretofores comes and comitatus were correlatives, and there was no comes or earl, but had a county or thire for his earldom, of latter years the number of earls increasing, and no more counties being left, divers have made choice of some eminent part of a county, as Lindsey, Holland, Cleveland, &c. some of a leffer part, as Stafford, &c. others have chosen for their title some eminent town, as Marlborough, Exeter, Bristol, &c. and some have taken for their title the name of a small village: their own seat or park, as Godolphin, Clarendon, &c. An earl is created by confrnure of sword, mantle of state put upon him by the king himself, a cap and a coronet put upon his head, and a charter in his hand. All the earls of England are denominated from some thire, town or place, except three; two of whom, viz. earl Rivers, and earl Paulet, take their denomination from illustrious families: the third is not only honorary, as all the rest, but also officiary, as the earl marshal of England.

Earl marshal of England, is a great officer who had antiently severall courts under his jurisdiction, as the court of chivalry, and the court of honour. Under him is also the herald's office or college of arms. He hath some pre-eminence in the court of Marshalsea, where he may sit in judgment against those who offend within the verge of the king's court. This office is of great antiquity in England, and antiently of greater power than now; and has been for several ages hereditary in the most noble family of Howard.

Earnest, arreba, money advanced to bind the parties to the performance of a verbal bargain. By the civil law, he who recedes from his bargain looses his earnest, and if the person who received the earnest give back, he is to return the earnest double. But with us, the person who gave it, is in strictness obliged to abide by his bargain; and in case he decline it, is not discharged upon forfeiting his earnest, but may be sued for the whole money stipulated.

Earth, terra, in physiology, a sotile, or terrestrial matter, whereof our globe partly consists. Earths are either simple or compound. The simple earths are friable, opake, insipid bodies, not inflammable, vitriifiable,
Ear [1007] Ear

fiable by extreme heat, diffusible in water, and separable from it by filtration. Of these we have five genera or kinds, viz. boles, clays, marles, ochres, and tripelas. See Boles, Clays, Marles, &c.

The compound earths are composed of argillaceous or marley particles separated and divided by adventitious matter, and never free from these mixtures, or in the state of pure earths. Of these we have four genera, two of loams, viz. thraustomicthes, and gliochromithec; and two of moulds, viz. thruptomicthes, and gloromicthes. See the articles Loams, Moulds, Thraustomicthes, Thruptomicthes, &c.

Besides these earths, there are frequently found in digging a kind of terra miscellanea, of no determinate species, nor to be known by any peculiar name, being composed of maffles of different sizes, of different species of earths, broken off from their strata, soon after their formation, and blended together at the time of the original subsidence of the strata. As for chian, etretian, lemian, and maltefe earths, together with all the sealed earths which are the subjects of the materia medica. See the articles Boles, Clay, Marle, &c.

Earth, in gardening and husbandry, if good, should be of a blackish colour, gravelly, fat, pliant, or easy to be digged; it should be neither cold nor light, it ought to have no ill smell or taste, and it should be of the same quality three or four feet deep for trees, which if they have not that depth, will languish and decay after they have been planted fix years. Fruit trees will thrive in a less depth, and they generally produce the most generous fruits, when their roots spread near the surface of the earth.

Husbandmen call that new earth which lying three or more feet deep, never served to the nourishment of any plant; or earth that has been a long time built upon, though it had formerly bore; earth likewise of a sandy loamy nature, where cattle have been a long time fed, may be accounted fuch, and be of excellent use for most sorts of plants, especially if it has been thrown up in heaps to grow richer.

Earth, in chemistry, is used for a principle or element, in the composition of bodies, entering them either as an ingredient, or giving them a power of performing various operations in nature and art. It is a body, as having three dimensions impenetrability, figurability, and its own particular gravity. In weight it exceeds water, falls, and the spirits of animals and vegetables. When pure, or perfectly separated from other bodies, it is conluent, hard, and fine, though brittle with regard to our senses, and easily reducible by trituration into a certain powder, in which respect it differs from the true metals and gems; though still more in this, that it remains fixed and unchanged in the most violent fire, even so far as not to flow therein.

Boerhaave says, he never could obtain elementary earth from metals, but it may be obtained from water, from calcined vegetables, from smok and foot, from putrified animals, from distilled animal fluids, from fofil farts, and from fluid and solid sulphurs. Whence he concludes, that the fame simple elementary earth contributes as a constituent principle to form the particular corporeal fabric of animals, vegetables, and some fofils of a fels permanent and fels simple nature, and in them all ferves as a firm bafis to their form, whilst it unites the other principles to itself, and to one another, fo as to constitute one determinate individual. Hence also, says he, the property of assimulating other substances into the nature of every body that receives nutriment, and consequentfly the feminal property of producing their like, is principally owing to the efficacy of this earth; for their properties no longer remain after the particular texture depending principally upon the earth is destroyed, or wanting in any body.

Earth, in astronomy and geography, one of the primary planets, being this terraqueous globe whereon we inhabit.

Figure of the Earth was accounted by some of the antients to be like that of an oblong cylinder; by others, of the form of a drum, and by others to be flat. The moderns demonstrate it to be nearly spherical from the following, among other considerations. 1. All the appearances of the heavens, both at land and at sea, are the fame as they would be if the earth were a globe. 2. In eclipses of the moon which are caused by the shadow of the earth falling upon the moon, this shadow is always circular, and a body can be no other than a globe, which in all situations casts a circular shadow. 3. Several navigators have failed quite round the globe, steering their course directly south and west till they came to the magellanic
magellanica sea, and from thence to the north and west, till they returned to their port from the eait; and all the phenomena which should naturally arise from the earth's rotundity, happened to them. Besides, their method of failing was also founded upon this hypothesis, which could never have succeeded so happily, if the earth had been of any other figure. It is true, the surface of the earth is not an exact geometrical globe, but then the inequalities are so inconsiderable, that the highest mountain bears no greater proportion to the bulk of the earth, than a grain of dust does to a common globe. The figure of the earth then was reckoned by mathematicians and geographers as spherical, excepting the small inequalities in its surface, of mountains and valleys, till an accident engaged the attention of Sir Isaac Newton, and Mr. Huygens, who demonstrated from the laws of hydrostatics, and the revolution of the earth about its axis, that its figure was not a true sphere, but an oblate spheroid flattened towards the poles. Monfieur Richer, when at the island of Cayenne, about five degrees distant from the equator, found that his clock, which at Paris kept true time, now lost two minutes and twenty-eight seconds every day. Now, though heat will lengthen pendulums, and consequently retard their motion, it is certain the heats of Cayenne were not sufficient to solve this phenomenon, which can flow only from a diminution in the pressure of gravity. For, as the earth revolves about its axis, all its parts will endeavour to recede from the axis of motion, and thereby the equatorial parts where the motion is quickest will tend less towards the center than the rest; their endeavour to fly off from the axis about which they revolve, taking off part of their tendency that way; so that those parts will become lighter than such as are nearer the poles. The polar parts, therefore, will press in towards the center, and raise the equatorial parts, till the quantity of matter in the latter is so far increased as to compensate for its lightness, and an equilibrium be restored. On which account, the form which the earth assumes will be that of an oblate spheroid, whose shorter axis passes thro' the poles. By virtue only of the rotation of the earth about its axis, the weight of bodies at the equator is less than at the poles, in the proportion of 288 to 289. From hence arises, as before observed, a spheroidal form of the earth, and from that spheroidal form arises another diminution of gravity at the equator, by which, if the earth were homogeneous throughout, bodies at the equator would lose one pound in 1121, and so on both accounts taken together, the gravity of bodies at the poles would be the same at the equator as 230 to 229. From whence, if we suppose the gravity of bodies within the earth to be directly as their distance from the center, those numbers will also express the relation between its polar and equatorial diameter. This is upon a supposition that the earth was at first fluid, or a chaos, having its solid and fluid parts confusedly mixed together; but if we suppose it at first partly fluid and partly dry, as it now is, since we find that the land is very nearly of the same figure with the sea, except raised a little to prevent its being overflowed, the earth must still be of the same form; for otherwise the major part of the water would flow towards the equator, and spread itself like an inundation over all the land in those parts. This theory met with great opposition from Monfieur Cassini, who having measured the meridian of France, declared (with great reason likewise if the observations had been correct) that the earth, instead of being flattened, was lengthened towards the poles, that is, instead of being an oblate, it was an oblong spheroid, higher at the poles by about ninety-five miles. So wide a difference, between philosophers of so high rank, determined at length the king of France, at an expense becoming a monarch, to employ two companies of mathematicians, the one to measure the length of a degree of the meridian at the equator, and the other the length of a degree at the polar circle, that by comparing them together, and with the length of the degree of France, it might be known whether the earth were oblong or flat towards the poles. It is certain, if the lengths of the degrees of latitude decrease, as we go from the equator towards the poles, then the axis is greater, and the figure an oblong spheroid; but on the contrary, if these lengths increase, as you remove towards the poles, the axis is less than a diameter at the equator, and consequently the figure an oblate spheroid. Suppose \( P \) \( T \) \( = \) \( \equiv \) (plate LXXXIII., fig. 1.) the earth's orbit, and \( S \) the sun. Thro' the center of the sun draw the right line \( \gamma \) \( S \) \( \equiv \) parallel to the common section of the equator and the ecliptic, which will meet with the ecliptic in two points \( \gamma \) \( \equiv \). And when the earth seen from the sun is in either of the points \( \gamma \) \( \equiv \) or \( \equiv \), a right line \( S \) \( \equiv \) or \( S \) \( \equiv \), joining the center of the earth and sun, will coincide with the common section of the equator and ecliptic, and will then be perpendicular to \( \overline{AB} \), the axis of the earth, \( \equiv \) of the equator, because it is in the plane of the equator. But the same line is also perpendicular to the circle which bounds the light and darkness, and therefore the axis of the earth will be in the plane of that circle, which will therefore pass through the poles of the earth, and will cut the equator and all its parallels into equal parts. When the earth, therefore, is in the beginning of \( \equiv \), the sun will be seen in \( \gamma \), in the common section of the equator and ecliptic, in which position, the circle of illumination touches both poles; the sun is vertical to the equator, and the days and nights are equal all the world over; and this will be the spring feaon, or vernal equinox. See the article Equinox.

The earth in its annual motion going through \( \equiv \), \( \equiv \), and \( \equiv \) towards \( \equiv \), and the common section of the equator and the ecliptic remaining always parallel to itself, it will no longer pass through the body of the sun; but, in \( \equiv \), it makes a right angle with the line \( SP \), which joins the centers of the sun and earth. And because the line \( SP \) is not in the plane of the equator, but in that of the ecliptic, the angle BPS, which the axis of the earth \( EA \) makes with it, will not now be a right angle, but an oblique one of \( 66^{\frac{1}{2}} \) degrees, which is the same with the inclination of the axis to the plane of the ecliptic. Let the angle SPL be a right angle, and the circle bounding light and darkness, will pass through the point \( L \), and then the arch BL, or the angle BPL, will be \( 23^{\frac{1}{2}} \) degrees, that is, equal to the compliment of the angle BPS to a right angle. Let the angle BPE be a right angle, and then the line PE will be in the plane of the equator. Therefore, because the arches \( BE \) and \( LT \) are equal, each of them being quadrants; if the common arch BT be taken away, there will remain TE equal to LB, equal to \( 23^{\frac{1}{2}} \) degrees. Take EM equal to ET, and through the points M and T describe two parallel circles TC, MN; the one represents the tropic of cancer, and the other the tropic of capricorn. And the earth being in this situation, the sun will approach the nearest that it can come to the north pole; he will shine perpendicularly on the point T, and consequently will be vertical to all the inhabitants under the tropic of cancer, when he comes to their meridians. It is manifest that the circle which bounds light and darkness, reaches beyond the north pole B to L; but towards the south it falls short to the south pole A, and reaches no further than F. Through L and F, let two parallels to the equator be described. These will represent the polar circles, and while the earth is in F, all that tract of it which is included within the polar circle KL continues in the light, notwithstanding the confant revolution round the axis. On the contrary, those that lye within the antarctic circle remain in continual darkness. Besides, it is also manifest, that all the parallels between the equator and the arctic circle, are cut by the circle bounding light and darkness into unequal portions, the largest portions of these circles remaining in the light, and the smallest in darkness; but these parallels which are towards the antarctic circle have their greatest portions in darkness, and their least in light; and the difference of these portions will be greater or less, according as the circles are nearer to the pole, or to the equator. Therefore, when the sun is seen in cancer \( \equiv \), the inhabitants of the northern hemisphere will have their days at the longest, and their nights at the shortest, and the feason of the year will be summer. The contrary of this will happen to the inhabitants of the southern hemisphere. As the earth moves on from \( \equiv \) by \( \equiv \), the north pole returns, the diurnal arches begin gradually to decrease, and the nocturnal to increase, and of consequence, the sun's rays will fall more and more obliquely, and his heat proportionably diminishes, till the earth comes to \( \equiv \), when the sun will appear in \( \equiv \), at which time, the days will again be equal to the nights to all the inhabitants of the earth, the circle bounding light
Fig. 1. Annual Motion of the Earth.

Fig. 2. Echinops, Glove-Thistle.

Fig. 3. Echium, Viper's Bugloss.

Fig. 4. Echo.
light and darkness passing, in this position, through the poles. This will be the season called autumn.

The earth moving on through $\gamma$ and $\pi$, the sun will be seen to go in the ecliptic through $\phi$ and $\delta$, and will appear to decline from the equator, towards the south, so that when the earth is really in $\omega$, the sun will appear in $\zeta$.

And whereas the axis $AB$ always retains its parallelism, the earth will have the same position and aspect in respect to the sun, that it had when it was in $\zeta$; but with this difference, that when the tract within the polar circle $KL$ was in continual light while the earth was in $\zeta$; now the earth arriving at $\omega$, that same tract will be altogether in darkness; but the opposite space within the circle $FG$, will be in a continual illumination, and at the pole $A$ there will be no night for the space of six months. Here likewise of the parallels between the equator and the north pole, the illuminated portions are much less than the portions which remain in darkness, the contrary of which happened in the former position, so likewise the sun at mid-day will appear vertical to all the inhabitants that live in the tropic $MN$; so that it will appear to have descended towards the south from the parallel $TC$, to the parallel $MN$, through the arch $CQN$, which is forty-seven degrees. This will be the season called winter.

Lastly, as the earth journeys on from cancer through $\gamma$ and $\pi$ to $\omega$, the sun appears to pass through $\omega$ and $\chi$ to $\zeta$, and the northern climes begin to return, and receive more directly the enlivening beams of the sun, whose meridian height does now each day increase; the days now lengthen, and the tedious nights contract their respective arches; and every thing conspires to advance the delightful season of the spring, with the equality of days and nights, as was shewn when the earth was in libra, from which point we began to trace its motion, Keill.

By the third motion of the earth, we mean that motion by which the poles of the world revolve about the poles of the ecliptic, and occasion what is commonly called the precession of the equinoxes, or more properly, the retrogression of the earth's nodes. See the article Precession of the equinoxes.
the matter contained in the body of the earth, the greatest part of which, as sand and clays, are vitrified, or vitrifiable substances; and, on the other hand, when we reflect upon the impossibility of the earth’s being ever in a state of fluidity produced by water, since there is infinitely more land than water; and, besides, water has not the power of dissolving sand, stines, and other substances of which the earth is composed. How far the inequalities in the face of the earth, the beds of rivers, lakes, &c. and the various strata in its internal parts, serve to confirm this hypothesis, may be seen in Histoire Naturelle, &c. tom. 1. by M. de Bufon, and in the articles Mountain, River, Strata, &c.

Latitude of the Earth. See Latitude. Longitude of the Earth. See Longitude. Earth-bags, face a terre, in fortification. See the article Sand-bags.

EARTHING, in agriculture and gardening, signifies the covering of shrubs and plants, as vines, celery, &c. with earth.

Earthquake, in natural-history, a violent agitation or trembling of some considerable part of the earth, generally attended with a terrible noise like thunder, and sometimes with an eruption of fire, water, wind, &c.

Causes of Earthquakes. Earthquakes and volcanoes are both produced from the same cause, which may be thus explained. Those countries which yield great stores of sulphur and nitre, or where sulphur is sublimed from the pyrites, are by far the most injured and incommoded by earthquakes; for where there are such mines, they must send up exhalations, which meeting with subterraneous caverns, must stick to the arches of them, as foot does to the sides of our chimneys; where they mix themselves with the nitre or salt-petre which comes out of these arches, in like manner as we see it come out of the inside of the arch of a bridge, and so makes a kind of crust which will very easily take fire.

There are several ways by which this crust may take fire, viz. 1. By the inflammable breath of the pyrites, which is a kind of sulphur that naturally takes fire of itself. 2. By a fermentation of vapours to a degree of heat, equal to that of fire and flame. 3. By the falling of some great stone which is undermined by water, and striking against another, produces some sparks that set fire to the neighbouring combustible matter, which being a kind of natural gunpowder, at the approach of the fire goes off with a sudden blast or violent explosion, rumbling in the bowels of the earth, and lifting up the ground above it, so as sometimes to make miserable havoc and devastation, till it gets vent or a discharge. Burning mountains and volcanoes, are only so many spiracles serving for the discharge of this subterranean fire, when it is thus preternaturally assembled. And where there happens to be such a structure and confirmation of the interior parts of the earth, that the fire may pass freely and without impediment from the caverns therein, it assembles into the said spirals, and then readily and easily gets out from time to time without shaking or disturbing the earth. See the article Volcano. But where a communication is wanting, or the passages are not sufficiently large and open, so that it cannot come at the said spiracles without first forcing and removing all obstacles, it heaves up and shocks the earth, till it hath made its way to the mouth of the vulcano; where it rusheth forth, sometimes in mighty flames, with great velocity, and a terrible bellowing noise. Earthquakes are sometimes confined to a narrow space, which is properly the effect of the re-action of the fire; and they shake the earth just as the explosion of a powder-magazine causes a sensible concussion at the distance of several leagues. Thus a violent eruption of Etna, will cause an earthquake over all the island of Sicily; but it will never extend to the distance of three or four hundred leagues. In like manner, when some new vents of fire have been formed in mount Vesuvius, there are felt at the same time earthquakes at Naples, and in the neighbourhood of the vulcano; but these concussions have never shaken the Alps, nor been communicated to France, or other countries remote from Vesuvius. Sometimes they are felt at considerable distances, and shake a long tract of ground without any eruption or vulcano appearing. We have instances of earthquakes which were felt at the same time in England, France, Germany, and even in Hungary, and these extend always a great deal more in length than in breadth; they shake a tract of ground with more or less violence in different places, in proportion as it is remote from the fire; and they are almost always accompanied with a dull noise like that of a heavy carriage rolling along with great rapidity. See
Dreadful effects of Earthquakes. Catanee, a city of Sicily, which was almost totally destroyed in the year 1693, is a melancholy instance of the dreadful effects of earthquakes. The shock was not only felt all over Sicily, but likewise in Naples and Malta; and it was so violent, that people could not stand upon their legs; and those who lay on the ground, were tossed from side to side, as if on a rolling billow. The earth opened in several places, throwing up large quantities of water; and great numbers perished in their houses by the fall of rocks that were rent from the mountains. The sea was violently agitated, and roared dreadfully; mount Etna threw up vast quantities of flame, and the earth opened from side to side, as if it were rent from the mountains. The shock lasted fifteen minutes. See an account of a terrible earthquake that happened at Jamaica in 1692, in Phil. Tr. n° 209, and an account of other earthquakes in n° 462, 463. See also Buffon's Hist. Nat. tom. 1.

EASE, among sailors. See EASING.

EASEL-Pieces, a denomination given by painters to such pieces as are contained in frames, in contradistinction from those painted on ceilings, &c.

EASEMENT, in law, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit: such are a way through his lands, a tink, or the like. These, in many cases, may be claimed.

EASING, in the sea-language, signifies the slackening a rope, or the like: thus, to ease the bow-line or sheet, is to let them go flacker; to ease the helm, is to let the ship go more large, more before the wind, or more larboard.

EASLOW, a borough of Cornwall, twenty-two miles south of Launceston, which lends two members to parliament.

EAST, one of the four cardinal points of the world; being that point of the horizon, where the sun is seen to rise when in the equinoctial. See COMPASS, HORIZON, EQUINOCTIAL, &c.

EAST is also frequently compounded with other words, as eait-indices, eait-dial, east-indies, &c. to signify their being situated towards the east. See the articles INDIES, DIAL, WIND, &c.

EASTER, a festival of the Christian church, observed in memory of our Saviour's resurrection. The Greeks call it Πάσχα, the Latins, Pæcha, an Hebrew word signifying pasage, applied to the Jewish feast of the passover, to which the Christian festival of Easter corresponds. It is called Easter in the English, from the goddes Eoétre, worshiped by the Saxons with peculiar ceremonies in the month of April. See the article PASSOVER.

The observation of this festival, is as ancient as the very time of the apostles. In the primitive ages of the church, there were very great disputes about the particular time when this festival was to be kept. The saffonic churches kept their Easter upon the very same day the Jews observed their passover; and others, on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that easter should be kept upon one and the same day, which should always be a Sunday in all Christian churches throughout the world. But though the Christian churches differed as to the time of celebrating easter, yet they all agreed in shewing particular respect and honour to this festival: hence, in ancient writers, it is distinguished by the name of dominica gaudii, i.e. Sunday of joy. On this day prisoners and slaves were set free, and the poor liberally provided for. The eve, or vigil, of this festival was celebrated with more than ordinary pomp, which continued till midnight, it being a tradition of the church that our Saviour rose a little after midnight; but in the east, the vigil lasted till cock-crowing.

EASE
It was in conformity to the custom of the Jews, in celebrating their passover on the fourteenth day of the first month, that the primitive fathers ordered that the fourteenth day of the moon, from the calendar, new moon, which immediately follows the twenty-first of March, at which time the vernal equinox happened upon that day, should be deemed the paschal full moon, and that the Sunday after should be Easter-day; and it is upon this account that our rubric has appointed it upon the first Sunday after the first full moon immediately following the twenty-first day of March. Whence it appears, that the true time for celebrating easter, according to the intention of the council of Nice, was to be the first Sunday after the first full moon following the vernal equinox, or when the sun entered into the first point of aries; and this was pope Gregory's principal view in reforming the calendar, to have Easter celebrated according to the intent of the council of Nice.

Having first found the epact and dominical letter, according to the method delivered under these articles, Easter-day may be found by the following rules.

1. To find Easter-limit, or the day of the paschal full moon, counting from March inclusive, the rule is: add 6 to the epact, and if this sum exceeds 50, take 50 from it; then from 50 subtract this remainder, and what is left will be the limit; if the sum of the epact, added to 6, does not amount to 50, it must be subtracted from 50, and the remainder is the limit required; which is never to exceed 49, nor fall short of 21.

2. From the limit and dominical letter, to find Easter-day: add 4 to the dominical letter; subtract this sum from the limit, and the remainder from the next higher number, which contains 7 without any remainder; lastly, add this remainder to the limit, and their sum will give the number of days from the first of March to Easter-day, both inclusive.

Thus, to find Easter-day for the year 1754, for instance. First find the epact 6, which added to 6 gives 12; and as this sum does not amount to 50, it must be subtracted from 50, and the remainder 38 is the limit. Then adding 4 to 6, the number of the dominical letter F, subtract this sum, viz. 10, from the limit 38, and the remainder 28 from 35, the next superior number that contains 7 a certain number of times without any remainder, and there remains 7, which being added to the limit 38, gives 45 for the number of days from the first of March to Easter-day, both inclusive: hence, allowing 31 for March, there remains the 14th of April for Easter-day. Here follows the operation at length.

\[
6 + 6 = 12 \\
50 - 12 = 38 = \text{Paschal Limit} \\
\text{Dominical Letter } F = 6 \\
6 + 4 = 10, \text{ and } 38 - 10 = 28; \text{ then } 35 - 28 = 7. \text{ And } 38 + 7 = 45; \text{ from which subtracting } 31, \text{ the number of days in March } \\
\text{there remains } 14, \text{ the day of April answering for Easter-day for the year } 1754. \text{ However, to save the trouble of calculation, we shall here give a table, by which Easter-day may be found by inspection till the year 1900, according to the Gregorian or new style.}

- EAS -
As to the use of this table, easter-day will be found in the common angle of meeting of the given dominical letter and the golden number; the name of the month lying in a direct line with it, towards the left hand.

EASTERN, an appellation given to whatever relates to the east: thus we say, eastern amplitude, eastern church, &c. See AMPLITUDE, CHURCH, &c.

EATON, a town of Buckinghamshire, situated on the north side of the Thames, opposite to Windsor, and famous for its collegiate school founded by King Henry VI. being a seminary for king's college Cambridge, the fellows of which are all from this school.

EAVES, in architecture, the margin or edge of the roof of an house; being the lowest tiles, flates, or the like, that hang over the walls, to throw off water to a distance from the wall. See the articles WALL and ROOF.

EAVES-LATH, a thick feather-edged board, generally nailed round the eaves of a house for the lowermost tiles, flates, or shingles to rest on.

EBRING of the tides. See TIDE.

EBDOMARIUS, in ecclesiastical writers, an officer formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, &c.

EBENUS, the EBONY-TREE. See the article EBONY.

EBIONITES, in church history, heretics of the first century, so called from their leader Ebion. They held the same errors with the Nazareens, united the ceremonies of the masonic institution with the precepts of the gospel, observed both the Jewish sabbath and Christian Sunday, and in celebrating the eucharist, made use of unleavened bread. They abstained from the flesh of animals, and even from milk. In relation to Jesus Christ, some of them held that he was born, like other men, of Joseph and Mary, and acquired sanctification only by his good works. Others of them allowed, that he was born of a virgin, but denied that he was the word of God, or had any existence before his human generation. They said, he was, indeed, the only true prophet, but yet a mere man, who by his virtue had arrived at being called Christ, and the son of God. They also supposed, that Christ and the devil were two principles, which God had opposed to each other. Of the New Testament, they only received the gospel of St. Matthew, which they called the gospel according to the Hebrews. See the article NAZAREENS.

EBLIS, the name used by the mahometans for the devil. See the article DEVIL.

EBONY, ebenus, in botany, a tree supposed to be of the palm-kind, the wood of which is imported from different countries of the East and West-Indies. Its wood is extremely solid, and capable of a fine polish; and, therefore, much used in toys and marquetry.

EBRBUHARITES, a kind of mahometan monks, so called from their founder Ebrubah. They make great profession of piety, and contempt of the world; but are accounted heretics by the rest of the mahometans, because they believe themselves not obliged to go in pilgrimage to Mecca.

EBRILLADE, in the manage, a check of the bridle given to the horse by a jerk of one rein, when he refuses to turn. Some confound the ebrillade with the faccade. See the article SACCade.

As the ebrillade is a chastisement, and not aid, the use of it is banished the academies.

EBRO, antiently IBERUS, a large river of Spain, which, taking its rise in old Cattle, runs through Bifcay and Arragon, passes by Saragossa, and continuing its course through Catalonia, discharges itself with great rapidity into the Mediterranean, about twenty miles below the city of Tortoza.

EBULLITION, the same with boiling. See the article BOILING.

EBULLITION is also used in a synonymous sense with effervescence. See the article EFFERVESCENCE.

EBULUS, in botany, the same with sambucus. See the article SAMBUSCUS.

EBUR, IVORY. See the article IVORY.

ECATOMBEON, or HECATOMBEON. See the article HECATOMBEON.

ECAYESSADE, in horsemanship, denotes a jerk of the eaveon. See CAYESON.

ECBOLIUM, in botany, the same with adhatoda. See the article ADHATODA.

ECCANTHIS, the same with enchantis. See the article ENCHANTIS.

ECCENTRIC and ECCENTRICITY. See EXCENTRIC and EXCENTRICITY.

ECCHO, or ECHO. See the article ECHO.

ECCHYMOsis, ecchymosis, in surgery, an extravasation of the blood from a vein in the arm between the flesh and skin.
There are various degrees of an ecchymosis, so that the arm is hereby not only much swelled, and of a black and blue colour, but is even sometimes violently inflamed with a most acute pain, and followed either with a suppurition or incipient mortification in the limb. This accident frequently proceeds from the veins being cut quite asunder by the phlebotomist, but often from the patient's using his arm too early after bleeding in violent and long exercises, in which the contractions of the muscles make the veins swell, and force their blood through the orifice into the interfaces betwixt the flesh and skin, either in a greater or less quantity, in proportion to the degree of violence and exercit. In a slight ecchymosis, there is little to be feared, as the stagnant blood may be generally dispersed without any great difficulty by the application of a compress dipped in vinegar and salt, or in spirit of wine. Sometimes the blood suppurates, which may be promoted by a diachylon-plaster; and when the matter is once brought to maturity, it generally makes its own way through the integuments, without any incision; after which, being discharged, the wound may be healed by a bit of diachylon-plaster. If the stagnant blood be very large, there are no hopes left to dispere it; then the disorder is in danger of terminating either in a large abscess or a gangrene: but to prevent these consequences, the surgeon should scarify, and make little incisions upon the hard part to discharge the blood, and then apply diachylon-plaster; and if the vein is already posseos with a violent inflammation or gangrene, it should be well scarified and inveted with diachylon plaster. At the same time it is necessary to bleed in some other part, and to administer attenuating medicines internally till it abates, or the gangrene spreads no farther.

ECCLESIA, in law, signifies a church or parsonage. See the articles CHURCH and PARSONAGE.

ECCLESTIASTES, a canonical book of the Old Testament, the design of which is to shew the vanity of all sublunary things. It was composed by Solomon, who enumerates the several objects on which men place their happiness, and then shews the insufficiency of all worldly enjoyments. The Talmudists make king Hezekiah to be the author of it; Grotius ascribes it to Zorobabel, and others to Isaiah; but the generality of commentators believe this book to be the produce of Solomon's repentance, after having experienced all the follies and pleasures of life.

ECCLESIASTICAL, an appellation given to whatever belongs to the church: thus we say, ecclesiastical polity, jurisdiction, history, &c. See the articles POLITY, JURISDICTION, HISTORY, &c. Ecclesiastical jurisdiction may be exercised by doctors of the civil law, though they are laymen.

ECCLESIASTICAL COURT. See COURT.

ECCLESIASTICUS, an apocryphal book, generally bound up with the scriptures, so called from its being read in the church, ecclesia, as a book of piety and instruction, but not of infallible authority. The author of this book was a Jew, called Jesus the son of Sirach. The Greeks call it the wisdom of the son of Sirach.

ECCEPE, in surgery, the fame with amputation. See AMPUTATION.

ECCEPOTRICKS, in pharmacy, the fame with gentle cathartics and evacuants. See CATHARTICS AND EVACUANTS.

ECHAPE, in the manage, a horse begot between a stallion and a mare of different breeds and countries.

ECHAPER, in the manage, a gallicism used in the academies, implying to give a horse head, or to put on at full speed.

ECHARPE, in the military art. See the article BATTERY.

ECHAUGETTE, in the military art, denotes a guerite of wood, and of a square form. See the article GUERITE.

ECHENEIS, in ichthyology, a genus of malacoverygious fishes, whereof the branchiotege membrane on each side contains about nine officies or small bones; its head is flat on the upper part, and marked with a number of rough transverse lines, or ridges. Of this genus, there is only one known species, the remora of authors. See the article REMORA.

ECHEVIN, scabinus, in the french and dutch polity, a magistrate elected by the inhabitants of a city or town, to take care of their common concerns, and the decoration and cleanliness of the city. At Paris, there is a prevôt, and four echevins; in other towns, a mayor and echevins. At Amsterdam, there are nine echevins; and, at Rotterdam, seven. In France, the echevins take cognizance of rents, taxes, and, the navigation of rivers, &c. In Holland, they judge of civil
E C H

civil and criminal causes; and if the criminal confesses himself guilty, they can see their sentence executed without appeal.

ECHERVIN of the palace, an officer of the household under the first race of the French kings.

ECHINATE, or ECHINATED, an application given to whatever is prickly, thereby resembling the hedge-hog.

ECHINATUS, in ichthyology, a species of ostracion. See OSTRACION.

ECHINATES, in natural history, the name by which authors call the fossil centronia, frequently found in our chalk-pits.

See the article CENTRONIA.

ECHINOMETRA, the same with ECHINOPHORA.

ECHINOPHORA, in botany, a genus of the ordination, or centronia, familiarly called hedgehog.

ECHINOPUS, a genus of the class of plants, the composites; the flower of which consists of five unequal, patulous petals; it has no pericarpium; the general involucrum is of a turbinated figure; and the seeds are two in number, and of an oblong form.

ECHINOPUS, in botany, a genus of the class of plants, the composites; the flower of which consists of five unequal, patulous petals; it has no pericarpium; the general involucrum is of a turbinated figure; and the seeds are two in number, and of an oblong form.

ECHINOPHORA is also used by Rivinus for the caucasii. See the article CAUCALIS.

Echinops, or Echinopus, Glove-thistle, in botany, a genus of the fyn-genetha-polygema-equalis class of plants, the flower of which is compound; consisting of a great number of floficles or small flowers, divided into several acute segments: there is no pericarpium: the seed, which is single, is of an ovato-oblong figure, narrower at the base, with an obtuse hairy apex. See plate LXXXII. fig. 2.

The roots and seeds of this plant are said to be attenuant and diuretic.

ECHINUS, in zoology, a name frequently used for the erinaceus, or common hedge-hog. See the article ERINACEUS.

ECHINUS MARINUS, the same with centronia. See the article CENTRONIA.

ECHINUS, in architecture, a member or ornament near the bottom of the Ionic, Corinthian, and Composite capitals.

ECHIUM, VIPER'S BUGLOSS, in botany, a genus of the petendria-mongamia class of plants; the flower of which consists of a single petal, the tube being very short, and the limb erect, growing gradually wider at the extremity, where it is divided into five unequal segments; the two upper segments are longer than the rest, and the lowest one is small, acute, and reflex; there is no pericarpium, instead of which the cup becomes rigid, and contains in it four roundish and obliquely acuminated seeds. See plate LXXXII. fig. 3.

A powder of the root of this plant is recommended against epilepsies; it is also a sudorific, vulnerary, and prescribed against the erysipelas.

ECHO, a sound reverberated or reflected to the ear from some solid body. Whereas the undulatory motion of the air, which constitutes sound is propagated in all directions from the sounding body, it will frequently happen that the air, in performing its vibrations, will impinge against various objects, which will reflect it back, and so cause new vibrations the contrary way: now if the objects are so situated as to reflect a sufficient number of vibrations back, viz. such as proceed different ways, to the same place, the second will be there repeated, and is called an echo: and the greater the distance of the objects is, the longer will be the time before the repetition is heard: and when the sound, in its progress, meets with objects at different distances, sufficient to produce an echo, the sound will be repeated several times successively, according to the different distances of these objects from the sounding body, which makes what is called a repeated echo. See SOUND and REFLECTION.

In order to account for the nature of echoes, we must consider that sound is perceived as coming from that place from which, as a center, the pulses are propagated. This is well known by experience; but to illustrate the matter, let A (plate LXXXII. fig. 4,) be the center from whence any sound is directly propagated, and strikes against any plane obstacle BC, sufficiently large; draw AF perpendicular to BC, and produce it to H, so that it may be AF=FH; the sound reflected will be perceived as coming from the point H. For let AE be the incident ray, impinging against the obstacle BC, in the point E; from E draw the ray ED in such a manner that the angle CED may be equal to the angle FEA, or that the angle of incidence may be equal to the angle of reflection; then will ED be the reflected ray of sound, and if produced will pass through the point H; for the angle FEH=CED=FEA. Therefore in the triangle AFE and EHF, since the angles of the one are respectively equal to the angles of the other, and the side EF is common to both, the sides of one triangle will be respectively equal to the sides of the
E C H  [ 1918 ]

The reflex sound found will be heard by a person at D, as coming from the point H. As the place of the auditor, or point D, approaches towards A, the echo will constantly be the same with respect to the center of sound H; the triangles will still be equal, and all their angles and sides respectively; and therefore when D coincides with H, the reflex sound or echo will be heard from the point H, which was to be demonstrated.

The fame sound is also heard twice by an auditor at D; first by the direct ray AD, and secondly by the reflex ray AED, provided the difference between AD and AED be sufficiently great, that the direct and reflex sounds do not, in the same sensible moment of time, affect the ear: for if the reflex sound arrives at the ear before the impression of the direct sound ceases, the sound will not be double, only rendered more intense.

From the velocity of sound it follows, that a person speaking or uttering a sentence in A aloud, in order to observe the echo by reflection from the obstacle BC, ought to stand at least 73 or 74 feet from it, that is, AF = 74: and since at the common rate of speaking, we pronounce not above 3½ syllables per second; therefore, that the echo may return just as soon as the three syllables are expreced, we must have twice AF equal to 1000 feet, or the speaker must stand about 250 feet from the obstacle BC, and so in proportion for any other number of syllables.

Echo, in architecture, a term applied to certain kinds of vaults and arches, most commonly of elliptical and parabolical figures, used to redouble sounds, and produce artificial echoes.

We learn from Vitruvius, that in several parts of Greece and Italy, there were brazen vellums artfully ranged under the seats of the theatres, to render the sound of the actors voices more clear, and make a kind of echo. A single arch or concavity can scarce ever stop and reflect the sound; but if there be a convenient disposition between it, part of the sound that is propagated thither, being collected and reflected as before, will present another echo; or if there be another concavity opposed at a due distance to the former, the sound reflected from the one upon the other will be tossed back again upon this latter, &c.

Echo, in poetry, a kind of composition wherein the last words or syllables of each verse contain some meaning, which being repeated apart, answers to some question or other matter contained in the verse, as in this beautiful one from Virgil:

Cruelis mater magis, an puer improbus ille?

Improbus ille puer, cruelis tu quoque mater.

The elegance of an echo consists in giving a new sense to the last words; which reverberate, as it were, the motions of the mind, and by that means affect it with surpris and admiration.

Echometer, among musicians, a kind of scale or rule, with several lines thereon, serving to measure the duration and length of sounds, and to find their intervals and ratios.

Echus, or Ecchus, a term sometimes used in a synonymous sense with piano. See the article Piano.

Eclectics, eclec³ici, ancient philosophers, who, without attaching themselves to any particular sect, selected whatever appeared to them the best and most rational, from each.

Potamon of Alexandria was the first of the eclectics: he lived in the reigns of Augustus and Tiberius; and being tired with the scepticism of the pyrrhonians, he resolved upon a scheme that would allow him to believe something, but without being so implicit as to swallow any entire hypothesis.

Eclectos, the same with what is more usually called linctus. See the article Linctus.

Eclipse, in astronomy, the deprivation of the light of the sun, or of some heavenly body, by the interposition of another heavenly body between our sight and it. Thus, eclipses of the sun happen by the moon's intervening between it and the earth; by which means the shadow of the moon falls upon the earth, when the latitude of the moon does not prevent it, by elevating the moon above, or deprefing it below the earth. On the other hand, an eclipse of the moon can only happen when the earth is interposed between the sun and it; for then, if the latitude of the moon does not prevent, the shadow of the earth may fall on the moon, and thereby cause either a partial or total eclipse. A total eclipse of the sun or moon is when their whole bodies are obscured; and a partial one is when part only
only of their bodies is darkened; again, a central eclipse is when it is not only total, but the eclipsed body passes through the center of the shadow.

**Astronomy of Eclipses.** The sun being a luminous body, vastly larger than the earth, will enlighten somewhat more than one half of it, and cause it project a long conical shadow, as represented in plate LXXXIII. no 1. where S is the sun, E the earth, and HBD its conical shadow.

The height or length of this shadow, at the mean distance of the sun, may be found by this proportion: as the tangent of the angle CBD, or the semi-diameter under which the sun appears at the earth, viz. $\tan 16° = 1$, the length of the shadow $\text{CBD} = 214.8$ semi-diameters of the earth: but when the sun is at its greatest distance, the length of the shadow $\text{CBD}$ will be equal to these semi-diameters. Hence it appears, that though the height of the shadow is near three times as great as the mean distance of the moon, yet it falls far short of the distance of mars, and consequently cannot eclipse none of the heavenly bodies but the moon.

To find the height of the moon's shadow, supposed to be similar to that of the earth, and consequently proportional to the diameters of the bases, the proportion is, as the diameter of the earth = 100 to the diameter of the moon = 28, so is the mean altitude of the earth's shadow 214.8 to the altitude of that of the moon = 60.148. The shadow of the moon therefore will just reach the earth in her mean distance, which it cannot do in her apogee; but in her perigee it will involve a small part of the earth's surface.

Besides the dark shadow of the moon, there is another, called the penumbra; to represent which, let $S$ (plate LXXXIV. no 2.) be the sun, $T$ the earth, $D$ the moon, $KCF$ and $ABE$ the two lines touching the opposite limbs of the sun and moon; then it is evident that $CFE$ will be the dark or absolute shadow of the moon, in which a person on the earth's surface, between $F$ and $H$, and $E$ and $G$, will see part of the sun, whilst the rest is eclipsed.

To calculate the angle of the cone $HIG$, draw $SB$; then in the oblique triangle $BIS$, the external angle $BID$ is equal to both the internal and opposite angles $IBS$ and $ISB$; but $ISB$, the angle under which the semi-diameter appears at the sun, being indefinitely small, the angle $BID$ will be equal to $IBS$, or $KBS$, equal to the apparent semi-diameter of the sun. Therefore the part of the penumbral cone $CIB$ is equal and similar to the dark shadow of the moon.

Next, to find how much of the earth's surface can be at any time involved in the moon's dark shadow, or the quantity of the arch $EF$ (plate LXXXIII. no 2.) let us suppose the sun to be in apogee, and the moon in perigee; and, in this case, the height of the moon's shadow will be about 61 semi-diameters, and the distance of the moon about 56; that is, $DK = 61$, $DT = 56$, and $TE = 1$. In this case also, the half angle of the shadow $TKE = 15° 50'$, as being least of all. Then the proportion is: as 1, or the side $TE$ to the side $TK = 61$ $50'$ is the sine of the semi-angle $TKE = 15° 50'$ to the sine of the angle $TEK = 1° 19' 40"$. Wherefore $TKE = ATE = AE = 1° 35' 31"$; the double of which $FE$ is $3° 10' = 90'$, or 220 miles, the diameter of the dark shadow on the surface of the earth when greatest.

After a like manner you may find the diameter of the penumbral shadow at the earth, $GFEH$ (plate LXXXIV. no 2.) when greatest of all, that is, when the earth is in perihelio, and the moon in apogee; for then will the sun's apparent diameter be equal to $16° 23'' = TIG$, the greatest semi-angle of the cone; and hence we shall find $ID = 58 \frac{1}{2}$ semi-diameters of the earth. In this case also, the distance of the moon from the earth is $DT = 64$ semi-diameters. Therefore as $TG = 1$ to $TI = 122 \frac{1}{2}$, so is the sine of the angle $TIG = 23^1_2''$ to the sine of the angle $IGN = 35^4_2'$. But $IGN = TIG + ITG$, and therefore $ITG = IGN - TIG = 35^4_2' - 23^1_2'' = 33^4_2'$; the double of which $70^0 50' = GFEH = 4900$ English miles nearly, for the diameter of the penumbral shadow when greatest.

From the principles of optics it is evident, that if the plane of the moon's orbit coincided
incided with that of the earth's orbit, there would necessarily be an eclipse of the sun every new moon: thus, if $S$ (plate LXXXIV. n° 1.) represent the sun, $B$ the moon, and $T$ the earth, since the apparent magnitude or disc of the sun is nearly the same with that of the moon, it must necessarily be hid or eclipsed as often as the new moon came between the earth and the sun. But if, as is really the case, the moon's orbit be not in the plane of the ecliptic, but inclined thereto under a certain angle, there may be a new moon, and yet no eclipse of the sun; and, therefore, when the moon is new, and the earth and the moon's orbit be not in the plane of the ecliptic, but inclined thereto under a certain angle, there may be a new moon, and yet no eclipse of the sun. To illustrate this, let $ABCDE$ be a circle in the plane of the ecliptic, described at the distance of the moon's orbit $FGH$, intersecting the same in the points $B$ and $D$, and making an angle therewith $ABF$, whose measure is the arch $GC$, as being $90^\circ$ distant from the angular points or nodes $B$ and $D$. Now it is evident if the arch $GC$ be somewhat greater than the sum of the apparent semi-diameters of the sun and moon, then at $G$, and some distance from $G$ towards $B$, there may be a new moon, and yet no eclipse of the sun; because, in this case, the disc of the moon $G$ is too much elevated or depressed above or below the apparent disc or face of the fun $C$, to touch it, much less to hide or eclipse any part thereof. But at a certain point $M$ (ibid.) in the moon's orbit, the moon will have a latitude only equal to the sum of the semi-diameters of the sun and moon; and, therefore, when the moon is new in that point, it will appear to a spectator in the point $Z$, to touch the sun only; from whence this point $M$ is called the ecliptic limit, insomuch as it is impossible there should happen a new moon in any part between it and the node $B$ on each side, without eclipsing the sun less or more: thus, in the figure, may be seen a partial eclipse at $K$, and a total one in the node itself $B$. What has hitherto been said regards the phenomenon of an eclipse of the sun, as they appear to a spectator on the earth's surface, in whose zenith the moon then is, and where there is no refraction to alter the true latitude of the moon: but when the moon has any latitude, there the process of calculating the appearances of a solar eclipse will be somewhat more complex, on account of the variation of the moon's latitude and longitude for every different altitude, and consequently every moment of the eclipse. See Refraction and Parallax.

The best way of representing a solar eclipse is by a projection of the earth's disc, and of the fection of the dark and penumbral shadow, as they appear, or would appear, to a spectator at the distance of the moon in a right line joining the centers of the sun and the earth. In order to this, we are to find the dimensions of the apparent semi-diameters of the earth, dark shadow, and penumbra at the distance of the moon. As to the first, viz. the earth's semi-diameter, it is equal to the moon's horizontal parallax. That of the dark shadow is thus estimated: let $C$ (plate LXXXIII. n° 5.) be the center of the moon, $DB$ its diameter, $DHB$ its dark shadow, and $KAL$ the penumbral cone. Then let $EF$ be the diameter of the penumbra at the earth, and $IG$ that of the dark shadow, and draw $CG$ and $CE$; then is the angle $CGB = BHC + GCH$, and $GCH = BGC - BHC$; that is, the apparent semi-diameter of the dark shadow, is equal to the difference between the apparent semi-diameters of the sun and moon. In like manner the angle $ECH = DEC + DAC$; that is, the apparent semi-diameter of the penumbra, at the earth, is equal to the sum of the apparent semi-diameters of the moon and sun. Now the semi-diameters of the sun and moon, and also the moon's horizontal parallax, are all ready calculated for their various distances from the earth, and for the least, mean, and greatest eccentricity of the lunar orbit, in the astronomical tables. Therefore, let $AE$ (plate LXXXIII. n° 3.) represent a small portion of the annual orbit, and $FH$ the visible path of the center of the lunar shadows, which will exactly correspond to the position of the moon's orbit with respect to the ecliptic in the heavens; so that the point of intersection $Q$ will be the node, and the angle $HQE$ the angle of inclination of the lunar orbit to the plane of the ecliptic, which is about $5^\circ$. Hence, if $AEPSQ$ represent the disc of the earth, according to the orthographic projection, in the several places $Q$, $B$, $C$, $D$, whose semi-diameter is made equal to the number of minutes in the moon's horizontal parallax at the time of the eclipse; and if, in the path of the shadows in the points $Q$, $R$, $N$, $G$, we describe a small circle whose semi-diameter is equal to the difference of the semi-diameters
femidiameters of the sun and moon, that
will be the circular section of the moon's
dark shadow at the distance of the earth:
again, if a circle is described on the same
center, with a semidiameter equal to the
sum of the semidiameters of the sun and
moon, it will represent the penumbral
shadow, expressed by the dotted area.
Here then it is evident, that if the moon,
when new, be at the distance $\mathcal{G}G$ (ibid.)
from the node, the penumbral shadow
will not fall near the earth's disc, and so
there cannot possibly happen an eclipse.
Again, if the moon's distance from the
node be equal to $\mathcal{G}N$, the penumbral
shadow will just touch the disc, and con­
sequently $\mathcal{G}C$ is the ecliptic limit, which
may be found by the following analogy,
that is, as the sine of the angle $\mathcal{N} \mathcal{G} \mathcal{C} = 5^\circ 30'$ (the angle of inclination of
the lunar orbit to the plane of the ecliptic)
is to the radius $r = 90^\circ$, so is the loga­
rithm of the sine $\mathcal{N} \mathcal{C} = T'C + NT = 62^\circ 10' + 16^\circ 52' + 16^\circ 23' = 95^\circ 2' 5''$ to the loga­
rithm of the sine $\mathcal{G} \mathcal{C}$ equal to the ecliptic
limit, which is found to be $16^\circ 36'$, be­
ond which distance from the node $\mathcal{G}$
there can be no eclipse; and within that
distance, if the moon be new, the shadow
will fall on some part of the earth's disc,
as at $B$; where all those places over
which the shadows pass, will see the sun
eclipsed, in part only by the dotted pen­
umbral shadow; but the fun will be cen­
trally eclipsed in all places over which the
center of the shadows pass, and if the moon
be new in the node, then will the cen­
ter of the shadows pass over the center of
the disc, as represented at $\mathcal{G}$. In this
case, if the apparent diameter of the moon
be greater than that of the sun, the face of
the sun will be wholly eclipsed to all places
over which the center of the shadows passes;
but if not, the sun will only be centrally
eclipsed, his circumference appearing in
the form of a bright annulus, or luminous
ring; the width whereof will be equal
to the difference of the diameters of the
luminaries. The disc of the earth, here
projected, represents the case of an eclipse
on an equinoctial day; $A$ $K$ being the
ecliptic, $\mathcal{A} \mathcal{B} \mathcal{Q}$, the equator, $X Y$ the axis
of the ecliptic, $P S$ the axis of the equator,
P and $S$ the north and south poles, &c.
By this projection the passage of shadows
over the earth's disc may be exhibited for
any place of the sun, or declination of
the moon.

As to the calculation of eclipses of the
fun, it is at best but a troublesome busi­
ness, which depends upon the following
data: 1. The mean conjunction, and
from thence the true conjunction, to­
gether with the place of the luminaries at
the apparent time of true conjunction.
2. The apparent time of the visible new
moon, at the apparent time of the true
conjunction. 3. The apparent latitude at
the apparent time of the visible conjunc­tion.
From these data, the other qua­siata
may be obtained; so that the greatest
part of the trouble arises from the paral­
laxes of longitude and latitude, without
which the calculation of solar eclipses
would be the same with that of lunar
ones.

Astronomy of lunar Eclipses. These be­
ing occasioned by the immersion of the
moon into the earth's shadow, all that
we have to do, in order to delineate a lu­
nar eclipse, is to calculate the apparent
semidiameter of the earth's shadow at the
moon. Thus, let $A B$ (plate LXXXIII.
n.o 6.) represent the earth, $T$ its center,
$A E B$ its conical shadow, $D C$ the diameter
of a section thereof at the moon; and
drawing $D T$, we have the outward
angle $A D T = D T E + D E T$; so that
$D E T = A D T - D E T$; that is, the
angle $D E T$, under which the semidi­
diameter of the earth's shadow appears
at the distance of the moon, is equal to the
difference between the moon's horizontal
parallax $A D T$, and the semidiameter
of the fun $D E T$. If, therefore, $A E$,
(ibid. n. o 4.) represent the path of the
earth's shadow at the distance of the moon
near the node $\mathcal{N}$, and $F H$ a part of
the lunar orbit, and the section of the earth's
shadow be delineated at $\mathcal{G}$, $B$, $C$, $D$;
and the full moon at $\mathcal{G}$, $I$, $N$, $G$; then
it is evident there can be no eclipse of the
moon, where the least distance of the
centers of the moon and shadow exceeds
the sum of their semidiameters, as at $D$.
But where this distance is less, the moon
must be eclipsed either in part or wholly,
as at $B$ and $\mathcal{G}$; in which latter case the
moon passes over the center of the sha­
dow. But in a certain position of the
shadow, as at $C$, the least distance of the
centers, $N C$, is equal to the sum of the
semidiameters; and consequently $\mathcal{G} C$
is the ecliptic limit for lunar eclipses; to
find which, we have this analogy, as the
line of the angle $\mathcal{N} \mathcal{G} \mathcal{C} = 5^\circ$ (the in­
6 P }
As to the obliquity of the ecliptic, or angle which its plane makes with that of the equinoctial, it is found to vary; the mean obliquity being found by Dr. Bradley to be 23° 28' 30"; which supposes this variation may be owing to a mutation of the earth's axis, or to a gradual approach of the ecliptic to the equinoctial, at about the rate of 1' in 100 years.

ECLIPTIC, in geography, a great circle on the terrestrial globe, not only answering to, but falling within the plane of the celestial ecliptic. See GLOBE.

ECLOGUE, эклога, in poetry, a kind of pastoral composition, or a small elegant poem, in a natural simple style. See the article Pastoral.

The eclogue, in its primary intention, is the same thing with the idyllium, but custom has made some difference between them, and appropriated the name eclogue to pieces wherein shepherds are introduced, and idyllium to those written like eclogues, but without any shepherds in them. The eclogue then is properly an image of pastoral life, upon which account the matter is low, and its genius humble. Its business is to describe the loves, sports, piques, jealousies, intrigues, and other adventures of shepherds; so that its character must be simple, the wit easy, and the expression familiar. Then the true character of the eclogue is simplicity and melody; its figures are near, the passions tender, the motions easy, and though sometimes it may have little transports, and defpairs, yet it never rises so high as to be fierce or violent. Its narrations are short, descriptions little, the thoughts ingenious, the manners innocent, the language pure, the verse flowing, the expessions plain, and all the discourse natural.

The models in this fort of poetry are Theocritus and Virgil, who both have some eclogues of a lofty character. The eclogue therefore occasionally raises its voice: yet M. Fontenelle blames some modern poets for having made matters of high concern the subject of some of their eclogues, and caused their shepherds sing the praises of kings and heroes. The Italians are thought faulty in this respect, for aiming generally to be too witty or superbe in their style; however, since the establishment of the Academy of Arcadians at Rome, the taste for eclogues has been greatly improved amongst them. Some imagine the name eclogue to have been originally applied to such poems as were wrote in imitation of others: such
are the Eclogues of Virgil, which are only imitations of Theocritus.

ECLOGUE is also applied to certain compositions in prose: such are those of Strabo, Diodorus, &c. in which feme, the word signifies only an extract, or collection.

ECOUTE, in the manage, a pace or motion of a horse, when he rides well upon the hands and the heels, is compatibly put upon his haunches, and hears or listens to the heels or piares, and continues duly balanced between the heels, without throwing to either side. This happens when a horse has a fine feme of the aids of the hand and heel.

ECPHONESIS, the same with exclamation. See the article EXCLAMATION.

ECPHORA, in architecture, commonly signifies the distance between the extremity of a member or moulding, and the naked of the column, or any other part it projects from.

Some authors, however, account for the ephora from the axis of the column, and define it to be the right line intercepted between the axis and the outermost surface of a member or moulding.

ECPHRACTICS, in medicine, remedies which attenuate and remove obstructions. See the articles ATTENUANTS and DEOBSTRUENTS.

ECPIESMA, in surgery, a fort of fracture of the cranium, when the bones are much shattered, and, pressing inwards, affect the membranes of the brain.

ECPIESMA, in pharmacy, signifies the mafs remaining after the juices of vegetables have been pressed out: and, in this feme, is the same as magma. It sometimes further imports the juice pressed out.

ECPIESMUS, or στομηνας, in the antient writers of medicine, a word used to express a diatemperature of the eye, consisting in a very great prominence of the entire globe of the eye, which is, as it were, thrust out of its socket or orbit, by a great flux of humours, or an inflammation.

ECPUCTICA, in pharmacy, the same with incraffants. See INCRASSANTS.

ECSTATICI, εκστασις in grecian antiquity, a fort of diviners, who were cast into trances or ecstasies, in which they lay like dead men, or perions asleep, deprived of all feme or motion, but after some time (it may be days, or months, or years, for Epimenides the Cretan is reported to have lain in this posture twenty-five years) returning to themselves, gave strange relations of what they had seen and heard.

ECTASIS, in grammar, the same with diastole. See the article DIASTOLE.

ECTHESIS, in church-history, a confession of faith, in the form of an edict, published in the year 639, by the emperor Heraclius, with a view to pacify the troubles occasioned by the eutychian heresies in the eastern church. However, the same prince revoked it, on being informed that pope Severinus had condemned it, as favouring the monothelites; declaring at the same time, that Sergius, patriarch of Constantinople, was the author of it.

ECTHILIPSIS, εκθιλψης, among latin grammarians, a figure of proody whereby the n at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verfe: thus they read mult ille, for multum ille.

The reason of an ecthilipsis, which in latin verse ought always to take place when the immediately following word begins with a vowel, is to prevent the harshnefs of an hiatus, or concourse of vowels.

ECTROPIUM, in surgery, is when the eye-lids are inverted, or retracted so as to shew their internal or red surface, and cannot sufficiently cover the eye. Sometimes this is a simple or original disorder, and sometimes only a symptom, or consequence of another, as an inflammation, farcoma, tumour, &c. When the disorder is simple, or original, it generally arises from a contraction of the skin of the eye-lid, by the scar of a wound, ulcer, burn, &c. or from an induration and contraction of the skin after an inflammation; and sometimes it may proceed, in a great measure, from the use of astringent collyria injudiciously applied, in disorders of the eyes.

The cure of this disorder consists in elongating, or relaxing, the external skin of the eye-lid so as to cover the eye. When the disorder is recent, it will be best to try the application of emollients, such as the vapours of hot milk or water, oil of almonds, or olives, mucilage of quinceseed, hare's foot, ung. diathése, &c. to be continued for several days on the scar, or contracted skin of the eye-lid, which must be often extended, either upwards or downwards, according as the disorder is in the upper or lower lid. And every night, when the patient goes to sleep,
to bed, it will be proper to bring the eye-lids close to each other, and to restrain them close by plaster, compres, and bandage, to be renewed every night. If none of these means take effect, it will be proper first to make a semilunar incision in the external skin of the eye-lid, next its tarsus; making the angles of the incision downwards in the upper lid, and upward in the lower lid, that the skin may be elongated. If the skin does not appear to be let out enough by one incision, two or three more must be made, running parallel to the first, and about the distance of a small packthread from each other, and when the eye-lid is thus sufficiently elongated, the incisions must first be fluffed with dry lint, and then with lint armed with vulnerary unguent; and lastly, a piece of sticking plaster should be fattened to the margin of the eye-lid, to keep it extended either up or down; which method should be continued till the eye-lids shut close. When the disorder arises from an inflammation, or flabby excrecence within the eye-lid, the inflammation must be removed, and arming the eye with a defensive plate, the excrecence must be removed by lapis infernal is. When the eye-lid, the inflammation must be removed, and arming the eye with a defensive plate, the excrecence must be removed by lapis infernal is. When the eye-lid has continued violently distorted any hopes of curing it. The edgings of box are now only planted on the sides of borders next walls, and not, as was some time since the fashion, all round borders, or fruit-beds, in the middle of gardens, unless they have a gravel-walk between them, in which case it serves to keep the earth of the borders from washing down on the walks in hard rains, and fouling the gravel. Daisies, thrift, or sea-july-flowers, and chamomile are also used, by some, for this purpose; but they grow out of form, and require yearly transplanting.

EDHELING, edhelings, the name with atheling. See ATHELING.

EDICT, edictum, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects. We find frequent mention of the edicts of the praetor, the ordinances of that officer in the roman law. In the french law, the edicts are of several kinds; some importing a new law or regulation; others, the erection of new offices; establishments of duties, rents, &c. and sometimes articles of pacification. In France edicts are much the same as a proclamation is with us, but with this difference, that the former have the authority of a law in themselves, from the power which issues them forth; whereas the latter are only declarations of a law, to which they refer, and have no power in themselves. Edicts can have no room in Britain, because that the enacting of laws is lodged in the parliament, and not in theking. Edicts are all sealed with green-wax, to shew that they are perpetual and irrevocable.

EDIFICE, the name with building. See the article BUILDING.

EDILE, or ÉDILE. See ÉDILE.

EDINBURGH, the capital city of Scotland, situated about one mile south of Leith and of the firth of Forth, eighty-two miles north west of Newcastle, and about three hundred north west of London.
Here the parliament of that antient kingdom used to assemble, before its union with England; and here the supreme courts of justice for North Britain are still held. It has likewise a celebrated university, and exceeds all the cities of the world for the loftiness of its buildings, which are all of hewn stone, fadhed, and ten, eleven, or more stories high: it is also remarkable for the spaciousshefs of its High-street, its Caffle, the palace of Holyrood-house, &c.

EDITOR, a person of learning, who has the care of an impression of any work, particularly that of an antient author: thus Erasmus was a great editor; the lou­vain doctors, Scaliger, Petavius, P. Sir­mond, bishop Walton, Mr. Hearne, Mr. Ruddiman, &c. are likewise famous editors.

EDMOND'S-BURY. See BURY.

EDUCATION, the instructing children, and youth in general, in such branches of knowledge and polite exercifes, as are suitable to their genius and station.

Education is a very extensive subject, that has employed the thoughts and pens of the greatest men: Locke, the archbishop of Cambray, Tanaquil Faber, M. Crou­faz, and Rollin may be consulted on this head.

The principal aim of parents should be, to know what sphere of life their children are designed to act in; what education is really suitable for them; what will be the consequence of neglecting that; and what chance a superior education will give them, for their advancement in the world.

Their chief study should be to give their children such a degree of knowledge, as will qualify them to fill some certain part or station in life: in short, to fit them for an employment suited to their condition and capacity, such as will make them happy in themselves, and useful to society.

The education of a nobleman should contain every thing that is both useful and ornamental. Next to languages, he ought to be instructed in philosophy and history, particularly the history of his own nation.

He should also be made acquainted with the customs, laws, and manners of different states, but more especially with the constitution of his own country. To this solid learning should be added the embellishment of polite literature, poetry, painting, and music; and, to complete the education, dancing, fencing, riding, and architecture.

As to the education of gentlemen, the plan above laid down will in general hold good. Every gentleman of fortune should certainly give all his sons the education of gentlemen; but the eldest ought to be graced with every ornament. Parents of this class, besides carefully attending to the genius, temper, and inclinations of their younger sons, should resolve on an employment suited to them; which being settled, they are to pursue their education accordingly. The three learned professions, divinity, law, and physic, require each a species of learning proper to itself. But besides these, the sea, the army, and the exchange, with many other genteel employments, are open for them to engage in: and hence appears not only the necessity of considering their fortune, but attending to their genius, temper and inclinations.

As many among the mercantile class are defended of the best gentlemen's families, and as intermarriages are frequent between them, it is highly proper that their children should be genteelly educated. However, even in this, regard should be had to their own fortune, and the real prospects before them: for nothing can be a greater misfortune than to educate a boy like a fine gentleman, and not be able to support it. A learned education is needless, in the case before us; but reading, writing, arithmetic, geography, and drawing, are extremely proper, or rather absolutely necessary.

With regard to manners, the quality should be cautioned never to sink beneath their rank; and while they learn to be humble, they must carefully avoid being mean. The gentry should approach as near to the quality in good behaviour, and politenes, as possible: and as to the trading part of the people, they should be taught that every thing coarse, vulgar, and mean is highly unbecoming them; is not only abusing the faculties providence has furn­ished them with, but is debasing their nature.

Before we conclude this article, it will be proper to take notice of the impropriety and inconvenience of not teaching young people to think and act of themselves. The art of a governor, and the lessons of a preceptor, change a child into a youth; they infuse into him a greater share of knowledge than he could be naturally supposed to have at his age. But this very child, when he arrives to that stage of life in which he must think, speak, and
EDULCORATION, which makes him wait for external impulses to resolve and act. The mind contracts a laziness with as much facility as the legs and feet. A man who never flirs without the assistance of some vehicle, becomes soon incapable of the same free use of his legs, as a person that has been constantly accustomed to walk. As, therefore, we must lend a hand to the one when he walks, so we must help the other to think, and even to will: where-as in a child bred up with less care, his inward part labours of itself, and his mind grows active. He learns to reason and determine of himself, in the same manner as other things are learned. At length he attains to argue and resolve rightly, by mere dint of reasoning and reflecting on the cause of his deception, when the events convince him of the error of his judgment.

EDULCORATION, in pharmacy, the same with dulcifying. See the article DULCIFYING.

EDULCORATION, in chemistry, the separating, by a washing, or solution, in water, the salt that any body may be impregnated with, or those that may be left adhering to a body, after any operation. See the article ABLUTION.

The solution here spoke of, is in metals only, and is properly a kind of moist one, the saline parts adhering to bodies not soluble in water, being by that menstruum taken up, and eaten off from the body, and the solution afterwards separated from the remaining solid, either by subfuscence or filtration. See the article FILTRATION.

It is proper in this operation to enlarge the surface of the body to be edulcorated, by pounding it in a mortar, that the solution may have the speedier success; and for this purpose it should always be kept stirring with a flick, while the water is on it, that all the parts of the body to be edulcorated, which otherwise would some of them sink to the bottom, may be made equally, at one time or other, contiguous to the particles of the edulcorating fluid, by which all the solutions are greatly facilitated. Boiling water is, in some cases, requisite; for the heat of that, by the inward motion and rarefaction it occasions, promotes in an extraordinary manner saline solutions. Very frequent repetitions of this operation are necessary; and, after all, a nice experiment will always find some small portion of salts remaining.

EEL, anguilla, in ichthyology, a species of murana. See MURÉNA.

The common eel is the simple coloured murana, with the lower jaw longest: it has three fins, viz. two pec­toral ones, standing one on each side; and a single low back-fin, which beginning at some distance from the head, runs along the back to the tail, and comes up again continuos as far as the anus: the extremity of this fin, which forms what may be called the tail, is neither round nor square, but subacute. See plate LXXXV. fig. 1.

It is common in all our fresh waters, ponds, ditches, and rivers; and its general standard is about two feet in length, though some are often caught much larger.

The fat of eels is accounted vulnerary, and good in an alopecia, cases of deal­ness, and the hemorrhoids.

Eel-fishing is of divers kinds, as snig­gling, bobbing, &c. See FISHING.

The silver-eel may be caught with several sorts of baits, as powdered beef, lobs, or garden-worms, minnows, hens-guts, sif­th-garbage, &c. The most proper time for taking them is in the night, fastening your line to the bank-fides, with your laying-hook in the water: or a line may be thrown with good store of hooks, bai­ted and plummed, with a float to discover where the line lies, that they may be taken up in the morning.

Microscopic EELS, those discovered by the microscope in pepper-water and other infusions of plants, as well as in the feed of most animals. See ANIMALCULES.

Sea-Eel, anguilla marina, a fish otherwise called conger; being a species of murana, with the upper edge of the back-fin black. See the articles CONGER and MURÉNA.

EEL-BACKED, an appellation given to such horses as have black lits along their back.

EEL-POUT, the English name of a fish of the gadus-kind, with three fins on the back, cirri at the mouth, and the two jaws equal: the generality of authors call it muselfa fluviatilis. See GADUS.

EEL-SPEAR,
EFFERDING, a town of upper Austria, about ten miles west of Lintz.

EFFERDING, a town of upper Austria, about ten miles west of Lintz.

Effervescence, in a general sense, signifies a slight degree of effusion in liquids excited to a due degree of heat: but the chemists apply it to that intense motion excited in various fluids, either by the mixture of fluids with others of a different nature; or by dropping salts, or powders, of various kinds into fluids.

The two most common opposites, acids and alkalies, on being mixed, cause a great effusion, or frothing, but no great heat: but the solution of some metals in aquafortis, causes intense heat, and emit flame. The mixing aromatic oils with acid mineral spirits, actually kindle and burn with violent explosions; and some vegetable substances, putrefying with moisture, will, sometimes, heat so as to kindle whatever lies dry about that part of the heap where the putrefaction happens.

Hence, effervescences are distinguished into hot and cold; that which produces heat in the substances so mixt, is called a hot effervescence, but if no heat is excited, it is called a cold effervescence.

Among the mixtures that excite a cold effervescence, is that of powdered coral mixt with distilled vinegar; which is accounted for hence, by Chauvin, that the pores of the coral being very great, it may be easily dissolved in the acid spirit, without any great friction, or collision of the parts, such as would be necessary to generate any considerable heat.

The principal bodies in which effervescences happen, according to Boerhaave, are, 1. Native vegetable acids, as most juices of trees, shrubs, and plants that run in the spring; most juices of unripe summer fruits; particular juices, remaining acid when ripe, as of oranges, citrons, lemons, tamarinds, forrel, wood-forrel; fermented acid vegetables, as the meals when they turn sour; renish and Moselle wine, and tartar vegetables twice fermented; native and distilled vinegars; the acids of animals from tarts or acid vegetable aliment, as in the chyle, four milk, whey, butter-milk. 2. The native acids of fossils; as the acid of sulphur, alum or vitriol; or those acids as they lie concealed in sulphur, or vitriol stones; or as thence extracted by a violent fire; or a stronger acid, as in the spirit of nitre, salt, alum, vitriol, and sulphur. 3. True fixed alkalies, made of any vegetable matter, by burning the more volatile alkalies, whether spontaneous, as in garlic, onions, scurvy-grass, mustard, &c. produced by putrefaction from animal or vegetable subjects, or procured from the same by distillation and burning. 4. Certain bodies improperly called alkalies, only on account of agreeing therewith in fermenting with acids; these are almost all the boles, bones, chalk, clays, coral, crab-eyes, earths, horns, hoofs, nails, pearls, shells, stones and teeth. 5. The seven metals.

6. The femimetals; antimony, bismuth, lapis calaminaris, lapis haematites, lune, &c.

Hence we have four general rules, viz. 1. The bodies of the first class constantly make an effervescence with those of the second and third, either sooner or latter, more or less; or as they are weak or strong. The effervescence continues till the point of saturation is gained, then ceases, and the acrimony, after a full saturation, is generally softened.

2. The
2. The bodies of the first clafs make an effervescence with those of the fourth, and at the end of the fatturation, vitriols are usually produced. 3. The bodies of the first clafs act in the fame manner with those of the fifth. 4. The bodies of the second, third, fourth, and fifth classes, being mixed together, are scarce found to make any effervescence.

Effervescence, in vintage, a term appropriated by Portzius and others, to signify that working of wine which is thereby confounding two very different things. See the article Fermentation.

Efficacious, a term used by divines, in speaking of grace; importing fuch grace, as never fails to produce its effect. See the article Grace.

Efficent cause. See Cause.

Efficents, in arithmetic, the fame with factors. See Factor.

Effigy, effigies, the portrait, figure, or exact representation of a perfon. See Image.

Efflorescence, among phyicinians, the fame with exanthema. See the article Exanthema.

Effluent fever, the fame with an inflammatory one. See the article Inflammatory.

Effluvium, in phylogeny, a term much used by philofophers and phyicinians, to exprefs the minute particles, which exhale from moft, if not all, terreftrial bodies in form of insensible vapours. See the articles Vapour and Exhalation. Sometimes indeed, these effluvia become visible, and are feen ascend ing in form of fmoak; conftituting what, in anim als and plants, makes the matter of perpiration. See Perspiration.

Nothing can exceed the fubtilty of the odoriferous effluvia of plants, and other bodies. Mr. Boyle tells us, that having expo ed to the open air a certain quantity of afa foetida, he found its weight diminished only the eighth part of a grain in six days: hence, if we fuppofe, that during all that time a man could fmmel the afa foetida at the distance of five feet, it will appear that its effluvia cannot exceed the part of an inch in magnitude.

The effluvia of mineral substances are called fteams; and when collected in mines, or other clofe places, damps. See the article Damps.

Malignant effluvia are assigned by phy-
EGG [1029]

The yolk on all sides, liquid, and the other more dense and vituous, and of a somewhat whiter colour, but, in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg, is as new laid eggs; as is also the vitellus. Quors feparated one from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen, so it is very probable that they are of different natures, and consequently appointed for different purposes. Aristotle says, that the vitellus is condensed by cold, but the albumen rather liquified. On the contrary, the albumen is condensed by fire; the vitellus retains its softness, if it be not burnt, and concretes more in boiling than in roasting. When the vitellus grows warm with incubation, it becomes more humid, and like melting wax, or fat; whence it swells, by the vitellus, as with milk.

When the vitellus grows warm with incubation, it becomes more humid, and like melting wax, or fat; whence it swells, by the vitellus, as with milk. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wafted, being conveyed into the small guts by a small duct. Aristotle says, that long eggs produce the female, and round the male kind: Scaliger seems to be of the same opinion. Pliny is of the opposite side, for he pretends, that the long eggs are for the males, and the round for the females: but these opinions are supported by no foundation, as the authors give neither good reason nor experiments to prove their respective assertions, and it is very likely that both the round and the long eggs may indifferently produce male and female.

Eggs differ very much according to the birds that lay them, according to their colour, form, bigness, age, and the different way of dreeving them: those most used in food, are hens eggs: of these, such as are new laid are best. Galen says, that the beet and wholeomeft eggs are those of the hen and the pheasant, but he disallows the use of theoie of the goose and the oifrich. Eggs should be moderately done: some authors allow, that they should be very white and long. Eggs are nourishing and good food, they incrcafe the feminal juices, qualify the sharp humours of the breaft, are good for phthisical people, easily digest, ease the piles, and are looked upon to be good to make the voice loud and fine. When eggs are too cold, they heat too much, produce bad juice, and are more especially noxious to those who are of a hot and bilious constitution: they contain much oil and salt, and agree at all times with any age and constitution, provided they are endued with the good qualities before-mentioned.

Aquapendente relates several ways how to know whether eggs are new laid or not; he would have them held to a candle, and then see whether the humours contained therein are clear, thin and transparent; for if they be otherwise, it is a sign the eggs are old, because the effervescence has embroiled and confounded the infensible parts of these humours, and made them dark. Lastly, hold an egg to the fire, and if a little watry moisture flicks to it, it is new; if not, it is old; because a new laid egg is moister than the old, and its humours being thinner, work easier through the pores of the shell.
As to the preservation of eggs, it is observed that the egg is always quite full when it is first laid by the hen, but from that time it gradually becomes less and less so, to its decay; and however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute for the discernment of our eyes, the effect of which is a daily decrease of matter within the egg, from the time of its being laid; and the perspiration is much quicker in hot weather than in cold.

To preserve the egg fresher, there needs no more than to preserve it full, and stop its transpiration; the method of doing which, is, by stopping up those pores with matter which is not soluble in watery fluids; and on this principle it is, that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresher for a long time, if they are carefully rubbed all over the shell: tallow, or mutton fat, is also good for this purpose, for such as are rubbed over with this will keep as long as those coated over with varnish.

It was antiently thought, that none but birds and fishes, with some other animals, were produced of these eggs, fecundated by the volatile and spirituous part of the seed of the male, are detached from the ovary, and fall down the fallopian tubes into the uterus, where they grow and increase. This system is countenanced by abundance of observations and experiments.

See the article GENERATION.

Artificial method of hatching EGGS. See the article HATCHING.

Other eggs, improperly so called, are the white oblong bodies whereof insects are formed: such are the eggs of flies, gnats, butterflies, &c. which the antients called ovamculi. The female fly, after a congress with the male, is felden so much as twenty-four hours before she begins to deposit her eggs upon some substantial proper to give nourishment to the worms that are to be produced from them: these eggs in general are white and oblong. The gnat arranges her eggs in the form of a small boat; each separate egg is of the form of a ninepin: the thicker end of these are placed downwards, and are all firmly joined to one another by their middles.

EGG, in architecture, an ornament in that form, cut in the echinus, or quarter round of the ionic and composite capitals.

The profile or contour of the echinus is enriched with eggs and anchors placed alternately.

EGLANTINE, in botany, a name frequently given to the sweet-briar, a species of rose. See the article ROSE.

EGLEFINUS, in ichthyology, the name by which authors call the common haddock, a species of gadus. See the articles GADUS and HADDOCK.

EGRA, a city of Bohemia, situated on a river of the same name, about seventy-five miles west of Prague: east long. 12° 22', north lat. 50° 10'.

It is remarkable for its medicinal waters, esteemed good in hypochondriacal cæses, and other diseases arising from intermissions of the bowels. They are gently cathartic, and afford a faft of the same with Negroport.

EGRIPOS, the same with Negroport. See the article NEGROPONT.

EGYPT, an extensive country of Africa, lying between 30° and 36° of east longitude, and between 21° and 31° of north latitude, and bounded by the Mediterranean on the north; by the Red sea and Isthmus of Suez, which divide it from Arabia, on the east; by Abyssinia or Ethiopia, on the south; and by the deserts of Barca and Nubia, on the west; being six hundred miles in length from north to south; and from one hundred to two hundred in breadth from east to west.

Egypt is subject to the grand signior, and governed by a beshaw, or viceroy. It owes its fertility to the annual overflowing of the Nile, which it begins to do in the months of May and June, and is usually at its height in September, from which time the waters decrease till May or June again. By this supply of water, Egypt is rendered fruitful, as to serve Constantinople, and other places with corn, as it did Rome and Italy of old. They only harrow their grain into the mud, on the retiring of the water, and in March following, usually have a plentiful
plentiful harvest; and the lands, not town, yield good crops of grains for the use of the cattle. According to Mr. Sands, no country in the world is better furnished with grain, &c. sugar, fruits, melons, roots, and other garden stuff, than the lower Egypt.

EGYPTEN, a town of Courland, seventy miles south-east of Mitau.

EGYPTIANS. See the article GYPSIES.

EJACULATOR, a muscle of the penis, otherwise called the elevator.

EICHERTENAC, a town of Luxemburg, seven miles north-west of Treves.

EIDER, in ornithology, the same article as Cuthbert's duck. See DUCK.

EJECTA, evacuation, through some of the minor of the heir. 'Ejectment is the like nature with this; as a writ, or a motion made for that purpose, may be defendant in the action with the tenant in possession, to defend his title; for the possession of the lands is primarily in question, and to be recovered, which concerns the tenant, and the title thereto is tried collaterally, which may concern some other.

EIJNHOVEN, a town of Dutch Brabant, fifteen miles south of Boisleduc.

EIFIELD, or EFIELD, a town of lower Saxony, six miles north-west of Mentz.

EIGHT, or PIECE OF EIGHT. See the article COIN.

EIGHTH pair of the nerves. See the article NERVE.

EIMBECK, a town of lower Saxony, belonging to the electorate of Hanover, twenty-five miles south of Hildesheim.

EINECIA, the same with EYRE. See the article EYRE.

EIRE, or EYRE, among lawyers. See the article EYRE.

EISLEBEC, a town of Upper Saxony, five miles east of Mansfield, remarkable for being the birth-place of Luther.

COPY of it on the tenant in possession, and gives notice, at the bottom, for him to appear and defend his title; or that he the feigned defendant will suffer judgment by default, whereby the true tenant will be turned out of possession; to this declaration the tenant is to appear, the beginning of next term, by his attorney, and content to a rule to be made defendant, instead of the casual ejector, and take upon him the defence, in which he must confes leafe, judgment, entry, and outher, and at the trial stand upon the title only; but in case the tenant in possession does not appear, and enter into the said rule in time, after the declaration served, then, on affidavit being made of the service of the declaration, with the notice to appear as aforesaid, the court will order judgment to be entered against the casual ejector by default, and thereupon the tenant in possession, by writ habeas facias possessor, is turned out of his possession. On the trial in ejectment, the plaintiff's title is to be set forth from the peron left seized in fee of the lands in question, under whom the leffor claims down to the plaintiff, proving the deeds, &c. and the plaintiff shall recover only according to the right which he has at the time of bringing his action. And here, another who hath title to the land, upon a motion made for that purpose, may be defendant in the action with the tenant in possession, to defend his title; for the possession of the lands is primarily in question, and to be recovered, which concerns the tenant, and the title thereto is tried collaterally, which may concern some other.
EISNACH, or EYSNACH. See the article EYSNACH.

LABORATORY, the fame with laboratory. See the article LABORATORY.

ELAGNUS, DUTCH MYRTLE, in botany, a genus of trees, belonging to the tetrandria-monogynia clas of Linnaeus, the characters of which are, that it has no flower-petals; the fruit is an oval, obtuse, and smooth drupe, including an oblong kernel or nut.

As to the medicinal virtues of its leaves, which are the only parts in use, they are reputed drying, difficult, and good against worms.

ELAGNON of ELEOSSACCHARUM, with the same name sometimes used for the parsnip. See PARSNIP.

ELAPHOBOSCUM, a name sometimes used in zoology, the fame with the glama, or peruvian camel. See the articles CAMEL and GLAMA.

ELAPS, or ELAPHIS, in zoology, a species of serpent, with longitudinal black lines running along the back from the head to the tail. See SERPENT.

ELASMIS, in natural-history, a genus of tales, composed of small plates in form of splangles, and either single, and not farther sifiile, or, if complex, only sifiile to a certain degree, and that in somewhat thick laminate. See the article TALE.

Of these tales there are several varieties, some with large and others with small splangles, which differ also in colour, and other peculiarities.

ELASTIC, in natural philosophy, an appellation given to all bodies endowed with the property of elasticiety. See the next article.

ELASTICITY, or ELASTIC FORCE, that property of bodies wherewith they restore themselves to their former figure, after any external pressure; being the same with what is otherwise called springiness, very observable in a bent bow, steel springs, and the like.

A perfectly elastic body, is that which restores itself with the same force where with it was bent, or deprefled; those which do not so restore themselves with exactly the same force, being called imperfectly elastic bodies.

Philosophers account for elasticiety from the principles of corporeal attraction and repulsion: thus, if a steel spring, wire, or piece of very thin glass, be bent out of its natural position, the particles on the convex part are forced from the intimate union they had before; and, on the concave part, they are forced nearer together, or harder upon each other, than in the natural state: in both which cases, there will be a considerable resistance to overcome, and consequently require a superior force. During this state of the particles, they may be laid to be under a fort of tension on one side, and comprefion on the other; and since by this force they are not drawn out of each others attraction, as soon as the force is remit ted or ceases to act, the attractive power reduces the particles, and unbends the wire. Now it is well known, that many
substances are composed of such fibrous parts or filaments which resemble fine wires, and are interwoven and disposed in such a manner, as in sponge, for instance, that they cannot be compressed without being bent or wrested from their natural position; whence all such bodies will, in such cases, exert a spring or force to restore themselves, in the same manner that the bent wire did.

All bodies that we know of, are in some degree or other elastic, but none of them perfectly so; such are most metals, semi-metals, stones, and animal and vegetable substancess, however they may differ in degree. Elasticity seems to vary, according to the different densities of bodies; for the more metals are hammered, the more elastic they become; and the elasticity of the hardest tempered steel to that of the softest, may be found to be as 7809 to 7738.

We may consider all elastic bodies to be made up of such strings or fibres as A B (plate LXXXV. fig. 2. n° 1.) or rather of elastic strata parallel to each other, represented by A B, in the ball D C. If this ball be struck at D by a hard or elastic body, all the strata will be bent in towards C, as expressed by the dotted lines, whilst the ball is flattened or dented at D. But the strata quickly restoring themselves, the surface of the ball resumes its first figure, and that more or less exactly, according as the elasticity is more or less perfect.

The great law of perfectly elastic bodies, is, that their relative velocity will remain the same before and after collision; that is, perfectly elastic bodies will recede from one another after the stroke, with the same velocity that they came together. Many curious phenomena may be explained from this property in bodies.

If the ivory ball A, (ibid. n° 2.) weighing two ounces, strike with the velocity 16 against B at rest, weighing also two ounces, the body B will move forward after the stroke with the velocity 16, A remaining at rest in its place. The reason of this is, that the body A looses one half of its motion by striking the equal body B, and the other half by the elasticity of B, recovering its former figure. From this experiment, several pretty odd phenomena arise: thus, if a row of shovell-board pieces (that is, metalline cylinders of about half an inch in height, and two inches diameter) be laid upon a smooth table, and you take a single piece, and drive it against the row, the last piece of the row will fly off; for if A (ibid. n° 3.) strike the row of pieces B, C, D, E, F, G, H, I, in the direction A a, then will the last piece I fly off to i with the same velocity that A struck B; and whatever be the velocity of A, no other piece but the last piece I will fly off. But if you take two pieces, as A and B, (ibid. n° 4.) and strike them together against the row C, D, E, F, G, H, I, the two last pieces, H and I, will fly off from the other end of the row with the same velocity that A and B made the stroke.

If three or more pieces are made use of to make the stroke, the very same number will fly off from the other end of the row; and, it is to be observed, that the same will happen with equal elastic balls, fulfilled in a row by strings of the same length.

Again, if the elastic body A, (ibid. n° 5.) weighing four ounces, strike the quiescent body B, weighing only two ounces, with a velocity equal to 12; then will the velocity of A, after the stroke, be 4, and that of B 16. Just the reverse of this happens, when a less body strikes against the greater; in which case, the striking or lesser body will be reflected with one fourth of its first motion, and the greater be carried forward with a motion which is as 16.

The magnitude and motions of spherical bodies perfectly elastic, and moving in the same right line, and meeting each other, being given, their motion after reflection may be determined thus: let the bodies be called A and B, and the respective velocities a and b; then, if the bodies tend the same way, and A, moving swifter than B, follows it, the velocity of the body A, after the reflection, will be:

$\frac{aA - bA + bB}{A + B}$

and that of the body

$\frac{aA - aB + 2bB}{A + B}$

But if the bodies meet, then, changing the sign of b, the velocity of A will be:

$\frac{aA - aB - 2bB}{A + B}$

and that of B:

$\frac{2aA + bA - bB}{A + B}$

and if either of these happen to come out negative, the motion after the stroke tends the contrary way to that of A before it; which is also to be understood of the motion of the body A, in the first case.

ELATE,
ELATE, in botany, the same with the phoenix of Linnaeus. See Phoenix.

ELATER, in zoology, a genus of four winged flies, of the order of the coleoptera; the body of which is oblong, and the antennae setaceous: add to this, that the creature, when laid on its back, leaps with great agility. There are a great many species of elater, distinguished by their different colours, as red, brown, green, blue, and black; which, in some species, are variously blended together.

ELATERIUM, in botany, a name by which Boerhaave calls the momordica of other botanists. See Momordica.

ELATERIUM, in pharmacy, imports, in general, any purging medicine; but is particularly applied to those which operate with violence. Hence the word was transferred to the wild cucumber, and the preparations thereof. See the article Cucumber.

In the writings of Hippocrates, elaterium is frequently mentioned as an external application, of a digestive and purgative nature.

ELATINE, FLUELLIN, in botany, a genus of the cistandra-tetragynia class of plants, the corolla of which consists of four ovated, obtuse, sessile, patent petals: the fruit is an orbiculate large capsule, compressed globose, containing four cells, and consisting of four valves: the seeds are numerous, luminary, erect, and surrounding the receptacle in the manner of a wheel. This plant is an aperient, relievollent, and vulnerary.

ELATINE is also used by Dillenius for antirrhinum, or snapdragon. See the article Snapdragon.

ELAWANDUM, in zoology, a species of monkey with whitish-grey hair, and a long black beard.

ELBE, a large river in Germany, which, rising on the confines of Silezia, runs through Bohemia, Saxony, and Brandenburg; and afterwards dividing the dutchy of Lunenburg from that of Mecklenburg, as also the dutchy of Bremen from Holstein, it falls into the German ocean, about seventy miles below Hamburg.

It is navigable for great ships higher than any river in Europe.

ELBOW, in anatomy, the juncture of the cubitus and radius; or the outer angle made by the flexure or bend of the arm. See Cubitus and Radius.

ELBOW, in architecture, a term used for an obtuse angle of a wall, building, road, &c. which divides it from its right line.

ELCESAITES, in church-history, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elcefait. The elecsaites kept a mean between the jews, christians, and pagans; they worshipped but one God, observed the jewish sabbath, circumcision, and the other ceremonies of the law. They rejected the pentateuch, and the prophets; nor had they more respect for the writings of the apostles, particularly those of St. Paul. They detached chastity and continence, and obliged their disciples to marry. They acknowledged a messiah, whom they called their great king; but we do not know whether they meant Jesus Christ, or some pretended messiah. They gave him a human form, but invisible, the dimensions of which were thirty-eight leagues in height, and so in proportion. They pretended that the Holy Ghost was a woman, and of the same size with the messiah. They were much addicted to judicial astrology, magic, and enchantments. They held that it is lawful to renounce the faith with the lips, provided a man kept it in his heart.

ELDER, or SENIORS, in Jewish history, were persons the most considerable for age, experience, and wisdom. Of this fort were the seventy men whom Moses associated to himself in the government of his people; such, likewise, afterwards were those who held the first rank in the synagogue, as presidents.

In the first assemblies of the primitive christians, those who held the first place, were called elders. The word presbyter, often used in the New Testament, is of the same signification: hence the first councils of christians were called presbyteria, or councils of elders.

ELDER is also a denomination still preferred in the presbyterian discipline. See the article Presbyterian.

They are officers who, with the ministers and deacons, compose the jeffions of the kirk. The elder's business is to assist the minister in visiting the congregation upon occasion, to watch over the morals of the people of his distrikt, and to give them private reproofs in cafe of any disorder; but if the scandal be gross, or the person obstinate, he lays the thing before the jeffion. The elders are chosen from among the most substantial, knowing, and regular people, by the jeffion or confistory.
The virtues of elecampane are much cried up, as a stomachic, alexipharmic, and sudorific; and therefore prescribed in crudities of the stomach, the cough, asthma, epilepsy. Externally, it has been recommended against the itch, convulsions, and melancholy. Among the star-worts. See the article Aster.

ELECT, elegi, among ecclesiastical writers, theof whom God has chosen, or predestinated to be saved. See the article Predestination.

ELECT, in matters of polity, is applied to archbishops, and other ecclesiastic officers, who are chosen, but not yet consecrated; as also to secular officers before they are invested with their office or jurisdiction: thus the emperor is said to be elected, before he is inaugurated; and the lord mayor, before his predecessor's mayoralty is expired.

ELECTARY, the same with electuary. See the article Electuary.

ELECTION, the choice that is made of a person, or thing, in preference of any other; as in the election of an emperor, of a pope, of a bishop, of members of parliament, &c. See Emperor, Conclave, Bishop, and Parliament.

Election is also the state of a person who is left to his own free will, to take or do one thing or another, which he pleases. If a person makes a lease of land rendering to much money in rent, or a quarter of corn, &c. the lessor shall have his election which he will render, as being the first agent, by payment of the one, or delivery of the other. Where nothing passes to a grantee before election, to have one thing or the other, and no time is appointed, the election ought to be made during the life of the parties, and not afterwards: but where an estate conveys immediately to the grantee, or donee, &c.

in that case, election may be made by them, or their heirs and executors. And when a donee, or grantee, has his election in what manner he will take the thing granted, there the title or interest passes immediately, and the party and his heirs, &c. are at liberty to make the election when they will.

Election of a clerk of statutes-merchant, is the writ that lies for the choice of a clerk, to take bonds, called statutes-merchant; and issue out of the court of chancery, upon suggestion, that the clerk formerly assigned is gone to dwell in another place, or is under some impediment to attend the duty of his office.

Election of ecclesiastical persons. There is to be a free election for the dignities of the church, in which no person shall give any disturbance, on pain of forfeiture. Where any person that has a vote in such elections take any reward for an election in any church, college, school, &c. the election shall be void.

Election of a warden of the forest, a writ which lies for the choice of a warden, on the death or removal of any such officer of the forest. It is directed to the sheriff, and the warden is to be elected by the freeholders of the county.

Election, in theology, signifies the choice which God, of his good pleasure, makes of angels and men for the objects of his grace and mercy. See Grace, Reprobation, and Predestination.

Election is also used, by some medical writers, as a part of pharmacy, which consists in a knowledge of the various simples which compose the materia medica, and directs the choice of drugs.

Election, in numbers, is, with regard to combinations, the different ways of taking any number of quantities given: thus, the quantities a b c may be taken different ways, as a b c, or a b c, a b, c, a c, b c.

Elective, something that is determined by election. See the preceding article.

The empire of Germany is elective, as is the kingdom of Poland; and among us, the magistrates of cities, and other corporate towns, members of parliament, &c. are elective.

Elector, a person who has a right to elect or choose another to an office, honour, &c.

Elector is particularly, and by way of eminence, applied to those princes of Germany in whom lies the right of electing the emperor: being all sovereign princes, and the principal members of the empire.
The electoral college, consisting of all the electors of the empire, is the most illustrious and augufit body in Europe. Bellarmine and Baronius attribute the institution of it to pope Gregory V. and the emperor Otho III. in the tenth century; of which opinion are the generalities of historians, and particularly the canonists: however, the number of electors was unsettled, at least, till the thirteenth century. In 1356 Charles IV. by the golden bull, fixed the number of electors to seven; three ecclesiastics, viz. the archbishops of Mentz, Treves, and Cologne; and four seculars, viz. the king of Bohemia, count Palatine of the Rhine, duke of Saxony, and marquis of Brandenburg. In 1648 this order was changed, the duke of Bavaria being put in the place of the count Palatine, who having accepted the crown of Bohemia, was outlawed by the emperor; but being, at length, restored, an eighth electorate was erected for the duke of Bavaria. In 1692, a ninth electorate was created, by the emperor Leopold, in favour of the duke of Hanover, of the house of Brunwic Lunenburg.

There is this difference between the secular and ecclesiastic electors, that the first have an active and passive voice, that is, may choose and be chosen; the last, an active only. The three archbishops are to be thirty years old, before they can be advanced to the dignity; the seculars, eighteen, before they can perform the office themselves. These last have each their vicars, who officiate in their absence.

Besides the power of choosing an emperor, the electors have also that of capitulating with, and depofiting him; so that, if there be one suffrage wanting, a protest may be entered against the proceedings. By the right of capitulation, they attribute to themselves great privileges, as making of war, coining, and taking care of the public interest and security of the states; and the emperor promises, upon oath, to receive the empire upon their conditions.

The electors have precedence of all other princes of the empire, even of cardinals and kings; and are addressed under the title of electoral highness.

Their several functions are as follow: the elector of Mentz is chancellor of Germany, convokes the states, and gives his vote before any of the rest. The elector of Cologne is grand chancellor of Italy, and confecrates the emperor. The elector of Treves is chancellor of the Gauls, and confers imposition of hands upon the emperor. The count Palatine of the Rhine is great treasurer of the empire, and presents the emperor with a globe at his coronation. The elector of Bavaria is great master of the imperial palace, and carries the golden apple. The marquis of Brandenburg is grand chamberlain, and puts the ring on the emperor's finger. The elector of Saxony is grand marshal, and gives the sword to the emperor. The king of Bohemia is grand butler, and puts Charlemaign's crown on the emperor's head. Lastly, the elector of Hanover, now king of Great Britain, is arch treasurer, though first created under the title of standard-bearer of the empire.

ELECTORAL, in general, something belonging to electors. See ELECTOR.

ELECTORAL CROWN, or CORONET. See the article CROWN.

ELECTORATE, a term used as well to signify the dignity of, as the territories belonging to, any of the electors of Germany: such are Bavaria, Saxony, &c. Contrary to the common usage of Germany, the electorale, or territories belonging to electors, is hereditary; passing entire to the eldest son.

ELECTRICITY, in physiology, that property of certain bodies, whereby, after being rubbed, excited, or heated in some particular degree, they acquire a power of attracting and repelling other remote bodies; and frequently of emitting sparks and streams of light.

The ancients, having observed that amber, which they called electrum, upon being rubbed, attracts bits of straw, down, and other light bodies, first gave this property the name of electricity, which they thought peculiar to amber and a few stones mentioned by Theophrastus, Pliny, and some others. But the philosophers of the last, and more particularly of the present age, have found that numbers of other bodies possess this quality; and made so many discoveries in electricity, that there is scarce any other subject in natural philosophy that has given occasion to more experiments.

This quality is of two sorts, viz. vitreous electricity, or that which belongs to glaés; and resinous electricity, or that which belongs to amber, rosin, wax, gum, and fuch like subftances.

The bodies susceptible of electricity, are also divided into two classes: the one are electrical of themselves, or electrica per se; that
that is, they contain that quality in themselves, and need only be rubbed, &c. to excite it: the others do not contain that virtue in themselves, or they have no little of it, as to be reckoned to have none at all; yet they acquire it by communication, or by emanation derived to them by a body that is electrical per se: these bodies are simply called non-electrics, or non-electrica per se.

The electrics per se, or, as they are otherwise called, the originally electrics, are, according to Mufchenbroeck, all sorts of gems, several stones, all chrysalids and refrinuous substances, sulphur, red arsenic, salts, alum; all sorts of glasses, porcelain, dried vegetables; all woods, ropes, threads of lint, paper, the leaves of trees, the harder reeds, pitch, cotton; parts of animals, as their feathers, hair, horns, bones, ivory, whale-bone, the hide, parchment, the shells of fishes, filk, strings made of dried guts, gum, sealing-wax, feathered or hairy living animals, as cats, dogs, cocks, &c.

The non-electrics are several naked animals, or such as are covered with neither hair nor feathers; metals, semi-metals, earths and dust, which, by reason of its minuteness, won’t bear to be rubbed separately; all watry gums, opium, galbanum, ammoniac, affafrida, camphor; all sorts of bodies that liquify with a small heat, all moist bodies, all fluids which will not bear rubbing, &c.

Electricity, according to the same author, consists in subtile exhalations, which, in exciting the electrical body, are put into motion; and which, by flying to and from it, agitate all those light bodies that fall within the sphere of their attraction.

That these exhalations, or subtile effluvia, constitute electricity, appears from hence.

1. From the touch, as these bodies are perceived to be surrounded with a moft subtile atmosphere, or covered with a gentle blast of wind, that continues to breathe every where around them.

2. From that offensive smell, which resembles phalporus, the phlegm of aqua regia, or the spirit of vitriol.

3. Being taken into the mouth, they yield an acid and astringent taste.

4. They seem to adhere to the extremities of the bodies which they surround, and from which they recede, in the form of sparks, and of a subtile lucid flame.

5. This flame is sometimes attended with an explosion, that may be heard at the distance of two hundred paces: besides, the greater flames occasion a continued hissing, or crackling noise in the air. Since, therefore, the electrical effluvia affect all the human senses, we can no longer doubt of their being a corporeal fluid.

Mr. Watson thinks, that electricity is not furnished from the electric bodies employed in the experiments, nor from the circumambient air; but that it is the effect of a very subtile and elastic fluid occupying all bodies, in contact with the terrestrial globe; that every where, in its natural state, it is of the same degree of density; that glass and other bodies, which are electrics per se, have the power of taking this fluid from one body and conveying it to another, in a quantity sufficient to be obvious to all our senses; that, under certain circumstances, it is possible to render the electricity in some bodies more rare than it naturally is, that, by communicating this to other bodies, to give them an additional quantity, and make their electricity more dense; and that these bodies will thus continue, until their natural quantity is restored to each; that is, by those which have lost part of theirs, acquiring what they have lost, and by those to whom more has been communicated, parting with their additional quantity. Both one and the other of these is, from the elasticity of the electric matter, attempted to be done from the nearest non-electric; and when the air is moist, this is soon accomplished by the circumambient vapours, which here may be considered as preventing, in a very great degree, our attempts to insulate non-electric bodies.

In order to illustrate the phenomena of electricity, we shall give some select experiments.

1. Get a glass tube A B, of about three feet and a half in length, an inch and a half in diameter, and its sides a line thick: rub it with a piece of fluff, paper, or, which is still better, with the hand, provided it be very dry: you will succeed better if your hands be rubbed with chalk, or white lead. Afterwards bring this rubbed tube near any light bodies, as gold-leaf laid upon a glass stand C D; then will the gold-leaf be attracted and repelled in the manner represented in plate LXXXVI. fig. 1.

If you do this in such a manner, that the gold-leaf, for example, be perpendicularly repelled above the tube, and that

6 R
When the rod, by this means, is strongly electrified, a stream of light, in diverging rays, will be seen to issue from that point of it which is most distant from the sphere; and if any non-electric body, as a finger, be placed within a quarter of an inch of the said flame, it will perceive a gentle blast of wind from the end of the iron; that is, the electrical fire will issue out from the point in such a manner, as to blow against the finger very sensibly; and if the finger be still held nearer, the large pencil of rays will be condensed in such a manner, as to run out from the point upon the finger, in a stream or body of denie, yellow fire, and strike the finger like a gentle jet d'eau. The rod suspended before the glais-sphere, is properly termed the prime conductor in this machine.

4. While the flame continues to appear from the end of the iron-rod, the finger being placed any where upon it, the flame at the end disappears immediately; and when the finger is taken off, it again instantaneously appears; and by putting the finger off and on successively, the electric flame will appear and disappear alternately. These eruptions of the electrical fire will snap very sensibly, both to the eye and the ear, upon any part of the rod that the finger is pointed to. See plate LXXXVI. n° 3.

5. If a chain, or hempen cord, be suspended by silken strings all round the room, of any length you please, and one end thereof be hung, by a loop, across the rod, the electrical fire will instantly be transmitted through the whole length of the chain, and appear upon every part at the approach of the finger, and be heard to snap and strike with as great force as from the rod itself.

6. Take two plates of metal, very clean and dry, whose surfaces are nearly equal; hang one of them horizontally to the electrified rod, and bring under it, upon the other, any thin light body, as silver leaf, &c. When the upper plate is made electrical, the silver will be attracted by it; and if the under plate is held at a proper distance, will be perfectly suspended at right angles to the plates, without touching either of them; but if they are either brought nearer together, or carried farther asunder, the leaf will cease to be suspended, and will jump up and down between them.

The same effect will be produced, if the experiment is reversed by electrifying the bottom...
bottom plate, and suspending the other over it.

7. The following improvement, upon the electrical machine of the abbe Nollet, already exhibited, was made by Mr. Watson in 1746. In the periphery of his machine, see plate LXXXVI. no. 4, were cut four grooves, corresponding with four globes, which were disposed vertically: one, two, or the whole number of these globes might be used at pleasure. They were mounted upon spindles, and the leather-cushion with which they were rubbed, was stuffed with an elastic substance, as curled hair, and rubbed over with whiting. One of the globes was lined to a considerable thickness with a mixture of wax and rosin, but no difference appeared in the power of this globe from the others.

For performing most of the following experiments, some have imagined a gun-barrel absolutely necessary, as the prime conductor; but Mr. Watton says, that a solid piece of metal, of any form, is equally useful; having observed the stroke from a sword, as violent as that from a gun-barrel.

If, to the suspended barrel, a sponge, thoroughly dry, be hung, it gives no appearance of fire, which shews it to be an electric substance; but if when the sponge has been immersed in water, it be suspended to the barrel, and the finger applied near it, the fire issues out with considerable force and snappings; and the drops, which, before the sponge was applied, fell very slowly, will now fall as fast: if the room be darkened, these drops will appear to be drops of fire, and illuminate the bason into which they fall.

8. If a phial of water is suspended to the prime conductor by a wire, let down a few inches into the water through the cork; and some metallic fringes, inserted into the barrel, touch the globe in motion, the electrical power may be so accumulated in the phial, that a man grasping it with one hand, and touching the gun-barrel with a finger of the other, will receive a violent shock through both his arms, especially at his elbows and wrists, and across his breast. The commotion arising from the discharge of accumulated electricity in a phial, may be felt by a great number of men at once. M. le Monnier, at Paris, is said to have communicated this shock through a line of men, and other non-electrics, measuring nine hundred toises, being more than an English mile; and the abbe Nollet made the experiment upon two hundred persons ranged in two parallel lines.

9. If the electrical machine, and the man who turns the wheel thereof, be mounted on electrical cakes, the electrical power is so far from being increased, that, on the contrary, it is so much diminished, as to be oftentimes not at all perceptible.

10. A person standing on a cake of rosin, holding a chain fastened to the prime conductor, will be electrized; that is, he will be all over possessed with electric virtue; and, at the same time, feel nothing of it, unless some person standing by put his finger near to any part, and then the virtue will be emitted in form of fire, and snap and become very sensible to both the parties. See plate LXXXVII. fig. 1.

11. A person standing on rosin, holding the chain of the conductor, points his finger to the warm spirits of wine; and by communicating the electric fire thereto, kindles the rising vapour, and sets the whole on fire. In this manner any sort of matter, which, when warmed, will send forth an inflammable vapour, will be set on fire. See plate LXXXVII. fig. 2.

The electrical commotion, mentioned in experiment 8, arising from an accumulation of the electrical fire, has been made very sensible quite across the river Thames, by the communication of no other medium than the water of that river, and spirit of wine fired at that distance.

By comparing the respective velocities of electricity and sound, that of electricity, in any distance yet experienced, appears instantaneous.

12. If the globe be exhausted of all its air, and then whirled about, the electricity will be observed to act wholly within the globe, where it will appear, in a darkened room, in form of a cloud or flame of reddish or purple-coloured light, filling the whole capacity of the globe.

13. If a lodestone, armed with iron, be hung on to the gun-barrel by an iron-wire, the electric virtue will rush out from every part, but more forcibly from the iron than from the stone itself: for from the stone, it seems to be emitted in a more lax manner, and diffused in a sort of steam, or fiery vapour; whereas from the iron, it issues in a more impetuous, dense, and penetrating steam; by which we learn, that the two most considerable powers of nature, electricity and magnetism,
netisin, do not always interfere, or impede each other's actions.

14. The method of firing gunpowder by the electric flame, has something particular in it; as it does not require any inflammable vapour to be previously raised. The powder may be fired thus: a small cartridge is filled with dry powder, hard rammed, so as to bruise some of the grains: two pointed wires are then thrust in, one at each end, the points approaching to each other in the middle of the cartridge, till within the distance of half an inch: then the cartridge being placed in the circle, when four electrified glass-jars are discharged, the electric flame leaping from the point of one wire to the point of the other within the cartridge, among the powder, fires it, and the explosion of the powder is at the same instant with the crack of the electrical discharge.

15. As to metals, Mr. Franklin tells us, that he has been able, by electricity, to give polarity to needles, and to reverze it. A flock from four large glass-jars sent through a fine Sewing needle, gives it polarity.

16. In consequence of Mr. Franklin's hypothesis, of being able, by a proper apparatus, to collect the electricity from the atmosphere during a thunder-storm, it has been found, that a pointed bar of iron, forty feet high, being placed upon an electric body; and a stormy cloud having passed over the place where the bar stood, those, appointed to observe it, attracted from it sparks of fire, perceiving the same kind of commotions as in the common electrical experiments. The like effect followed when a bar of iron ninety-nine feet high was placed upon a cake of rosin two feet square, and two inches thick: there were the first experiments made, but they have since been sufficiently varied and verified, so that it seems now certain, 1. That a bar of iron, pointed or not, is electrized during a storm. 2. That a vertical, or horizontal situation, is equally fitting for these experiments. 3. That even wood is electrized. 4. That, by these means, a man may be sufficiently electrized to set fire to spirit of wine with his finger, and repeat almost all the usual experiments of electricity.

17. Mr. Franklin has contrived a very ingenious and easy method of trying experiments of this kind, by means of an electrical kite, made of a large thin silk handkerchief, extended and fastened, at the four corners, to two flight strips of cedar, of sufficient length for this purpose. This kite being accommodated with a tail, loop, and string, will rise in the air like thole of paper. To the top of the upright stick of the cross, is to be fixed a very sharp-pointed wire, riling a foot or more above the wood. To the end of the twine, next the hand, is to be tied a silk ribbon; and, where the twine and silk join, a key may be fastened. The kite is to be raised when a thunder-gust appears to be coming on; and as soon as the thunder clouds come over the kite, the pointed wire will draw the electric fire from them, and the kite, with all the twine, will be electrified; and the loose filaments of the twine will stand out every way, and be attracted by an approaching finger. When the rain has wet the kite and twine, so that it cannot conduct the electric fire freely, it will stream out plentifully from the key on the approach of a man's knuckle. At this key a phial may be charged; and from the electric fire, thus obtained, spirits may be kindled, and all the other electrical experiments be performed, which are done by the help of a glass-sphere or tube; and the sameness of the electric matter with that of lightning, may thereby be completely demonstrated.

From this identity some have conceived hopes of depriving the clouds of all their thunder, and thereby rendering thunderstorms harmless.

18. Mr. Stephen Gray, just before he died, hit upon an experiment which seemed to indicate, that the attractive power, which regulates the motions of the heavenly bodies, is of the electric kind. The experiment was thus: he fixed a large, round, iron-ball upon the middle of a large cake of rosin and wax; and exciting the virtue strongly in the cake, a fine feather, suspended by a thread, and held near the iron-ball, was carried round it, by the effluvia, in a circular manner, and performed several revolutions: it moved the same way with the planets, from west to east, and its motion, like theirs, was not quite circular, but a little elliptical.

These being most of the capital experiments hitherto exhibited in electricity, we shall conclude this article by mentioning some of the medicinal virtues lately attributed to this subject of philosophy. It has been pretended, that odours will
will pervade electrified globes and tubes of glass; and that the medicinal effects of drugs might likewise be transmitted this way; as also, that, if persons were to hold in their hands, or place under their naked feet, odoriferous or purging substances, and were then to be electrified, they would be sensible of the effects of these substances: but this seems now to be an imposition on the credulity of the world, no such effects having ever been perceived. However, it does not follow that medicinal advantages are not to be gained from electricity itself; so subtle and so elastic a fluid admitted in a large quantity into our bodies, as, from undoubted experience, it greatly heats the flesh and quickens the pulse, may more especially, when affixed with the expectation of success in the patient, in particular cases, be attended with advantages. In effect, we meet with some cures performed in paralytic cases, by the force of electricity.

**ELECTRUM**, amber, in natural history. See the article AMBER.

**ELECTUARY**, in pharmacy, a form in which both officinal and extemporaneous medicines are frequently made. It may be considered as a number of boluses united together, but is made somewhat softer, by an addition of a due proportion of syrups or mixtures. When the consistence is very soft, it is called, sometimes, by the name of opiate. See the articles BOLUS and OPIATA.

The principal consideration in prescribing officinal electuaries is, that such things only be put together, as will not, by any opposite qualities, destroy one another, or lose their natural properties, by lying long in this manner; and likewise that the whole be of a consistence that will hold ingredients of different gravities in equal mixture. Extemporaneous electuaries differ principally from the officinal, in that the latter are confined to such things as will for a long time keep together; whereas the former may be ventured on with materials which will not remain long without change, provided they agree in intention; as conjoins with the effusious powders, preparations with steel, and the like, will continue together long enough for present use, but will not lie many days without fermenting and spoiling. The stronger catharticks ought not to be trusted in this form, because the manner of taking does not sufficiently atertain the dose. The most powerful alexipharmics also, which are commonly given in acute cases, are not conveniently thus trusted, so that an electuary is hardly ever met with in a fever. The quantity of an extemporaneous electuary should seldom exceed three ounces; and thereabout will an ounce and a half of conserve, two drams of the common powders, with a sufficient quantity of syrup, amount to; though cinnabar, and some of the heavier things, will not take up so much; and if this rule, as to quantity, be not observed by the prescriber, but more be ordered, it is a common thing for the compounder to do it for him, by proportioning the materials suitable there-to, as by making up half, or a third of what is directed.

**ELEUMOSYNÆ** and **ELEUMOSYNARIUS**. See ALMS and ALMNER.

**ELEGANCE, or Elegancy**, an ornament of polite fenes and agreeableness, shown in any discourse, with such a choice of rich and happy expressions, as to rise politely above the common manners, so as to strike people of a delicate taste, and diffuse a relish which hits every body.

It is observed that elegance, though irregular, is preferable to regularity without elegance: that is, by being so scrupulous of grammatical construction, we lose certain licences wherein the elegance of language consists.

**ELEGANCY, in painting**, a certain manner which embellishes and heightens objects, either as to their form, colour, or both, without destroying or perverting the truth. It is not seen in the correctness of the design, as appears from Raphael, and the antique. It is most sensibly perceived in works otherwise careless and inaccurate, as in Corregio, where, notwithstanding all the defects as to justness of design, there is an elegance even in the manner of the design itself, as well as in the turn of the attitudes, &c.

**ELEGICAC, in ancient poetry**, any thing belonging to elegy. See ELEGY.

Elegiac verses are alternately hexameter and pentameter, as in the following verses of Ovid. See the articles HEXAMETER and PENTAMETER.

_**Flehitis indignus, elegia, folus capillos:**_ 
_Ah nimi ex vero munc tibi nomen erit._

Sometimes, though very rarely, the pentameter preceded the hexameter, as in the following verses of Athenæus.

_Εὐοδίους Χαρίτον, καὶ Μελάντεος ἐποῦ_ 
_Θείας πυγμης ἐφεμερίς φιλοτιτίς._

Who
ELEGIT, in law, a writ of execution.

ELEGY, a mournful and plaintive kind of poem. See the article ELEGIAIC.

As elegy, at its first institution, was intended for tears, it expressed no other sentiments, it breathed no other accents but those of sorrow: with the negligence natural to affliction, it sought less to please than to move; and aimed at exciting pity, not admiration. By degrees, however, elegy degenerated from its original intention, and was employed upon all sorts of subjects, gay or sad, and especially upon love. Ovid's book Of Love, the poems of Tibullus and Propertius, notwithstanding they are termed elegies, are sometimes so far from being sad, that they are scarce serious. The chief subjects then to which elegy owes it rife, is death and love: that elegy therefore ought to be esteemed the most perfect in its kind which has somewhat of both at once; such, for instance, where the poet bewails the death of some youth or damsel falling a martyr to love.

ELEMENT, in physiology, a term used by philosophers to denote the original component parts of bodies, or those into which they are ultimately resolvable. The elements or principles to which all bodies may be ultimately reduced, are these five: 1. Water, or phlegm, which, in the chemical analysis of them, rifes first in form of vapour. 2. Air, which escapes unleas in great quantities from all bodies, so as to constitute half the substance of some of them. 3. Oil, which rifes after, and appears swimming on the surface of the water. 4. Salt, which is either volatile, or rifes in the still, as that of animal subfiances; or fixed, as that of vegetables, which is obtained by reducing them to ashes, making a lixivium or lye of these, and afterwards evaporating the moisture; by which means the salt shoots into crystals. 5. Earth, or what is called the caput mortuum, being what remains of the ashes after the salt is extracted. This is the last element of all bodies, which can be no farther altered by any art whatsoever. See the articles WATER, AIR, &c.

The elements of Aristotle were four, earth, water, air, and fire. The cartesians admit only three elements, the first a materia subtilis, or fine dust; the second, a coarser, but round kind; and the third, a still more irregular and hooked kind of particles. See the article CARTESIAN, &c.

For the doctrine of elements, as delivered by Sir Isaac Newton, see the article NEWTONIAN PHILOSOPHY.

ELEMENT, in a figurative sense, is used for the principles and foundations of any art or science, as Euclid's Elements, &c.

ELMII, or ELEMY, in the materia medica, a kind of resin, very improperly called gum-elemi. There are two sorts of it kept in the shops, the one genuine, and brought from Ethiopia; the other spurious, and the produce of America. The true kind is a yellowish resin, with a caft of green and white; its smell is acrid and pleasant, and its taste acrid and bitter. It is very inflammable, and readily dissolves in oil, and other fat subfiances, over the fire; which two characters alone sufficiently distinguish it from the gums: but this genuine elemi is very rare in Europe.

The spurious elemi is a whitish resin, produced from a tall tree, with pinnated leaves, not unlike those of the pear-tree.
Fig. 1. The Elephant.

Fig. 2. The Elk.

Fig. 3. Epicycloid.

Fig. 4. Ermin.

Fig. 5. Ermine.
It is in some degree pellucid, and of a fragrant smell. It is only used externally, being greatly recommended for resolving tumours, deterging ulcers, wounds,

ELENCHUS, in logic, a sophism, or fallacious argument, which deceives the hearer under the appearance of truth. See the article SOPHISM.

ELEPHANTIASIS, or ELEOSACCHARUM. See ELEOSACCHARUM.

ELEPHANT, elephas, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which, according to Linnaeus, are these: it has no fore-teeth; the upper canine, or dog-teeth, are considerably long; it has a very long flexible proboscis or trunk, and two paps placed on the breast. See plate LXXXVIII. fig. 1.

The teeth of this animal is what we call ivory. See the article IVORY.

The elephant, of which there is only one known species, is, when full grown, from seventeen to twenty feet high; and its body is withal so enormously bulky, that the belly reaches nearer the ground than could easily be conceived of a creature of its height. The trunk is, properly speaking, nothing but the nose continued to a great length; its substance is fleshly, but firm, being composed of three series or orders of fibres: this trunk the creature can contract or protrude forward with great violence, from the length of one foot to five or more.

ELEPHANT'S TRUNK, an east-indian species of acus, or needle-fish. See ACUS.

Knights of the ELEPHANT, an order of knighthood in Denmark, conferred upon none but persons of the first quality and merit. It is also called the order of St. Mary. Its institution is said to have been owing to a gentleman among the danish croissées having killed an elephant, in an expedition against the Saracens, in 1184. in memory of which king Canutus instituted this order, the badge of which is a towered elephant, with an image of the holy virgin encircled with rays, and hung on a watered sky-coloured ribbon, like the George in England.

ELEPHANTIASIS, elephas, called also the lepra of the Arabians, in medicine, a chronic disease, one of the two species of leprosy, which affects the whole body, where even the bones as well as the skin are covered with spots and tumours, which being red, at last turn black. See the article LEPROSY.

In this disease the body falls away, while the legs and feet are enormously swelled. When the disease is inveterate, the fingers and toes are hid in the tumour, and a flight fever arising, carries the patient off.

Lucretius supposed this disease to be generated in Egypt, and no where else; but if the leprosy of the Jews is the same with that of the negroes, which is highly probable, then it may be affirmed that it is endemical to the southern and inland parts of Africa.

ELEPHANTINE, in roman antiquity, an appellation given to the books wherein were registered the transactions of the senate and magistrates of Rome, of the emperors or generals of armies, and even of the provincial magistrates; the births and clajses of the people, and other things relating to the census.

They are supposed to have been so called as being made of ivory; though some will have them to have been written on the intestines of elephants.

ELEPHANTOPUS, Bastard-Scabius, in botany, a genus of the fungus-polygama-equalis class of plants, the compound flower of which is tubulose, consisting of four or five hermaphrodite and ligulated corollae, with a narrow limb, divided into five nearly equal segments: the flaminae are five very short filaments: the seeds are solitary, and contained in the cup, being of a compressed figure, and crowned with bristly hairs.

ELEPHAS, the ELEPHANT, in zoology. See the article ELEPHANT.

ELEVATION, elevatio, the same with altitude or height. See ALTITUDE.

Angle of ELEVATION, in gunnery, that comprehended between the horizon and the line of direction of a cannon or mortar; or it is that which the chafe of a piece, or the axis of its hollow cylinder, makes with the plane of the horizon.

ELEVATION, in architecture, the same with an orthographic, or upright draught of a building. See ORTHOGRAPHY.

ELEVATION of the hoft, in the church of Rome, that part of the mafs where the priest raises the hoft above his head for the people to adore. See the articles MASS and HOST.

ELEVATOR, in anatomy, the name of several muscles, so called from their serving to raise the parts of the body to which they belong: such are the elevator also raise, the elevator of the auricle
or external ear, the elevator of the epiglottis, of the eye-lids, humerus, lips, urethra, and those of the anus, called allo levatores. See MuscLe.

The elevator of the eye-lids is also called superbus, as being used when people put on a haughty or high look.

ELEVATORY, elevatorium, in surgery, an instrument for raising depressed or fractured parts of the skull, to be applied after the integuments and periosteum are removed. If there is any hole, the instrument must be fastened to it; but if there is none, the screw-end of the instrument must be applied. See plate LXXXV. fig. 3, n° 1.

But as these elevators are so contrived, that, where the neighbouring bones are fractured or depressed, they cannot be applied without greatly increasing the pain, surgeons have invented another kind which might be applied with more safety, called tripes, from the number of its feet. It is near twice as big as the figure we have given of it; (ibid. n° 2.) and the feet A A A stand nearer or farther from each other, as there is occasion. The manner of applying it is this: the feet are to be applied to the sound parts of the head, and the screw B C, by frequently turning its handle D D, will presently lay hold of the depressed part of the cranium, especially if a small hole has been made in it with the point of a sharp awl. Then upon turning the screw, E E, the trepan is raised by degrees, and with it the depressed part of the cranium. But if any opening shall appear between the fractured parts, it will be proper to take off the pointed end of the instrument B, and in its room fix the elevator G, by the screw H, about the part F of the figure n° 2, by the assistance of which it will be easy to raise the depressed part. See the manner of applying this instrument represented ibid. n° 3.

ELEVE, a French term, sometimes met with in our language, signifying a disciple. Formerly there were twenty eleves in the academy of sciences at Paris, and ten in that of inscriptions; but the term has since been changed for adjunct. See the articles Academy and Adjunct.

ELEUSINIA, in grecian antiquity, a festival kept in honour of Ceres, every fourth, by some states, but by others, every fifth year. The Athenians celebrated it at Eleusis, a town of Attica, whence the name.

It was celebrated with a world of ceremony, and perfons of both sexes were initiated in it; it being deemed impious to neglect doing so. The mysteries were of two sorts, the lesser, and the greater; whereof the former were sacred to Proserpine, Ceres’s daughter, and the latter to Ceres herself. According to Laëntius, they consisted in a mystical representation of what mythologists teach of Ceres; though some of the christian fathers will have the great mystery, or secret, which they were forbidden by law, upon pain of death, to divulge, to have been the representation or figures of both male and female privities, which were handed about and exposed to the company.

ELEUTHERIA, another festival celebrated at Platea, by delegates from almost all the cities of Greece, in honour of Jupiter Eleutherius, or the affteror of liberty.

It was instituted in memory of the victory obtained by the Grecians, in the territories of Platea, over Mardonius, the persian general, left by Xerxes with a mighty army to subdue Greece.

ELF, a term, now almost obsolete, formerly used to denote a fairy, or hobgoblin, an imaginary being, the creature of ignorance, superstition, and craft. See the article Fairy.

ELF-ARROWS, in natural history, a name given to the flints, antiently fashioned into arrow-heads, and still found fossil in Scotland, America, and several other parts of the world.

ELFIELD, or ELFFIELD. See Elffield.

ELGIN, the capital of the county of Murray, in Scotland, situated on the river Lofey, about six miles north of the Spey: west long. 5° 25', north lat. 57° 40'.

ELICHRYSUM, or HELICHRYSUM, in botany, a species of gnaphalium. See the article Gnaphalium.

ELICIT, in ethics, is applied to an act of the will immediately produced by; and of, the will, and received within the name: as to be willing, unwilling, loving, hating, &c. Acts of which nature are termed elicit, because that, being before in the power of the will, they are now brought forth into act. But they are so far intrinsic, that some authors consider them as the will itself, and deny that they ought to be distinguished from it any more than light is to be distinguished from the sun. Chawin.
ELIGENDO VIRIDARIO. See the article Viridario Eligendo.

ELIGIBILITY, in the roman canon law, a bull granted by the pope, to certain persons to qualify them to be chosen to an office, or dignity, whereof they were before incapable by want of age, birth, or the like.

ELIQUATION, in metallurgy, a separation of the different parts of mixed bodies, by the different degrees of fire required to melt them. When the nature of ores, or of metallic mixtures, is such, that while one part of them melts in the fire, the other, more refractory and difficult of fusion, remains still solid; the first, when the mass is placed in a mild fire, flows out of the interfices of the other, and is thus separated from it. The perfection of this operation requires a different fluidity of the parts that constitute the mass. Lead, for instance, melts into one mass with copper, by a strong fire, whereas these metals cannot dissolve each other in a moderate one, but if the mass composed of both these, thus blended together, is afterwards exposed to a mild fire on an inclined plane, the lead alone melts, the copper becoming only brittle and spungy, and remaining in its solid form, even when the lead has run out of it. This separation, however, is not so perfectly made, but that there ever remains some lead in the copper, and some small part of the copper is also carried away with the lead: wherefore it is necessary, for this experiment, that the metals are not mixed in too minute proportions; for if one thousandth part of lead were to be mixed with copper, or the same small proportion of copper with the lead, the separation by eliquation could not be effected.

It is generally necessary also, to make this operation succeed, to add ingredients that are capable either of destroying the force by which the different parts cohere together, or of procuring an easier flux of the metals: for the mixture of the other metals will not be separated like those of copper and lead, without the admixture of other substances. For instance, gold, silver, and copper melted together, and perfectly blended by that means with one another, remain in the same state in any degree of fire; to make the eliquation of the gold and silver, therefore, out of such a mixture, the fame additions must be used as in the operation of precipitation by fusion.

ELIRE, or CONCE D'ELIRE. See the article Conce.

ELISIUM, or ELYSIUM. See Elysium.

ELISION, in grammar, the cutting off, or suppressing a vowel at the end of a word, for the sake of found, or measure, the next word beginning with a vowel. Elixions are pretty frequently met with in English poetry, but more frequently in the Latin, French, &c. They chiefly consist in suppressions of the a, e, and i, though an elision suppresses any of the other vowels: In the following example from Virgil there are three elisions.

Phellida amo ante alias -----

ELIXATION, in pharmacy, the extracting the virtues of ingredients by boiling or stewing. See Decoction.

ELIXIR, in medicine, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir seems to be this, that a tincture is drawn from one ingredient, sometimes with an addition of another to open it, and to dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time. See the article Tincture.

There are a great number of elixirs described by chemical writers, and in the dijensatories, the most remarkable of which are prepared as follows.

ELIXIR of aloes. Take of the tincture of myrrh a quart; saffron, lococotrine aloes, of each three ounces. After digestion, strain off the spirit.

The paregoric ELIXIR. Take flowers of benjamin, and opium, strained, of each a dram; of camphor, two scruples; of the essential oil of anniseeds half a dram, or rectified spirit of wine a quart. After digestion, strain off the spirit.

Acid ELIXIR of vitriol. Take of the aromatic tincture a pint; of the strong spirit, or oil of vitriol the weight of four ounces; mix them gradually, and when the feaces are subdivided, filter thro' paper.

Dulced Elixir of vitriol. Take of aromatic tincture a pint; of dulced spirit of vitriol, eight ounces in weight; mix them. This preparation is intended, for stomachs which cannot bear the acidity of the preceding.

The compound ELIXIR of myrrh. Take of the extract of favine, one ounce; of the tincture of calfor, a pint; of the tincture of
of myrrh, half a pint. After digestion, strain off the liquor.

ELIXIS, in pharmacy, a name formerly used for a linctus. See LINCTUS.

ELK, altce, in zoology, an animal of the deer-kind, with the horns palmed, and without a stem. It is a native of the northern parts of Europe, and is a very large and strong animal; being equal in size to a horse, but much less beautiful. See plate LXXXVIII. fig. 2.

Elk’s hoofs stand recommended for the cure of the epilepsy, but at present are only used as an ingredient in some old compositions.

ELK-HOLM, a port-town of Gothland, in Sweden, twenty-four miles west of Carel-Croon.

ELL, ada, a measure of length, different in different countries; but those mostly used in England, are the English and Flemish ells; whereof the former is three feet nine inches, or one yard and a quarter; and the latter only twenty-seven inches, or three quarters of a yard.

In Scotland, the ell contains 37½ English inches. See MEASURE.

ELLERA, a town of Estremadura, in Spain, fifty miles south-east of Merida.

ELLIPSES, in geometry, a curve line returning into itself, and produced from the section of a cone by a plane cutting both its sides, but not parallel to the base. See CONIC SECTIONS.

The easiest way of describing this curve, in plano, when the transverse and conjugate axes A B, E D, (plate LXXXVII. fig. 3. n. 1.) are given, is thus: First take the points F, f, in the transverse axis A B; so that the distances C F, C f, from the center C, be each equal to \( \sqrt{AC - CD} \); or, that the lines F D, f D be each equal to A C. Then, having fixed two pins in the points F, f, which are called the foci of the ellipsis, take a thread equal in length to the transverse axis A B; and fastening its two ends, one to the pin F, and the other to f; with another pin M stretch the thread tight: then if this pin M be moved round till it returns to the place from whence it first let out, keeping the thread always extended so as to form the triangle F M f, it will describe an ellipsis, whose axes are, A B, E D.

The greater axis, A B, passing through the two foci F, f, is called the transverse axis; and the lesser one D E, is called the conjugate, or second axis: these two always bisect each other at right angles, and the center of the ellipsis is the point C, where they intersect. Any right line passing through the center, and terminated by the curve of the ellipsis on each side, is called a diameter; and two diameters, which mutually bisect all the parallels to each other, bounded by the ellipsis, are called conjugate diameters.

Any right line, not passing through the center, but terminated by the ellipsis, and bisected by a diameter, is called the ordinate, or ordinate-applicate, to that diameter. And a third proportional to two conjugate diameters, is called the latus rectum, or parameter of that diameter which is the first of the three proportions.

The reason of the name is this: let B A, E D, be any two conjugate diameters of an ellipsis (see plate LXXXVII. fig. 3. n. 2. where they are the two axes) at the end A, of the diameter A B, raise the perpendicular A F, equal to the latus rectum, or parameter, being a third proportional to A B, E D, and draw the right line B F: then if any point P be taken in B A, and an ordinate P M be drawn, cutting B F in N, the rectangle under the absciss P A, and the line P N will be equal to the square of the ordinate P M. Hence drawing NO parallel to A B, it appears that this rectangle, or the square of the ordinate, is less than that under the absciss A P, and the parameter A F, by the rectangle under A P and O F, or NO and O F; on account of which deficiency, Apollonius first gave this curve the name of an ellipsis, from ELIPsis, to be deficient.

In every ellipsis, as A E B D, (ibid. n. 2.) the squares of the semi-ordinates M P, M p, are as the rectangles under the segments of the transverse axis A P x P B, A P x p B, made by these ordinates respectively; which holds equally true of the circle, where the squares of the ordinates are equal to such rectangles, as being mean proportional between the segments of the diameter. In the same manner, the ordinates to any diameter whatever, are as the rectangles under the segments of that diameter.

As to the other principal properties of the ellipsis, they may be reduced to the following propositions. 1. If from any point M in an ellipsis, two right lines, MF, M f, (ibid. n. 1.) be drawn to the foci F, f, the sum of these two lines will be equal to the transverse axis A B. This is evident from the manner of describing an ellipsis.
ELLIPSIS. 2. The square of half the less or axis is equal to the rectangle under the segments of the greater axis, contained between the foci and its vertices; that is, $DC^2 = AF \times FB = A + FB$. 3. Every diameter is bisected in the center $C$. 4. The transverse axis is the greater, and the conjugate axis the least, of all diameters. 5. Two diameters, one of which is parallel to the conjugate diameter, touches the ellipsis in that vertex. 6. If four tangents be drawn through the vertices of two conjugate diameters, the parallelogram contained under them will be equal to the parallelogram contained under tangents drawn through the vertices of any other two conjugate diameters. 7. If a right line, touching an ellipsis, meet two conjugate diameters produced, the rectangle under the segments of the tangent, between the point of contact and these diameters, will be equal to the square of the semi-diameter, which is conjugate to that passing thro' the point of contact. 8. In every ellipsis, the sum of the squares of any two conjugate diameters, is equal to the sum of the squares of the two axes. 9. In every ellipsis, the angles $FGH$, $fGH$, $fGI$, etc. made by the tangent $HI$, and the lines $FG$, $fG$, drawn from the foci to the point of contact, are equal to each other. 10. The area of an ellipsis is to the area of a circumscribed circle, as the less axis is to the greater, and vice versa, with respect to an inscribed circle; so that it is a mean proportional between two circles, having the transverse and conjugate axes for their diameters. This holds equally true of all the other corresponding parts belonging to an ellipsis.

The curve of any ellipsis may be obtained by the following series. Suppose the semi-transverse axis $AB = r$, the semi-conjugate axis $CD = c$, and the semi-ordinate $= a$; then the length of the curve $MB = a + \frac{r^2}{6} + \frac{r^2c^2}{40} - \ldots + \frac{2cr^2a^2}{112c^4} + \frac{r^5a^5}{40ca^5} + \ldots$, &c. And, if the species of the ellipsis be determined, this series will be more simple: for if $c = 2r$, then $MB = a + \frac{a^3}{96} + \frac{2a^5}{2048r} + \ldots$ and $\frac{\sqrt{113a^7}}{\sqrt{458752a^6}} + \frac{\sqrt{3419a^9}}{\sqrt{7549747278}}$, &c. This series will serve for an hyperbola, by making the even parts of all the terms affirmative, and the third, fifth, seventh, &c. terms negative.

The periphery of an ellipsis, according to Mr. Simpson, is to that of a circle, whose diameter is equal to the transverse axis of the ellipsis, as $1 - \frac{d^2}{2.2} \ldots \frac{d^3}{2.2.4.4} \ldots \frac{d^5}{2.2.4.4.6.6} \ldots$, &c. is to 1, where $d$ is equal to the difference of the squares of the axes applied to the square of the transverse axis.

Those who desire to be more particularly informed concerning the properties of the ellipsis may consult Simon's Conic Sections, and Wolfius's Elements of Mathematics, tom. 1, also Maclaurin's Fluxions, Art. 699, sect. and the marquis de l'Hôpital's Seét. Conic. lib. 6.

Infinita ELLIPSIS. See ELLIPSOIDES.

Ultimacy of the ELLIPSIS. See the article QUADRATURE.

ELLIPSIS, in grammar, a figure of syntax, wherein one or more words are not expressed; and from this deficiency, it has got the name ellipsis.

To this figure, besides the ellipsis properly so called, belong apposition, synecdoche, alynthia, zeugma, syllepsis, and prolepsis. See the articles APPPOSITION, SYNECDOCHE, &c.

The ellipsis, properly so called, is when the deficient word or words must be supplied from elsewhere; as Hecatoris Andromache, where utor is understood; that is, Andromache Hector's wife.

ELLIPSIS, in rhetoric, a figure nearly allied to preterition, when the orator, through transport of passion, passes over many things; which, had he been cool, ought to have been mentioned.

In preterition, the omission is designed; which, in the ellipsis, is owing to the vehemence of the speaker's passion, and his tongue not being able to keep pace with the emotion of his mind.

ELLIPtical, or ELLIPtical, something belonging to an ellipsis. See ELLIPSIS.

Thus we meet with elliptical compass, elliptic conoid, elliptic space, elliptic flairs, &c. See the articles COMPASS, CONOID, &c.

The elliptic space is the area contained within the curve of the ellipsis, which is to that of a circle described on the transverse axis, as the conjugate diameter is to the transverse axis; or it is a mean proportional...
proportional between two circles, described on the conjugate and transverse axis.

**ELLIPOMACROSTYLA**, in natural history, a genus of imperfect crystals, with single pyramids; one end of their column being affixed to some solid body. They are dodecahedral, with thinner hexagonal columns, and hexagonal pyramids. See the article **CRYSTAL**.

Of these crystals authors enumerate a great many species; among which are the whitish pellucid sprig crystal, a bright brown kind, a dull brown kind, and a bright yellow kind, all which are farther distinguished according to the different lengths of their pyramids.

**ELLIPOPACHYSTYLA**, in natural history, a genus of imperfect crystals, composed of twelve planes, in a hexagonal column, terminated by an hexagonal pyramid at one end, and irregularly affixed to some other body at the other, with shorter columns. See the article **CRYSTAL**.

There are two species of these crystals, one short, bright and colourless, found in great plenty in New Spain, and other parts of America; the other a short, dull, and dusky brown one, found in Germany and sometimes in England.

**ELLIPTOIDES**, in geometry, a name used by some to denote infinite ellipses, defined by the equation \( a y^m + n = bx^m \).

Of these there are several sorts: thus, if \( ay^2 = bx^2 \) \((a-x)\) it is a cubical ellipsoid; and if \( ay^4 = bx^2 \) \((a-x)^2\), it denotes a biquadratic ellipsoid, which is an ellipse of the third order in respect of the apollonian ellipsis.

**ELM**, *ulmus*, in botany. See the article **ULMUS**.

The elm is very serviceable in places where it may lie continually dry, or wet in extremes. Accordingly, it is proper for water-works, mills, the ladies and foles of the wheel-pipes, pumps, aquisducts, pales, and ship-planks beneath the water-lines. It is also of use for wheelwrights, handles for single saws, axletrees, and the like. The clearness of the grain, makes it also fit for all kinds of carved works, and most ornaments relating to architecture. As to the medicinal uses of elm, the leaves are astringent, and the bark good for allaying the pains of the gout.

**ELNA**, a town of Catalonia in Spain, but subject to France, situated ten miles south of Perpignan.

**ELOCUTION**, in rhetoric, the adapting words and sentences to the things or sentiments to be expressed. It consists of elegance, composition, and dignity. The first, comprehending the purity and perspicuity of a language, is the foundation of elocution. The second ranges the words in proper order; and the last adds the ornaments of tropes and figures to give strength and dignity to the whole. See **STYLE**, **PERIOD**, **FIGURE**.

**ELODES**, in botany, a species of hypericum. See the article **HYPERICUM**.

**ELOGY**, *elodium*, a prairie or panegyric bellowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Elogiums should not have so much as one epithet properly so called, nor two words synonymous. They should strictly adhere to truth, for extravagant and improbable elogies rather leffen the character of the person or thing they would extol.

**ELOINED**, in law, signifies restrained or hindered from doing something: thus it is said, that if those within age be eloined, so that they cannot sue personally, their next friends shall sue for them.

**ELONGATION**, in astronomy, the direction or recedes of a planet from the sun, with respect to an eye placed on our earth. The term is chiefly used in speaking of Venus and Mercury, the arch of a great circle intercepted between either of these planets and the sun, being called the elongation of that planet from the sun:

But here it is to be observed, that it is only a circle which has the sun for its center; that the greatest elongation is in a line touching the planet's orbit. For in an elliptic orbit it may be, that the elongation from the sun may grow still greater, even after it has left the place where the line joining the earth and planet touches its orbit. For after that, the true distance of the planet from the sun may increase, whilst the distance of the sun and planet from the earth does not increase, but rather decrease. But because, the orbits of the planets are nearly circular, such small differences may be neglected in astronomy. The greatest elongation of Venus is found by observation to be about forty-eight degrees
It is one of the strongest fortresses in Portugal.

ELY, in botany, a genus of fungiæ, smooth both on the upper and under side. Micheli calls this genus fungoides and fungoidaefter.

ELYA, in antient chronology, the twelfth month of the jewifh civil year, and the sixth of the ecclesiastical: it consisted of only twenty-nine days, and answer'd pretty nearly to our August.

ELYTRATION, in metallurgy, the separating the lighter matters from the mixt ores of metals, by means of great quantities of fair water. Solid bodies not dissoluble in water, are by this operation separated from each other, by water very well fir'd, so that the lighter and more subtile parts are carried away by the water, while the heavier and more solid bodies remain at the bottom of the vessels. Some of the stones, earths, and other bodies naturally mixt with the ores of metals, are much lighter than the metallic parts of these ores, and are therefore very easily separated by elutriation, either by barely pounding and washing them, or by previous calcination, and then extinguishing them in water, and washing them.

The kinds of ores proper for elutriation are known, 1. By the heterogeneous matter, and the ores themselves being in such large masses, as to be very visible, and easily broken and separated by hammers, wedges, &c. 2. By the great specific gravity of the ore, which shews us that the metallic masses adhere to their matrix in firm, solid molecules, and are not scattered and dispersed sparingly through it. 3. From the lightness of the stony matrix. And, 4. From its brittleness, whether this property be naturally inherent in the stony matter, or procured by fire in calcination; for in each case it renders the comminution of the compound mass easy. In this case, however, it is necessary that the ore itself be of a nature sufficiently fixed, and that it do not fly off in the roasting, but only melt into solid spheroidal molecules. See Cramer's Art. Docim. pars i. § 381, 535.

ELY, a city and bishop's see of Cambridge-shire, situated about twelve miles north of Cambridge: east lon. 15° and north lat. 52° 24'. It is a county of itself, including the territory around, and has a judge who determines all causes civil and criminal within its limits.

ELYMUS,
ELYMUS, in botany, a genus of the triandria-digynia class of plants, the calyx of which is a common involucrem, consisting of four leaves, and containing several flowers in two spicule: the particular corolles are composed of two valves: the seed is oblong.

ELYSIUM, or ELYSIAN FIELDS, in heathen mythology, certain plains abounding with woods, fountains, verdure, and every delightful object; supposed to be the habitation of heroes and good men, after death.

According to some, the fable of elysium is of phoenician extraction, or rather founded upon the account of paradise delivered in the scriptures. As to the situation of these happy regions, authors are not agreed: Homer makes them the same with certain pleasant meadows near Memphis, on the banks of the acheronian lake, mentioned by Diodorus Siculus in his description of the funerals of the Egyptians.

Virgil seems to place them in Italy, only under-ground: and others in other places. But the generality of authors will have them to be situated in the fortunate isles. See Fortune Islands.

ELYTROIDES, or VAGINALIS, in anatomy, the second proper membrane that involves the testes. See Testicle.

EMANATION, the act of flowing or proceeding from some source or origin; or, the thing that proceeds from that action.

EMANATION, among schoolmen, is used for the production of a leffer thing, in order to the production of a greater, by virtue of some natural connection or dependence between them: for, as when several moveables are joined together, the same power that moves the first, moves all the rest; as in pulling up the trunk of a tree, you pull up the branches, roots, &c. or in drawing one link of a chain, you bring forwards all the rest: the same is to be understood in all conjunct natural effects, viz. that the same power whereby the first is produced, does also produce all the rest naturally connected to it, in that, by means of the connection the action of the agent is conveyed from the one to the other, so that the first determines the agent to the production of all the rest; and hence that is called an emanative cause, in contradistinction to an efficient cause, which produces an effect by its mere presence, without the intervention of any action.

EMANCIPATION, in the roman law, the setting free a son from the subjection of his father; so that whatever moveables he acquires, belong in propriety to him, and not to his father, as before emancipation.

Emancipation put the son in capacity of managing his own affairs, and of marrying without his father's consent, though a minor. Emancipation differs from manumission, as the latter was the act of a master in favour of a slave, whereas the former was that of a father in favour of his son.

There were two kinds of emancipation, the one tacit, which was by the son's being promoted to some dignity, by his coming of age, or by his marrying, in all which cases he became his own master of course.

The other, express; where the father declared before a judge, that he emancipated his son. In performing this, the father was first to sell his son imaginarily to another, whom they called pater fiduciarius, father in trust, of whom being bought back again by the natural father, he manumitted him before the judge, by a verbal declaration. See Manumission.

Emancipation still obtains in France with regard to minors or pupils, who are hereby set at liberty to manage their own effects, without the advice or direction of their parents or tutors.

EMARGINATED, among botanists, an appellation given to such leaves as have a little indenting on their summits: when this indenting is terminated on each side by obtuse points, they are said to be obtusely emarginated; whereas when these points are acute, they are called acutely emarginated.

EMASCULATION, the act of castrating or depriving a male of those parts which characterize his sex. See Castration.

EMAUX DE L'ESCU, in heraldry, the metal and colour of the shield or escutcheon. See the article Shield.

EMBALMING is the opening a dead body, taking out the intestines, and filling the place with odoriferous and deficcative drugs and spices, to prevent its putrefying. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some that they have embalmed upwards of two thousand years ago, remain whole to this day, and are often brought into other countries as great curiosities. Their manner of embalming was thus: they scooped out the brains with an iron scoop, out at the nostrils, and threw in medicaments to fill up the vacuum:
EMB [1051] EMB

vacuum: they also took out the entrails, and having filled the body with myrrh, cedars, and other spices, except frankincense, proper to dry up the humour, they pickled it in nitre, where it lay soaking for seventy days. The body was then wrapped up in bandages of fine linen and gums, to make it stick like glue, and so was delivered to the kindred of the deceased, entire in all its features, the very hairs of the eye-lids being preserved. They used to keep the bodies of their ancestors, thus embalmed, in little houses magnificently adorned, and took great pleasure in beholding them, alive as it were, without any change in their size, features, or complexion. The Egyptians also embalmed birds, &c. The prices for embalming were different; the heighth was a talent, the next twenty mine, and so decreasing to a very small matter: but they who had not wherewithal to answer this expense, contented themselves with infusing, by means of a syringe, thro' the fundament, a certain liquor extracted from the cedar, and leaving it there, wrapped up the body in salt of nitre: the oil thus preyed upon the intestines, so that when they took it out, the intestines came away with it, dried, and not in the least putrid: the body being enclosed in nitre, grew dry, and nothing remained besides the skin glued upon the bones.

EMBARCADERO, in the Spanish commerce, the port-town of some considerable inland city; such is Arica to Potosi. See the articles ARICA and POTOSI.

EMBARGO, in commerce, an arrest on ships, or merchandize, by public authority; or a prohibition of state, commonly on foreign ships, in time of war, to prevent their going out of port; sometimes to prevent their coming in; and sometimes both, for a limited time. The king may lay embargoes on ships, or employ those of his subjects, in time of danger, for service and defence of the nation; but they must not be for the private advantage of a particular trader, or company; and therefore a warrant to lay a single ship is no legal embargo. No inference can be made from embargoes which are only in war-time; and are a prohibition by advice of council, and not at prosecution of parties. If goods be laden on board, and after an embargo, or restraint from the prince or state, comes forth, and then the matter of the ship breaks ground, or endeavours to fail, if any damage accrues, he must be responsible for the same; the reason is, because his freight is due, and must be paid, notwithstanding the goods be seized as contraband.

Embargo differs from quarantine, inasmuch as this last is always for the term of forty days, in which persons from foreign parts infected with the plague, are not permitted to come on shore. See the article QUARANTINE.

EMBASSADOR, or AMBASSADOR, a public minister sent from one sovereign prince, as a representative of his person, to another.

Embassadours are either ordinary or extraordinary. Embassador in ordinary is he who constantly resides in the court of another prince, to maintain a good understanding, and look to the interest of his matter. Till about two hundred years ago, embassadours in ordinary were not heard of; all, till then, were embassadours extraordinary, that is, such as are sent on some particular occasion, and who retire as soon as the affair is dispatched.

By the law of nations, none under the quality of a sovereign prince can send or receive an embassador. At Athens, embassadours mounted the pulpit of the public orators, and there opened their commiffions, acquainting the people with their errand. At Rome, they were introduced to the senate, and delivered their commiffions to them.

Embassadours should never attend any public solemnities, as marriages, funerals, &c., unless their matters have some interest therein; nor must they go into mourning on any occasions of their own, because they represent the perons of their prince. By the civil law, the moveable goods of an embassador, which are accounted an accession to his person, cannot be seized on; neither as a pledge, nor for payment of a debt, nor by order or execution of judgment, nor by the king's or state's leave where he resides, as some conceive; for all actions ought to be far from an embassador, as well that which toucheth his necessaries, as his person: if, therefore, he hath contracted any debt, he is to be called upon kindly, and if he refuses, then letters of reqeust are to go to his master. Nor can any of the embassador's domestic servants, that are registered in the secretaries of state's office, be arrested in person or goods: if they are, the process shall be void, and the parties suiting out...
out and executing it, shall suffer and be liable to such penalties and corporal punishment as the lord chancellor, or either of the chief justices, shall think fit to inflict. Yet embassadors cannot be defended when they commit any thing against that state, or the person of the prince, with whom they reside; and if they are guilty of treason, felony, &c. or any other crime against the laws of nations, they lose the privilege of an embassador, and may be subject to punishment as private aliens.

EMBASSY, the office or function of an embassador. See the preceding article. The rights of embasses are, in some measure, founded on the law of nature, which authorizes all that is necessary for procuring and maintaining peace and friendship among men. All fancied and profane histories mention the sacred rights of embasses, and are full of instances of wars undertaken for violating them. In the scriptures we read of a war made by king David upon the Ammonites on that account. Cicero says, that the rights of embasses are guarded by all laws both divine and human; wherever to violate this right, is not only unjust, but impious; and for this reason, if, for instance, whilst embassadors of any nation are resident with us, war be declared against their sovereigns, they still remain at liberty; thus are embassadors safe even amidst the arms of contending foes: and in case a banished man is appointed on an embassy to the country from whence he is banished, he may not be detained nor molested there; and, to speak in general, it is an established custom among all the nations of the world, even barbarians themselves, to reverence the characters of embassadors.

EMBATLED, in heraldry, the same with crenelle. See CRENELLE.

EMBDEN, a port-town and city of Germany, capital of a county of the same name, now in possession of the king of Prussia; it is situated at the mouth of the river Ems: east long. 6° 45', and north lat. 53° 40'.

EMBER-WEEKS, OR DAYS, in the christian church, are certain feasons of the year set apart for the imploring God's blessing, by prayer and fasting, upon the ordinances performed in the church at such times. These ordination-safts are observed four times in the year, viz. the Wednesday, Friday, and Saturday after the first Sun-

---

day in lent, after Whit-sunday, after the fourteenth of September, and the thirteenth of December; it being enjoined, by a canon of the church, that deacons and ministers be ordained, or made, only upon the sundays immediately following these ember-safts.

The ember-weeks were formerly observed in different churches with some variety, but were at last settled as they are now observed, by the council of Placentia, anno 1095. The council of Mentz, convened by Charlemagne, mentions the ember-weeks as a new establishment.

EMBERIZA, in ornithology, a genus of birds, the characters of which are, that the beak is of a conic shape, each chap whereof is wholly entire at the point; the upper one gapes a little at the base from the under, which laft is inflected, or turned inwards, at the sides. To this genus belong the green-finch, bunting, yellow-hammer, &c. See the articles GREEN-FINCH, BUNTING, &c. Besides these, the schomburger of the Spanish West-indies seems to claim a place among the emberizas: the upper part of the body is of a bright brown colour, somewhat inclining to orange, and the whole under part is of a pleasant light reddish brown.

EMBLEM, εμβλήμα, a kind of painted enigma, or certain figures painted or cut metaphorically, expressing some action with reflections underneath, which, in some measure, explain the sense of the device, and, at the same time, instruct us in some moral truth, or other matter of knowledge. The emblem is somewhat plainer than the enigma, and the invention is more modern, it being entirely unknown to the antients. P. Bouhours has a long and accurate dissertation upon emblems, wherein he has precisely defined their nature, laid down rules for their composition, and for distinguishing the true from the false. The Greeks gave this name to inlaid or mosaic work, and even to all kinds of ornaments of vases, garments, &c. and the Latins used emblem in the same sense.

EMBLEMatical, something belonging to an emblem. See the preceding article.

EMBLEMATES, among lawyers, denote the profits of town lands; but are sometimes used, more largely, for any products that naturally arise from the ground. If a tenant for life fow the land, and afterward dies, his executors shall have the emblems,
EMBLEMATIC, or EMBOLUS, EMBOSSED, EMBRACE

Elements, and not the person in reversion. The estate is otherwise with respect to a tenant for years; for if he ow the land, and his term expires before he has reaped them, the lessor, or he in reversion, is entitled to the emblems. Again, if a person devolves town lands by will, and dies before severance, the devisee shall have the emblems, provided no exception was made of corn.

EMBOLISMIC, or INTERCALARY, a term used by chronologists in speaking of the additional months and years, which they inferred to bring the lunar to the solar year. Since the common lunar year consists of twelve synodic months, or 354 days nearly, and the solar consists of 365 days (throwing away the odd hours and minutes) it is plain that the solar year will exceed the lunar by about 11 days; and consequently in the space of about 33 years the beginning of the lunar year will be carried through all the feasons, and hence it is called the moveable lunar year. This form of the year is used at this time by the Turks and Arabians; and because in three year’s time, the solar year exceeds the lunar by 33 days, therefore, to keep the lunar months in the same feasons and times of the solar year, or near it, chronologists added a whole month to the lunar year every third year, and so made it consist of 13 months; this year they called the embolismic year, and the additional month the embolismic, or embolimem, or intercalary month. This form of the year is called the fixed lunar year, and it was used by the Greeks and Romans till the time of Julius Caesar. See INTERCALARY, YEAR, &c.

EMBOLUS, the moveable part of a pump, or syringe, called also the piston, or sucker. See the article PISTON, PUMP, SYRINGE, &c.

EMBOSSING, or IMBOSING, in architecture and sculpture, the forming or fashioning works in relevo, whether cut with a chisel, or otherwise. Embossing is a kind of sculpture, wherein the figures stick out from the plane whereon it is cut; and according as the figures are more or less prominent, they are said to be in alto, mezzo, or basso relevo; or high, mean, or low relief. See the article ENGRAVING.

EMBRACE the volt, in the manage. A horse is said to embrace a volt, when, working upon volts, he makes a good way every time with his fore-legs.

EMBRACEOR, among lawyers, a person, who, having received a reward for to do, comes to the bar with one of the parties, and speaks in the cafe; or privily labours the jury, or stands in court to over-look them, whereby they are awed or put in fear. Abuses of this kind will be embracery, whether the jurors give verdict on the side of the party or not. The penalty of this offence is 20l. and imprisonment of the party at the discretion of the court; and may be prosecuted either by indictment at common law, as well as by action on the statute. But attorneys and other lawyers are excepted.

EMBRASURE, in architecture, the enlargement made of the aperture of a door or window, on the inside of the wall; its use being to give the greater play for the opening of the door, or casement, or to admit the more light. When the wall is very thick, they sometimes make embrasures on the outside.

EMBRASURE, in fortification, a hole or aperture in a parapet, through which the cannon are pointed to fire into the moat or field. Embrasures are generally twelve feet distant from one another, every one of them being from six to seven feet wide without, and about three within: their height above the platform is three feet on that side towards the town, and a foot and a half on the other side towards the field; so that the muzzle may be sunk on occasion, and the piece brought to shoot low.

EMBROcation, in surgery and pharmacy, an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c. by means of a woollen or linen cloth, or a sponge, dipped in the same. The use of embrocation is either to attenuate and dilate something obstructed underneath the skin, to ease pains, or to irritate the part into more warmth and a quicker sense of feeling. The pumping used in natural baths is properly an embrocation.

EMBROIDERY, a work in gold, or silver, or silk-thread, wrought by the needle upon cloth, stuffs, or muslins, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked. As to muffins, they spread it upon a pattern ready defined; and sometimes, before it is stretched upon the
the pattern, it is starched, to make it more easy to handle. Embroidery on the loom is less tedious than the other, in which while they work flowers, all the threads of the mullin, both lengthwise and breadthwise, must be continually counted; but on the other hand this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarce susceptible of this ornament, and in effect we seldom see them embroidered. The thinnest mullins are the best for this purpose, and they are embroidered to the greatest perfection in Saxony: in other parts of Europe, however, they embroider very prettily, and especially in France.

There are several kinds of embroidery, as 1. Embroidery on the flamp, where the figures are raised and rounded, having cotton or parchment put under them to support them. 2. Low embroidery, where the gold and silver lie low upon the sketch, and are stitched with silk of the same colour. 3. Guimped embroidery: this is performed either in gold or silver; they first make a sketch upon the cloth, then put on cut vellum, and afterwards low on the gold and silver with silk-thread; in this kind of embroidery they often put gold and silver cord, tinsel, and frangles. 4. Embroidery on both sides; that which appears on both sides of the stuff. 5. Plain embroidery, where the figures are flat and even, without cords, frangles, or other ornaments.

EMBRUN, or AMBRUN, a city of Dauphiny, in France, near the confines of Piedmont: east longitude 6° 6', and north lat. 44° 35'.

EMBRYO, in physiology, the first rudiments of an animal in the womb, before the several members are distinctly formed; after which period it is denominated a foetus. See the articles CONCEPTION, GENERATION, and FOETUS.

EMBRYO-PLANT, the same with plantula feminalis. See the article PLANTULA.

EMBRYO-SULPHUR, embryonatum sulphur, that united with metals or other mineral substances. See SULPHUR.

EMBRYO-WORMS, those contained in the bodies of viviparous two-winged flies, in surprising multitudes. See the articles FLY and WORM.

EMBRYOTHLASTES, in midwifery, an instrument contrived for breaking the bones, for the more easy extraction of the foetus, in difficult labours.

EMBRYOTOMY, the cutting a foetus to pieces whilst in the womb, practised in cases of necessity, when there is no other way of saving the mother.

EMBRYOLOGY, a hook for extracting the child, in difficult labours. See plate LXVIII. fig. 2, where no. 1 represents the broad steel-hook of Palpynus, for extracting a live infant without danger, when its head sticks in the vagina. It is necessary to have two of them, that one may be applied to each side of the head. No. 2 is the hook commonly used for extracting dead foetuses. See the article DELIVERY.

EMENDALS, in the accounts of the Inner temple, where so much in emendals, at the foot of an account, signifies so much money in the bank, or flock of the house, for repairing losses, and to supply other emergencies.

EMENDATIO PANIS, &c. in law. See the article ASSIZE.

EMERALD, jnvaragdus, in natural history, a genus of precious stones, of a green colour, and next in hardness to the ruby.

Our jewellers distinguish emeralds into two kinds, the oriental and occidental: the emeralds of the East-Indies are evidently finer than those of any other part of the world; but our jewellers, seldom meeting with these, call the american emeralds the oriental, and usually fell crytal accidentally tinged with green, under the name of the occidental emerald: these being also the most common, there has grown an opinion among the lapidaries, that the emerald is no harder than the crytal; because what they take to be emeralds, are in general only crytals.

The genuine emerald, in its most perfect state, is, perhaps, the most beautiful of all the gems; it is found of various sizes, but usually small; a great number of them are met with of about the sixteenth part of an inch in diameter, and they are found from this to the size of a walnut. We have accounts of very large sizes among the antients, but they are certainly erroneous, the stones not being emeralds, but jaspers or other green stones: the larger specimens are at present very scarce, and are of considerable value, tho' much more so, when of the East or West-Indies.

The emerald is of different figures like the diamond and many of the other gems, being sometimes found in a roundish or pebble-like form, but much more frequently in a columnar one, resembling common crytal.
EMERALDS. The crystal: the pebble-emeralds are always the hardest and brightest, but are seldom found exceeding the size of a pea: the crystal-like form ones grow several together, and are often larger: the pebble-kind are found loose in the earths of mountains, and sands of rivers; the columnar are found usually bedded in, or adhering to, a white, opaque, and coarse crystalline mass, and sometimes to the jasper, or the praeus.

The oriental emerald is of the hardnes of the sapphire and ruby, and is second only to the diamond in lustre and brightness; the american is of the hardness of the garnet, and the European somewhat softer than that, yet considerably harder than crystal: but the coloured crystals, usually sold under the name of emeralds, has much debauched the credit of this gem. It loses its colour in the fire, and becomes un-distinguishable from the white sapphire.

The oriental emeralds are very scarce, and at present found only in the kingdom of Cambay; very few of them have of late been imported into Europe, in such numbers that it has been supposed there were no oriental emeralds but within these ten years, some few have been brought from Cambay into Italy, that greatly excel the American ones. The American, being what our jewelers call oriental emeralds, are found principally about Peru; and the European, are principally from Sile sia.

The medicinal virtues ascribed to this stone, are, that it stops hemorrhages and diarrhoeas, and sweetens or obviates the too acute humours.

To counteract Emeralds. Take of natural crystal, four ounces; of red-lead, four ounces; verdigrise, forty-eight grains; crocus martis, prepared with vinegar, eight grains; let the whole be finely pulverized and sifted; put this into a crucible, leaving one inch empty: lute it well, and put it into a potter's furnace, and let it stand there as long as they do their pots. When cold, break the crucible, and you will find a matter of a fine emerald-colour, which, after it is cut and set in gold, will surpass in beauty an oriental emerald.

EMERGENT YEAR, in chronology, the same with the epocha, whence any era, or method of reckoning time, commences: such is that of the creation of the world, of the birth of our Saviour; &c. See the article BOCHA.

EMERSION, in astronomy, is when any planet that is eclipsed begins to emerge or get out of the shadow of the eclipsing body. It is also used when a star, before hid by the sun as being too near him, begins to reappear or emerge out of his rays.

Scrapes of Emersion, an arch of the moon's orbit, which the moon's center passes over from the time she begins to emerge out of the shadow of the earth, to the end of the eclipse. See the articles Eclipse, Trajectory, &c.

EMERUS, in botany, &c. the same with corolla. See the article CORONILLA.

EMERY, in natural history, a rich iron ore found in large masses of no determinate shape or size, extremely hard, and very heavy. It is usually of a dusky brownish-red on the surface, but when broken, is of a fine, bright, iron-grey, but not without some tinge of redness, and is spangled all over with shining specks, which are small flakes of a foliaceus tale, highly impregnated with iron. It is also sometimes very red, and then usually contains veins of gold. It makes no effervescence with any of the acid menstrums, and is found in the island of Guernsey, in Tuscany, and many parts of Germany.

Emery is said to have a corroding and almost caustic quality, but this without any just foundation. It is recommended by the antiquaries as an astringent and dentificre. In this last intention, however, it must be used with great caution, as its hardness and sharpness will be apt to wear off the enamel of the teeth.

Emery is prepared by grinding in mills, and the powder is separated into parcels of different degrees of fineness by washing; these are called the first, second, and third sort; the first being that which remains longest suspended in water, the others, such as sink sooner from the same liquor, and from which it is poured, while yet turbid, to settle for the finer kind. These several sorts are of great use to various artificers in polishing and burnishing iron and steel works, mable, cutting and polloping glafs, &c. The lapidaries cut the ordinary gems on their wheels, by sprinkling the wetted powder over them, the wheels they use being usually of lead, with a small admixture of pewter, that their softness may admit the emery the better. It will not cut diamonds.

The red emery of Peru is in great esteem with
EMETIC, a medicine which induces vomiting. Emetics and purges are so much alike in their operations, that one cannot be well apprehended without the other. Thus much, therefore, is common to them both, that any medicine which so far vellicates the membranes and coats of the stomach and bowels as to draw them into convulsive twitchings, or much accelerate their natural motions, will be emetic or cathartic, and sometimes both. But the action of vomiting is more properly a convulsive motion in the stomach than in the bowels. Whatevour, therefore, for velocities the fibres of the stomach as to make them contract with great force, will throw its contents upwards, the vent being much larger that way than through the pylorus, which would send them down by ftoil. The difference, therefore, between an emetic and a cathartic, lies only in this, that the latter consists of such particles as pass the stomach without any violent vellications of the fibres, and the former, of such as have that effect almost as soon as they come there, so that an emetic seems stronger than a cathartic; and this is the reason why a cathartic in an increased dose will prove emetic. Some are of opinion, that the substance itself which procures a vomit, is thrown up again in the first or second ejection; and that the following solicitations are caused by the acrimony of the juices which the first motions pumped, as it were, and occasioned to drain into the stomach. Be that as it will, it is certain that the action of vomiting, gives the strongest flakes to all the muscles and solids of the body that any motion can give; and that the last reachings generally discover a drai of humours derived into the stomach from some considerable distance. The service to be expected from emetics, is not so much, therefore, what they discharge upwards, as what their violent emotions and convulsions render fit for separation, and force through the skin and other outlets. Tinctures, extracts, and refins, are always observed to operate rougher this way than more simple preparations; and the reason seems to be, that such management of an ingredient, divides its parts too much, and makes them come too intimately into contact with the fibres; whence they are not so soon shaken off by their convulsive twitchings, as more gross parts might be. Upon this account, therefore, most of the simples which come under this head, are best ordered in their natural forms; and the elaborate preparations of the chemical pharmacy especially, produce no emetic so good as we find amongst nature’s own productions. Sydenham lays it down as a rule, that whenever a vomit and bleeding are necessary, bleeding should always precede the exhibition of an emetic. Dr. Harris informs us, that antimonial vomits are very safe in the heat of the summer, but are very dangerous in the cold of the winter. When emetics are too violent, common salt is used to check the operation. Mild aromatics and opiates also have the same effect, and corroborating medicines whether taken internally, or applied by way of cataplasm to the region of the stomach. The infusion of ipecacuanha in wine, according to Dr. Shaw, is the most safe, gentle, and agreeable emetic hitherto known; whence, says he, it may in most cases be properly substituted for the vinum benedictum, the tartarum emeticum, and all the other antimonial emetics which are attended with some degree of virulence and uncertainty in their operation.

EMETIC TARTAR. TARTAR.
EMETIC POWDER. See ALGAROT.
EMETIC WINE. WINE.

EMEU, in ornithology, the same with the cassowary. See CASSOWARY.

EMINENCE, a title of honour peculiar to cardinals. See the article CARDINAL.

EMINENCE, in the military art, a high or rising ground, which overlooks and commands the low places about it: such places within cannon-shot of a fort, are a great disadvantage; for if the besiegers become masters of them, they can, from thence, fire into the fort.

EMINENTIAL EQUATION, an artificial equation, containing another equation eminently: it is sometimes used in the investigation of the areas of curved lines. See EQUATION.

EMINENTLY, emi-nent, a term used in the schools in regard to things which possess some quality or virtue in a high degree.

EMIR, a title of dignity among the Turk signifying a prince. This title was first given to the caliph
but when they assumed the title of fulans, that of emir remained to their children, as that of Caesar among the Romans. At length the title became attributed to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban instead of the white. The Turks make an observation, that the emirs, before their fortieth year, are men of the greatest gravity, learning, and wisdom; but after this, if they are not great fools, they discover some signs of levity and stupidity. This is interpreted by the Turks as a sort of divine impulse in token of their birth and maternity. The Turks also call the viziers, balhaws, or governors of provinces, by this name.

**EMISSARY**, in a political sense, a person employed by another to found the opinions of people, spread certain reports, or act as a spy over other people's actions. See the article Spy.

**EMISSARY VESSELS**, in anatomy, the name with those more commonly called excretory. See the article Excretory.

**EMISSION**, in medicine, a term used chiefly to denote the evacuation of the semen, or seed, in the act of coition. See Coition and Generation.

**EMMENAGOGUES**, in pharmacy, medicines which promote the menies, or monthly courses, either by giving a greater force to the blood in its circulation, whereby its momentum against the vessels is increased; or by making it thinner, whereby it will more easily pass through any outlet. The former intention is helped by chalybeates, and other substances of the like gravity and elasticity; and this is the cause of a leuco-phlegmatic habit, or the green-sicknes, and its cure: but in the latter case, where the blood is florid and too high, attenuating alternatives and detergents are the only remedies, because they are fittest to carry the blood through these little apertures destined for its discharge into the uterus. Obstructuons are removed by the five aperient roots, birthwort, rhubarb, bryony, and wall-flowers, especially if exhibited by way of decoction with some stimulus of the taine kind, such as borax.

**EMMERIC**, a city of Westphalia, in Germany, subject to Prussia: east long. 58° 45', north lat. 51° 48'.

**EMOLLIENTS**, in medicine and pharmacy, are such remedies as feaath and soften the alperity of the humours, and relax and supple the solids at the same time. It is very easy to conceive how both these are brought about by the same medicine. By what means soever, whether in the stomach or any other parts, the juices have obtained a sharpness and aperity, so as to vellicate and render uneasy the fibres and nervous parts, which often happens, those things that are smooth, soft, and yielding, cannot but wrap up their points, and render them imperceptible, whence they may gradually, by the proper course of circulation, be brought to some convenient emunctory, without doing any injury by the way. Such parts likewise draw the fibres into spams, keeping them too tense, and thereby frequently occasion obstructions of the worst kind. In all such cases, emolllients lubricate and moisten the fibres, so as to relax them into their proper dimensions, whereupon such disorders cease.

The chief of the emollient and softening remedies, are the roots of marsh-mallow, of white lillies, of liquorice, and of viper's grass; the five emollient herbs, lettuce, bear's breech, pellitory of the wall, the flowers of elder, of meillot, of mallow, of mullein, of yarrow, of chamomile, of white lilies, of borage, of the wild poppy, of the lime tree, of the egyptian thorn, of violets, and, most of all, saffron; the seeds of flax, of fenugreek, of anise, of quinces, of feabane, of white poppies; of the four greater and lesser cold-feeds, the siliqua, sweet almonds, figs, pine-nuts, pistachas, cherry-tree gum, gum arabic, gum tragacanth, flavings and jelly of hartthorn, human grease, that of a dog, of a caupon, the marrows of their bones, the fat about their omament, bones, and meseutery; the native ols of animals, fresh butter, cream, milk itself, crysals of milk, perrna cett, honey, the yolk of an egg, and its white, dried and reduced to a powder. Of the prepared medicines, oil of sweet almonds, linseed-oil, rape-oil, oil of the male basilan apple, decoctions of hartthorn and viper's grass, mixed with the juice of citrons, the pittia, sweet whey, Ferne lius's sirup of marsh-mallows, ointment of marsh-mallows, limple dyachyon planter, that of meillot, and that of frog's spawn.

**EMPALEMENT**, an antient kind of punishment, which consisted in thrulfting a flake up the fundament.

**EMPALEMENT of a flower**, among herbalists, the same with calyx. See Calyx.
EMPANELLING, or IMPANELLING, in law. See the article IMPANELLING.

EMPARLANCE, or IMPARLANCE, in law. See the article IMPARLANCE.

EMPASTING, or IMPIASTING, in painting, is the laying on of colours thick and bold, or the applying several layers of colours, so as they may appear thick. The term is also used when the colours are laid distinct and asunder, and not softened or lost in each other. See the article COLOURING.

EMPATTEMPIENT, in fortification, the fame with talus. See the article TALUS.

EMPRESS, or EMPRESS, denotes either the wife of an emperor, or a woman who governs singly an empire, in her own right. See EMPEROR and EMPIRE.

EMPEROR, imperator, a title of honour among the ancient Romans, conferred on a general who had been victorious, and now made to signify a sovereign prince, or supreme ruler of an empire. The title of emperor adds nothing to the bole, depreifed, dignity is more-eminent than that dignity. In the Eaft, the title of emperor is more frequent than with us; thus the sovereign princes of China, Mogul, &c. are called emperors. In the Weft, the title has been a long time restrained to the emperors of Germany. The first who bore it was Charlemagne, who was crowned by pope Leo III. in 800. And it is to be observed, that there was not a foot of land or territory annexed to the emperor's title.

In the year 1723, the czar of Muscovy assumed the title of emperor of all the Russian. The kings of France were also called emperors, when they reigned with their sons, whom they associated in the crown: thus Hugh Capet was called emperor, and his son Robert, king. The kings of England were antiently called emperors, as appears from a charter of king Edgar.

The emperor of Germany is a limited monarch in regard to the empire, though he is an absolute sovereign in most of his hereditary dominions; the late emperors of the austria family, having hereditary dominions, enumerated all of them in their title. Charles VI. was called emperor of the Romans, always auguf, king of Bohemia and Hungary, archiduke of Austria, &c. but the present empêts inheriting those countries, her confori enjoys only the title of emperor of the Romans, duke of Lorraine and Tuscany. The emperor creates dukes, marquisses, and other noblemen; and he appoints most of the officers, civil and military, in the empire: he is elected by the nine electors; and he summons the general diet of the empire. See ELECTOR and DIET.

The emperor of Russia is an absolute hereditary monarch.

EMPETRUM, BERRY-BEARING-HEATH, in botany, a genus of the traccia-polygarnica class of plants, the flower of which consists of three petals, of an oval-oblong figure: the flamina are three very long capillary filaments: the fruit is a globose, depressed, and unilocular berry, containing nine seeds, gibbous on one side, and angulated on the other.

EMPETRUM is also used for the heath-spurge, a species of tithymalus. See the article TITHYMALUS.

EMPHASIS, in rhetoric, a particular stress of the voice and action, laid on such parts or words of the oration, as the orator wants to enforce upon his audience. See the article ACCENT.

EMPHEREPIYRA, in mineralogy, a genus of siderochita, composed of various coats surrounding a nucleus of the same substance and stucture with themselves. See the article SIDEROCHITA.

Of this genus there are several species, distinguished by the different-colours of their coats or crusts, as brown, yellow, purple, green, white, &c.

EMPHRACTICS, in medicine and pharmacy, obstructing topics, such as, when applied to the body, adhere and stop the pores.

EMPHYSEMA, in surgery, a windy tumour generally occasioned in a fracture of the ribs, and formed by the air insinuating itself, by a small wound, between the skin and muscles, into the substance of the cellular or adipose membrane, spreading itself afterwards up to the neck, head, belly, and other parts, much after the manner in which butchers blow up their veal. See the articles FRACTURE and RIBS.

When an emphysema happens, it will be very proper to enlarge the opening in the skin,
skins, when too narrow, with the scalpel, and to bring down the tumor with fric-
tions and bandage; carrying the com-
presfion gradually towards the opening, fo as to expel the included air by degrees.
Emphysema, in Hippocrates, imports an
inflation of the belly, and sometimes a
tumour in general. Its surprizing to what
degree the cellular membrane will be
inflated by the air retained and rarefied in
its cells. To this purpose Mr. Mery
gives a very remarkable his-
tory in the memoirs of the royal academy of sciences for 1713, which the curious may consult.
EMPHYTEUSIS, in the civil and canon
law, the letting out of poor barren lands
for ever, or, at least, for a long term of
years, on condition of the tenant's cul-
vating, meliorating, or mending them,
and paying a certain yearly com-
futation. Emphytese are a kind of alienations,
differing from false, in
which
Emphysema are a kind of alienations,
differing from false, in
which
In order to discharge this matter, or
blood extravasated into the cavity of the
thorax, in wounds of that part, it must
be perforated; which operation is called
paracentesis. See PARACENTESIS.
After the affected side is opened, the pus
must be drawn off slowly, and at several
times; and the cavity is to be cleansed
by injections of decoctions with honey;
which done, the wound is to be healed,
giving at the same time plenty of vulner-
ary decoctions inwardly, of such things
as deterge and refit pustulation. See the
article ANTISEPTICS.
EMPYREUM, a term used by divines for the
highest heaven, where the blessed en-
joy the beatific vision.
Some of the fathers suppose the empy-
reum to have been created before the
heavens which we behold. See HEAVEN.
EMPYREUMA, among chemists and phy-
icians, the fiery taint or offensive smell
which brandishes, and other bodies pre-
bred by fire, are impregnated with. See
DISTILLATION and BRANDY.
EMR0DS, or HEMORRHoids. See the
article HEMORRHoids.
EMULGENT, or RENAL ARTERIES,
those which supply the kidneys with
blood; being sometimes single, some-
times double on each side. See ARTERY.
EMULSION, in pharmacy, a sofit liquid
remedy, of a colour and consistence re-
ssembling milk. It is compounded by draw-
ing phylic in a regular way. Some even
use the term, in a still worfe sense, for a
quack who prescribes at random, with-
out being at all acquainted with the prin-
ciples of the art.
EMPLASTER, emplafrum, in pharmacy,
the same with plaster. See PLASTER.
EMPLASTICS, the same with emphracti-
cies. See the article EMPhRACTICS.
EMPRESS, or EMPERESS. See the article
EMPRESS.
EMPRIRED, a term used by sportsmen
for a hart that has forsaken the herd.
EMPRASTHOTONOS, a species of con-
vulsion, wherein the chin presses against
the breast. See CONVULSION.
EMPYEMA, in medicine, a disorder
wherein purulent matter is contained in
the thorax or breast, after an inflamma-
tion and suppuration of the lungs and
pleura; which, if it be not timely dis-
charged, not only obliterates respiration,
but also returning into the blood occa-
sions a continual hectic, with a consump-
tion of the whole body, and other bad
symptoms.
In order to discharge this matter, or
blood extravasated into the cavity of the
thorax, in wounds of that part, it must
be perforated; which operation is called
paracentesis. See PARACENTESIS.
After the affected side is opened, the pus
must be drawn off slowly, and at several
times; and the cavity is to be cleansed
by injections of decoctions with honey;
which done, the wound is to be healed,
giving at the same time plenty of vulner-
ary decoctions inwardly, of such things
as deterge and refist pustulation. See the
article ANTISEPTICS.
ENALURON, ENALLAGE: EN~OREMA, ENALLAGE, EMUNCTORY; ENMEON, "ju:s; part of seeds or kernels by contusion, with proper liquors. Emulsions, if carefully made, are a very neat form, but a very small part of the materia medica is reducible thereunto, or only those seeds which yield a soft milky juice; and therefore the only intention which this form can properly be prescribed for, is that of an emollient, though some few are given for other purposes, but they are not so suitable: oils, likewise, may, by the help of an egg, and a little of any of the turpentine balams, be reduced under this head, and, if well managed, will make an elegant medicine. In all emulsions the seeds are to be husked or blanched, and beat in the mortar to a paste: then the liquors ordered are to be put in by a little at a time at first, and beat with the mafs, so that the whole pulp may be washed out, and nothing but a little like chaff be left behind: this is always to be done in a marble mortar, and with a wooden pestle. EMUNCTORY; in anatomy, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such more especially are the kidneys, bladder, and most of the glands. See the articles KIDNEY, BLADDER, &c.

ENZEMON, "en зе мо н", in medicine, an epithet often applied by Hippocrates and Galen, to such topical medicins as are appropriated to a wound newly inflicted, before the blood be stopped.

ENZOREMA, in medicine, that pendulous substance which floats in the urine. It is also called sublimamentum and nuclecula, from its resemblance to little clouds. See URINE, SUBLIMAMENTUM, and NUCLECULA.

ENLALLAGE, in grammar, is when one word is subsituted for another of the same part of speech; a substantive for an adjective, as exercitus victor, for victorius; fecus, for fecellus: a primitive for a derivative, as dardana arma, for dardania; laticem lyeum, for lyeatum: an active for a passive, as nox bumida cabo precipitat, for precipitatur, &c.

ENLALLGE; in rhetoric, is a figure whereby the discourse is changed and reverted contrary to all the rules of the language; but this is not done altogether at pleasure, or without reason.

ENALURON, according to Guillim, is a bordure charged with birds; tho' others will have it to signify, in orle, or form of a bordure. See the article BORDURE.

ENAMEL, a kind of coloured glass, used in enamelling and painting in enamel. Enamels have for their bases a pure crystal-glass or silt, ground up with a fine calx of lead and tin prepared for the purpose, with the addition usually of white salt of tartar. These ingredients baked together, are the matter of all enamels, which are made by adding colours of this or that kind to powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri De Arte Vitriar. directs only manganese to be added to the matter which constitutes the bases. For azure, zaffier mixed with calx of brafs. For green, calx of brafs with scales of iron, or with crocus martis. For black, zaffier with manganese, or with crocus martis; or manganese with tartar. For red, manganese or calx of copper and red tartar. For purple, manganese with calx of brafs. For yellow, tartarie and manganese. And for violet-coloured enamel, manganese with thrice calcined brafs.

In making these enamels, the following general cautions are necessary to be observed. 1. That the pots must be glazed with white glass, and must be such as will bear the fire. 2. That the matter of enamels must be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it must be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamels is this: powder, sift, and grind all the colours very nicely, and first mix them with one another, and then with the common matter of enamels; then let them in pots in a furnace, and when they are well mixed and incorporated, cast them into water; and when dry, set them in a furnace again to melt; and when melted, take a proof of it. If too deep-coloured, add more of the common matter of enamels; and if too pale, add more of the colours.

Enamels are used either in counterfeiting or imitating precious stones, in painting in enamel, or by enamellers, jewellers, and goldsmiths, in gold, silvers and other metals. The two first kinds are usually prepared by the workmen themselves, who are employed in these arts. That used by jewelers, &c. is brought to us chiefly from Venice or Holland, in little cakes of different sizes, commonly about four inches diameter, having the mark of the
the maker strike upon it with a puncheon, it pays the pound 1s. 7½d. on importation, and draws back 1s. 5½d. at the rate of 4s. per pound.

**ENAMELLING**, the art of laying enamel upon metals, as gold, silver, copper, &c. and of melting it at the fire, or of making divers curious works in it at a lamp. It signifies also to paint in enamel.

The method of painting in enamel. This is performed on plates of gold or silver, and most commonly of copper, enamelled with the white enamel; whereof they paint with colours which are melted in the fire, where they take a brightness and lustre like that of glass. This painting is the most prized of all for its peculiar brightness and vivacity, which is very permanent, the force of its colours not being effaced or fulfilled with time, as in other painting, and continuing always as fresh as when it came out of the workman's hands. It is usual in miniature, it being the more difficult the larger it is, by reason of certain accidents it is liable to in the operation. Enamelling should only be practised on plates of gold, the other metals being less pure: copper, for instance, scales with the application, and yields fumes; and silver turns the yellowish white. Nor must the plate be made flat; for in such case, the enamel cracks; to avoid which, they usually forge them a little round or oval, and not too thick. The plate being well and evenly forged, they usually begin the operation by laying on a couch of white enamel (as we observed above) on both sides, which prevents the metal from swelling and blistering; and this first lay, serves for the ground of all the other colours. The plate being thus prepared, they begin at first by drawing out exactly the subject to be painted with red vitriol, mixed with oil of spike, marking all parts of the design very lightly with a small pencil. After this, the colours (which are to be before ground with water in a mortar of agate extremely fine, and mixed with oil of spike somewhat thick) are to be laid on, observing the mixtures and colours that agree to the different parts of the subject; for which it is necessary to understand painting in miniature. But here the workman must be very cautious of the good or bad qualities of the oil of spike he employs to mix his colours with, for it is very subject to adulterations. See Oil.

Great care must likewise be taken, that the leaf dust imaginable come not to your colours while you are either painting or grinding them; for the leaf peck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red hot, will leave a hole, and do deface the work.

When the colours are all laid, the painting must be gently dried over a flow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red hot in a fire, like what the enamellers use. Afterwards that part of the painting must be passed over again which the fire hath any thing effaced, strengthening the shades and colours, and committing it again to the fire, observing the same method as before, which is to be repeated till the work is finished.

**Method of Enamelling by the lamp.** Most enamelled works are wrought at the fire of a lamp, in which, instead of oil, they put melted horse-grease, which they call caballine oil. The lamp, which is of copper or white iron, consists of two pieces, in one of which is a kind of oval plate, six inches long, and two high, in which they put the oil and the cotton. The other part, called the box, in which the lamp is inclosed, serves only to receive the oil which boils over by the force of the fire. This lamp, or where several artists work together, two or three more lamps are placed on a table of proper height. Under the table, about the middle of its height, is a double pair of organ-bellows, which one of the workmen moves up and down with his foot, to quicken the flame of the lamps, which are by this means excited to an incredible degree of vehemence. Grooves made with a gauge in the upper part of the table, and covered with parchemin, convey the wind of the bellows to a pipe of glass before each lamp; and that the enamellers may not be accommodated with the heat of the lamp, every pipe is covered at six inches distance with a little tin plate, fixed into the table by a wooden handle. When the works do not require a long blast, they only use a glass-pipe, into which they blow with their mouth. It is incredible to what a degree of fineness and delicacy the threads of enamel may be drawn at the lamp. Thofe which are used in making false tufts of feathers are so fine, that they may be wound on the reel like silk or thread. The ficti-
ENCANTHIS, in surgery, a tubercle arising either from the caruncula lachrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lachrymalia, but also part of the sight, or pupil itself.

In this disorder, the tears continually run down the cheek, which greatly deforms the eye and face.

It is of two kinds, viz. mild, without hardness or pain; or malignant, which is kivid and very painful. The mild kind is to be treated first by scourifying, and afterwards applying ephomatic or caustic medicines; and if this proves insufficient, the tumour may be touched, but with great caution, with lapis infernalis; and to divert the humours from the eye, ointments, with phlebotomy and cooling purges, are proper. If all these fail, the surgeon is to extirpate the tumour; in which case, it is better to leave part of the morbid tubercle, than cut off any part of the lachrymal caruncle, as the remains of it may be afterwards cleared away by epharotic. After the operation, it is proper to apply deteging and healing medicines, or a callyrium of lapis tuitz; myrrh, &c. till the wound is healed.

As to the malignant encanthis, inclining to be cancerous, it is generally better to let it alone, and to mitigate its uneasiness with cooling and lenient collyria, rather than exasperate it by the operation, or by epharaotic medicines. Heifer.

ENCAPUSTUM and ENCAUSTIC, the same with enamelling and enamel. See ENAMELLING and ENAMEL.

ENCEINTE, in fortification, is the wall or rampart which surrounds a place, sometimes composed of bastions or curtains, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a roman wall.

ENCEPHALI, in medicine, worms generated in the head, where they cause so great a pain, as sometimes to occasion distraction.

The encephali are very rare, but there are some diseases wherein they swarm; from whence we are told pestilential fevers have wholly arisen. Upon the direction of one who died of this fever, a little, short, red worm was found in the head, which malmey wine, wherein horse-radish had been boiled, could only destroy. This medicine was afterwards tried on the sick, most of whom it cured.
The like worms have also been taken out by trepanning, and the patient cured. Those worms that generate in the nose, ears, and teeth, are also called encephalii.

ENCEPEPPE, in heraldry, denotes fettered, chained, or gilt about the middle, as is usual with monkeys.

ENCHANTER, a person supposed to practice enchantment, or fascination. See FASCINATION, WITCHCRAFT, &c.

ENCHASHING, in botany. See the article CIRCÆA.

ENCHASIING, or CHASING, the art of enriching and beautifying gold, silver, and other metal-work, by some design, or figures represented thereon, in low relief. See the articles RELIEVO, and SCULPTURE.

Enchasing is practised only on hollow thin works, as watch-cafes, cane-heads, tweezers-cafes, or the like. It is performed by punching or driving out the metal, to form the figure, from within side, so as to stand out prominent from the plane or surface of the metal. In order to this, they provide a number of fine steel-blocks, or punchions, of divers sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tops of these blocks, directly under the lines or parts of the figures; then, with a fine hammer, striking on the metal, sustained by the block, the metal yields, and the block makes an indentation, or cavity, on the inside, corresponding to which there is a prominence on the outside, which is to stand for that part of the figure.

Thus the workman proceeds to chase and finish all the parts by successive application of the block and hammer, to the several parts of the design. And it is wonderful to consider with what beauty and justness, by this simple piece of mechanism, the artists in this kind will represent foliages, grotesques, animals, histories, &c.

ENCHELYS, էքհես, the eel, in ichthyology. See the article EEL.

ENCEELIDES is also used to denote the capillary eels discovered by the help of microscopes in pepper-water, and the like. See the article ANIMALCULE.

ENCHESON, in old law-books, signifies the occasion, cause, or reason wherefore anything is done.

ENCHYSMA, in medicine, the name with enema. See the article ENEMA.

ENCELAVE, in heraldry, denote a thing's being let into another, especially when the piece, so let in, is square.

ENCLITICA, in grammar, particles which are so closely united with other words, as to seem part of them, as in virgule, &c.

There are three enclitic particles in Latin, viz. que, ne, &c: but there are a great many in the Greek, as τώ, τε, μόν, μόνιμα, εις, &c.

ENCRASICOLUS, the anchovy, in ichthyology. See ANC HavY.

ENCRARITITES, encratites, in church-history, heretics who appeared towards the end of the second century: they were called engravites, or continentes, because they gloried in abstaining from marriage, and the use of wine and animal food. Their chastity, however, was a little suspected, on account of their using all sorts of means to draw women into their feets, and always keeping company with them.

EN CR AULOS, the anchovy. See the article ANCHovy.

ENCRoACHMENT, or incroachment, in law. See INCROACHMENT.

ENCURECK, a poisonous insect, frequent in Persia, thought to be a species of tartanula. See the article TARANTULA.

ENCYCLOPAEDIA, Ενκυκλοπαίδεια, in literary history, the name with cyclopaedia. See CYCLOPAEDIA and DICTIONARY.

END FOR END, in the sea-language, is said of a rope that has run quite out of the block, wherein it was received.

ENDECAGON, in geometry, the same with hendecagon. See HENDECAGON.

ENDECASYLLABUS. See the article HENDECASYLLABUS.

ENDECERIS, in antiquity, denotes a vessel, or galley, with eleven tires of oars.

ENDEMIC, or ENDEMICAL DISEASES, those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living. See the article DISEASE.

It has been always observed, that people of particular countries were peculiarly subject to particular diseases, which are owing to their manner of living, or to the air and effluvia of the earth and water. Hoffman has made curious observations on diseases of this kind: he observes, that the Laplanders have often distempers of the eyes, which is owing to their living in smoke, or being blinded with the snow; &c.
attempts to pump. In Sweden, Pomerania, and the
German states, in the rear of the church, they tie
the bodies of traitors, who publicly publish
their crimes, with care, and with expense. In
many places, and in all ages, they have been
used as a provision upon a benefice, though
the government, he shall be puni-
lished as a traitor.
charit; at least, this was the practice of some churches: and though they were under the care of exorcists, yet it was thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present. See the article EXORCISM.

ENERGY, en'fisis, a term of Greek origin, signifying the power, virtue, or efficacy of a thing. It is also used, figuratively, to denote emfhasis of speech. See the article EMPHASIS.

ENFANS PERDUS, the same with forlorn hope. See the article FORLORN.

ENFILADE, in the act of war, is used in speaking of trenches, or other places, which may be scoured by the enemy's shot, along their whole length. In conducting the approaches at a siege, care must be taken that the trenches be not enfiled from any work of the place. See the article TRENCHES.

ENFRANCHISEMENT, in law, the incorporating a person into any society or body politic: thus, where any person is enfranchised, or made free, of any city, borough, or company, he is said to have a freehold therein during life; and cannot, for barely endeavouring any thing against the corporation, forfeit the same. Naturalization is also another kind of enfranchisement. See NATURALIZATION.

ENGASTRIMYTHI, in pagan theology, the pythians, or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips. See PYTHIA. The antient philosophers, &c. are divided upon the subject of the engastrimythi. Hippocrates mentions it as a delirium. Others will have it a kind of divination. Others attribute it to the operation or possession of an evil spirit. And others to art and mechanism. M. Scottus maintains that the engastrimythi of the antients were poets, who, when the priest could not speak, interpreted the defect by explaining in verse what Apollo dictated in the cavity of the bason on the sacred tripod.

ENGERDING, a term sometimes used for the act of producing or forming any thing; thus meteors are said to be engendered in the middle region of the atmosphere, and worms in the belly. See the articles GENERATION, METEOR, WORM, &c.

ENGERS, the capital of a county of the same name, in Germany, situated on the river Rhine, about seven miles north of Coblenz.

ENGLISH, a city of Hainalt, about fourteen miles south-west of Bruxells.

ENGINA, an island on the north-east of the Morea, about fifty miles east of Corinth.

ENGINE, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. Engines are extremely numerous; some used in war, as the battering-ram, ballista, waggons, chariots, &c. others in trade and manufactures, as cranes, mills, presses, &c. others to measure time, as clocks, watches, &c. and others for the illustration of some branch of science, as the orrery, cometarium, and the like. See BATTERING-RAM, BALLISTA, &c. In general we may observe, concerning engines, that they consist of one, two, or more of the simple powers variously combined together; that in most of them the axis in peritrochio, the lever, and the screw are the constituent parts; that in all a certain power is applied to produce an effect of much greater moment; and that the greatest effect, or perfection, is when it is set to work with four ninths of that charge which is equivalent to the power, or will but just keep the machine in equilibrio. See the articles MAXIMUM and MECHANICS.

In all machines, the power will just sustain the weight, when they are in the inverse ratio of their distances from the center of motion. See the articles POWER and EQUILIBRIUM.

It being of the utmost importance to diminish the friction of engines, several contrivances have been invented for this purpose. See the article FRICTION.

ENGINE for extinguishing fires, a machine for railing a considerable quantity of water, in one continued stream, for the extinguishing accidental fires.

The best engine of this kind is that of Mr. Newthall, an engine-maker of London, which is so contrived that part of the men who work it, exert their strength by treading, the very best way of working such engines; the whole weight of the body being successively thrown on the forces of the pumps, and even part of a man's strength may be added to the weight, by means of horizontal pieces, to which he may apply his hands when treading. This is the reason why, with the same number of men, his engine will throw
throw water farther, higher, and in greater quantities than any engines of the same size, hitherto contrived. See a perspective view of the whole engine, ready for working, in plate LXXXIX.

ENG

The nature and effect of this engine will be easily understood from a perpendicular section of it represented ibid. n° 2.

The water is raised by the pressure of the atmosphere, by the force of the pistons, and by the spring of condensed air, in the following manner: thus, when the piston \( R \) is raised, a vacuum would be made in the barrel \( T V \), did not the water follow it from the interior canal \( E M \) (through the valve \( H \)) which rises through the glass tube \( E F \),immered in the water of a vessel, by the pressure of the atmosphere on the surface thereof. By the depression of the piston \( R \), the water in the barrel \( T V \) is forced through the superior canal \( ON \), to enter by the valve \( I \), into the air-vessel \( abed \); and the like being done alternately by the other barrel \( WX \), and its piston \( S \), the air-vessel is by this means continually filling with water, which greatly compresses the air above the surface of the water in the vessel, and thereby proportionally augments its spring, which is at length so far increased, as to react with great force on the surface \( YZ \) of the subjacent water; which ascending through the small tube \( ef \), to the stop-cock \( eg \), is there, upon turning the cock \( p \), suffered to pass through a pipe \( b \), fixed to a ball and socket, from the orifice of which it issue with a great velocity, to a very great height or distance, in a small continued stream, directed every way, or to any particular place, by means of the ball and socket.

The greatest artifice of this engine is its contrivance to produce a continued stream, which is done by compression, and the consequent increased elasticity of the air in the barrel \( abed \), called the air-vessel. See the article \( A I R \).

When, therefore, the air-vessel is half filled with water, and the air thereby compressed into half its first space, its spring will be equal to twice the pressure of the atmosphere; so that, on turning the stop-cock \( p \), the air within pressing on the subjacent water with twice the force it meets with from the external air in the pipe \( ef \), will cause the water to spout out of the engine to the height of 32 or 33 feet, if the friction be not too great.

When the air-vessel is \( \frac{2}{3} \) full of water, the space which the air takes up is only \( \frac{1}{3} \) of its first space; whence its spring being three times as great as that of the common air, it will project the water with twice the force of the atmosphere, or throw it to the height of 64 or 65 feet. In the same manner, when the air-vessel is \( \frac{3}{4} \) full of water, the air will project it to the height of 96 or 99 feet; and when \( \frac{4}{5} \) full of water, to the height of 122 feet. Hence it is easy to calculate the different heights to which the water will rise, as in the following table.

<table>

As the air-vessel is the cause of the continued stream, we may naturally infer, that if such an air-vessel were adapted to the common houtic-pump, it would become a useful engine for extinguishing accidental fires. Now this may be effected in the following or some other analogous manner: let \( ABCD \) (ibid. n° 3.) be the barrel of the pump, \( PH \) the rod and piston, \( CW \) the pipe going down to the water of the well at \( W \). Towards the lower part of the barrel is a short tube, by which the air-vessel \( FE \) is fixed to, and communicates with, the barrel of the pump. \( A M N L \) is a collar of leather, so fixed on the top of the barrel, and adapted to the rod, that it may move freely in the leathers, without permitting the air to pass in or out between. The nozzle or spout \( D \) has a stop-cock \( S \), to let out or keep in the water at pleasure. \( Q \) is a piece screwed on to direct the stream, by a small leather-pipe at the end. When the piston is raised from the bottom of the pump-barrel, the water above will be forced into the air-vessel, and there compress the air; it will also compress the air on the top of the barrel, for the water will not be higher than the spout \( D \) at first, when the stop cock is shut; but afterwards,
Pile-Engine, one contrived for driving piles, whereof there are several kinds. See the article Pile.

The most common and simple engine of this kind, as represented in plate XC. fig. 1. no 1., consists of the sill K I, and the frame F L, on which are fixed the upright pieces L H, L G, supported by the side braces C, C, and the hind brace F E (which has pins on it to make it serve as a ladder) and held together by a square collar E D. The rammer A, being a very heavy piece of wood, or iron, slides up and down between the cheeks or upright pieces L H, L G, and is drawn up by means of its hook B, with two ropes H O, G O, having each five smaller ropes with handles at N, N, for ten men to pull up the rammer to a certain height (the great ropes running over two pulleys or rollers on the iron-pin. H G) and then let it fall again all at once upon the head of the pile at M, to drive it into the ground. Now, suppose the rammer A, weighs 500 lb, and falls the height of one foot, it will fall that height in a quarter of a second, and consequently have a velocity able to carry it uniformly 4 feet in the same time, that is, at the rate of 8 feet in a second, at the very instant it strikes the pile M. Therefore, measuring the mass by the velocity, viz. 500 x 8 we shall have 4000 for the momentum of the rammer with such a fall. See the article Descent. But if the rammer be raised up to the height of four feet, it will fall that height in half a second, and have, at the time of percussion, a velocity to carry it 8 feet in half a second, without any farther help from gravity, so that we must now multiply 16 feet (the present velocity, since it goes at the rate of 16 feet in a second) by 500, the mass of the rammer, which will give us a double momentum, wherewith it will strike the pile in the last case: for 500 x 16 = 8000. If we consider any other height from which the rammer falls (for one may employ a captain) windlasses, or pulleys to raise it to a very great height) the momentum with which it strikes the pile, will always be as the square root of the height from which the rammer fell.

If a pile is to be driven obliquely, the engine must be set so that the cheeks may have the same obliquity, and the blow will still be perpendicular to the head of the pile; but then the force of the blow must not be estimated from the length, but from the height of the descent, in the manner already shown.

Mr. Paulet's Engine for driving piles, used at the new bridge of Wilmington, is constructed as follows. A (plate XC. no 2.) is the great shaft, on which are the great wheel and drum: B the great wheel with coggs, that turns a trundle-head with a fly, to prevent the horse's falling when the ram is discharged; C the drum on which the great rope is wound; D the follower (with a roller at one corner) in which are contained the tongs, to take hold of the ram, and are fastened to the other end of the great rope, which passe over the pulley, near the upper end of the guides between which the ram falls; E the inclined planes, which serve to open the tongs, and discharge the ram; F the spiral barrel that is fixed to the drum, on which is wound a rope with a counterpoise, to hinder the follower from accelerating, when it falls down to take up the ram; G the great bolt which locks the drum to the great wheel; H the small lever, which has a weight fixed at one end, passe through the great shaft below the great wheel, and always tends to push the great bolt upwards, and lock the drum to the great wheel; I the forcing bar, which passe thro' the hollow axis of the great shaft, bears upon the small lever, and has near the upper end a catch by which the crooked lever keeps it down; K the great lever, which presses down the forcing bar, and discharges the great bolt at the time the long end is lifted up by the follower; L the crooked lever, one end of which has a roller, that is pressed upon by the great rope, the other end bears upon the catch of the forcing bar during the time the follower is descending; M the spring that presses against the crooked lever, and discharges it from the catch of the forcing bar as soon as the great rope slackens, and gives liberty to the small lever to push up the bolt.

By the horse's going round, the great rope is wound about the drum, and the ram is drawn up, till the tongs come between
Steam-engine, a machine to raise water by fire, or rather by the force of water turned into steam.

The following is a description of this engine in its first state, and original simplicity. ABC (plate XCI. fig. 2.) is a copper-vessel, partly filled with water to DE, which, being let over a fire and made to boil, will fill the upper part DBE with an elastic vapour, the sufficient strength whereof is known by its forcing open a valve at e: this heated elastic steam is, by turning a cock at F, let into the barrel abcd, where, by its elastic force, it raises the piston G, which drives the air above it through a proper check at the top. After this, that the piston may by its weight descend, a little cold water from the cistern fighi, is let in at the bottom by turning a cock at k, which, in form of a jet, condenses the hot steam in the barrel into 15000 times less space than before it took up, which makes a sufficient vacuum for the piston to defend in. The piston G, and lever HI being thus put into motion, do accordingly raise and depress the piston K. in the barrel of the forcing pump LM, on the other side, which, by the pipe N, draws the water from the depth W, and forces it to rise and spout through the tube O, continued to any height at pleasure. See pump. Thus is the steam-engine a very simple and plain machine, where a very powerful stroke for working of pumps is performed by only turning two cocks alternately; and yet a person who knows nothing of it, would imagine it to be very complex, by the number of parts that offer themselves to view. But here we must distinguish between what performs the material operations of the engine, and what serves for convenience and the just regulation of the said operations; for not above the hundredth part of the power of this engine is employed to turn the cocks and regulate all the motions, as will appear from what follows.

The structure of the steam-engine, as used at present, is represented in plate XCI. n° 1., concerning which we are to observe, 1. That there may be always water in the cistern g, to inject into the steam to condense it, there is an arch z, fixed near the arch H, at the pump end, from whence another pump-rod k, with its piston, draws water from a small cistern near the mouth of the pit, supplied from the water raised at p, and forces it up the pipe mmm, to keep the injecting cistern g always full. 2. As the piston C, which moves up and down the cylinder ought to be air-tight, a ring of leather, or a piece of match, which lies upon its circumference next to the inside of the cylinder, must be kept moist and swelled with water; this is supplied from the injecting cistern by a small pipe z, always running down upon the piston, in a very small quantity, if the work be well performed. L is a leaden cup, whose office is to hold the water that lies on the piston, left it should flow over. When the piston is arrived at its greatest height in the cylinder, as W, at which time if the cup is too full, the water will run down the pipe LV, into the waffewell at Y. 3. As the water, in the boiler B, must waste by degrees, as it is constantly producing steam, and that steam continually let out for working the engine, there ought to be a constant supply of the water to boil: this is performed by means of the pipe Ff, about three feet long, going down a foot under the surface of the water in the boiler, with a funnel F, at top, always open, and supplied by the pipe W, with water from the top of the cistern, which has the advantage of being always warm, and, therefore, not apt to check the boiling of the water in the copper. 4. That the boiler may not have the surface of the water too low (which would endanger burfting) or too high (which would not leave room enough for steam) there are two gauge-pipes at G, one going a little below the surface of the water when at a proper height, and the other standing a little above it: when every thing is right, the stop-cock of the shorter pipe being opened gives only steam, and that of the long one
one water; but if otherwise, both cocks will give steam when the surface is too low, and both give water when it is too high; and hence the cock which feeds the boiler at F may be opened to suffice a degree as always to keep the surface of water to its due height. 5. As cold water is injected into the cylinder at every stroke, and as that water might in time fill the cylinder, and hinder the operation of the engine, there is a pipe coming from the bottom of the cylinder \( dT \), called the eduction pipe, through which the water that has been injected, comes down every time the steam is let into the cylinder. This eduction pipe goes an inch or two under water in the waite well \( Y \), and having its end turned up is shut with a valve \( Y \) to keep out the air from prefling up the pipe, but permitting the injected air coming the other way to be discharged; by which means the cylinder is kept empty. 6. Left the steam should grow too strong for the boiler, and burst it, there is a valve fixed at \( b \) with a perpendicular wire:standing up from the middle of it, to put weights of lead upon, by which to examine the strength of the steam pushing against it from within. Thus the steam is known to be as strong as the air, if it will raise up so much weight on the valve as is at the rate of \( x_{16} \) to an inch square; because that is the weight of the air, nearly, on every inch square. When the steam becomes stronger than what is required, it will lift up the valve and go out. This valve is called the puppet-clack. 7. The steam is always in a fluctuating condition, yet never \( \frac{1}{2} \) stronger or weaker than common air. For it has been found that the engine will work well, when there is the weight of one pound on every square inch of the valve \( b \). This shows that the steam is then \( \frac{1}{2} \) part stronger than the common air. Now as the height of the feeding pipe from the funnel \( F \) to the surface of the water \( S \) is not above three feet, and \( 3 \frac{3}{4} \) feet of water is \( \frac{7}{8} \) of the preflure of air; if the steam were \( \frac{1}{8} \) part stronger than air, it would push the water out at \( E \); which since it does not do, it cannot be stronger than air, even in this case, where the regulator being shut, it is most of all confined. 8. When the regulator is open, the steam gives the piston a push on the underside, then occupying more space, the steam comes to be a balance only for the outward air, and so only sustains the piston; but the over weight of the pump-rod at the contrary end of the beam \( b \), \( d \), draws up the piston beyond \( C \) as far as \( W \). The steam, then, expanded so as to fill all the cylinder, would not quite support it, if it was not for the over weight above-mentioned. If this was not true, when the end \( b \) is down as low as it can go, and rests upon the beams that bear its center, the chain \( L H \) above the piston would grow slack, and the piston might sometimes be pushed out of the cylinder, which never happens. Again, when first the steam is let into the cylinder, the injected water is pushed out at the eduction pipe \( dT \), and is all out of the cylinder by that time the piston is got up to \( C \). If then the steam was stronger than air, it would fly out at \( Y \) after the water, the valve \( Y \) not being loaded. If it were exactly equal to the strength of the air, it would just drive all the water out at \( Y \), but could not follow itself, the pressure being equal on each side of the valve by supposition. If it be weaker than the air, it will not force all the water out of the pipe \( dT \), but the surface will stand, suppose at \( T \), where the column of water \( T Y \) added to the strength of the steam, is equal to the preflure of the air. When the steam is \( \frac{1}{8} \) weaker than the air, the height \( T Y \) is equal \( 3 \frac{1}{2} \) feet. Now since the whole perpendicular distance from \( d \) to \( Y \) is but four feet, and the steam is always sufficient to expel the water; it is plain it can never-be more than \( \frac{1}{8} \) part weaker than the air, when weakest. 9. As there is air in all the water injected, and that air cannot be taken out, or condenfed with the steam by the jet of cold water coming in at \( n \), the whole operation would be disturb'd, and only a very imperfect vacuum made, were it not for the following contrivance. We are to remember that when steam is become as strong as air, it is above sixteen times rarer; so that air will precipitate in steam, as quicksilver would in water. Therefore all the air extricated from the injected water, lies at the bottom of the cylinder over the surface of so much of the injected water as is come down to \( d \). Now there is without the cylinder at \( 4 \), a little cup with a valve, and from 6 X
the cylinder above its bottom to receive the air into the cup. When, therefore, the steam first rushes into the cylinder, and is a little stronger than the outward air, it will force the precipitated air to open the valve at 4, and make its escape; but the steam cannot follow, because it is weaker than the external air, as the piston, by ascending, gives it room to expand. This valve from the noise it makes is called the sniffling cock. 10. But amongst the greatest improvements of this engine, we reckon that contrivance by which the engine itself is made to open and shut the regulator and injection-cock, and that more nicely than any person attending could possibly do it. For if the man who turns the regulator at E, and the injection cock N, when the piston is coming down, opens the regulator and lets in the steam too soon to raise the piston again, the stroke will be shorter than it ought to be; and if he does not open the regulator soon enough, the piston coming down with a prodigious force, will very probably strike against the throat pipe D at d, and crush it to pieces. Likewise when the regulator is open, the steam going into the cylinder, and the piston rising, the stroke will not have its full length, if the steam is turned off, and the cold water injected too soon; and if injected too late, the steam may throw the piston quite out of the cylinder's top at L. To prevent, therefore, all such accidents, there is fixed to an arch Z, at a proper distance from the arch P, a chain, from which hangs a perpendicular piece, or working beam Q Q, which comes down quite to the floor, and goes through it in a hole which it fits very exactly. This piece has a long slit in it, and several pin holes and pins for the movement of several levers defined to the office of opening and shutting the cocks after the following manner. 11. Between two perpendicular pieces of wood on each side of P, there is a square axis AB (ibid. n° 2.) which has upon it several iron pieces of the lever kind. The lift is the piece CED called the Y, from its representing that letter inverted by its two shanks, E and D; on the upper part is a weight F, to be raised higher and lower, and fixed as occasion requires. This Y is fixed very fast upon the said iron axle AB.

12. From the axle hangs a sort of an iron stirrup, IKLG, by its two hooks IG, and having on the lower part two holes K L, through which paffes a long iron pin L K, and keyed in the fame. When this pin is put in, it is also paffed through the two holes in the ends E N of the horizontal fork or spanner E Q N, joined at its end Q to the handle of the regulator V 10. From Q to O are several holes, by which the said handle may be fixed to that part of the end which is most convenient. 13. Upon the axis AB is fixed at right angles to the Y an handle or lever G 4, which goes on the outside of the piece QQ, and lies between the pins. Another handle is also fastened upon the same axle, viz. H 5, and placed at half a right angle to the former G 4; this paffes through the slit of the piece QQ, lying on one of its pins. Hence we see that when the working beam goes up, its pin in the slit lifts up the spanner H 5, which turns about the axle so fast, as to throw the Y with its weight F from C to 6, in which direction it would continue to move after it paffed the perpendicular, were it not prevented by a strap of leather fixed to it at a, and made fast at the ends m and n, in such manner as to allow the Y to vibrate backwards and forwards about a quarter of a circle, at equal distance on this side and that of the perpendicular. 14. As things are represented in the figure, the regulator is open, its plate TY being shewn on one side of the pipe S, which joins the cylinder and boiler. The piston is now up, and the working beam near its greatest height, the pin in the slit has so far rais'd the spanner H 5, that the weight F on the head of the Y is brought so far from n, as to be past the perpendicular and ready to fall over towards m, which when it does, it will by its shank E, strike the iron pin K L with a smart blow, and drawing the fork ON horizontally towards the beam Q, will draw the end 10 of the regulator towards z, and thereby shut it, by flipping the plate Y under the holes of the throat-pipe S. 15. Immediately after the regulator is shut, the beam rising a little higher with its pin S on the outside upon the lower part, lifts up the end i of the handle of the injecting-cock, and opens it by the turning of the two parts with teeth. The jet immediately making a vacuum, the beam again descends, and the pin r depressing
depressing the handle $k$, shuts the injection-ock; and the beam continuing to descend, the pin $p$ bears down the handle $G$, and throwing back the $Y$, its shank $D$ throws forward the fork $N$, and again opens the regulator to receive fresh steam. After every thing returns as before, and thus is the engine most wonderfully contrived to work itself.

16. Many years after the engine had been made, as above described, it received another improvement of very great advantage, and that was, instead of feeding the boiler with warm water, from the top of the cylinder (fig. n°. 2) by the pipe $W$ above, and $F$ below, they contrived to supply it with the scalding hot water which came out of the education-pipe $T Y$, which now, instead of going into the waste well at $Y$, was turned into the boiler on the top, and as the education pipe before went out at the side of the cylinder, it was now inserted in the bottom of it; and though the pressure of the steam in the boiler be somewhat stronger than in the cylinder, yet the weight of water in the education-pipe being added to the force of steam in the cylinder will carry the water down continually, by overcoming the resistance in the boiler.

This is the lever-engine with the improvements of Mr. Newcomen and others; but as captain Savary's, or rather the marquis of Worcester's, is very cheap in respect of this machine, and as it is also applicable with great advantage when the height to which the water is to be raised does not exceed 100 or 150 feet, we shall here subjoin a view of that engine, with the improvements of Dr. Defaguirers.

The boiler $B B$ (plate XCII.) is a large copper body of a globular form, which will hold all withstanding the very great force of steam that in this case is necessary. Round the body of this boiler the fire and flame are conducted as shewn at $T T T$. It has a copper-cover screwed on, which contains the steam-pipe $C D$, and two gage-pipes $n, o$, which by turning their cocks, shew the height of the water within as in the other engine. On the same cover $F$ is a valve, over which lies a feel-yard, with its weight $Q$ to keep it down, the strength of the vapour being this way most exactly estimated. For being in the nature of a lever of the third sort, it is plain, if the beam of the lever be divided into ten equal parts, and the first of them be upon the middle of the valve, and the weight $Q$ hangs at the $2d$, $3d$, $4th$, &c. divisions, that then the force of the steam which can raise up the valve will be $2$, $3$, $4$, &c. times as great as the weight. If the area of the valve be a square inch, and $Q = 15$ lb. hanging at the second division is raised by a steam pushing up the valve, it will shew that the steam will then press with the force of two atmospheres, and so on to ten atmospheres; but great care must be then taken that the steam fo very strong burst not the boiler to pieces. The steam is carried from the boiler to a copper-veffel $A$, by means of the pipe $C D$, and is let into it by turning the handle $K$ of the steam-cock $D I$. The key of this cock is kept down by the screw $L$, held up by the gibbet $D L$. The handle turned from $K$ to $k$ admits a passage to the steam into the copper-receiver $A$.

This receiver $A$ communicates at bottom with the sucking pipe $Z H$ going down to the water $H$ in the well $X$, and above with the forcing pipe $E E$, which goes up a little above the water of the reservoir $R$, and between these pipes are two valves $F$ and $G$ both opening upwards. The steam being let in upon the water of the receiver $A$, forces it up through the valve $F$, and the pipe $E E$ to the reservoir, and then the receiver is full of hot steam. This steam in the receiver is condensed by a jet of cold water coming from the forcing pipe by the small pipe $M I$, being let in and shut off by the cock at $M$. The steam being condensed by this jet will be reduced within a very small space, and so make a vacuum, upon which the water in the well will rush up the forcing pipe to restore the equilibrium, and thus again fill the receiver $A$, the little air being compassed within a small compass at the top above $B C$. That there may be always water in the forcing-pipe for the jet, there is a little pipe which brings the water to it from the reservoir with the small stop-cock $Y$, to shut it off upon occasion. The valves at $F$ and $G$ are examined at any time by unscrewing the pin $r$ to loosen the flap $2$, and let down the flanch $3$, all which parts are shewn larger in the figures n°. 5. By the particular contrivance of the cock at $D I$, and its key, the water is made to pass from the force-pipe to the boiler to supply the waste in steam.
steam. This is plainly shewn in the sections of the cock and key, where $5$ is the top of the key, $6$ is a hole on one side, which goes down to the bottom to convey the steam, or jet of water alternately to the receiver; $7$ is a notch on the other side to take in the water from the force-pipe, and conduct it to the boiler $B$. How this is done is easy to conceive from a view of the two sections of the cock and key, in two positions within it. The boiler may hold about five or six hogheads, and the receiver one hoghead. It will work four or five hours without recruiting: about four strokes a minute will produce upwards of 200 hogheads per hour. This steam makes a vacuum so effectually, as to raise water from the well to the height of twenty-nine or thirty feet; and suppose the steam able to lift up the steel-yard with its weight hanging at the 6th division, it will then be able to raise a column of water above fifty yards high, as being then six times stronger than the preffure of the atmoßphere, as is easily understood from what has been laid upon the fire-engine, the water being raised in a familiar manner in both machines, there by the preffure of condensed elastic air, and here by the preffure of rarefied elastic steam. See the article ENGINE for extinguishing fires.

This engine consists of so few parts, that it comes very cheap in proportion to the water that it raises, but it has its limits. On the other hand, the lever-engine, often called Newcomens, has its limits 150; that is, it must not be too small, for then it will have a great deal of friction in proportion to the water that it raises, and will cost too dear; having as many parts as the largest machines, which are the best and cheapest in proportion to the water they raise. In the philosophical transactions there is an account of an improvement made in the steam-engine by Mr. Payne, as follows. He has contrived two iron-pots or vessels of a conical form inverted as represented by $ABEF (n^o 6.)$ on the upper part of which is fixed a globular copper-head, of about $5\frac{1}{2}$ feet diameter, as $LMN$. Then there is placed on the inside a small machine $H$, called the dispenser, with spouts $abcde$, &c., round the sides fixed to it, and the bottom thereof reds on a center pin $O$. In this machine is fixed an upright tube $G$ with holes at the bottom, and a funnel $P$ on the top, to receive a spout of water from a conduit-pipe $Q$, by the stop-cock $R$. Two or more of these vessels are placed in a reverberatory arch for conveying the intense heat of a strong fire, the flame whereof encompasses the iron-vessels, and keeps them in a red heat during the time of their use, at which time the cog-wheel $I$ being turned by proper machinery, whirls the dispenser about with great velocity, and cause the water in it to fly through the spouts against the sides of the red hot pots. By this means, the greatest part of the water is converted into vapour or elastic steam, which is conveyed by a common pipe and cock to the barrel of the engine to put the piston in motion, and the waffe water is conveyed away at bottom by means of a pipe $C_D$, with a valve at $D$ to keep out the air.

Before we conclude the subject of steam-engines, we shall add a most curious and useful table of the calculation of the power of the lever-engines, for the various diameters of the cylinder, or steam-barrel, and bore of the pump that are capable of raising water from 48 to 440 hogheads per hour, at any depth from 15 to 100 yards. It was composed by Henry Beighton, and is founded on this principle, that the ale-gallon of 282 cubic inches of water weighs 101.5, 33. averdupois, and a superficial square inch is pressed with the weight of 14th 13\frac{1}{3} of air, when the mercury stands at a medium in the barometer. But allowing for several frictions, and to give a considerable velocity to the engine, it is found by experience that no more than 315 of preffure must be allowed to an inch square on the piston in the cylinder, that it may make about sixteen strokes in a minute at about six feet to each stroke. This calculation is but the ordinary power in practice, for with large boilers the piston will make twenty or twenty-five per minute, and each of them seven or eight feet; and then a pump of nine inches bore will discharge more than 320 hogheads per hour, and for other sizes proportionally.

Table
Table showing the Diameter of the Cylinder and Bore of the Pump, that is capable of raising any Quantity of Water, from 48 to 440 Hogsheads an Hour, at any Depth from 15 to 100 Yards.

An example of the use of the table. Suppose it were required to draw 150 hogsheads per hour, at 90 yards deep: in the seventh column I find the nearest number 149 hogheads; and against it, in the first column, I find a seven inch bore; then, under 90, the depth, on the right in the same line, I have 27 inches, the diameter of the cylinder fit for that purpose: and so for any other.

*Water-Engines*, those made for raising water: such is the steam-engine, already described. See also *Water-works*, where several curious engines of this kind, moved by water, will be described.

**Engineer**, or **Engineer**, properly denotes a contriver, or maker, of engines. See the preceding article. **Engineer**, in the military art, an able, expert man, who, by a perfect knowledge in mathematics, delineates upon paper, or marks upon the ground, all forts of forts, and other works proper for offence and defence. He should understand the art of fortification, so as to be able, not only to discover the defects of a place, but to find a remedy proper for them, as also how to make an attack upon, as well as how to defend, the place. Engineers are extremely nec-
ENG [1074] ENG

celary for these purposes: wherefore it is requisite that, besides being ingenious, they should be brave in proportion. When at a siege the engineers have narrowly surveyed the place, they are to make their report to the general, by acquainting him which part they judge the weakest, and where approaches may be made with most success. Their business is also to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries, and lodgments, taking care that none of their works be flanked or discovered from the place. After making a faithful report to the general of what is a doing, the engineers are to demand a sufficient number of workmen and utensils, and whatever else is necessary.

ENGLAND, the southern division of Great Britain, situated in the Atlantic ocean, between 2° east and 6° west longitude, and between 49° 55' and 55° 55' north latitude. There are in England, including Wales, fifty-two counties, two archbishops, twenty-four bishoprics, two universities, twenty-nine cities, upwards of eight hundred towns, and near ten thousand parishes; supposed to contain about 7,000,000 of people.

As to the polity, trade, law, civil and religious antiquities, &c. of England, their several branches are treated of under the articles PARLIAMENT, PRIVY COUNCIL, COURT, CUSTOM-HOUSE, ADMIRALTY, &c.

NEW-ENGLAND, comprehending the colonies of Massachusetts, New Hampshire, Connecticut, Rhode Island, and Providence Plantation, is situated between 67° and 73° west longitude, and between 41° and 45° north latitude. The provinces into which New England is divided, have different constitutions, and generally different governors, who have a negative voice in the choice of the members who are to serve as their council; and besides, all laws must be sent to Old England to receive the approbation of the crown, and no act of government is valid without the governor's consent in writing.

ENGLECERIE, ENGLESHIRE, or ENGLISHERY, an ancient word signifying the being an Englishman, which was used in the time of King Canutus, to distinguish the English from the Danes, especially in the case of murder, and its punishment; as where a person was privately killed, such a person was deemed francigena, which comprehended every alien, till englecery was proved; that is to say, till he was made out to be an Englishman, in which case the town, &c. wherein it was committed, was exempted from amercement, which it was liable to if the murderer of a Dane escaped out of it unpunished. The manner of proving the party slain to be an Englishman, was before the coroner, by two men that knew his father, and two women that knew his mother. This was taken away by statute 14 Ed. III. c. 4.

ENGLISH, or the ENGLISH-TONGUE, the language spoken by the people of England, and, with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The antient language of Britain is generally allowed to have been the same with the gaulic, or French; this island, in all probability, having been first peopled from Gallia, as both Caesar and Tacitus affirm, and prove by many strong and conclusive arguments, as by their religion, manners, customs, and the nearness of their situation. But now we have very small remains of the antient British tongue, except in Wales, Cornwall, the islands and highlands of Scotland, part of Ireland, and some provinces of France; which will not appear strange, when what follows is considered.

Julius Cæsar, some time before the birth of our Saviour, made a descent upon Britain, though he may be said rather to have discovered than conquered it; but, about the year of Christ forty-five, in the time of Claudius, Aulus Plautius was sent over with some Roman forces, by whom two kings of the Britons, Codigunus and Caractacus, were both overcome in battle: whereupon a Roman Colony was planted at Malden in Essex, and the southern parts of the island were reduced to the form of a Roman province: after that, the island was conquered as far north as the Firths of Dumbarton and Edinburgh, by Agricola, in the time of Domitian; whereupon, a great number of the Britons, in the conquered part of the island, retired to the west part called Wales, carrying their language with them.

The greatest part of Britain being thus become a Roman province, the Roman legions,
Legions, who resided in Britain for above two hundred years, undoubtedly disseminated the Latin tongue; and the people being afterwards governed by laws written in Latin, must necessarily make a mixture of languages. This seems to have been the first mutation the language of Britain suffered.

Thus the British tongue continued, for some time, mixed with the provincial language of Britain suffered. Latin, till, the Roman opportunity to attack and harass England: upon which, K. Vortigen, about the year 440, called the Saxons to his assistance, who came over with several of their neighbours, and having repulsed the Scots and Picts, were rewarded for their services with the island of Thanet, and the whole county of Kent: but growing too powerful, and not being contented with their allotment, dispossessed the inhabitants of all the country on this side of the Severn: thus the British tongue was in a great measure destroyed, and the Saxon introduced in its stead.

What the Saxon tongue was long before the conquest, about the year 700, we may observe in the most antient manuscripts of that language, which is a gloss on the Evangelists, by bishop Edfrid, in which the three first articles of the Lord's prayer run thus: "Uren fader thie arth in heofnos, sic "gehalgud thin noma, so cymeth thin "ric. Sic thin willa sue is heofnos, and "in eorthe, &c." In the beginning of the ninth century, the Danes invaded England, and getting a footing in the northern and eastern parts of the country, their power gradually increased, and they became sole masters of it in about two hundred years. By this means the antient British obtained a tincture of the Danish language: but their government, being of no long continuance, did not make so great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, A.D. 1067, was subdued by William the Conqueror, duke of Normandy in France: for the Normans, as a monument of their conquest, endeavoured to make their language as generally received as their commands, and thereby rendered the British language an entire medley.

About the year 900, the Lord's prayer in the antient Anglo-Saxon, ran thus: "Thu ure fader the eart on heofenum, "fi thin nama gehalgod; cume thin "rice fi thin willa on eorthan swa, twa "on heofenum, &c."

About the year 1100, under Hen. II., it was rendered thus by pope Adrian, an Englishman, in rhyme:

"Ure fader in heaven rich, "Thy name be huyed ever lich, "Thou bring us thy michell blisse: "Als hit in heaven y-doe "Evar in yeart beene it alfo, &c."

Dr. Hicks gives us an extraordinary specimen of the English, as spoken in the year 1585, upon the very subject of the English tongue.

"As it is know by how many maner "peole beeth in this lond; there beeth "alto fo many dyvers longages and "tonges. Notheles Walchemen and "Scots that beeth nought medled with "other nations, holdeth wel nyh hr "fire langage and speche; but yif the "Scottes that were sometyme confederat "and woned with the pites drawer "somewhat after hir speche; but the "Flemynge that woneth on the wolfe "side of Wales, haveth loft her strange "spech and speketh fexonliche now. "Alto englifhemen, they had from "the bygynynge thre maner speche: "northerne, southerne, and middel "speche in the middel of the lond, as "they come of three maner of peole of "Germania: notheles with commynation "and mellynge firft with Danes, and "afterwards with Normans in meny "the contrary langage is apayred. "(corrupted.)

"This apayrynge of the burthe of the "tunge is bycaule of tweie thinges; "oon is for children in scole agenfhit "the ufigage and maner of all other "nations, beeth compelle for to leve "hire own langage, and for to con­ "true hire lefson and here thynges in "French, and fo they haveth ferhe Nor­ "mans come firft into Engeland. Alto "gentlemen children beeth taught to "speke Frenliche from the ymyne that "they beeth rokke in here cralde, and "kunneth speke and play with a childes "broche; and uplundifche men will "lykne hymself to gentilmen, and "fondeth with great belynennes for to "spekffe Frenliche to be told of,---Hit "seemeth a greet wonder how englifheme­ "men and her own langage and tounge "is fo dyverse of fown in this con "lond; and the lions of Nor­ "mandie
mandie is comlynge of another lond,
and hath oon manner foun amonge.
alle men that speketh hit aright in
Engelond. Allo of the forefaid
saxon tonge that is deiled (divided) a
three, and is aside scarceliche with
fewe uplandiffhe men is great wonder.
For men of the eff, with men of the
gwell, is, as it were, undir the same
partie of hevene acordeth more in
fownyng of speche, than men of the
north, with men of the south. There-fore it is that merci, that beeth men
of myydel Engelond, as it were, par-
teners of the endes, underfondeth
better the fide longages northerne, and
southerne, than northerne or southerne
underfondeth either other. -- All the
longage of the Northumbers and
specialliche at York, is fo scharp,
flitting and frotynge, and unshape,
that we southerne men may that
longage unnethe underfonde, &c.

"Hick's Thefaur. liter. lef." In the year 1537, the Lord's prayer was
printed as follows: "Ooure father
which arte in heven, halowed be thy
name: let thy kingdome come, thy
will be fulfilled as well in erth as it
is in heven; give us this daye in
dayly bred, &c." Where it may be
observed that the diction is brought al-
mot to the present standard, the chief
variations being only in the orthography.
By these instances, and many others
that might be given, it appears, that the
english saxon language, of which the
Normans defpoiled us in a great measure,
had its beauties, was signifcant and em-
phatical, and preferable to what they
imposed on us. "Great, verily," says
Camden, "was the glory of our tongue,
before the norman conquest, in this,
that the old english could express,
most aptly, all the concepions of the
mind in their own tongue, without
borrowing from any." Of this he
gives several examples.
Having thus shewn how the antient
british language was, in a manner, ex-
tiripated by the Romans, Danes, and
Saxons, and succeeded by the Saxon, and
after that the Saxon blended with the
Norman French, we shall now mention
two other caufes of change in the lan-
guage: the first of these is owing to the
Britains having been a long time a trading
nation, whereby offices, dignities, names
of wares, and terms of traffic are in-
troduced, which we take with the
wares from the persons of whom we
have them, and form them anew, ac-
cording to the genius of our own tongue;
and besides this change in the language,
arising from commerce, Britains having
been a considerable time subject to the
see of Rome, in ecclesiastical affairs,
must unavoidably introduce some italian
words among us. Secondly, as to the
particular properties of a language, our
tongue, has undergone no small muta-
tion, or rather has received no small im-
provement upon that account: for, as
to the Greek and Latin, the learned have,
together with the arts and sciences, now
rendered familiar among us, introduced
abundance; may almost all the terms of
art in the mathematics, philolophy, phy-
sic, and anatomy; and, we have ent-
tained many more from the Latin,
French, &c., for the sake of neatness and
elegancy: so that, at this day, our
language, which about 1800 years ago,
was the antient Britifh, or Welsh, &c.
is now a mixture of Saxon, Teutonic,
Dutch, Danifh, Norman, and modern
French, embellifhed with the Greek and
Latin. Yet this, in our opinion, is fo
far from being a disadvantage to the
english tongue, as now spoke (for all
languages have undergone changes, and
do continually participate with each
other) that it has fo enriched it, as now
to become the most copious, signifcant,
fluent, courteous, amourous and malifcule
language in Europe, if not in the
world: This, indeed, was Camden's
opinion of it in his time, and Dr.
Heylin's in his time: if then the english
tongue, in the opinion of thofe learned
authors, deferved such a character in their
days, how much more now, having
since received fo considerable improve-
ments from fo many celebrated writers.

ENGONASIS, a name given to the con-
stellation Hercules. See Hercules.

ENGRAFTING, or GRAFTING, in gar-
dening. See the article GRAFTING.

ENGRAILED, or INGRAILED, in he-
eraldry, a term derived from the french
grefy, bail; and signifying a thing the
bail has fallen upon and broke off the
edges, leaving them ragged, or with
half rounds, or semicircles, struck out of
their edges.

ENGRAVING, the art of cutting metals
and precious stones, and representing
thereon figures, letters, or whatever de-
vice, or design, the artist fancies.

Engraving, properly a branch of skul-

ENG

ENG

ture, is divided into several other branch-

es, according to the matter wherein it

is employed, and the manner of per-

forming it. See the article SCULPTURE.

The original way of engraving on wood

is denominated, at present, with us, by

cutting in wood; that on metals with

aquafortis, is named etching; that by

the knife, burnisher, punch, and scraper,
is called mezzotinto; that on stones

for tombs, &c. stone-cutting; and that per-

formed with the graver, on metals or

precious stones, keeps alone the primitive

name of engraving, being that which

we shall at present attend to. See the ar-
ticles CUTTING, ETCHING, MEZZO-

TINTO, and STONE-CUTTING.

ENGRAVING on copper, is employed in re-

prenting portraits, histories, landscap-
s, figures, buildings, &c. either

after paintings, or designs, for that pur-

pose. See DESIGN and PAINTING.

It is performed with the graver on a

plate of copper, which, being well

polished, is covered over thinly with

virgin-wax, and then smoothed, while

waxing, with a feather, so that the wax

be of an equal thickness on the plate;

and on this the draught or design, done

in black lead, red chalk, or ungummed

ink, is laid with the face of the draw-
ing on the wax; then they rub the back-

side, which will cause the whole design

of the drawing to appear on the wax.

The design, thus transferred, is traced

through on the copper, with a point, or

needle; then heating the plate, and

taking off the wax, the strokes remain

to be followed, heightened, &c. accord-
ing to the tenor of the design, with the

graver, which must be very sharp, and

well pointed. See the article GRAYER.

In the conduct of the graver consists al-
mot all the art, which depends not so

much upon rules as upon practice, the

habitude, disposition, and genius of the

artist, the principles of engraving being

the same with those of painting; for if

an engraver be not a perfect master of

design, he can never hope to arrive at a

degree of perfection in this art. In con-
ducting the strokes, or cuts, of the graver,

he must observe the action of the fingers,

and of all their parts, with their out-
lines; and remark how they advance

towards, or fall back from his sight, and

then, conduct his graver, according to

the ridings or cavities of the muscles, or

folds, widening the strokes in the light,

and contrasting them in the shades;
as also at the extremity of the outlines,
to which he ought to conduct the cuts
of the graver, that the figures or objects
represented, may not appear as if they
grown; and lightening his hand, that the
outlines may be perfectly found,
without appearing cut or flat; and, al-
though his strokes necessarily break off
where a muscle begins, yet they ought
always to have a certain connection with
each other, so that the first stroke should
often serve to make the second, be-
cause this will shew the freedom of the
graver.

If hair be the subject, let the engraver
begin his work by making the outlines
of the principal locks, and sketch them
out in a careless manner, which may be
finished, at leisure, with finer and

thinner strokes to the very extremities.

The engraver must avoid making very
acute angles, especially in representing
fefts, when he crosses the first strokes
with the second, because it will form a

very disagreeable piece of tabby-like
lattice-work, except in the representa-
tion of some clouds, in tempests, the
waves of the sea, and in representations
of skins of hairy animals, and leaves
of trees. So that the medium between

square and acute seems to be the best

and most agreeable to the eye. He that
would represent sculpture, must re-

member that, as statues, &c. are most

commonly made of white marble, or

stone, whose colour does not produce

such dark shades as other matters do,

have no black to their eyes, nor hair

of the head, and beard flying in the air.

If the engraver would preserve one
quality and harmony in his works, he
should always sketch out the principal
objects of his piece before any part of
them are finished.

The instruments necessary for this sort of
engraving are, besides a graver, a

cushion, or hand bag, made of leather,
to lay the plate on, in order to give it

the necessary turns and motions; a bur-

nisher made of iron, or steel, round at

one end, and usually flattish at the other,
to rub out slips and failures, soften the

strokes, &c. a scraper, to pare off the

surface, on occasion; and a rubber of

a black hat, or cloth rolled up, to fill

up the strokes that they may appear

the more visible.

In engraving on precious stones, they use

either the diamond, or the emery. The

diamond, which is the hardest of all

stones,
stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving, is to cement two rough diamonds to the ends of two sticks big enough to hold them steady in the hand, and to rub or grind them, against each other, till they be brought to the form desired. The dust, or powder that is rubbed off serves afterwards to polish them, which is performed with a kind of mill that turns a wheel of soft iron. The diamond is fixed in a brass-dish, and, thus applied to the wheel, is covered with diamond-dust, mixed up with oil of olives; and when the diamond is to be cut facet-wise, they apply first one face, then another, to the wheel. Rubies, sapphires, and topazes, are cut they begin with the wheel, and then are moistened from emery and water, and polished with tripoli, on a pewter wheel. Lapis-lazuli, they give it a self, which, that, when the stone is held, the jewellery or other wise, the relievo or otherwise the tools being moistened, from time to time, with diamond-dust and oil; or, at least, emery and water. To engrave figures or devices on any of these stones, when polished, such as medals, seals, &c. they use a little iron wheel, the ends of whose axis are received within two pieces of iron, placed upright, as in the turner's lathe; and to be brought closer, or set further apart, at pleasure: at one end of the axis are fitted the proper tools, being kept tight by a screw. Lastly, the wheel is turned by the foot, and the stone applied by the hand to the tool, and is shifted and conducted as occasion requires.

The tools are generally of iron, and sometimes of brass; their form is various, but it generally bears some resemblance to chisels, gouges, &c. Some have small round heads, like buttons, others like ferrets, to take the pieces out, and others flat, &c. when the stone has been en-graven, it is polished on wheels of hair-bristles and tripoli.

**ENGRAVING ON STEEL** is chiefly employed in cutting seals, punches, matrices, and dyes proper for striking coins, medals, and counters. The method of engraving with the instruments, &c. is the same for coins as for medals and counters: All the difference consists in their greater or less relievo, the relievo of coins being much less considerable than that of medals, and that of counters still less than that of coins. Engravers in steel commonly begin with punches, which are in relievo, and serve for making the creux, or cavities, of the matrices, and dyes: though sometimes they begin with the creux, or hollows, but then it is only when the intended work is to be cut very shallow. The first thing done, is that of designing the figures; the next is the moulding them in wax, of the size and depth they are to lie, and from this wax the punch is engraved. When the punch is finished they give it a very high temper, that it may the better bear the blows of the hammer with which it is struck to give the impression to the matrix. See the articles **Punch and Matrix**.

The steel is made hot to soften it, that it may the more readily take the impression of the punch; and after striking the punch on it, in this state, they proceed to touch up or finish the strokes and lines, where, by reason of their fineness, or the too great relievo, they are any thing defective, with steel gravers of different kinds, chisels, flats, &c. being the principal instruments used in gravmg on steel.

The figure being thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engraved ring, letters, &c. with little steel punches, well tempered, and very sharp.

**ENGRAULIS,** in ichthyology, a name given to the anchovy. See **ANCHOVY**.

**ENGROSSING,** or **INGROSSING.** See the articles **INGROSSER** and **INGROSSING.**

**ENGUICHE,** in heraldry, is laid of the great mouth of a hunting horn, when its rim is of a different colour from that of the horn itself.

**ENYSCOPE,** the same with microscope. See the article **MICROSCOPE**.

**ENHARMONIC,** in the ancient music, one of their genera or kinds of mule, so called from its superior excellence; tho' wherein it confisted, says Mr. Malcolm,
is hard to say: it was allowed by all to be so very difficult, that few could ever practice it.

Others say it is a species of music, the modulation whereof proceeds by intervals less than semitones; as the semitone minor, enharmonic diads, and third major. See Semitone, Diesis, and Third. This genus, says Broffard, was greatly used in the greek music, especially in dramatic performances. But as those almost inexpressible elevations and fallings of the voice, whereas it consists, are too difficult, and as they sometimes make the concord false, it has been laid aside, and even loft, though several great authors have made many attempts to recover it. See the articles Genus, Interval, and System.

Inheritance, or Inheritance. See the article Inheritance.

Enhydrus, in natural history, a genus of siderochita or crustated ferruginous bodies, formed in large and in great part empty cæsæ, inclining a small quantity of an aqueous fluid. Of this genus there are only two species.

1. The thick-shelled enhydrus, with black, reddish-brown, and yellow crusts.
2. The thinner-shelled kind, with yellowish-brown, and purple crusts; neither of which ferments with aqua fortis, or gives fire with steel.

Enigma, or Ænigma. See the article Ænigma.

Enixum, among chemists, a kind of neutral salt, generated of an acid and an alkali.
The sal enixum of Paracelsus, is the caput mortuum of spirits of nitre with oil of vitriol, or what remains in the retort after the distillation of this spirit; being of a white colour, and pleasant acid taste. If this be dissolved in hot water, and crystallized, it will be a yet more pleasant medicine, agreeing in virtues with vitriolated tartar. It is diuretic, and may be given from a fcruple to a dram, in broth or water-gruel.

Enlarge, in the manege, is to make a horse go large, or embrace more ground than he before covered.

To this purpose you should prick with both heels, or aid him with the calves of the legs, and bear your hand outwards; or rather prick him with the inner heel, sustaining him with the outer leg, in order to press him forwards, and make his shoulders go.
celsius speaks much of the ens primum of minerals, gems, herbs, and liquors; by which he means, the parts in which their virtues reside, or the very virtue or efficacy itself. Authors relate wonders of the renovating power of the ens primum of baum, and other plants, which is different in each kind.

Ens veneris, the sublimate of equal quantities of dulcified calx of vitriol, and the dried flowers of sal ammoniac, a small proportion of which turns a large one of the infusion of galls black; it is red, saline, and astringent; and said to be an excellent medicine in distempers arising from a weakness of the solids, as the rickets, and the like. Ens, in geography, a city, situated at the confluence of the Danube and the river Ens, about eighty miles south of Vienna: east long. 14° 20', north lat. 48° 16'.

Ensal, a term used by some for the small cardamom of the shops. Ensconced, or insconced. See the article insconced.

Ensseed, in falcyry, is said of a hawk that has a thread drawn through her upper eye-lid, and made fast under her beak, to take away the sight.

Ensient, and ensiature, among lawyers, signifies a woman's being pregnant, or with child. See the article pregnancy.

Ensiform, in general, something resembling a sword, ensis: thus we find mention of ensiform leaves, ensiform cartilage, &c. See leaf and xiphoides.

Ensign, in the military art, a banner under which the soldiers are ranged according to the different companies or parties they belong to. See the articles colours, flag, standard, &c.

The european ensigns are pieces of taffety with various figures, arms, and devices painted on them, in different colours: the turkish ensigns are horsetails.

Ensign is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordinate to the captain and lieutenant. It is a very honourable and proper post for a young gentleman, at his first coming into the army: he is to carry the colours both in assault, day of battle, &c. and should not quit them but with his life: he is always to carry them himself on his left shoulder: only on a march he may have them carried by a soldier. If the ensign is killed, then the captain is to carry the colours in his stead.

Ensheim, a town of Germany, in the regiment of Alsace, about fifty miles south of Straussburg: east long. 7° 30', north lat. 47° 50'.

Enskirken, a town of Germany, fifteen miles south-west of Cologn.

Entablature, or entablament, in architecture, is that part of an order of a column, which is over the capital, and comprehends the architrave, frieze, and cornice. The entablature is also called the trabeation, and seems borrowed from the latin, tragus, a beam; though others derive it from tabulatum, a ceiling, because the frieze is supposed to be formed by the ends of the joints which bear upon the architrave.

It is different in different orders; for notwithstanding that it consists of the three above-mentioned divisions in all, yet these parts are made up of more or fewer particular members or subdivisions, according as the order is more or less rich. Vignola makes the entablature a quarter of the height of the whole column in all the orders. In the tuftan and doric, the architrave, frieze, and cornice, are all of the same height. In the ionie, corinthian, and composita, the whole entablature being of fifteen parts, five of these go to the architrave, four to the frieze, and six to the cornice. See the articles Tuscan, Doric, &c.

Mr. le Clerc observes, that were we to regard only the laws of strength and weakness, we should rather diminish the entablature of such columns as have pediments, than those which have none. As to the projection of the entablature, it should never be forgot, that its principal design is to shelter what is underneath.

Entablature, in masonry, is used sometimes to denote the last row of stones on the top of the wall of a building, on which the timber and covering rest. This is often made to project beyond the naked of the wall, to carry off the rain.

Entabler, in the manage, the fault of a horse whose croupe goes before his shoulders in working upon volts; which may be prevented by taking hold of the right rein, keeping your right leg near, and removing your left leg as far from the horse's shoulder as possible. This is always accompanied with another fault called aculer. See aculer.

Entail,
ENTAIL, in law, is a fee-estate intailed; that is, abridged and limited to certain conditions prescribed by the donor or grantor. See the articles Fee, Recovery, and Tail.

ENTALIUM, a name used by some for the dentalium. See Dentaliun.

ENTÉ, in heraldry, a method of marshalling more frequent abroad than with us, and signifying grafted or ingrafted.

We have, indeed, one instance of enté in the fourth grand quarter of his majesty's royal ensign, whose blazon is Brunswick and Lunenburg, impaled with ancient Saxony, ente en points, grafted in point.

ENTELECHIA, εντελεχία, a word used by Aristotle to express the soul, and which, not occurring in any other author, has given the commentators upon that philosopher great trouble, to discover its true meaning. See the article Soul. Hemolus Barbarus is even said to have consulted the devil about it, after which, in his paraphrase on Theophrastus, either from the devil or himself, renders it perfecthability, which is nothing clearer.

Cicero, whose interpretation of this word should be esteemed preferable to that of any modern writer, defines entelechia quidam quaes continua et perpetua motio, a certain continued and perpetual motion: whence it would appear, that Aristotle took the soul for a mode of the body, a continuous and perpetual motion being undoubtedly a mode of body. The vulgar peripatetics hold entelechia to signify act, and under it suppose the form of the compound or animal to be understood. The late philosophers agree, that the act, or entelechia, whereby Aristotle meant to explain the nature of the soul, is either some mode of the body, or it is nothing at all.

Chauvin.

ENTENDMENT, or INTENDMENT, in law. See the article Intendment.

ENTERING, in the manage, the same with cutting. See Cutting.

ENTERING of a hawk, among sportmen, the letting her kill for the first time.

ENTERING of bounds, is the instructing them how to hunt. See Entrance.

ENTERMEWER, in falconry, a hawk that changes the colour of her wings by degrees. See the article Hawk.

ENTEROCELE, εντέροκελε, in surgery, a tumor formed by a prolapse of the intestines through the rings of the abdominal muscles, and proceeds of the peritoneum, into the scrotum. It is sometimes termed an ophclocele and complete hernia, in contradistinction to the bubonoccele. See the article Bubonoccele, &c.

This disorder arises from a violent dilatation of the peritoneum and rings of the abdominal muscles, through which the intestine prolapses into the scrotum; and proceeds from some violence by a fall, blow, or straining to leap, lift up great weights, vomiting, &c. and according to the nature of the cause, the rupture is formed either, instantly or imperceptibly by degrees. This rupture is always attended with pains, and usually happens but in one side, never in both at a time: sometimes the intestine alone falls down; at other times, it is accompanied with the omentum. The tumor appears soft to the touch like an intestine, or bladder, distended with wind; it first appears small in the inguinal, and gradually descends down to the teaticle of the same side in the scrotum, which is thereby sometimes distended halfway down the thigh, and even down to the knee: the other symptoms are the same with those of the bubonoccele.

The tumor is encreased by crying, plentiful eating, lifting, or carrying any burden; is contracted with cold, and dilated with heat: it may be distinguished generally from the hydrocele or pneumonia, by its returning into the abdomen with a murmuring noise.

This kind of rupture may be sustained with but little inconveniences by men not much addicted to hard labour, and women with child; but it should never be left to itself without a support or truss, lest, by some accident, the intestines should become incarcerated, and incapable of being returned. When the disorder is recent, and in a young subject, it may be perfectly cured without danger of a relapse; as it may also in adults and old people, by constantly wearing a proper truss. It is less dangerous when the intestine is attended with the omentum. When the intestine is returnable, the surgeon should immediately reduce the parts, and retain them in their proper situation, and to clofe up the aperture firmly with a truss, bandage, or by incision, termed celotomy.

Another method consists chiefly in passing a small gold-wire round the upper part of the procès of the peritoneum, near the ring of the abdominal muscles, leaving
leaving the tefticle in its natural position: the wire is twisted by a pair of forceps, so as to confine the procels of the péritionæum without comprefting the spermatie vessels, in order to prevent the intestines from falling through it again: this method, however, is not thought effectual in many cases by Heister.

In order to preserve the tefticle, some furgeons do not tie the peritonæum, but having returned the intestines and omentum, they then fcarify the ring of the abdomen, through which the intestines prolapsed, together with the skin, in order to render the cicatrix more firm.

If in the enteroccele the intestines cannot be reduced, especially if it adhere to the procels of the péritionæum, ring of the abdominal muscles, fcrotum, or tefticle, no trufs or bandage will be of any service; there is, then, but one method of faving the patient by a severe operation; in order to which the integuments are to be divided; and when the lacculus appears, it is to be separated, and a small aperture in it; big enough to introduce a quill, or some other instrument to separate the intestines from all its adhesions, before it is procured into the abdomen, which should always be done when the intestines adhere; after which the wound is to be healed, and the patient secured from a relapse, by wearing the bandagefpica. See Bandage and Truss.

If the ftriure of the intestines is so great as to render all means ineffectual to reduce the rupture, the surgeon must then have recourse to the knife to take the patient.

ENTERO-EPITOLECE, a species of rupture, wherein the omentum, together with the intestines, fall into the fcrotum. See the preceding article.

ENTEROLOGY, a term used by physicians, for a discourse or treatise on the contents of the head, breath, and abdomen. See the articles Head, &c.

ENTHROMPHALUS, the name with a hernia umbilicalis, or rupture at the navel. See the article Exomphalus.

ENTERPLEADER, in law, signifies the discussing or trial of a point, incidentally falling out, before the principal caufe can be determined.

It is allowed that a defendant cannot be twice charged with the fame thing, or to two severally, where no default is in him; thus if one man brings detinue against the defendant upon bailment of goods, and another a trover against the fame person; in this case there shall be an enterpleader, to ascertain which of the parties has a right to his action.

Judgment may be given on an enterpleader, to recover what is demanded against the defendant; and where two have enteredpleaded, the perfon recovering shall have damages of the other.

ENTERMENT, or INTERMENT. See the articles Burial and Interment.

ENTERSOLE, in architecture, a kind of little story, sometimes called a mezanzinethe fruit or an occasional at the top of the first story, for the convenience of a wardrobe, &c.

ENTERTAINMENT, in a theatrical scene. See the article PArRE.

ENTHALIUM, in natural history, a kind of tubulus marinus. See Tubulus.

ENTHUSIASM, in natural history, implies a transport of the mind, whereby it fancies itself inspired with fome revelation, impulfe, &c. from heaven. Mr. Locke gives the following description of enthusiasm: "In all ages, men in whom melancholy has mixed with devotion, or who are conceived of themselves has raised them into an opinion of a great familiariry with God, and a nearer admittance to his favour than is afforded to others, have often flattered themselves with a perination of an immediate intercourse with the deity, and frequent communications from the divine Spirit. Their minds being thus prepared, whatever groundless opinion comes to settle itself strongly upon their fancies, is an illumination from the fpirit of God, and prefently of divine authority. And whatsoever odd action they find in themselves a strong inclination to do, that impulse is concluded to be a call or direction from heaven, and must be obeyed. It is a commiffion from above, and they cannot err in executing it. This I take to be properly enthusiasm, which, though arising from the conceit of a warm and overweening brain, works when it once gets footing more powerfully on the peruations and actions of men, than either reason or revelation, or both together. Men being"
ENTHUSIAST, a person possessed with enthusiasm. See the preceding article.

ENTHUSIAST, a person possessed with enthusiasm. See the preceding article.

ENTHYMEME, ἐνθυμομα, among logicians, denotes a syllogism, perfect in the mind, but imperfect in the expression, by reason one of the propositions is suppressed, as being easily supplied by the understanding of those with whom we discoursed. e.g. In every right-lined triangle, the three angles are just equal to two right ones; therefore, those of an isosceles are so: where the proposition, every isosceles is a right-lined triangle, is omitted, as being sufficiently known. But to give a more familiar example; suppose the enthymeme to be, every man is mortal; therefore every king is mortal; where the minor proposition, every king is a man, is omitted for the reason already mentioned. There is a particular elegance in the enthymem form of arguing, as leaving somewhat to the exercise and invention of the mind; for which reason it is very frequent, as well in common conversation, as in the most polite writers. It not only shortens discoursed, and adds a certain force and liveliness to our reasoning, but gives the reader a pleasure not unlike that the author himself feels in composing. By this means we are put upon exerting ourselves, and seem to share in the discovery of what is proposed to us.

ENTER, in the manage, a restless horse that not only refuses to turn, but relights the hand; provided he flies or parts for the two heels, you have a remedy for him, by using a cavefont made after the duke of Newcastle's way.

ENTER also denotes a bit-mouth. See the article BIT.

ENTERITY, or ENTERTIE, among lawyers, signifies the whole of a thing, in contradistinction to a moiety; thus a bond, damages, &c. are said to be intuitive, when they cannot be apportioned.

ENTIRE TENANCY, in law, is when the sole possession is in one person; in contradistinction to several tenancy, which is a joint or common possession in two or more.

ENTITIVELY and ENTITY, among metaphysicians. See the article Ens.

ENTOMON PYRAMIDALE, in zoology, a name by which some call the pyramidal onion. See the article ONISCUS.

ENTOYER, in heraldry, denotes a burden charged wholly with things without life; it seems to be a corruption of the French entour, round about.

ENTRAILS, the same with intestines. See the article Intestines.

ENTRANCE of hounds, among sportsmen, denotes the instructing them how to hunt; for which purpose, it is proper to lead them through warrens and flocks of sheep, to ensue them to be under command, and to run at nothing without the huntsman's orders; and when the game appears, the young hounds are to be entered along with the best and staunchest hounds that can be got, and not one barking dog suffered to be near. The hare is the best game on such an occasion, because, in this chase, the young hounds will learn all the doublings they can possibly meet with in any other kind. When the hare is killed, they must not be allowed to break her up; but the huntsman is to skin and cut her in pieces, with which the young hounds are to be rewarded.

ENTRE MINHO DOURO, a province of Portugal, having the river Minho on the north, Douro on the south, and the Atlantic Ocean on the west.

ENTRE TAVO and GUADIANA, a province of Portugal, having that of Étremadura on the north, and the Atlantic ocean on the west.

ENTREPAS, in the manage, a broken pace or going that is neither walk nor trot, but has somewhat of an amble. This is the pace or gait of such hares as have no reins or back, and go upon their shoulders; or, of such as are spoilt in their limbs.

ENTRING a ship, the same with boarding. See the article Boarding.

ENTRING-LADDERS, in a ship, are of two sorts; one used by the vessel's sides, in a harbour, or in fair weather, for persons to go in and out of the ship; the other is made
made of ropes, with small flaves for steps; and is hung out of the gallery to enter into the boat, or to come aboard the ship, when the sea runs so high that they dare not bring the boat to the ship's side for fear of having it.

ENTRING-PORTS. See the article Port.

ENTRING-ROPE. See the article Rope.

ENTROCHUS, in natural history, a genus of extraneous fossils, usually of about an inch in length, and made up of a number of round joints, which when separate and loose, are called trochites: they are composed of the same kind of plated spar with the fossil shells of the echiniti, which is usually of a bluish-grey colour, and very bright where fresh broken; they are all stratiated from the center to the circumference, and have a cavity in the middle. See plate xciii. fig. 3.

The entrochi are found of all sizes, from that of a pin's head to a finger's length, and the thickness of one's middle finger; and are plainly of marine origin, having often sea-hells adhering to them. They seem to be the petrified arms of that singular species of the sea-florida, called itella amoenicans.

They are esteemed very powerful diuretics, and prescribed in nephritic cases with good success; the dose being as much of the powder, as will lie on a pin's head.

ENTRUSION, or intrusion, in law. See the article Invasion.

ENTRY, in law, signifies taking possession of lands or tenements, where a person has a right fo to do.

It is also used for a writ of possession, which is of divers kinds, as, 1. A writ of entry fur different, which lies for the diffeiior against the dillferior. 2. A writ of entry fur different in le per, that lies for the heir by descent, who succeeding in right of his ancestor, is fed to be in the per or pers. 3. A writ of entry fur different in le per & cui, which lies where the feoffee of the dillferior makes a feoffment to another. 4. A writ of entry fur different in le per, which lies where after a different the land is removed from one hand to another beyond the degrees, that a writ of entry can be made in the usual form.

The writ of entry is put out of the degrees by five things. 1. Intrusion, as when the dillferior dines seised, and a stranger enters. 2. Succession, when the successor in office or profession enters. 3. Diffession upon dillferior, when the dillferior is dized by another. 4. Judgment, where a person recovers against the dillferior. 5. Escheat, which is when the dillferior dies without heir, or commits felony, &c., on which account the lord enters. In all which cases, a dillferior, or his heir, shall not have a writ of entry within the degrees of the per, but in the pof.

There are several other writs of entry, which lie for the person in reversion, where a tenant for life, for term of years, or by courtesy, aliens, and afterwards dies: and so in other cases.

Forcible ENTRY. See forcible.

ENTRY, among sportmen, denotes the places or thicket through which deer are found lately to have passed.

Bill of ENTRY, in commerce. See Bill.

In making entries inwards, it is usual for merchants to include all the goods they have on board the same ship in one bill, though sometimes they may happen to be upwards of twenty several kinds; and in case the goods are short entered, additional or post entries are now allowed; though formerly the goods, so entered, were forfeited. As to bills of entry outwards, or including goods to be exported, upon delivering them, and paying the customs, you will receive a small piece of parchment called a cocket, which testifies your payment thereof, and all duties for such goods. See the article Exportation.

If several sorts of goods are exported at once, of which some are free, and others pay customs, the exporter must have two cockets, and therefore must make two entries; one for the goods that pay, and the other for the goods that do not pay customs.

Entries of goods, on which a drawback is allowed, must likewise contain the name of the ship in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken that the customs for those goods were paid as the law directs, you must carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant a warrant, which must be given to the surveyor, searcher, or land-waiter, for them to certify the quantity of goods; after which the certificate must be brought back to the collector and comptroller, or their deputies, and oath made that the said goods are really shipped, and not landed.
ENVELOPE, in fortification, a work of
earth, sometimes in form of a simple parapet, and at others, like a small rampart with a parapet: it is raised sometimes on the ditch, and sometimes beyond it. Envelopes are often made to include a weak ground, where that is practicable, with single lines, to take the great charge of horn-works and tennils, or where there is not room for such large works. Some give the name of screen, counter-guard, condor, and torque, to envelopes raised in the most.

ENVIRONMENTS, in heraldry, signifies surrounded with other things; thus, they say, a lion environed with so many bezants. See the article BEZANT.

ENULA-CAMPANA, Helenium, or Elecampane, in botany. See the article ELECAMPANE.

ENUMERATION, an account of several things, in which mention is made of every particular article.

ENUMERATION, in rhetoric, a part of oration, in which the orator, collecting the scattered heads of what has been delivered throughout the whole, makes a brief and artful relation, or recapitulation thereof.

ENUMERATION of the parts, in rhetoric, is much the same with distribution. See the article DISTRIBUTION.

ENUNCIATION, a declaration of a thing either in terms of affirmation or denial.

ENUNCIATION, among logicians, the same with proposition. See the article PROPOSITION.

ENVOICE, the same with invoice. See the article INVOICE.

ENVOY, a person deputed to negotiate some affair with any foreign prince or state. Those sent from the courts of France, Britain, Spain, &c. to any petty prince or state, such as the princes of Germany, the republics of Venice, Genoa, &c. go in quality of envoys, not ambassadors; and such a character only do those persons bear, who go from any of the principal courts of Europe to another, when the affair they go upon is not very solemn or important. There are envoys ordinary and extraordinary, as well as embassadors; they are equally the same under the protection of the law of nations, and enjoy all the privileges of embassadors, only differing from them in this, that the same ceremonies are not performed to them.

ENURE, in law, signifies to take effect, or avail: thus, they say, a release made to a tenant for life, shall ensure and be of force to the person in reversion.

ENURNY, in heraldry, is applied to a bordure charged with beasts.

ENVY, in ethics, is defined to be an uneasiness of the mind, caused by the consideration of a good we desire, obtained by one we think less worthy of it than ourselves. See the article PASSION.

EON, among anatomists, is sometimes used for the whole ambit of the eye.

EON, or AION, in church-history. See the article AION.

EPACT, in chronology, a number arising from the excess of the common solar year above the lunar; whereby the age of the moon may be found out every year. See the articles YEAR and MOON.

The excess of the solar year above the lunar is 11 days; or the epact of any year expresses the number of days from the last new moon of the old year, which was the beginning of the present lunar year, to the first of January. The first year of the cycle of the moon, the epact is 0, because the lunar year begins with the solar. On the second, the lunar year has begun 11 days before the solar year, therefore the epact is 11. On the third, it has begun twice 11 before the solar year, therefore the epact is 22. On the fourth, it begins three times 11 days sooner than the solar year, the epact would therefore be 33; but 30 days being a synodical month, must that year be intercalated; or, that year must be reckoned to consist of thirteen synodical months, and there remain three, which is the true epact of the year; and so on to the end of the cycle, adding 11 to the epact of the last year, and always rejecting 30, gives the epact of the present year. Thus to adjust the lunar year to the solar, through the whole of 19 years, 12 of them must consist of 12 synodical months each, and 7 of 13; by adding a month of 30 days to every year, when the epact would exceed 30, and a month of 30 days to the last year of the cycle, which makes in all 209 days, i.e. 19 × 11; so that the intercalary or embolimastic years, in this cycle are 4, 7, 10, 12, 15, 18, 19. See the article CYCLE.

If the new moons returned exactly at the
Example for the year 1754.

G. N. 7. $1 \times 11 = 66$

$66 - 30 = 6 = \text{Epaat.}$

A table of golden numbers, and their corresponding epaets, till the year 1900.

EPANORTHOSIS, in rhetoric, a figure by which a person corrects, or ingeniously revokes what he just before alleged, as being too weakly expressed, in order to add something stronger, and more conformable to the passion with which he is agitated.

The epanorthosis is distinguished into two kinds, the one is when we correct or revoke the word, as in the following example of the apostle, but I laboured more abundantly than they all; yet not I, but the grace of God, which was with me. 1 Cor. xv. 10. where what he first attributed to his own merit, he chooses afterwards to call the work of grace, as being the principal cause. The second kind of epanorthosis, is when we correct or revoke the sentiment, as in the following of Cicero: Italian ornare, quam domum suas, maluit: quamquam, Italia ornata, domus ipsa mibi videtur ornatrix.

EPARER, in the manage, signifies the flinging of a horse, or his yerning and striking with his hind legs. See YERK.

In caprioles, a horse must yerk out behind with all his force; but in balottades, he strikes but half out; and, in croupades, he does not strike out his hind legs at all. All such yerning horses are reckoned rude. See the articles CAPIROLE, BALLOTADE, &c.

EPAULE, in fortification, denotes the shouder of a bastion, or the place where its face and flank meet, and form the angle called the angle of the shouder. See the article BASTION.

EPAULEMENT, in fortification, a work raised to cover sidewise, is either of earth, gabions,
EPAULEMENT also denotes a mass of earth, called likewise a square orilllon from its figure, raised to cover the cannon of a casemate, and faced with a wall.

It is likewise used for any work, thrown up to defend the flank of a post, or other place.

EPHEDRA, in botany, a name used by authors for the olinerus, with seventeen rays in the fin beside the anus, and called in English the nettle. See the article PAREMBOLE.

EPHEDRA, in botany, a name used by authors for the olinerus, with seventeen rays in the fin beside the anus, and called in English the nettle. See the article PAREMBOLE.

EPHEDRA, the sea-grape, or shrub horse-tail, in botany, a genus of the dioecia-fyngenefia class of plants, which has no corolla or flower-petals: the flamina are seven filaments, coalescing into a fubulated column; the antherae are roundish, three being superior, and the other four inferior: the seeds are acutely oval, convex on one side, and plain on the other, and contained in a baccated cup. The fruit is red, succulent, and of an acid auffere taste: its juice, taken in wine, is said to be good for the colic or jaundice.

This species of fever has this peculiarity to it, that the pulse is at first large, but as it becomes afterwards moderately quick and frequent, so it is equal, soft, and regular, as in a natural state. The urine undergoes little or no change, nor is the disorder preceded by a loathing of food, a spontaneous latitude of the body, disturbed sleep, preternatural yawning, or horror; but it seizeth the patient suddenly, and afflitieth him with no other symptoms than a pain of the head and stomach, a naus, heat and restlessness. The perons most subject to this fever, are young men who have much blood, and fee heartily, and such as have had any habitual discharge of blood stopped upon them, whether natural, as in the hemor­hoidal or menstrual discharges, or artificial, such as frequent bleeding, cupping, and the like. And those who have thrown their blood into violent emotions by the too free use of spirituous liquors, too violent exercise, unusual watchings, long stay by large fires, a sudden reflexion of sweats by cold water, or by violent passions, particularly anger. In the treatment of this fever, the proper course is to attemperate the violent motions of the blood with nitrous and the fixed antimonials medicines, and occasionally with gentle acids. Sweat is to be promoted. Nitre, crabs-eyes, &c. may be preferred in small doses every three or four hours; and towards night, sudorifics should be joined to these, such as the contrayera-root, or the like. The ephemera, properly so called, differs in nothing except the time of its duration, from that which commonly lasts four days.

EPHEMERA MALIGNA, is also a term by which some authors have called the fudor anglicanus, or malignant diary fever, which generally destroyed the patient in twenty-four hours. See the article SUDOR ANGLICANUS.

EPHEMERA MALIGNA, is also a term by which some authors have called the fudor anglicanus, or malignant diary fever, which generally destroyed the patient in twenty-four hours. See the article SUDOR ANGLICANUS.

EPHEMERIDES, in literary history, an appellation given to those books or journals, which shew the motions and places of the planets for every day of the year. It is from the tables contained in these ephemeredies, that eclipses, and all the variety of aspects of the planets, are found. See the articles ECLIPSE, CONJUNCTION, OPPOSITION, &c.
EPHMERUM, in botany, the same with the tradescantia of Linnaeus. See the article Tradescantia.

EPHIALTES, in medicine, the same with the incubus, or night-mare. See the article Incubus.

EPHIPPUM, in anatomy, the same with the cells turcica, being a part of the os iphenoides. See the article Sphenoides.

EPHOD, in jewel antiquity, one part of the priestly habit; being a kind of girdle which, brought from behind the neck over the two shoulders, and hanging down before, was put cro's the stomach, then carried round the wait, and made use of as a girdle to the tunic.

There were two sorts of ephods, one of plain linen for the priests, and the other embroidered for the high priest. Of this last Moses gives an ample description. It was composed of gold, blue, purple, crimson and twisted cotton. Upon part of it, which passed over the shoulders, were two large precious stones, one on each shoulder; upon these were engraven the name of the twelve tribes, six upon each stone.

The ephod was peculiar to the priesthood, and thought essential to their character; it being the opinion of the Jews, that no worship, true or false, could subsist without a priesthood and ephod.

EPHORI, in grecian antiquity, magistrates established in ancient Sparta to balance the regal power. The authority of the ephori was very great. They sometimes expelled and even put to death the kings, and abolished or suspended the power of the other magistrates, calling them to account at pleasure. There were five of them, others say nine. They presided in the public fchews and festivals. They were entrusted with the public treasure, made war and peace, and were so absolute, that Aritotle makes their government equal to the prerogative of a monarchy. They were established by Lycurgus.

EPHYDRUM, in botany, the same with the equisetum, or horse-tail. See the article Equisetum.

EPIBATERION, in ancient poetry, a poem rehearsed at a person's return from a voyage, thanking the immortal gods for his preservation.

EPIC, or Heroic Poem, a poem exprested in narration, formed upon a story partly real, and partly feigned; representing, in a sublime style, some signal and fortunate action, distinguished by a variety of great events, to form the morals, and affect the mind; with the love of heroic virtue. See the article Poem.

We may distinguish three parts of the definition, namely, the matter, the form, and the end. The matter includes the action of the fable, under which are ranged the incidents, episodes, characters, morals, and machinery. The form comprehends the way or manner of the narration, whether by the poet himself, or by any person introduced, whose discourses are related; to this branch likewise belong the moving of the passions, the descriptions, discourses, sentiments, thoughts, style, and verfification; and besides those, the families, tropes, figures, and, in short, all the ornaments and decorations of the poem. The end is to improve our morals, and increase our virtue. See the articles Action, Fable, Episode, Character, &c.

There are two things which chiefly distinguish epic from tragedy, the manner of the representation, and the event or catastrophe. As to the former it is certain that tragedy is formed upon action, and epic upon narration. This is the principal character in an heroic poem, and a very difficult part of it. The qualities a narration must have to be perfect, are these: it must be short and succinct, that nothing may be idle, flat, or tedious; it must be lively, quick, and delightful: it must be simple and natural. The most ordinary graces of a narration, must come from the figures, the transitions, and from all those delicate turns that carry the reader from one thing to another, without his regarding it. It must never point out all the matter, that some may be left for the natural reflections of the reader. It must likewise avoid the particulars and length of affected descriptions. Lastly, the narration must be delightful, not only by the variety of things it relates, but by the variety of its numbers. It is this variety that makes the grecian verfification more harmonious and more proper for narration than the Latin.

Epic also differs from tragedy in the event, or conclusion. In tragedy, the conclusion is generally unfortunate, but never so in epic: the reasons of which rule are the examples of Homer and Virgil, who are, and ought to be, our guides and patterns in this particular, and in which they have been universally followed by all who would have been thought epic.
EPI  [ 1089 ]  EPI

epic writers; and not only their authority, but the very reason of the thing supplies us with arguments for this rule.

1. Although in tragedy, where the action is much shorter, more simple, and finished, as it were, at a heat, an unfortunate conclusion may be so far from pleasing, that it may be more agreeable to the audience: yet in epic, after such a series and variety of adventures, after sustaining so many and such great difficulties, the reader must be out of humour with the poet, unless the whole should conclude happy at last. The chief end of tragedy is to excite the passions, especially those of terror and pity, by a short and brisk emotion; but the design of an epic poem is, by more flow and leisure operations, to remove bad habits, and restore good ones; to subdue vice and recommend virtue, which would be done with a very ill grace, if the hero of the poem should come to a deplorable end.

2. An epic poem, properly so called, is, and should be, written in honour of the country and religion of the author, between which and the hero there is a near relation; and therefore he ought to come off in triumph at last. These two differences are, as the schools call them, specific differences, being so in nature: the others are only accidental, being differences in degree, extent, and greatnes.

Although epic poetry is directed to the morals and the habit rather than the passions, yet it likewise has passions, but in an inferior degree to tragedy: for though it has a mixture of all the passions, yet joy and admiration are the most essential to it.

An epic poem must be formed upon a story partly real and partly fictitious. In tragedy, which is much shorter, the performance may not only be excusable, but commendable, though the whole fable should be fictitious; but in such a long work as that of an epic poem, the reader will be tired unless he has the pleasure of finding some truth interwoven with the fable.

The moderns seem to mistake that part of the epic and tragedy which contain the wonderful, confounding it with improbable, and using the two words promiscuously. If it was really so, the wonderful would be always faulty; for that is always so which is improbable. The great art is a just temperament and mixture of both, to make it natural and probable. Scarcely any of the poets but Virgil had the art, by the preparation of incidents, to manage the probability in all the circumstances of an epic poem.

Homer is not altogether so scrupulous and regular in his contrivances: his machines are less just, and all his matters, to save the probability, are less exact. Lastly, the sovereign perfection of an epic poem, in the opinion of Aristotle, consists in the just proportion and perfect connection of all the parts. It is not sufficient that all be grand and magnificent in an epic poem, but all must be just, uniform, and proportionable, in the different parts that compose it.

This is all that can be observed most essential to an epic poem: little need be said about the machinery, which, among the antient heathens, was the agency of their false gods, and of angels and demons among us christians: its beauty and magnificence is well known. The dignity of an epic poem would scarce be kept up without it, especially since the marvellous depends on it. The verification of epic poetry, among the Greeks and Romans, consists of hexameters, a sort of verse so peculiar to epic, that when it is used upon other occasions, it is called heroic verse. Our English verse comes nearest to it both in gravity and majesty, but at how great a distance? See the article HEXAMETER.

An epic or heroic poem, is the best and most perfect kind of poetry; it is the greatest work which the soul of man is capable of performing; and here it is the utmost bounds are set to human composition. All the nobleness and the elevation of the most perfect genius, can hardly suffice to form such a one as is requisite for an heroic poet: the difficulty of finding together fancy and judgment, heat and imagination, and sobriety of reason, precipitation of spirit, and solidity of mind, renders this character so very rare: it requires great images, and yet a greater wit to form them. There must be a judgment so solid, a discernment so exquisite, such perfect knowledge of the language in which he writes, such obblinate study, profound meditations, and vast capacity, that scarce whole ages can produce one genius fit for an epic poet: even among the antients themselves, if we except Homer and Virgil, we should scarce find one that is truly an epic poet.
EPICALYMMMA, in the history of shellfish, the name with operculum. See the article OPERCULUM.

EPICARPIS, in ancient pharmacy, denotes a remedy applied in form of a plaster to the wrists: it consist of penetrating ingredients, as garlic, onion, camphor, &c.

EPICÆDIUM, in ancient poetry, a poem rehearsed during the funeral solemnity of person of distinction. See the article Nenia.

We find two beautiful epicediums in Virgil, one of Euryalus, and the other of Pallas.

EPICERAS, a name used by some for foenuugreek. See the article FOENUGRECK.

EPICERASTICS, in pharmacy, denote much the name with emollients. See the article EMOLLIENTS.

Epicerastic medicines obtund the acrimony of the humours, and mitigate the uneazy sensation therefore arising.

To this class belong, 1. The emollient roots, as marshmallow, liquorice, &c. 2. The leaves of mallows, water-lily, the large houfe-leek, purslane and lettuce. 3. The feeds of barley decorticated, henbane, lettuce, flax, white poppy, and rue. 4. Fruits, as jubebs, raisins, sweet apples, prunes, and sweet almonds. 5. Cooling juices, whites of eggs, whey, oils, sirop, and sugar of violets, &c.

EPICHIREMA, in logic, a mode of reasoning, which comprehends the proof of one or both the premises of a syllogism, before the conclusion is drawn.

EPICHORDIS, in anatomy, a name by which some call the mesentery.

EPICOENE, in grammar, a term applied to nouns, which, under the same gender and termination, mark indifferently the male and female species. See GENDER. These nouns are otherwise called promisus, and comprehend the names of a great number of the wild beasts, more of the wild fowls, and almost all the fishes, whereof the difference of sexes is either difficult to be discerned, or is rarely adverted to; such are, in Latin, elephans, paffer, aquila, falmo, which equally signify a male or female elephant, sparrow, eagle, or salmon. As often as either of the sexes are to be distinctly mentioned, it is generally done by prefixing to the word male (mas) or female (femina.)

EPICUREAN PHILOSOPHY, the doctrine or system of philosophy maintained by Epicurus and his followers. Epicurus, the Athenian, one of the greatest philosophers of his age, was obliged to Democritus for almost his whole system, notwithstanding he piqued himself upon deriving every thing from his own fund. He wrote a great number of books, which are made to amount to above 300. Though none of them are come down to us, no antient philosopher's system is better known than his, for which we are mostly indebted to the great Lucretius, Diogenes Laertius, and Tully.

His philosophy consisted of three parts, canonical, physical, and etherial. The first was about the canons, or rules of judging. The cenature which Tully paffes upon him for his despising logic, will hold true only with regard to the logic of the stoics, which he could not approve of, as being too full of nicety and quirk. Epicurus was not acquainted with the analytical method of division and argumentation, nor was he fo curious in modes and formation as the stoics. Soundness and simplicty of sense, affilied with some natural reflections was all his art. His search after truth proceeded only by the senses, to the evidence of which he gave so great a certainty, that he considered them as an infallible rule of truth, and termed them the first natural light of mankind.

In the second part of his philosophy he laid down atoms, space, and gravity as the first principles of all things: he did not deny the existence of a God, but thought it beneath his majesty to concern himself in pleasuring, and to divinitie the evidence of which he gave so great a certainty, that he considered them as an infallible rule of truth, and termed them the first natural light of mankind.

In the second part of his philosophy he laid down atoms, space, and gravity as the first principles of all things: he did not deny the existence of a God, but thought it beneath his majesty to concern himself in pleasuring, and to divinitie the evidence of which he gave so great a certainty, that he considered them as an infallible rule of truth, and termed them the first natural light of mankind. As to his ethics, he made the supreme good of man to consist in pleasure, and consequently supreme evil in pain, Nature, itself, says he, teaches us this truth, and prompts us from our birth to procure whatever gives us pleasure, and avoid what gives us pain. To this end he proposes a remedy against the sharpness of pain: this was to divert the mind from it, by turning our whole attention upon the pleasures we have formerly enjoyed: he held that the wise man must be happy, as long as he is wise; that pain,
pain, not depriving him of his wisdom, cannot deprive him of his happiness. There is nothing that has a fairer shew of honesty than the moral doctrine of Epicurus. Gaffendus pretends, that the pleasure in which this philosopher has fixed the sovereign good, was nothing else but the highest tranquility of mind in conjunction with the most perfect health of body: but Tully, Horace, and Plutarch, as well as almost all the fathers of the church, give us a very different representation: indeed the nature of this pleasure, in which the chief happiness is supposed to be seated, is a grand problem in the morals of Epicurus. Hence there were two kinds of Epicureans, the rigid and the remiss: the first were those who understood Epicurus's notion of pleasure in the best sense, and placed all their happiness in the pure pleasures of the mind, resulting from the practice of virtue. The loose or remiss Epicureans, taking the words of that philosopher in a gross sense, placed all their happiness in bodily pleasures, or debauchery. Thus we have the whole mystery of this celebrated doctrine. It was innocent in expression, but criminal in thought; it had a beautiful outside, but it was all corruption within. These loose philosophers took up a feeming austerity to disguise their secret indulgence, and all their schemes of morality were but so many veils for their immoral behaviour.

EPICYCLE, ἐπίκυκλος, in the ancient astronomy, a little circle whose center is in the circumference of a greater circle; or it is a small orb, or sphere, which being fixed in the deferent of a planet, is carried along with it; and yet, by its own peculiar motion, carries the planet fastened to it round its proper center. It was by means of epicycles, that Ptolemy and his followers solved the various phenomena of the planets, but more especially their stations and retrogradations. See the articles PTOLEMAIC SYSTEM, STATION, and RETROGRADATION.

The great circle they called the excentric or deferent, and along its circumference the center of the epicycle was conceived to move; carrying with it the planet fixed in its circumference, which in its motion downwards proceeded according to the order of the signs, but, in moving upwards, contrary to that order.

The highest point of a planet's epicycle they called apogee, and the lowest perigee. See APOGEE and PERIGEE.

EPICYCLOID, in geometry, a curve generated by the revolution of the periphery of a circle, A C E (plate LXXXVIII. fig. 3.) along the convex or concave side of the periphery of another circle, D G B.

The length of any part of the curve, that any given point in the revolving circle has described, from the time it touched the circle it revolved upon, shall be to double the verfed sine of half the arch, which all that time touched the circle at rest, as the sum of the diameters of the circles, to the semidiameter of the resting circle, if the revolving circle moves upon the convex side of the resting circle; but if upon the concave side, as the difference of the diameters to the semidiameter of the revolving circle.

In the philosophical transactions, no. 218, we have a general proposition for measuring the areas of all cycloids and epicycloids, viz. The area of any cycloid or epicycloid is to the area of the generating circle, as the sum of double the velocity of the center and velocity of the circular motion to the velocity of the circular motion: and, in the same proportion, are the areas of segments of those curves to those of analogous segments of the generating circle.

EPICYEMA, among physicians, denotes a superfetation; being a false conception or mole happening after the birth of a regular fetus. See MOLE.

EPIDEMIA, ἐπιδημία, in grecian antiquity, festivals kept in honour of Apollo and Diana, at the stated seasons when those deities, who could not be present every where, were supposed to visit different places, in order to receive the vows of their adorers. The festival took its name epidemic, from ἐπί, among, and δημος, people; on account of the imaginary presence of those deities among the people.

EPIDEMIA is also used for private feasts, or rejoicings, on account of the safe return of a friend from a voyage or journey.

EPIDEMIC, among physicians, an epithet of diseases which at certain times are popular; attacking great numbers at or near the same time. See DISEASE.

Epidemic diseases differ from those called endemic. See the article ENDEMIC.
Boerhaave observes, that though every particular disease, in various epidemical conftitutions, appear, to unattentive obfervers, the fame with regard to their names, signs, and conftquences in some measure; yet to the judicious, they will appear quite otherwise, fo as to require a different administration of the non-naturals, different treatment, and different medicines. This variety, however, in epidemical diseases, is so obscure, that physicians have not yet been able to deduce it from any abuse of non-naturals: and yet there are many circumstances which make it highly probable, that the caufes reside in the air, but depend more upon the inexplicable variety of exhalations contained therein, which, by their mixture with the fluids of the body, or their ferment, injure the human machine, than upon any change in the fensible qualities thereof. See Effluvia.

Upon the invasion of any unknown epidemical diftemper, the physician will receive some information with refpect to the cure. 1. By reducing the diftemper to some more known kind, which it most resembies. 2. By observing its tendency at the vernal and autumnal equations; at which seasons it is generally most prevalent. 3. By attending to the spontaneous phenomenas, which precede, accompany, or follow the death or recovery of the patient; and the better or worse state of the disorder. 4. By diligently remarking the benefit or injury received, from whatever the patients are unavoidably obliged to do; and from whatfoever is taken into, or discharged out of the body. 5. By comparing the caufes of a great many patients, labouring under the diftemper at the fame time. 6. By abfaining from all remedies which are dubious, which irritate and induce a confiderable change in the humour, and thereby obfure the nature and tendency of the diftemper. According to Van Swieten, the origin of epidemic fevers, and we may add of other epidemic disorders, is always from some caufe in common to the whole people who inhabit any particular place: thus, for example, when in befieged cities the fcantines of the market oblige all to use an ill course of diet; hence it is, that they have ufually the fame caufe and symptoms, in different patients, and therefore require the fame method of cure. See the articles Fever, Small-pox, &c.

EPIDENDRA, in botany, a term used by some naturalists for the paraftical plants, or thofe which grow on trees, shrubs, and other vegetables: such are mistletoe, dodder, &c. See the articles Misletoe, Dodder, &c.

EPIDENDRUM, BASTARD-VANILLA, in botany, a genus of the gynandria di-andria class of plants, the flower of which consists of five very long and patent petals; the flamina are two very short filaments, growing upon the pith, the fruit is a very long, rounded, and carnole pod, containing a multitude of minute seeds.

EPIDERMIS, in anatomy, the fame with the cuticle. See the article Cuticle.

EPIDIDYMIS, in anatomy, the name by which some call the two bodies more ufually known by that of paraftate. See the article Parastate.

EPIGASTRIC REGION, a part or subdivision of the abdomen. See the article Abdomen.

EPIGASTRIC VESSELS, the arteries and veins belonging to the epigastric region; the former being branches of the coeliac artery, and the latter of the hiac veins. See the articles Artery and Vein.

EPIGLOTTIS, in anatomy, one of the cartilages of the larynx, or wind-pipe. It is often of the shape of an ivy-leaf, and joined to the thyroide cartilage; over which it appears erect, immediately behind the root of the tounge; to which it is also connected by its middle ligament, by two lateral ones to the cornua of the os hyoïdes, and by two posterior ones, to the arytenoide cartilage. In the act of swallowing, it covers the glottis, or aperture of the larynx, and prevents anything getting into it. See the articles Larynx and Glottis.

EPIGRAM, in poetry, a short poem in verse, treating only of one thing, and ending with some lively, ingenious, and natural thought or point.

Epigram originally signified the fame as inscription, it being usual among the antients to cut inscriptions upon columns, walls, statues, trophies, shields, &c. which inscriptions, when expreffed in poetical conveys, were afterwards termed epigrams. In process of time, other poems of the like nature went by the name of epigrams, from their affinity with thofe inscriptions, and people began to
to use them for the relating of little facts and accidents, the characterizing of person, &c.

The chief characteristics of the epigram are acuteness and facetiousness. It should only tend to one point, which is always to be expressed with strength and poignancy in the last verse, excepting some that are more remarkable for their softness and delicacy, or some other elegance. But above all things, a redundancy, or superfluity of expression, is to be avoided.

Authors are much divided as to the length of an epigram. There are instances both among the antients and moderns of very long ones, but still it is allowed, that the shorter are the better, as seeming most natural to this kind of poem. The Greek epigrams run upon a turn of thought which is natural, but fine and subtle. They have nothing that bite, yet they are not inipid except a few, which are quite flat and spiritless.

We speak of these collected in the anthology. The Latin epigram, by a false taste that prevailed in the beginning of the decay of pure latinity, endeavours to surprize the reader by a point. Catullus writ after the greek manner, for he endeavours to close a natural thought with a delicate turn of words, and with the simplicity of a very soft expression. Martial was in some measure the author of the other way. Boileau says, the fineness and subtility of the epigram should turn upon the words, rather than the thoughts, by which means he reduces it to the nature of a pun, or equivocque. See the article Pun.

EPIGRAPHES, επίγραφα, among antiquarians, denotes the inscription of a building, pointing out the time when the person by whom, the uses, and the like, for which it was erected.

EPILEPSY, ἐπιλέπτης, in medicine, the same with what is otherwise called the falling-sicknes, from the patient's falling suddenly to the ground:

Sometimes this disease comes upon the patient unawares; but it more frequently gives notice of its approach, by a latitudine of the whole body, a heavy pain in the head, with some disturbance of the senses, unquiet sleep, unusual dread, dimness of sight, and a noise in the ears; in some there is a violent palpitation of the heart, a puffing or inflation of the breast, difficult respiration, a murmuring noise in the belly, fetid stools, a flux of the urine, and a refrigeration of the joints: in others, there is a sensation as it were of cold air, ascending from the extreme parts towards the brain and heart. At length falling senseless to the ground, the thumbs are shut up close in the palms of the hands, and are with difficulty taken out: the eyes are distorted or inverted, so as nothing but the whites appear: all sensation is suspended, insomuch that no smell, no noise, nor even pinching of the body is able to bring them to themselves: they frothe at the mouth, with a hissing kind of noise; the tongue is lacerated, or torn by the teeth, and there is a shaking or trembling of the joints. However, in different patients, the symptoms vary; for sometimes instead of convulsive motions, the limbs are all stiff, and the patient is as immovable as a statue; in infants, the penis is erected; and, in young men, there is an emision of the semen, and the urine sometimes streams out to a great distance. At last there is a remission of the symptoms, and the patients come to themselves after a longer or shorter interval; then they complain of a pain and heaviness of the head, and a latitude of all their joints.

These fits usually return on certain days, or age of the moon, but especially about the new or full moon; in women, chiefly about the time of menstruation; and as to the prognostics, they generally leave the patient about the time of puberty. As to the cure, in adults, or grown persons, it is extremely difficult; but, in children, it is just the reverse. Blister laid on the back part of the head are of great use a little before the fit is expected; which may the more certainly be foreknown, as this disease is influenced by the moon. The most proper medicines to correct the juices seem to be native cinnabar, and wild valerian-root; a dram of which may be taken morning and evening for three or four months, and afterwards two or three days before the new and full moon. Or, two scruples of the powder of wild valerian-root, mixed with one of that of native cinnabar may be taken morning and evening. Ambergrease and musk are also accounted excellent.

It must not however be forgot, that this disease owes its origin to so many different causes, and is bred in so many different constitutions of the body, that the same remedy which succeeds in one case, often fails in another; and, there-
fore, different medicines are to be tried, especially in adults. In cafe of a pleth-
ora, bleeding: in the ankles will be proper. If the humours be in fault, cathartics, iffues, cauteries, and blisters must be used. If in children, it pro-
cceeds from gripes, or the breeding of teeth, nothing is better than to cleanse the belly by milk cliters, with a little venice-fop dissolved in them. Some epile-
ptic powder with cinnabar, or extract of rhubarb, and made into an electuary with syrup of roses and manna, may likewise be given in proper doses.

During the fit, too free an use of vola-
tiles, spirituous liquors, and strong smells are hurtful, as causing the humours to flow too much to the head. The best method is to place the patient in an erect posture, and to rub the hands and feet pretty briskly; and the best drink is pure water, which will mitigate, if not cure, the symptoms.

When the disease is caused by external violence, or extravasations of humours in the head, cinnabar reduced into an impalpable powder, and given in large doses with other cephalics and diapha-
retics, has a kind of specific virtue. According to Dr. Cheyne, a milk-diet will cure the most inveterate epilepsy. Mistletoe is also said to cure it, as liare as the bark does an intermitting fever: its dofe, to grown people, is half a dram or more, in powder, to be taken every sixth hour, drinking after it a draught of a strong infusion of the same plant; and if to every ounce of the powder, a dram of afia fectida be added, the medi-
cine will be still more effectual. Cinn-
abar of antimony is also greatly cele-
broaded for the cure of this disease, and may be taken from four grains to a fcruple, in conserve of rofemary-flowers. If the disease is invertebrate, some advice to give the following pills for a month, viz. Take caftar and gum ammoniac, of each eight grains; wild valerian-root, half a fcruple; falt of tartar, seven grains; and as much of tincture of caftar as is sufficient to form them into pills, one of which makes a dofe. On every seventh day, a cathartic fhould be given; and sometimes, instead of the caftar and gum, flings of feele may be sub-
tituted.

A decoction of guaiacum, or faffras, taken twice a day, fix or eight ounces at a time, and continued for thirty or forty days, is also said to cure the epilepsy,
especially, if male piony-root, or the like, be added.

The following electuary is also recom-
mended as a moat excellent and certain anti-epileptic: Take of peruvian bark, pulverified, fix drams; of virginia flake-
root, likewise pulverified, two drams; and of the syrup of piony-flowers, as much as is sufficient to make a soft elec-
tuary. The dofe, after proper evacu-
ations, in adults, is a dram; which should be taken morning and evening for three or four months; and after-
wards only repeated three or four days before the new and full moon.

EPILINUM, in botany, the fame with cucutta or dodder.

EPLOBIUM, in botany, the willow-
herb, a genus of the oèandria-monogynia claf of plants, the cornula whereof con-
sists of four roundish patent petals, some-
what emarginated: the fruit is a very long capfule of a cylindraceous form, ftriated, made up of four valves, and containing four cells: the feeds are nu-
merous, oblong, and crowned with down.

EPILOGUE, in oratory, the end or con-
clusion of a difcourfe, ordinarily con-
taining a recapitulation of the principal matters delivered. See PEORATION.

EPOLOGUE, in dramatic poetry, a speech ad-
ressed to the audience after the play is over, by one of the principal actors therein, ufually containing some re-
fections on certain incidents in the play, especially those in the part of the perfon that speaks it.

The epilogue is but of modern date, much later than the prologue: feveral have taken the exodium of the Greek drama for an epilogue; but it appears that they are very different; as the ex-
odium was the laft of the four parts of the tragedy, containing the unravell-
ing the plot, answering to the laft act of modern tragedy.

In the modern tragedy the epilogue has ufually somewhat of pleafantry, intended, in all probability, to compose the faffions raised in the courfe of the representation. This is ridiculed by the Spectator, and compared to a merry jigg upon the organ, after a good fermo, to wipe away any impressions that might have been made thereby, and fend the people away just as they came. This practice, however, has the countenance of an-
tiquity, for the Romans had something of the fame nature, though under a different
different name; but their exodium was a kind of farce or pantomime, brought on the stage when the tragedy was over, to compose the minds of the audience.

EPIMEDIUM, BARREN-WORT, in botany, a genus of the terrandra-moneymeda class of plants, the flower of which consists of four ovated, obtuse, concave, petal petals: the fruit is an oblong annuminated pod, composed of one cell, but divided by two valves, containing several oblong seeds.

If we may believe Dioscorides, the leaves of this plant, triturated and drank to the quantity of five drams in wine, for five days together, after the menstrual purification, effectually prevent conception.

EPIMELIS, a term used by some authors for the medlar. See MEDLAR.

EPIMYTHION, in rhetoric, the fable. See the article FABLE.

EPINICON, in the greek and latin poetry, denotes a poem or composition on occasion of a victory obtained. It also signifies a rejoicing, or festival, on account of a victory.

EPIPACTIS, in botany, the same with the helleborine. See HELLEBORINE.

EPIPETRON, a name sometimes given to the epimedium. See the article EPIMEDIUM.

EPIPHANY, a christian festival, otherwise called the Manifestation of Christ to the Gentiles, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi, or wise men, who came to adore him, and bring him presents. The feast of epiphany was not originally a distinct festival, but made a part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were high or chief days of solemnity, either of these might properly be called epiphany, as that word signifies the appearance of Christ in the world.

The kings of England and Spain offer gold, frankincense, and myrrh, on epiphany, or twelfth day, in memory of the offerings of the wise men to the infant Jesus.

The festival of epiphany is called by the Greeks the feast of lights, because our Saviour is said to have been baptized on this day; and baptism is by them called illumination.

EPIPHONEMA, in rhetoric, a sententious exclamation containing a lively remark placed at the end of a discourse or narration; such is that of Virgil,

EPIPHORA; in medicine, a preternatural defluxion of the eyes, when they continually discharge a sharp fercous humour, which excoriat the cheeks. The cure is performed by a derivation of the offending humour elsewhere, by bleeding, cupping, blisters, purges, &c. The acri- mony is likewise to be correct by bitter chalybeate wine: sometimes wine drank alone will perform the cure; after which, astringent topics are to be made use of. See the article RHEUM.

If an epiphora has been of long standing, it is difficult to be cured, and often degenerates into a fistula lachrymalis. See the article PISTULA LACHRYMALIS.

Pitcairn calls an epiphora a sort of catarrh in the glands of the eye. See the article CATARRH.

EPIPHYLOSPERMUS PLANTS, the same with the capillary ones. See the article CAPILLARY.

EPIPHYSIS, in anatomy, a bony sub stance, or as it were a thicker bone, affixed to a larger or principal bone, by the intervention of a cartilage. In young subjects these epiphyses are not continuous to the principal bone, but are only connected by the intermediate cartilage, and hence they are called appendages to the bones. It is to be observed of epiphyses, 1. That they are all cartilaginous in infants; and though they afterwards grow hard, yet they never arrive at the true density of a bone. 2. That most of them degenerate into apophyses in adults. 3. That they do not grow along the plain surface of the bone, but unequally, or by a mutual ingress with the body of it.

The use of the epiphyses is very different in adults and in infants: in adults they seem to serve the bones which contain large quantities of marrow, by way of operation, that this soft matter may not run out. 2. They are of service to the articulations, rendering the motions more

7 A 2
easy, as well as more determinate. 3. They make the whole bone lighter than it would be, if their place were supplied by absolute bony matter. 4. They increase the power of the muscles about the tendons, by means of their prominences. 5. They add to the fize of the places defined for receiving the insertions of the muscles. 6. They give a firmer cohesion to the ligaments which serve in the articulations, and allow an entrance to the blood-vessels. The uses of the epiphyseal processes in infants are, 1. That by means of their yielding softness, they may give way to the compresion in the uterus, and suffer the whole bulk to be more folded together than otherwise it could, so that it may lie in a smaller compass. 2. That they may give way to the elongation and growth of the bones. 3. That they may prevent the frequent fractures, which would otherwise unquestionably happen to children from their falls, and the other accidents they are liable to.

EPIPLOPLASMA, the same with cataplasm. See the article CATAPLASM.

EPIPLOCELE, in medicine, is a kind of hernia, or rupture, in which the omentum subsides into the feromum. The cure consists principally in a reduction of the tumour, by returning the omentum again into the abdomen, and in securing the parts from a relapse by a truss or bandage. See HERNIA and ENTEROCELE.

EPIPLOS, in anatomy, a term applied to the arteries and veins distributed throug the subjacent tissue of the epiploon and caulis; thus, the dextra epiplos is a branch of the right side of the cælic artery, and the sinister epiplos and gastro-epiplos are terms by which anatomists call branches from the left side of the cælic artery. See the articles CÆLIC and ARTERY.

EPIPLOOMPHALON, επιπλοομφαλόν, in medicine, an hernia umbilicalis, proceeding from the omentum falling into the region of the umbilicus or navel. See the article EXOMPHALUS.

EPIPLOON, the same with what is otherwise called omentum. See OMENTUM.

EPIPLOOSARCOMPHALUS, in surgery, a kind of exomphalus. See the article EXOMPHALUS.

EPISARCIDIUM, a term antiently used for the anaesarca. See ANASARCA.

EPISCOPACY, the quality of episcopal government, or that form of church discipline, wherein diocesan bishops are established distinct from and superior to priests or prebysers. See BISHOP.

EPISCOPAL, something belonging to bishops. See the articles BISHOP and EPISCOPACY.

EPISCOPALIANS, in church-history, an appellation given to those who prefer the episcopal government and discipline to all others. By the term, none but episcopalians, or members of the church of England, are qualified to enjoy any office civil or military. See the article TEST.

EPISCOPUS, BISHOP. See BISHOP.

EPISODE, πεδος, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events: though, in a more limited sense, all the particular incidents whereof the action or narration is compounded, are called episodes. See the articles EPIC and TRAGEDY. The episode, in its original, was only something rehearsed between the parts of the chorus, or antient tragedy, for the diversion of the audience. Episodes serve to promote the action, to illustrate, embellish, and adorn it, and carry it to its proper period. Episodes are either absolutely necessary, or very requisite. All episodes are incidents, tho' all incidents are not episodes; because some incidents are not adventitious to the action, but make up the very form and feries of it. Examples will clear up this distinction: the storm in the first Æneid of Virgil, driving the fleet on the coast of Carthage, is an incident, not an episode, because the hero himself and the whole body of his forces are concerned in it; and so it is a direct and not a collateral part of the main action. The adventures of Niulus and Euryalus, in the ninth Æneid, are episodes, not incidents, i. e. not direct parts of the main action. It is particularly by the art of episodes that the great variety of matter which adorns a poem is brought into the principal action: but though the episodes are a kind of digression from the subject, yet they ought to have a natural relation to the principal action, never be far-fetch ed, and must be handled with judgment, to avoid confusion and burdening the subject with too much action. Without this restriction the episode is no longer probable, and there appears an air of affectation which becomes ridiculous. Aristotle calls all those fables episodic, which abound in episodes not necessarily not properly connected with each other.
The most natural episodes are the proper to circumstantiate the principal actions, namely, the causes, the effects, the beginnings, and the consequences of it. Homer and Virgil have shown their principal art in this particular: the action of the Iliad and that of the Æneid were in themselves exceeding short, but are so beautifully lengthened and diversified by the intervention of episodes, that they make up an agreeable story, sufficient to employ the memory without overcharging it. See the article Epic.

Our noble poet Milton has excelled in this art; he has no other episodes than what naturally arise from the subject, and yet his poem of Paradise Lost is filled with a multitude of astonishing incidents. Those great actions, the battle of the angels, and the creation of the world, are by way of episode to this noble poem. With the like art, and in the same manner, in that part of it which regards the fall of man, he has related the fall of these angels who are his professed enemies; besides the many other beauties of such an episode, its running parallel with the great action of the poem, hinders it from breaking unity so much as another episode would have done, that had not so great an affinity with the principal subject.

Episodic, an episode given epic poems swelled too much with episodes. See the preceding article.

Epipsastic, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part. See Vesicatory.

Epistates, in the Athenian government, was the president of the proedri. See the article Proedri.

To the custody of this officer was committed the public seal, and the keys of the citadel and the public exchequer: this therefore was an office of so great trust and power, that no man was permitted by the laws to continue in it above one day, nor to be elected into it a second time. The epistles were elected by lot out of the prytanes. See the article Prytanes.

Epistles were also the president of the assembly, chosen by lot out of the proedri, the chief part of whose office seems to have confided in granting the people liberty to give their voices, which they were not permitted to do till he had given the signal. If the people were remiss in coming to the assemblies, the magistrates used their utmost endeavours to compel them, for they shut up all the gates, that only excepted through which they were to pass to the assembly, and took care that all vendibles should be taken out of the market, that there might be nothing to divert them from appearing.

Epitemonarch, in the ancient Greek church, an officer of great dignity, who had the care of every thing relating to faith, in the quality of censor. His office answered pretty nearly to that of matter of the sacred palace at Rome.

Epistle, epistola, denotes the same with a missive letter; but is now chiefly used in speaking of antient writings, as the epistles of St. Paul, epistles of Cicero, epistles of Pliny, &c. See the article Letter.

The epistles of St. Paul, which are fourteen in number, make part of the canon of the New Testament; besides which there is one general epistle of St. James, two of St. Peter, three of St. John, and one of St. Jude. Dedicatory Epistle, in matters of literature. See DEDICATION.

Epistolary, something belonging to an epistle. See the article Epistle.

The art of epistolary-writing is acknowledged to be very entertaining and instructive. The Romans ranked it in the number of liberal and polite accomplishments. And, indeed, it enters so much into all the occasions of life, that no gentleman can avoid shewing himself in this kind of composition; the chief excellence of which consists in expressing ordinary occurrences, in an elegant and uncommon manner. However, it is proper to observe, that such is the nature of epistolary writings, in general, as unavoidably renders them obscure, since the writer passes by many things, as being well known to him to whom the letter is adressed, which must be laid open to a stranger, before he can fully comprehend what is said. Hence it is, that the epistles of the antients, whether sacred or profane, are so difficult to be understood.

Epistrophe, in rhetoric, a figure, wherein that which is supposed of one thing, is strongly affirmed of another: thus, Are they Hebrews? So am I. Are they Israelites? So am I. Are they of the seed of Abraham? So am I, &c.

Epistyle, in the ancient architecture, a term used by the Greeks for what we call architrave, viz. a massive piece of stone or wood, laid immediately over the capital.
EPITAPH, a monumental inscription in honour or memory of a person defunct, or an inscription engraved or cut on a tomb, to mark the time of a person's decease, his name, family; and, usually, some eulogium of his virtues, or good qualities.

The elegance of an epitaph, as well as an elegy, chiefly consists in an expressive brevity. The French have a proverb, he lies like an epitaph, by reason they sometimes give characters absolutely false. At Lacedaemon epitaphs were only allowed to those who died in battle. The rest of the Greeks allowed of epitaphs, the form of which was generally as follows:

**ΕΠΙΤΑΦΙΟΝ ΖΗΝΩΝΟΣ**
**ΧΡΗΣΤΗ ΧΑΙΡΕ.**

Nicon, son of Zenon,
Good man, happy to you.

**ΟΛΥΜΠΙΑΣ**
**ΧΡΗΣΗ ΧΑΙΡΕ.**

Olympia, Good woman,
Happy to you.

The Romans, in their epitaphs, introduced their dead speaking, as in the following, wherein the dead wife thus be-speaks her surviving husband:

*Immatura peri: sed tu, felicior, annos*  
*Vivit tuae, conjux optime, vivae nos.*

Sometimes the Roman epitaphs were full of moral expressions, and adorned with fine carved work, &c. At the top they always had the words *DIIS MANIBUS.* It has been much disputed by learned men whether or not epitaphs were in use among the antient Hebrews: however this be, it is certain the Jews have, of a very ancient date, received this custom, of which Buxtorf produces several instances.

**ΕΠΙΤΑΦΙΟΣ,** in antient poetry, the second part or division of a dramatic poem, wherein the plot, entered upon in the first part, or prothesis, was carried on, heightened, and worked up, till it arrived at its state, or height, called catastrophe. See **PROTHISIS, CATASTASIS, DRAMA,** &c.

In the epitaxis, accidents, as they are called by the moderns, arise; all things are in confusion, and involved in doubts and difficulties. Voelius says, the epitaxis is contained in the second, sometimes in the third and fourth, but very rarely any part of it in the fifth act; but Dr. Trap says, that there is no act to which the epitaxis is not suitable; nay, that some of it ought always to be in the fifth act.

It is the epitaxis that supports the weight and burden of the poem; upon it the crisis of the action chiefly turns. This division of tragedy is laid aside in the modern drama, instead whereof plays are divided into acts. See the article **ACT.**

**ΕΠΙΤΑΦΙΟΣ,** in medicine, the increase of a disease, or beginning of a paroxysm, particularly in a fever. See **FEVER.**

**ΕΠΙΘΑΛΑΜΙΟΝ,** in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

Among the Greeks, the married couple were no sooner bed, than the young men and maidens gathered round the door, dancing and singing the epithalamium, shouting and stamping with their feet, with intention to drown the maid's cries. When they returned again in the morning, to salute the married couple, they sung the *πεντάλαμιον θαλάμων,* so named from the design of them, which was to wake and enliven the bridegroom and bride; as those sung the night before were designed to dispel them to sleep, and on that account, were termed *πεντάλαμιον νυμφών.*

**ΕΠΙΘΕΜΙΟΝ,** in pharmacy, a kind of fomentation, or remedy of a spiritual or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperance thereof. See the article **FOMENTATION.** There are principally three kinds of these external applications, the liquid, the solid, and the soft or poultice-kind. The liquid epithems are sometimes considerably thick; but when they are intended to penetrate deep, they are much better if very thin and fluid. As to the part to which the epithem is immediately applied, it is not what it is always intended to act upon, as this frequently lies deep within: the epithems, therefore, intended for this purpose, should consist of the most penetrating ingredients, for which reason astringents and insippiating remedies can be of no use; but in this form hot wine alone is sometimes used as an epithem, and often such medicines as are not to be safely taken internally, such as highly rectified spirits, preparations of lead, henbane, mandrake, and other poisonous plants, and the like: but we are carefully to remember in regard to these, that the pores are capable of absorbing them, and ought therefore
therefore to know the effects they are capable of producing, when thus absorbed in the body. As to the vehicles of the liquid epithems, they are various, as linen or woollen-cloths, silk, flupes, toast-ed bread, &c. They are in some cases to be applied hot, in others, cold: when the intention is to resolve, penetrate, and attract, then the hot are to be preferred; but these are injurious to parts constricted by intense cold.

The dry epithems are medicated powders, usually sewed up in a cloth, and applied to different parts of the body; for which purpose the powders must be coarse. Sometimes the liquid epithems are added to the dry, to reduce the whole to a consistence, such as may be spread upon cloth, and applied.

Volatile epithem, is a form of medicine prescribed in the London dispensatory, ordered to be made up of equal weights of common turpentine and spirit of sal damar, by ftrirring them together in a mortar.

EPITHET, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description. Nothing, says Aristotle, tires the reader more than too great a redundancy of epithets, or epithets placed improperly; and yet nothing is so essential in poetry as a proper use of them. The writings of the best poets are full of them, especially Virgil.

We may distinguish two kinds of epithets, viz. 1. Those which add a new idea quite distinct from the general nature of a substantive. Thus Virgil in his Georgics,

Inter cuntantias cecidit moribunda mi-nifros.

And, 2. Those that bring with them some light and ornament, but not new ideas. Thus the same poet,

Timidi damn, corvique fugaces.

The first kind of epithets entertain the mind with a more agreeable variety, but those of the second require, perhaps, more care and judgment in the proper choice of them. For instance, because Virgil has said, the fearful deer and fleeting flags, it by no means follows that these epithets are applicable whenever 2475 and deer shall happen to be mentioned. They are proper in the place where he uses them, but may not be so always.

EPITHYME, epithymum, the name by which some call the cufcuts, or dodder.

EPITOME, in literary history, an abridgment or summary of any book, particularly of a history. See ABRIDGMENT. It is pretended that the epitomizing of authors, frequently occasions the loss of the originals. Thus the los of Pompeius Trogus, is ascribed to his epitomizer Justin; and the loss of a great part of Livy, to Lucius Annaeus Florus.

EPITRITEUS, in prodigy, a foot consisting of three long syllables and one short. Of these, grammarians reckon four kinds; the first consisting of an iambus and spondee, as faltantes: the second, of a trocheus and spondee, as concitati: the third, of a spondee and an iambus, as communicans: and the fourth, of a spondee and trocheus, as incantare. See the articles SPODEUS, TROCHEUS, &c.

EPITROPE, in rhetoric, a greek term for the same figure which the Latins call concepfo. See the article CONCESSION.

EPITROPOS, among the modern Greeks, a kind of arbitrator chosen by the greek christians under the dominion of the Turks, to terminate their differences, and avoid carrying them before the turkish magistrates. See ARBITRATOR.

EPIZEUXIS, in rhetoric, a figure which repeats the same word, without any other intervening: such is that of Virgil, nunc, nunc, inurgite remis.

EPLYOE!, in heraldry, the same with the article DISPLAYED.

EPOCA, in chronology, a term or fixed point of time, whence the succeeding years are numbered or accounted. See the article AERA.

The most remarkable epochas are those that follow.

EPOCA of the creation of the world. According to the vulgate, archbishop Ufher places this event 4064 years before the birth of Christ; Scaliger makes it 3950; Petavius, 3984; and Ricciolus, 4184 years before Christ. According to the lepintagint, Eusebius places the creation 4500 years before the nativity of our Lord; the alphonsine tables, 6934; and Ricciolus, 6534. The creation, therefore, as we follow the archbishop, happened in the year 710 of the julian period. See the article JULIAN PERIOD.

Sir Isaac Newton, again, makes the creation of the world later by 500 years than all other chronologists; and the proofs by which this illustrious philosopher supports
ports his opinion, are of two different kinds. The Egyptians counted 341 generations from Menes to Seth, allowing an hundred years for three generations; and the antient Greeks compared one generation at about forty years. Now, says Sir Isaae, it is true, three ordinary generations may be computed at about 120 years; but generations are longer than the reigns of kings, because it is evident that mankind in general live longer than kings. The duration of a reign, therefore, taking one with another, is, according to him, about twenty years; whence he concludes, that the antients have erred in their calculation in allowing forty years for every generation. The second kind of proof is taken from the precession of the equinoxes. See Precession, &c.

According to Clemens Alexandrinus, Chiron, who was in the expedition of the argonauts, fixed the vernal equinox at the fifteenth degree of aries, and consequently the summer solstice at the fifteenth degree of cancer. Meto fixed the summer solstice at the eighteenth degree of cancer, a year before the Peloponelian war. Now since one degree answers to the retrograde motion of the equinoctial points in 72 yrs., there are seven times 72 years from the expedition of the argonauts to the beginning of the Peloponessian war; that is 504 years, and not 507 years, as the Greeks affirm. By combining these two different proofs, Sir Isaae concludes, that the expedition of the argonauts ought to be placed 909 years before Jesus Christ, and not 1400, as is generally believed; and therefore that the creation of the world ought to be placed about 500 years later than chronologists generally place it.

Epocha of the deluge. According to the hebrew text, there are 1656 years from the creation to the deluge; 1307, according to the Samaritan; 2242, according to Euebius and the Septuagint; 2256, according to Josephus and the epitautagint, and 2252, according to Julius Africanus, Petavius, and the Septuagint. In following the hebrew text, this epocha begins in the year 2366 of the Julian period.

Epocha of the olympiads, used principally by the Greeks, had its origin from the Olympic games, which were celebrated at the beginning of every fifth year. This epocha begins 776 years before the incarnation, or in the 3938 of the Julian period.

Varroian Epocha of the building of Rome, is fixed 753 years before our Saviour's birth, and in the 3961 of the Julian period.

Epocha of Nabonassar king of Babylon, made use of by Ptolemy, Cenforinus, and several other authors, began 747 years before the incarnation, and in the 3967 of the Julian period.

Julian Epocha. The first year of Julius Cæsar's correcting the calendar stands 45 years before our Saviour's birth, and coincides with the 4669 of the Julian period.

Epocha of Christ. The christian world generally reckoned from the epocha of the creation, the building of Rome, the confuls regifter, or the emperor's reign, till about 500 years after Christ, when the epocha of the nativity of our blefled Lord was introduced by Dionysius Exiguus. He began his account from the conception or incarnation properly called Lady-day. Most countries in Europe, however, at present reckon from the first of January next following, except the court of Rome, where the epocha of the incarnation still obtains for the date of their bulls and briefs. But here we are to observe, that there are different opinions touching the year of our Saviour's birth. Capellus and Kepler fix it at about the 745th year from the building of Rome. Deckar and Petavius place the incarnation in the 745th of Rome. Scaliger and Vossius make it fall on the 751st of Rome. Dionysius Exiguus, Bede, &c. fix the birth of our Saviour to the year 751 of Rome; the diversity of these opinions proceeding from the difficulty of fixing Herod the great's death, who, as is evident from the evangelists, was living at our Saviour's birth, the taxation of Cyrenius, and the time of our Saviour's beginning his ministry. But let this be as it will, it is generally agreed, that as to computation and use, the common epocha is to be followed, which places the birth of Christ in the 4713th of the Julian period, although the true birth rather corresponds with the 4711th of the same period.

Dioecelian Epocha, or Epocha of martyrs, called also the era of the copthi or Egyptians, because the emperor Dioecelian made a great many martyrs in Egypt, begins in the year 263 of our Lord, and the 4997 of the Julian period.

Epocha of the Hegira, or flight of Mahomet, used among the Turks, is the year of the Julian period 5335, answering to the year of Christ 622.
EQUABLE, an appellation given to such motions as always continue the same in degree of velocity, without being either accelerated or retarded.

When two or more bodies are uniformly accelerated or retarded, with the same increase or diminution of velocity in each, they are said to be equally accelerated or retarded.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality.

Mathematicians speak of equal lines, angles, figures, circles, ratios, solids, &c., see the articles LINE, ANGLE, &c.
EQUATION, that agreement between two or more things, whereby they are denominated equal.

The equality of two quantities, in algebra, is denoted by two parallel lines placed between them: thus, \(4 + 2 = 6\), that is, 4 added to 2, is equal to 6.

EQUANITY, in ethics, denotes that even and calm frame of mind and temper, under good or bad fortune; whereby a man appears to be neither puffed up, or overjoyed with prosperity; nor disappointed, foured, or rendered uneasy by adversity. See the articles ETHICS and PASSIONS.

EQUANT, in the old astronomy, a circle described on the center of the deferent, for accounting for the eccentricity of the planets. See EXCENTRICITY.

EQUATION, in algebra, the mutual comparing two equal things of different denominations, or the expression denoting this equality; which is done by setting the one in opposition to the other, with the sign of equality (=) between them; thus \(3 \times 2 = 6\), or 3 feet = 1 yard. Hence, if we put \(a\) for a foot, and \(b\) for a yard, we will have the equation \(3a = b\), in algebraical characters.

When a problem is proposed to be resolved by means of equations, the first thing to be done is to form a clear conception of the conditions and nature of it; taking care to substitute the first letters of the alphabet for known quantities, and the last letters of the alphabet for unknown ones. Then by due reasoning from the conditions of the question, let the quantities concerned therein be justly stated, and carefully compared; so that their relation to one another may appear, and the difference, which renders them unequal, be discovered; and, consequently, the same thing found expressible in two ways, or brought into an equation, or several equations independent on each other. And here it is to be observed, 1. That if there are as many equations given, as there are quantities sought, then the question has a determinate number of solutions, or is truly limited, viz. each quantity sought hath but one single value. Thus, suppose a question proposed concerning the age of three persons, was conditioned as follows, viz. the second is seven years older than the first, the age of the third is triple that of the first and second, and the sum of all their ages is 68. Required the age of each. In order to bring this question to an equation, put \(z\) for the age of the first; then will the age of the second be \(z + 7\), and the age of the third \(6z + 12\); the sum of all their ages \(z + z + 7 + 6z + 12 = 68\). So that here is but one equation given, and one quantity required, viz. the age of the first.

2. When the number of the quantities sought exceed the number of the given equations, the question is capable of an indeterminate number of answers; and, therefore, can but be imperfectly determined.

Reduction of EQUATIONS. If the question, when stated, is found to have a determinable number of solutions, then the equation, directly drawn from the conditions of the question, must be reduced into another, by equal augmentation and diminution; so that the known quantities may stand on one side, and one of the unknown quantities, or some power of it, on the other side of the equation. This is called reduction of equations, and depends upon a right application of the five following axioms:

1. If equal quantities be added to equal quantities, the sum of those quantities will be equal.
2. If equal quantities be subtracted or taken from equal quantities, the quantities remaining will be equal.
3. If equal quantities be multiplied by equal quantities, their products will be equal.
4. If equal quantities be divided by equal quantities, their quotients will be equal.
5. Quantities that are equal to one and the same thing, are also equal to one another.

If these axioms be well understood, the reduction of equations will appear very plain, and the operations be easily performed. 1. Reduction by transposition, is performed by transferring a quantity to the other side of the equation with a contrary sign; or by equal addition, if the quantity be negative; and by equal subtraction, if affirmative. Thus the equation \(x - 10 = 40\), is reduced by adding +10 to each side, and the result will be the same as if \(-10\) had been transposed to the opposite side with the contrary sign; for \(x - 10 + 10 = 40 + 10\), is the same with \(x = 40 + 10\), the \(-10\) and \(+10\) destroying each other. In the same manner \(x + 10 = 40\), is reduced to \(x = 40 - 10\), by transposing the \(+10\) with a contrary sign. 2. Reduction is performed by equal multiplication; in case there are fractional quantities, for by multiplying every
every term in the equation by the denominator of the fractions, it will be cleared of fractions: thus by multiplying every term of the equation \( \frac{z}{a} = b \) by the denominator \( a \), we will have \( z = ab \). Again, if \( \frac{z^2 + 3a^2 + n + a}{c} = z + a \); then by multiplying by the denominator \( c \), we will have an equal equation free from fractions, viz. \( z^2 + 3a^2 + cn + ac = cz + ac \), or \( z^2 + 3a^2 + cn = cz \), the \( ac \) on each side being rejected. 3. By equal division, as in the equation \( ax = c \); for by dividing each side by \( a \), we will have \( x \left( \frac{ax}{a} \right) = \frac{c}{a} \). In the same manner, in the equation \( ax + ae = cb \), by dividing each side by \( a + e \), we get the equation \( z = \frac{cb}{a + e} \). 4. Equations are cleared of surd quantities by involution; thus, if the equation be \( \sqrt[3]{a} = 6 \); then by involution or squaring each side of the equation, we have the equation \( a = 36 \). If both sides be similar surds, or of the same power, all that we have to do is to reject the radical sign; thus, for \( \sqrt[3]{a} = \sqrt[3]{d+e} \), we write \( a = d + e \), rejecting the radical sign of both. 5. When any single power of the unknown quantity is on one side of the equation, evolve or extract the root of both sides, according as the index of that power denotes, and their roots will be equal. Thus if \( z = z \), by extracting the root of each side we have \( z = \pm z \). In the same manner, if \( a^m = 27 \), their cube roots will be equal, viz. \( a = \pm 3 \). Or, if any compound power of the unknown quantity be on one side of an equation, that hath a true root of its kind; then, by evolving both sides of the equation, it will be expressed in lower terms: for example, \( a^3 + 2ba + b^2 = d^3 \), by evolving both sides, comes out \( a + b = d \). 6. A proportion may be converted into an equation, affecting the product of the extremes to be equal to that of the means; or, any one of the extremes may be made equal to the product of the means divided by the other extreme: thus, if \( 12 - x = \frac{2}{4} \cdot 1 \), then \( 12 - x = 2x \); and by transposing the \(-x\), we will have \( 3x = 12 \), and dividing by \( 3 \), \( x = 4 \), by the preceding rules. 7. If any quantities be found on both sides of the equation, with the same sign prefixed, they may be taken away from both: thus, for \( 3x + b = a + b \), we say \( 3x = a \). Also, if all the quantities of the equation be multiplied or divided by the same quantity, it may be struck out of them all; thus, if \( 3ax + 5ab = 8ac \), dividing by \( a \), we have \( 3x + 5b = 8c \); and transposing \( 5b \) and dividing by \( 3 \), we have \( x = \frac{8c - 5b}{3} \), according to the first and third rules. 8. Instead of any quantity in an equation, you may substitute another equal to it: thus, if \( 3x + y = 24 \), and \( y = 9 \); then \( 3x + 9 = 24 \), or \( x = \frac{24 - 9}{3} = 5 \).

Solution of simple Equations. 1. After an equation is formed, if you have only one unknown quantity, then, by the preceding rules, bring it to stand alone on one side, so as to have none but known quantities on the other side; by which means you will discover its value. Thus, if the question proposed be that of the three persons ages already mentioned, the equation thence resulting has been found to be as in

Example I.

By quest. 1. \( x + x + 7 + 6x + 21 = 68 \) 2. \( 8x = 68 - 2a = 40 \) 3. \( \frac{x}{8} = 5 = \text{first age} \). Hence \( 4. \frac{x + 7}{12} = \text{second age} \). And \( 5. \frac{12 + 5x}{3} = \text{third age} \).

Example II.

\[ \frac{3x}{4} \times \frac{x}{12} = x \]

\[ \frac{3x^2}{48} = \frac{x}{12} \]

and \( \frac{3x^2}{48} \) by the second rule.

and \( 3x = 48 \) by the seventh rule.

and \( x = \frac{48}{3} = 16 \) by the third rule.

2. If there are two unknown quantities, then there must be two equations arising from the conditions of the question; suppose \( x \) and \( y \). The rule is, to find a value of \( x \) or \( y \) from each of the equations, and then by putting these two values equal to each other, there will arise a new equation involving only one unknown.
known quantity, which must be reduced by the same rules as formerly.  

Example: let the sums of two quantities be, $s$, and their difference $d$, let $s$ and $d$ be given, and let it be required to find the quantities themselves. Suppose the quantities to be $x$ and $y$; then, by the question, $x + y = s$, and $x - y = d$; whence $x = s + y$ and $y = s - d$; and, by transposition, $2y = s - d$; so that dividing by 2, we have $y = \frac{s - d}{2}$; and by comparing $x = \frac{s + d}{2}$, the value of $x$, viz. $s - y$, we find $x = s - \frac{s + d}{2}$, or $2x = 2s - s + d$, and dividing by 2, the value of $x = \frac{s + d}{2}$, as expressed in the margin.  

3. In one of the given equations, the unknown quantity is of one dimension, and in the other of a higher dimension; you must find a value of the unknown quantity from that equation where it is of one dimension, and then raise that value to the power of the unknown quantity in the other equation; and by comparing it, found involved, with the value you deduce from that other equation, you will obtain an equation that will have only one unknown quantity and its powers: That is, when you have two equations of different dimensions, if you cannot reduce the higher to the same dimension with the lower, you must raise the lower to the same dimension with the higher.  

Example: the sum of two quantities,  

$$x + y + z = 12$$  

$$x + 2y + 3z = 20$$  

$$x + \frac{y}{3} + z = 6$$  

Then,  

$$x = \frac{12 - y - z}{2}$$  

$$y = \frac{20 - 2y - 3z}{x}$$  

$$z = \frac{18 - \frac{5y}{2} - 3z}{2}$$  

These two last equations involve only $y$ and $z$, and are to be resolved by the second direction. Thus,  

$$2y - 3z = -2$$  

$$y + 2z = 3$$  

$$3y - 6z = 24$$  

$$12 = y + 4z$$  

Whence $y = \frac{8 - 2z}{12 - 4z}$ first  

and $z = \frac{8 - 2z}{12 - 4z}$ second  

value  

and the difference of their squares, being given, to find the quantities themselves. Suppose them to be $x$ and $y$, their sum $s$, and the difference of their squares $d$. Then,  

$$x + y = s$$  

$$x^2 - y^2 = d$$  

$$x = s - y$$  

$$x^2 = s^2 - 2sy + y^2$$  

$$x^2 = d + y^2$$  

whence  

$$d + y^2 = s^2 - 2sy + y^2$$  

$$2y = s^2 - d$$  

$$2y = s^2 - d$$  

$$y = \frac{t - d}{2s}$$  

$$x = \frac{t^2 + d}{2s}$$  

4. If there are three unknown quantities, there must be three equations in order to determine them, by comparing which you may, in all cases, find an equation involving only one unknown quantity; which may be resolved by the rules for reduction of equations already mentioned. From three equations involving any three unknown quantities, $x$, $y$, and $z$, to deduce two equations involving only two unknown quantities, the following rule will always serve: find three values of $x$ from the given equations; then, by comparing the first and second value, you will find another equation involving only $y$ and $z$; again, by comparing the first and third, you will find another equation involving only $y$ and $z$; and, lastly, those equations are to be solved by the second direction. Example: suppose
Solution of quadratic equations. 1. If, after the equation is reduced as directed above, and the unknown quantity brought to stand on one side, it is found to be a simple square power, all that you have to do is to evolve both sides of the equation, by which means you will find the value of the simple unknown quantity. Thus, if \( x^2 = 36 \); then, by evolution or extraction, \( x = 6 \). See Extraction.

2. In the solution of any question, where you have got an equation that involves only one unknown quantity, but involves at the same time the square of that quantity, and the product of it multiplied by some known quantity; then you have what is called a self-affected quadratic equation, which may be resolved by the following rules: 1. Transpose all the terms that involve the unknown quantity to one side, and the known terms to the other side of the equation. 2. If the square of the unknown quantity is multiplied by any coefficient, you are to divide all the terms by that coefficient, that the coefficient of the square of the unknown quantity may be unit. 3. Add to both sides the square of half the coefficient prefixed to the unknown quantity itself, and the side of the equation that involves the unknown quantity will then be a complete square. 4. Extract the square root from both sides of the equation, which you will find, on one side, always to be the unknown quantity with half the foresaid coefficient subjoined to it; so that by transposing this half, you may obtain the value of the unknown quantity expressed in known terms. Thus, suppose the quadratic to equation be,

\[
\begin{align*}
\frac{a}{2}y^2 + ay &= b \\
\frac{a}{2}y^2 + ay + \frac{a^2}{4} &= b + \frac{a^2}{4} \\
\frac{a}{2}y + \frac{a}{2} &= \pm \sqrt{b + \frac{a^2}{4}} \\
y &= \sqrt{b + \frac{a^2}{4}} - \frac{a}{2}
\end{align*}
\]

and \( 32y - y^2 = 240 \)

transpose, \( y^2 - 32y = -240 \)

add \( 16 \), \( y^2 - 32y + 256 = -240 + 256 \)

extract \( \sqrt{y - 16} = \pm \sqrt{16} \)

and \( y = \pm \sqrt{16 + 16} = 20 \)

\( y(32 - y) = 12 \)

Example II. Three merchants join flocks; the stock of the first was less than that of the second by 131. and the sum of the second and third man's flock amounted to 175. In trading they gained 48\( \frac{1}{2} \) more than their whole flock was; and the first man's share of the gain was 78\( \frac{1}{2} \). Required each man's flock and share of the gain?

Suppose \( z, y, z \), to represent each man's flock,

Then \( x + y + z = s \), the whole flock,

By the question \( x + z = y \)

\( 5 + x \)

therefore \( 32 - y = \frac{240}{y} \)

Suppose 1 \( x, y, z \), to represent each man's flock,

Then 2 \( x + y + z = s \), the whole flock,

By the question 4 \( x + 13 = y \)

\( 5 + x \)
Solution of cubic EQUATIONS. The second term of a cubic equation can be taken away, so that it will be transformed to this form $x^3 + qx + r = 0$. See the article Transformation.

Let us suppose that $x = a + b$; and $x^3 + qx + r = a^3 + 3a^2b + 3ab^2 + b^3 + qx + r = a^3 + 3abx + b^3 + qx + r = (by supposing $3ab = -qa^3 + b^3 + r = 0$). But

$$a = \sqrt[3]{-\frac{q}{2}} \pm \sqrt[3]{\frac{r^2}{27} - \frac{q}{27}}$$

in which expressions there are only known quantities. This method is commonly called Cardan's rule.

But when, in a cubic equation $x^3 - qx \pm r = 0$, $q$ is negative; in this case the expression $\sqrt[3]{\frac{r^2}{27} - \frac{q}{27}}$ will be transformed into $\sqrt[3]{\frac{r^2}{27} - \frac{q}{27}}$; which root becomes impossible, or imaginary, when $\frac{q^3}{27} > \frac{r^3}{27}$; as being the square root of a negative quantity. And yet, even in this case, the root $x$ may be a real quantity; though algebraists have not, hitherto, been able to find a real expression of its value. See the article IRREDUCIBLE.

Again, any cubic equation may be reduced to this form, and the value of $x$ discovered, without exterminating the second term.

$$x^3 - 3px^2 - 3qx - 2r = 0$$

by supposing $x = z + p$, will be reduced to $z^3 - 3pz^2 - 3qz - 2r = 0$, in which the second term is wanting. But, from what is advanced above, it follows that $z = \sqrt[3]{r + \sqrt{r^2 - q^3}}$, which is the square root of the binomial $r + \sqrt{r^2 - q^3}$.

Example: let it be required to find the roots of the equation $x^3 - 12x^2 + 41x - 42 = 0$.

Comparing
Comparing the coefficients of this equation with those of the general equation, viz.

\[ x^3 - 3px^2 + 3q \cdot x - r = 0, \]

will find, \( 3p = 12 \), so that \( p = 4 \) and \( 3p^2 = 48 \), \( -3q = 48 - 3q \), so that \( q = \frac{4}{3} \); and \( -r = \frac{4}{3} \), so that \( r = 4 \), and consequently \( r^2 - 3q = 4 - 3 \cdot \frac{4}{3} = 4\).

Now the cubic root of this binomial is found to be \( -1 + \sqrt{-3} \). Hence

\[ y^2 + 2qy + q^2 - 4x \cdot y - r^2 = 0. \]

Suppose \( \epsilon = y \), and it becomes \( \epsilon^2 + 2q\epsilon^2 + q^2 - 4\epsilon^2x + \epsilon^2 = 0 \).

\[ \text{Solution of biquadratic Equations. The roots of these may be found by reducing them to cubic ones, thus:} \]

Let the second term be taken away, as directed under the article Transformation of equations.

And let the equation that results, be \( x^4 + qx^2 + rx + s = 0 \). Suppose this biquadratic to be the product of these two quadratic equations:

\[ x^2 + ex + s = 0, \]
\[ x^2 - ex + g = 0. \]

\[ x^4 + qx^2 + rx + s = x^2(x^2 + ex + s) = x^2(x^2 - ex + g) = 0. \]

Where \( e \) is the coefficient of \( x \) in both equations, but affected with contrary signs; because when the second term is wanting in an equation, the sum of the affirmative roots must be equal to the sum of the negative. Compare now the proposed equation with the above product, and the respective terms put equal to each other, will give \( f + g = e^2 = q, \) \( eg = e^2 - r, \) and \( f \cdot g = s. \) Whence it follows, that \( f + g = q + e^2, \) and \( f \cdot g = s. \) Consequently, \( f + g = \frac{-r}{e^2} \) and \( g = \frac{-r}{e^2} + q. \) Therefore, \( f \cdot g = s. \)

In the same manner you will find, by subtraction, \&c., \( f = \frac{q + e^2 - r}{2}, \) and \( f \cdot g = \frac{q + e^2 - \frac{r}{e^2}}{2}; \) and, multiplying by \( 4e^2, \) and ranging the terms, you have this equation, \( e^6 + 2q\epsilon^2 + q^2 + 4\epsilon^2x^2 = -r^2 = 0. \) Supposing \( \epsilon^2 = y, \) and it becomes \( \epsilon^2 + 2q\epsilon^2 + q^2 + 4\epsilon^2x^2 = -r^2 = 0. \) Therefore, \( \epsilon^2 = \frac{-r^2}{4\epsilon^2} = y. \)

\( \text{Every equation has as many roots, as the unknown quantity of the first term has dimensions, or as the exponent thereof contains units. See the articles Roots and Exponent.} \)

All equations have as many affirmative roots as there are permutations of signs; and as many negative roots as there are successions of them; thus, in the quadratic \( x^2 + x + b = 0, \) there is only one solution.
succession of signs, +; and one permutation of them, +−; hence the equation has two roots, one affirmative +2, and the other negative −1. Also in the cubic equation \( x^3 - 3x^2 + 2x + 24 = 0 \), there are two permutations of signs, +− and +−; and only one succession −−: hence its roots are found to be two affirmative +2 and +4, and only one negative −3. For the methods of approximating to the roots of equations, by means of their limits and series, see the articles Limit and Series.

Construction of Equations. See the article Construction.

Exponential Equation. See the article Exponential.

Transcendental Equation. See the article Transcendental.

Annual Equation of the mean motion of the sun, and moon's apogee and nodes. The annual equation of the sun's mean motion depends upon the excentricity of the earth's orbit round him, and is \( 16\frac{1}{2} \) such parts, of which the mean distance between the sun and earth is 1000; whence some have called it the equation of the center, which, when greatest, is \( 1\times 56'30'' \).

The equation of the moon's mean motion is \( 11\frac{1}{4}30'' \); of the apogee, \( 20'' \); and of its node, \( 9''30'' \).

These four annual equations are always mutually proportional to each other; so that when any of them is at the greatest, the other three will also be greatest; and when one diminishes, the rest diminish in the same ratio. Wherefore the annual equation of the center of the sun being given, the other three corresponding equations will be given; so that one table of the central equations will serve for all.

Equation of a curve, an equation expressing the nature of a curve, the relation between an absciss and a corresponding ordinate, or the relation of their fluxions. See the article Curve.

Equation of time, in astronomy and chronology, the reduction of the apparent time or motion of the sun, to equable, mean, or true time.

The difference between true and apparent time arises from two causes, the excentricity of the earth's orbit, and the obliquity of the ecliptic. Thus, if the earth revolved in the plane of the equator, and in a circle about the sun, then would the angle \( ASB \) (pl. XCVI, fig. 3, n° 1.) and consequently the angle \( eBm \), be always of the same quantity; and, therefore, the time of describing the said angles, \( eBm \), would always be equal; and the solar days and hours be equal among themselves. But neither of these two cases have place in nature; for the earth's orbit being an ellipse, her annual motion cannot be equable, or the angle \( ASB \) (ibid.) described in the same space of time, will not be always equal; since, in the aphelion, the velocity of the earth will be less than in the perihelion, and consequently the arch \( AB \), and the similar arch \( em \), will be less; and, therefore, likewise the time of describing it. But the most considerable part of the equation of time is that which arises from the plane of the earth's orbit, or ecliptic, being inclined to that of the equator, or plane of the diurnal motion. To explain this, let \( \gamma \beta \phi \in \alpha \) (ibid. n° 2.) be a semi-circle of the ecliptic, and \( \gamma H \in \alpha \) of the equinoctial, \( S \) the center of the sun, and \( A \) that of the earth, in the third quarter of the ecliptic, \( \beta \in \beta \); \( h \) the meridian passing through the true fun \( S \), and its apparent place at \( I \), in the first quarter of the ecliptic \( \gamma \in \gamma \). Suppose now the motion of the earth in every respect equable, and first that it fet out from \( \alpha \), and proceeded in the equinoctial in a given time to \( D \); the fun would apparently describe, in the same time, the arch of the equinoctial \( \gamma I \). Again, suppose it fet out from the same point, \( \alpha \), and spent the same time, with the same equable velocity, in the ecliptic, it would arrive to the point \( A \); so that the arch \( \alpha A = \alpha D \), and \( \gamma I = \gamma C \). Then it is evident, as the earth revolves about its axis from west to east, the meridian of any place will first arrive at the sun \( I \), in the ecliptic, and afterwards at the sun \( C \), in the equinoctial; that is, the time of noon by the sun in the ecliptic will be sooner than that by the sun in the equinoctial, by the quantity of the arch \( \beta D \), turned into time.

Now the arch \( \beta D = BC \) is the difference of the sun's longitude \( \gamma I \) or \( \gamma C \), and his right ascension \( \gamma B \). Draw \( \gamma B \) parallel to \( DC \), and the angle \( \gamma A \) will be equal to the angle \( DSB \), and the arch \( \gamma B \) similar to the arch \( DB \). Therefore, the time in which the meridian \( h \) revolves into the situation \( e \), is that which
is to be added to the ecliptic noon, to
equate it with the time of the equinoctial
noon, in the first and third quarters of the
ecliptic. In the second and fourth quar-
ters the said equation is to be subtrac-
ted, as would easily appear, by making the
same construction there.
Since, in different parts of the quadrant
this arch $DB$, or $BC$, is of different
lengths, the equation of time will be a
variable quantity; and, therefore, as the
motion and time measured by the fun in
the equinoctial is always equal, it follows
that the times measured by the fun in the
ecliptic must be always unequal; or, in
other words, the solar days are sometimes
shorter, sometimes longer, than the equal
time measured out in the equinoctial.
As the true motion of the earth precedes
its mean motion in the first semi-circle of
anomaly, and is preceded by the mean in
the second, it follows, that while the
earth is going from the aphelion to the
perihelion, or while the fun apparently
moves from the apogeeum to the perigee-
um, the apparent time will be before the
mean; and, in the other semi-circle of
anomaly, it will be after it. The differ-
ce of these motions, converted into
time, is the equation of time in this re-
spect, and is to be substracted from the
apparent time to gain the mean, or added
to the mean to gain the apparent, in the
first semi-circle of anomaly; and, vice
verfa, in the latter.
Both these parts of the equation of
time are calculated by astronomers for
every degree of the sun's longitude in the
ecliptic, and disposed in tables with di-
rections for adding or subtrac-ting, as the
case requires; by which means the true
equal time may, at all times, be had.
From what has been said it appears, that
the apparent time, or that shown by a
fun-dial, is but four days in the whole
year the same with the mean or equal
time, shown by a good clock or watch,
viz. about April 15, June 17, Aug. 31,
and Dec. 24. It is also remarkable, that
about the third of November the equa-
tion is greatest of all, clocks being then
about $16'15''$ slower than sun-dials.
As, therefore, the solar days are unequal,
the hours must be $16$ of course; and, ac-
cording as the above-mentioned causes,
which are independent on each other,
concur, or counteract each other, this in-
equality is more or less. Besides, as the
former of these causes, viz. the excen-
tricity of the earth's orbit, is affected by
the precession of the equinoxes, tables of
the equation of time, made for any year,
must continually afterwards deviate more
and more from the truth; yet, as this va-
riation is extremely slow, the same tables
may very well serve for an age, or more,
without any sensible error.
Here follows a table of the equation of
time, calculated for the new or gregorian
style, and shewing how much equal or
true time is faster or slower than apparent
time, for every day throughout the year;
or, which comes to the same thing, how
many minutes and seconds a good clock or
watch is faster or slower than a good fun-
dial.

</table>

**EQUATOR**, in geography, a great circle of the terrestrial globe, equidistant from its poles, and dividing it into two equal hemispheres; one north, and the other south. See the article **GLOBE**.

It passes through the east and west points of the horizon, and at the meridian is raised as much above the horizon as is the complement of the latitude of the place. From this circle, the latitude of places, whether north or south, begin to be reckoned, in degrees of the meridian. See **LATITUDE** and **MERIDIAN**.

All people living on this circle, called by geographers and navigators, the line, have their days and nights constantly equal. See the article **EQUINOCTIAL**. It is in degrees of the equator, that the longitude of places are reckoned; and as the natural day is measured by one revolution of the equator, it follows that one hour answers to \( \frac{360}{24} = 15 \) degrees; hence one degree of the equator will contain four minutes of time; fifteen minutes of a degree will make a minute of an hour; and, consequent, four seconds answer to one minute of a degree.

**EQUERRY**, in the British customs, an officer of state, under the master of the horfe.

There are five equerries, who ride abroad with his majesty; for which purpoze they give their attendance monthly, one at a time, and are allowed a table.
EQUUS [III] EQUUS

As to the equerries of the crown-stable, they have this distinct appellation, as being employed in mounting, managing, and breaking the saddle-horses for his majesty's use, and holding his stirrup.

EQUUS AURATUS, is used for a knight batchelor, called auratus, q. d. gilt, because antiently none but knights were allowed to beautify their armour, or other habiliments for war, with gold.

This term is not used in law, but instead of it miles & chevaliers are made use of.

EQUESTRIAN STATUE, signifies the statue of a person mounted on horseback.

EQUESTRIAN ORDER, among the Romans, signified their knights, or equites; as also their troopers, or horsemen in the field; the first of which orders flood in contradistinction to the senators, as the last did to the foot, military, or infantry; each of these distinctions was introduced into the state by Romulus. See the articles Senator and Pedites.

EQUIANGULAR, in geometry, an epithet given to figures, whose angles are all equal: such are a square, an equilateral triangle, &c.

EQUICRURAL, in geometry, the same with isosceles. See the article Isosceles.

EQUICULUS, or EQUELEUS. See the article Equeleus.

EQUIDIFFERENT NUMBERS, in arithmetic, are of two kinds. 1. Continually equidifferent is when, in a series of three numbers, there is the same difference between the first and second, as there is between the second and third; as 3, 6, 9.

And, 2. Discretely equidifferent, is when in a series of four numbers or quantities, there is the same difference between the first and second, as there is between the second and third; as 3, 6, 7, 10.

EQUIDISTANT, an appellation given to things placed at equal distance from some fixed point, or place, to which they are referred.

EQUILATERAL, in general, something that hath equal sides, as an equilateral angle.

EQUILATERAL HYPERBOLA, one whose transverse diameter is equal to its parameter; and so all the other diameters, equal to their parameters: in such an hyperbola, the asymptotes always cut one another at right angles in the center. Its most simple equation, with regard to the transverse axis, is \( y^2 = x^2 - a^2 \); and, with regard to the conjugate, \( y^2 = x^2 + a^2 \); when \( a \) is the semi-transverse, or semiconjugate. The length of the curve cannot be found by means of the quadrature of any space, of which a conic section is any part of the perimeter. See the article Hyperbola.

EQUILIBRIUM, in mechanics, is when the two ends of a lever or balance hang so exactly even and level, that neither doth ascend or descend, but keep in a position parallel to the horizon; which is occasioned by their being both charged with an equal weight.

EQUIMULTIPLES, in arithmetic and geometry, are numbers or quantities multiplied by one and the same number or quantity. Hence, equimultiples are always in the same ratio to each other, as the simple quantities before multiplication: thus, if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other, as 6 to 8.

EQUINOCTIAL, in astronomy, a great circle of the celestial globe, whose poles are the poles of the world.

It is so called, because whenever the sun comes to this circle, the days and nights are equal all over the globe; being the same with that which the sun seems to describe, at the time of the two equinoxes of spring and autumn. See the article Equinox.

All stars, directly under this circle, have no declination, and always rise due east, and set full west. The hour circles are drawn at right angles to it, passing thro' every fifteenth degree; and the parallels to it are called parallels of declination. See the articles Declination and Circle.

EQUINOX, the time when the sun enters either of the equinoctial points, where the ecliptic intersects the equinoctial. See the preceding article.

It is so called, because when the sun is in these points, the days and nights are of an equal length all the world over. As the sun is in one of them, in the spring, viz. March 20th, it is called the vernal equinox; and in the other, in autumn, viz. September 23d, it is called the autumnal equinox.

Precession of the Equinoxes. See the article Precession.
EQUINOX BARBATUS, in astronomy, a kind of comet, called also hippeus. See the article HIPPEUS.

EQUINUS VENTER, among chemists. See the article VENTER EQU.

EQUIPOLLENCE, in logic, is when there is an equivalence, or agreement, either as to the nature of the thing, or as to the grammatical sense of any two, or more propositions; that is, when two propositions signify one and the same thing, though they express it after different manners.

EQUISELE, or EQUISELIS, in ichthyology, the fame with the guaracapema.

EQUISELIS is also the name of a two-winged fly, resembling the hornet both in size and shape.

EQUISETUM, HORSETAIL, in botany, a genus of the cryptogamia class of plants, and order of filices, or ferns; the fructifications of which are disposed on an oblong spike, and are of an orbicular figure, dividing in various angles from the base. The plant itself consists of jointed fillets, in some simple, in others branched; producing fetae, or smaller divisions, of the same structure with the larger ones.

Horse-tail is accounted vulnerary, and astringent, and therefore would be gladly treated ourselves, we understand aright of which letter of collection larges, and in soever deemed a felon, if a madman, or an infant, that has no discretion, as for principal, interest, and costs, which is to be paid within the time limited by the decree, and therupon the estate mortgaged is to be reconveyed to the mortgagor, otherwise for default of payment, the mortgagor is decreed to be foreclosed from all equity of redemption, and absolutely to convey the mortgaged premises to the mortgagor. See the article MORTGAGE.

EQUITY, also frequently signifies the court of chancery, where controversies are determined according to the exact rules of equity and conscience, by mitigating the rigor of the common law; though even by the common and statute law there is also an equity. See the article CHANCERY.

Equitas sequitur legem, is an old maxim in law, but from the great increase of suits in chancery, some have thought fit to give it this construction, that in all causes, after a man hath been at law, he must go to equity.

EQUIVALENT, an appellation given to things which agree in nature, or other circumstances, as force, virtue, &c.

EQUIVOCAL TERMS, or WORDS, among logicians, are those which have a doubtful, or double meaning. According to Mr. Locke, the doubtfulness and uncertainty of words has its cause more in the ideas themselves, than in any incapacity of the words to signify them; and might be avoided, would people always use the same term to denote the same idea, or collection of ideas: but, adds he, it is hard to find a discourse on any subject where this is the case; a practice which can only be imputed to folly, or great dishonesty; since a man,
EQUUS [1113] ERE

in making up his accounts, might with as much fairness use the numeral characters sometimes for one, sometimes for another collection of units.

equivocal action is, where the effect is of a different kind from the cause producing it.

equivocal cause. See Cause.

equivocal generation, the production of animals, without the intercourse between the sexes, by the influence of the sun or stars, &c.

The equivocal generation of plants, is dueing it. This kind of opinion, that there is no generation iifue that thor feCts, arid, that appearances of such things as spontaneous or equivocal terms.

The equuleus was made of wood, having holes in it that horse-hairs, thrown into water, will become animated bodies; by shewing, that appearances of this kind are hair-worms bred in the bodies of other insects, and particularly of the common black beetle.

equicotation, in ethics, the crime of wilfully using equivocal terms. See the article equivocal.

equuleus, or equuleus, in antiquity, a kind of rack used for extorting a confession, at first chiefly practised on slaves, but afterwards made use of against the christians.

The equuleus was made of wood, having holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth, or fifth holes, his arms and legs being fastened on the equuleus with cords; and thus was hoisted aloft, and extended in such a manner, that all his bones were dislocated. In this state red hot plates were applied to his body, and he was goaded in the sides with an instrument called ungula.

Equuleus, in astronomy, a constellation of the northern hemisphere, whose stars, according to Ptolemy, and Tycho's catalogues, are four, but in Mr. Flamsteed's ten.

Equus, the horse, in zoology. See the article horse.

Equus marinus, in ichthyology, the same with the morse. See Morse,

Era, or Era. See the article era.

Eranchæ, a public officer among the ancient Greeks, whose business was to preside over, and direct, the alms and provisions made for the poor. Cornelius Nepos, in his life of Epaminondas, describes his office thus; when any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. the eranarchæ called an assembly of friends and neighbours, and taxed each according to his means and estate, to contribute towards his relief.

Eranthemum, in botany, a genus of the diandria-monogynia class of plants, the corolla of which is quinquifid, the tube filiform, and the stigma fiddle.

Eranthemum is also a name given to the adonis flos. See the article adonis.

erased, in heraldry, the same with arrache. This also denotes parts of animals torn, not cut off, from the part to which nature fixed them.

erect flowers, such as grow upright without hanging or reclining the head. See the article flower.

erect dial. See the article dial.

erect vision. See the article vision.

errection, in a general sense, the art of raising or elevating any thing, as the erection of a perpendicular, &c.

Erection is also used in a figurative sense, as the erection of a bisliporic, marquifate, &c.

Erection is particularly used by medical writers, for the state of the penis, when swelled and distended by the action of the muscles called ereectors. See the article erector.

There is also an erection of the clitoris, which is performed by muscles for that purpose. See the article clitoris.

De Graaf assigns two kinds of vessels with its muscles, for the performance of this office; the nerves, by which the animal spirits flow into its membranous parts, and render them more rigid and tumid, and the arteries carrying the blood to distend the corpora cavernosa.

Erector clitoris, in anatomy, one of the two muscles of the clitoris that serve for its erection.

The ereectors of the clitoris arise from the osa ischi, and are inserted into the corpora cavernosa.

Erector penis, one of the two muscles of the penis, that serve for its erection.

Their
These arise on each side from the olla orchi between the tubercle of this bone and the beginning of the corpus cavernosum, and each of them is inserted into the corpus cavernosum of its own side. These muscles when they act together, press the veins of the back of the penis against the olla pubis, by which they prevent the reflux of blood from the penis; and consequently when at the same time the blood flows impetuously into the part by the arteries, and cannot get back this way, the penis becomes erected.

EREMIT, or HERMIT. See HERMIT.

EREMITA, the HERMIT, in zoology, a species of iquill, with a long soft tail, and the right claw the larger. See the article SQUILL.

Authors call it cancellus, or the little crab, as being only two inches and a half in length.

ERESIA, in botany, the same with theophrasta. See the article THEOPHRASTA.

ERETRIAN EARTH, in natural history, a kind of bole. See the article BOLE.

ERFURT, a large and beautiful city of upper Saxony, in Germany, capital of Thuringia, and subject to the elector of Mentz: east long. 11° 6', north lat. 51°.

ERGOT, in farriery, is a stub, like a piece of soft horn, about the bigness of a chestnut, placed behind and below the patern-joint, and commonly hid under the tuft of the fet-lock.

To diergot, or to take it out, is done by cleaving it to the quick, with an incision-knife, in order to pull up a bladder full of water, that lies covered with the ergot. This operation is scarce ever performed in France, but in Holland 'tis frequently performed upon all four legs, with intent to prevent watery fores, and other foul ulcers.

ERICA, HEATH, in botany. See the article HEATH.

ERICA MARINA, SEA-HEATH, in botany, a plant of the fucus-kind. See the article FUCUS.

ERICHTHONIUS, in astronomy, a constellation more usually called auriga.

ERIDANUS, in astronomy, a constellation of the southern hemisphere; containing, according to different authors, 39, 30, or even 68 stars.

ERIE, a vast lake to the westward of Pennsylvania, in north America, situated between 80° and 87° west lon. and between 41° and 42° north lat.

ERGERON, SWEET FLEABANE, in botany, a genus of the fingenelia pogygma superficis class of plants, the compound flower whose is radiated; the partial hermaphrodite one infundibuliform; and the female flower is ligulated, linear, and subulatum: The fruit has no pericarpium, the cup is connivent: the seeds of the hermaphrodite flower are oblong, small, and crowned with long down. This plant is a diuretic, and promotes the menses: the smell of it drives away flies, and kills lice and other like vermin.

ERINACEUS, in botany, the same with hydnum. See the article HYDNUM.

ERINACEUS, in zoology, the name by which authors call the hedge-hog.

ERINGO, in botany, the English name of the Eryngium. See ERYNGIUM.

ERIOCAULON, in botany, a genus of the triandria trygynia class of plants, the general corolla of which is uniform and convex; the partial flower consists of three lancedolate, obtuse, hairy petals, narrow at the base, where they all three unite into one styliform hairy pedicle: the cup changes into a capsule, and contains a single seed winged with down.

ERIOCEPHALUS, in botany, a genus of the fingenelia pogygmae necessaria class of plants, the compound flower of which is radiated; the proper hermaphrodite one is funnel-shaped; the female ones, being five in number, are ligulated, in the radius: there is no pericarpium: the seed of the hermaphrodite produces no fruit; the seed of the female is single, roundish, naked, and placed vertically.

ERIOCEPHALUS is also used by Vaillant for a species of thistle.

ERIOPHORUM, in botany, a genus of the triandria monogynia class of plants, without any flower petals; the cup is a spike imbricated with oval, oblong spines; the seed is a triquetrous and acuminate seed, furnished with hairs longer than the spike.

ERIOPHORUS, in botany, the same with the andryala. See ANDRYALA.

ERIX, in ichthyology, a name used by some for the salmon. See SALMON.

ERITHACE, the same with the antients to rough, or crude wax, as collected by the bees. See WAX.

ERITHACEUS, in botany, a species of motacilla, called also rubecula. See the articles MOTACILLA and RUBECULA.

ERIVAN,
ERIVAN, a city of Persia, on the frontiers of Turkey, situated on the south end of a lake of the same name: east long. 45°, north lat. 45° 6'.

ERKELENS, a city of Westphalia, in Germany, ten miles north of Julica: east long. 6°, north lat. 51°.

ERMINE, ermineum, in zoology, a species of mustela, with narrow ears, and of the size of the weasel. See MUSTELA. The whole body of the ermin is of a pure snow-white, except the tip of the tail, which is of a deep black, and some spots of a greyish yellow about the head and shoulders. Its fur is much valued. See the article FUR.

ERMINE, in heraldry, is always argent and fable, that is, a white field, or fur, with black spots. These spots are not of any determinate number, but may be more or less, at the pleasure of the painter, as the skins are thought not to be naturally so spotted; but serving for lining the garments of great persons, the furriers on the coast of Abax in Africa: east long. 59°, north lat. 49° 42'.

ERQUIKO, a port-town of the Red-sea, on the coast of Abax in Africa: east long. 39°, north lat. 17°.

ERRANT, or ITINERANT, is a title that is applied to justices that go the circuits, and also to bailiffs at large. See the article EYRE.

ERRATA, a list of the errors or faults in the impression of a book, generally placed at the beginning thereof.

ERRATIC, in general, something that wanders, or is not regular: hence it is, the planets are called erratic stars; as those fevers, which observe no regular periods, are denominated erratic fevers.

ERRHINES, elirhines, in pharmacy, medicines which, when sniffed up the nose, promote a discharge of mucus from that part. The excretion of the mucous lymph is excellently promoted by errhines and sternutatories, the former of which stimulate the pituitary coats but gently, whereas the latter more forcibly stimulate them, to an excretory motion. See the article STERNUTATORY.

Among the milder kind of the errhines, we may reckon marjoram, basilicon, thyme, hyssop, savory, marum syriacum, the tops of origanum, flowers of lilies of the valley, and benjamin, the resin of guaiacum, fine rasplings of aloes wood, dry volatile salt of fal-ammoniac perfumed with oil of marjoram, as also white vitriol. On the contrary, violent errhines are euphorbium, the powder of white hellebore, and, in a milder degree, several
ferveral forts of snuffs, precipitate mercury, and pepper.
Errhines are more friendly to the constitution and nerves than fermentatories, by their subtile, acrid, and volatile, fall, gently stimulating the pituitary membrane, and drawing the mucid humours from it. They are also much safer than fermentatories, in their effects.
Errhines prepared of cephalic herbs are of singular service in oppressive pains of the head, a hemicrania, the little labour bestowed upon natural philosophy, 3. Few entirely addicted to natural philosophy. 4. The end of the sciences wrong fixed. 5. A wrong way chosen. 6. The neglect of experiments. 7. Regard to antiquity and authority. 8. Admiration of the works in use. 9. The artifice of teachers and writers in the sciences. 10. Oftentatious promises of the moderns. 11. Want of proposing worthy talks. 12. Superstition and zeal being opposite to natural philosophy, as thinking philosophy dangerous, on account of the school-theology; from the opinion that deep natural enquiries should subvert religion. 13. Schools and academies proving unfavourable to philosophy. 14. Want of rewards. And, 15. Dèpair and the supposition of impossibility.
Eruc, the caterpillar, in zoology. See the article Caterpillar.
Eruc, the white-rocket, in botany, a species of brassica, with lyrate leaves, white, broad, or purple, or red colour; or they are sometimes broad, or of an oblong or some other shape: they show themselves in the skin up and down the
sent to the common received opinions either of our friends or party, neighbours or country.
The causes of errors in philosophy, or the reasons why all former philosophers have through so many ages erred, according to lord Bacon, are these following.
Erula, the catterpillar, in zoology. See the article Caterpillar.
Erula, the white-rocket, in botany, a species of brassica, with lyrate leaves, hairy stalks, and smooth pods. See the article Brassica.
Erula marina, a sea-insect, more usually called aphroditia. See Aphroditia.
Erucago, corn-rocket, in botany, a genus of plants called also bunias. See the article Bunias.
Eructations, in medicine, are the effect of flatulent foods, and the cruelties of men underhandings, apprehensions, and reasonings. Thirdly, he remarks, that though some have opportunities and leisure enough, and want neither parts, learning, nor other helps, that they never come to the knowledge of several truths within their reach, either upon the account of their attachment to pleasure or business; and otherwise because of their laziness or aversion to study. The fourth cause of error, viz. wrong measures of probability, he imputes, 1. To the practice of taking for principles propositions that are not in themselves certain and evident, but, on the contrary, doubtful and false. 2. To received hypotheses. 3. Predominant passions or inclinations. And, 4. To authority, or the giving up our af
the body. See the articles Plague, Buboe, Caruncle, &c.

Spots of a purple, black, greenish, or violet colour, at whatever time they appear, are always fatal signs.

Scabby Eruptions in the heads of children. See the articles Crusta lactea, and Achor.

The heads of children are often troubled with scabby eruptions: these are expelled by the benefit of nature; and before the eruption, the child is often troubled with epileptic fits from the irritation of the morbid matter. If the humour strike in, either spontaneously, or by improper applications; or if the exanthemata are of a blackish colour, they are very dangerous, and the child generally falls into an asthma, or a fatal epilepsy.

Harris prescribes the tinctures of powders for infants in this case. Heiffer, if the child is suspected of the venereal disease, would have a grain or two of mercurius dulcis added with gentle purges between whiles, especially if the body is not loose. Externally, nothing of sulphur, or mercury should be applied, or repellent lotions, or any cold thing. To mollify the scabs, fresh butter, or calves marrow, or cream, is sufficient. This case often proves obstinate, and then the nurse should observe a strict regimen, use a good diet, take sweeteners of the blood, and purgatives now and then.

ERVUM, a genus of the diadelphus-decan-dria class of plants, the corolla of which is papilionaceous; the vexillum plane, slightly turned up, and of a roundish form; the ase are obtuse, and shorter by half than the vexillum; the carina is acuminated, and shorter than the ase: the fruit is a thick, knotty, obtruse and oblong pod, with protuberant feeds, which are four in number, and of a roundish figure. This plant, abounding with diuretic salt, is recommended for the stone.

ERYNGIUM, Erincho, in botany, a genus of the pentandria-digynia class of plants, the general corolla of which is uniform and roundish; the partial one consists of five oblong petals, knotted together by a longitudinal line. The fruit is of an oval figure, and divisible in two parts: the feeds are oblong and roundish. The root of eryngium is attenuated and deobtrusent, and is therefore esteemed a good hepatic, uterine, and nephritic. Its whole virtue consists in the external or cortical part.

ERYNGIUM is also used by some for aloe and a species of summi. See the articles Aloe and Ammi.

ERYSIMUM, hedge-mustard, in botany, a genus of the tetradynamia-filiquea class of plants, the corolla whereof consists of four oblong, cruciform petals, with a very obtuse point: the fruit is a long, linear, four-cornered pod, containing of two valves, and divided into two cells: the feeds are numerous, small, and roundish.

This plant is recommended in paralytic and epileptic cafes; it expels poison, destroys worms, strengthens the stomach, and cures ulcers of the mouth.

ERYSIPelas, in medicine, an eruption of a fiery or acrid humour, from which no part of the body is exempted, though it chiefly attacks the face.

As to the material cause of an erysipelas, it seems to be of a caustic, acrid, and putrefying nature; perhaps corrupted bile, which, being conveyed into the maws of blood, inflames the whole nervous and vascular systems, and excites a fever, till it is at last driven out to the surface of the body. Perions of a sanguine habit, young people, and pregnant women, are most subject to it; and all hot things, violent passions, and whatever occasions other inflammation, likewise give rise to this. See the article INFLAMMATION.

The patient is taken suddenly, whilst he is in the open air, with chills, a shivering, and other symptoms common in a fever: the part affected swells a little with great pain, and intense redness, and is beset with a vast number of small pustules, which, when the inflammation is increased, are converted into small blisters. The malady gradually creeps further and further, spreads itself from place to place, and is attended with a fever. See the article Fever.

There is another sort, though it seldom happens, commonly arising from a surfeit, or a debauch of drinking spirituous liquors. A small fever which precedes it, is followed presently by an eruption of pustules, almost all over the body, which look like the stings of nettles, and sometimes rise up into bladders: presently they go away again, with an itching scarce tolerable; but as often as they are scratched, they appear again.

This distemper has a great affinity with a pestilential fever, as it is attended with most of the symptoms in that case: but
this is to be understood of the worst kind of erysipelas. On the third and fourth day, the malignant matter is thrown out on the surface of the body, and then the symptoms a little abate. There is often a pain, redness, and tumour in the inguinal glands, from whence the matter, of a hot, fiery quality, descends to the feet. If the head is attacked, the parotid glands are affected; if the breath, the axillary. The mammary and axillary glands are not seldom ulcerated, and affect the joints with a virulent corruption; and likewise, as in the plague, there is nothing more dangerous than the expelled matter to return back from the surface of the body to the inward parts.

In some, especially young persons, the matter is not so violent, nor the fever so great; the glands remain unaffected, and the eruption happens on the second day. This is not at all dangerous. In children, the umbilical region generally suffers, with a fatal event. In a day or two the tumor subsides, the heat and pain cease, the roly colour turns yellow, the cuticle breaks, and falls off in scales, the danger is over. When the erysipelas is large, deep, and falls upon a part of exquisite sensibility, the patient is not very safe; but if the red colour changes into black and blue, it will end in a mortification. If the inflammation cannot be diffused, it will suppurate, and bring on stiaturas and a gangrene: when the patient is cachochymical, the leg will sometimes swell three times as big as the natural size, and is cured with great difficulty. Those who die of this disease, die of the fever, which is generally attended with difficulty of breathing; sometimes a delirium, sometimes with sleepiness; and this in seven days time.

Let the patient's diet be water-gruel or barley-broth, with roasted apples. If he drinks any beer, let it be very small, and let him keep out of bed some hours in a day. The medicinal writers do not agree in their opinions, concerning purging in the cure of the erysipelas; but what they deliver upon this subject, is full of doubts and uncertainties, and that at a point of time when the distemper is most dangerous and threatening: however, it is the general opinion in this case, that it is a right practice, more especially if the head is affected with an erysipelas, and there comes upon it a coma, a delirium, or convulsions, wherein the brain is evident-ly attacked; then purging is the only indication that can afford any hopes of recovering the patient; nor in these difficulties should the matter be delayed till the fever is abated, or the humor subfided. Therefore, the best practice appears to be that of taking away nine or ten ounces of blood, and the next morning giving the patient the common purging potion.

It will be safest to avoid external applications, unless a powder made of elder-flowers and liquorice sprinkled on the part; or lime-water mixt with a fourth part of spirit of wine and camphor, dipping a linen cloth in it several times doubled, and applying it hot to the part. An infusion of scorndium, elder-flowers, and fennel-feed, drank in the manner of tea, is useful to expel the morbid matter. If the disease does not yield to the first bleeding, let it be repeated. If that will not do, let it be reiterated twice more, one day being interposed between. On the days free from bleeding, prescribe a clyster of milk, and syrup of violets; also the cooling emulsion and julep.

Turner commends much a mixture of ol. fambucin. and aqua calcis, with some spirit of wine camphorated. A ca­plasm of cow's dung is very good to ease the pain.

In a symptomatical erysipelas, the following liniment is good: R OI. fambucin. lixiv. tenueor. ana p. æ. m. let them be shaken well in a phial till they unite in an ointment.

In a scarbotic erysipelasbesides externals, sudorifics are to be given; as Rob. fambucin. sp. fambuci bezoar. min. sp. fal. armon. cochlear, &c.

ERYTHOXYLUM, a name given by some to brafil-wood. See BRASIL.

ERYTHRINA, CORAL-TREE, in botany, a genus of the diadelphus-decandria class of plants, the corolla of which is papil­laneous, and consists of four petals: the fruit is a very long pod, protuberated by the seeds, terminating in a small point, and constricting of one cell: the seeds are kidney-shaped.

ERYTHRINUS, in ichthyology, a species of sparav, of a strong and elegant red colour, and the iris of the eyes of a fine silver-white: its tail is very much forked. See the article SPARUS.

ERYTHROCYANEUS, the red and blue macaw, with a wedge-like tail, and the sides of the head naked and rugose.

This
Fig. 1. Erythrocyaneus, or the Red and Blue Mackaw.

Fig. 2. Eschara.

Fig. 3. Entrochus.

Fig. 4.

Equation of Time.
ERYTHROIDANUM, a name sometimes used for madder. See Madder.

ERYTHROIDEIS, in anatomy, the first of the proper tunics or coats which cover the testicles. See Testicle.

ERYTHRONIUM, DOG'S TOOTH-VIOLET, in botany, a genus of plants belonging to the hexandria-monogynia class; the flower consists of six oblong and lanceolated petals; and the fruit is a sub-globose capsule, with three cells, in which are contained numerous ovato-acuminate seeds.

The root of this plant is recommended against the colic, epilepsy, and worms: it is also reckoned a provocative to venery.

ERYTHROPHTHALMUS, the SARPE, or RED-EYE, in ichthyology, a species of cyprinus, with the iris of the eye, all the fins, and tail red. See Cyprinus.

It somewhat resembles the roach, and is only ten inches in length.

ERZERUM, the capital of the province of Turcomania, or Armenia; east long. 41°, north lat. 40°.

It is a great thoroughfare from Persia and India to Constantinople, by the way of Trebizon and the Black-Sea.

ESCALADE, or SCALADE, in the art of war. See the article SCALADE.

ESCAMBIO, or EXCAMBIO, the same with exchange. See Exchange.

ESCAPE, in law, a violent or privy evasion out of some lawful restraint, without being delivered by due course of law. There are two sorts of escapes, voluntary and negligent. Voluntary, when a man arraigns another for felony, or other crime, and afterwards lets him go freely by consent; in which case, the party that permits such escape, is held guilty, committed, and must answer for it. Negligent escape, on the contrary, is where one is arrested, and afterwards escapes against the will of the person that arrested him; and is not puriued with fresh fuit, and re-taken before the person pursuing hath lost sight of him. By statute 8 & 9 Will. III. c. 26, the keepers of prisons, conniving at escapes, shall forfeit 500 l. and, in civil cases, the sheriff is answerable for the debt.

ESCAPE-WARRANT, a process which issues out against a person, committed in the king's bench or fleet prisons, that, without being duly discharged, takes upon him to go at large.

Upon this warrant, which is obtained on oath, a person may be apprehended on a Sunday.

ESCHALOT, cepa ascalonica, a species of onion cultivated in gardens, for its use in cookery. See the article Cepa.

ESCHAR, in surgery, the crust or scab occasioned by burns or cutaneous medicines. See the articles Burn and Caustics.

ESCHARA, in botany, a genus of plants, composed of a gritty matter, but not very hard, of a reticulate texture, and sometimes disposed in the form of holes, perforated with numerous round holes: these are so equally distributed, as to give the whole the appearance of a net. See plate XCIII. fig. 1.

There are several species of escara, distinguished from the fuculæ, no less by their brittlenefs, than by their net-like texture. See the article Fucus.

ESCHAROTICS, in pharmacy, medicines which produce escars. See Eschar.

ESCHEAT, in law, signifies any lands or tenements that casually fall to a lord within his manor, by way of forfeiture, or by the death of his tenant, without any heirs general or special.

The word escheat is sometimes used for the place or circuit within which the king or other lord is entitled to escheats; also for a writ, to recover the same from the person in possession after the tenant's death.

ESCHEATOR, in our old customs, an officer formerly appointed in every county, to make inquests of escheats due to the king; but since abolishing the court of wards, has been laid aside as useless.

ESCHELLES, a town of Savoy, sixteen miles south-west of Chambery.

ESCHEVIN, or Echevin. See the article Echevin.
ESCHRAKITES, in matters of religion, a sect of Mahometans, who believe that man's sovereign good consists in the contemplation of God. They avoid all manner of vice, and appear always in good humour, defiling the sensual paradise of Mahomet. The most able preachers, in the royal mosques, are of this sect.

ESCHYNOMENOUS, or ESCHYNOMENOUS. See ESCHYNOMENOUS.

ESCLAIRCISSEMENT, a French term adopted into our language, signifying the explanation or clearing up of some difficulty or obscurity.

ESCLATTE', a nullity that has been forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCALATTE', in heraldry, signifies a thing forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCORT, in the art of war, the fame with convoy. See the article Convoy.

ESCROW, among lawyers, a deed delivered to a third person, to be the deed of the party making it upon a future condition, that when a certain thing is performed, it shall be delivered to the party to whom it was made, to take effect as the deed of the person first delivering it.

ESCUAGE, in our old customs, a kind of knight-service, called service of the shield, by which the tenant was bound to follow his lord to the wars at his own charge. It is also used for a sum of money paid to the lord, in lieu of such service; or even for a reasonable aid, levied by the lord upon his tenants who held by the knight's service.

ESCUALENT, an appellation given to such plants, or the roots of them, as may be eaten: such are beets, carrots, artichokes, leeks, onions, parsnips, potatoes, radishes, scorzonera, &c. See the articles Beet, Carrot, &c.

ESCULUS, the Horse-Chesnut, a genus of trees, belonging to the heptandria-monogynia class of plants: its flower consists of five roundish petals; and the fruit is a roundish, echinated, and coriaceous capsule, with only one cell, in which are contained two roundish seeds, tho' sometimes only one.

ESCULARIA, a palace of the king of Spain, twenty-one miles north-west of Madrid; being one of the largest and most beautiful in the world. It has eleven thousand windows, fourteen thousand doors, one thousand eight hundred pillars, seventeen cloysters or piazzas, and twenty-two courts; with every convenience and ornament that can render a place agreeable in so hot a climate, as an extensive park, groves, fountains, cascades, grottos, &c.

ESCUTCHEON, or SCUTCHEON, in heraldry, is derived from the French escutjon, and that from the Latin sectum, and signifies the shield whereon coats of arms are represented.

Most nations, of the remotest antiquity, were wont to have their shields distinguished by certain marks painted on them; and to have such on their shields was a token of honour, none being permitted to have them till they had performed some honourable action.

The escutcheon, as used at present, is square, only rounded off at the bottom. As to the bearings on shields, they might at first be arbitrary, according to the fancy of the bearer; but, in process of time, they came to be the gift of kings and generals, as the reward of honourable actions.

ESCUTCHEON of pretence, that on which a man carries his wife's coat of arms; being an heiress, and having issue by her. It is placed over the coat of the husband, who thereby shows forth his pretensions to her lands. See the article Heiress. Points of an Escutcheon. See Point. Quartering of an Escutcheon. See the article Quartering.

ESDRAS, the name of two apocryphal books, usually bound up with the scriptures. They were always excluded the Jewish canon, and are too absurd to be admitted as canonical by the papists themselves. The first book is chiefly historical, giving an account of the return of the Jews from the babylonic captivity, and the building of the second temple; the second is written in the prophetical way, pretending to visions and revelations, but such as are extremely ridiculous.

ESENS, a town of Westphalia, twenty-five miles north of Embden.

ESK, a river which forms part of the boundary between England and Scotland; and, running from north-east to south-west, falls into the Solway-firth; it gives name to the country of Eskdale.

ESKIMAUX, sometimes called New Britain, and Terra de Labrador, is an extensive country of North America, situated between 49° and 80° west long., and between 40° and 64° north lat.

It is bounded by Hudson's straits, which separate it from Greenland, on the north; by the Atlantic ocean, on the east; by the
the river and bay of St. Lawrence, on
the south-eaft; and by Hudfon's bay, on
the weft.

ESLINGEN, an imperial city of Swabia,
in Germany, seven miles south-eaft of
Stuttgart.

ESLIRASS, in law, persons particularly
appointed or chosen to impanel juries.

ESNECY, in law, a private prerogative
allowed to the eldest coparcener, where an
estate is descended to daughters for
want of an heir male, to choose first, after
the estate of inheritance is divided.

It has been also extended to the eldest
son and his issue, holding first, this right be-
ing jus primogenitute.

ESOX, in ichthyology, a genus of ma-
lacopertegious fishes, wherein the mem-
brane of the gills contains from twelve to
fourteen officles or little bones, and there
is a fin on the back very near the tail.

To this genus belong the lucius or pike,
the acus or needle-fish, and the greatest
squamofe acus. See the articles LUCIUS
and ACUS.

ESPALIERS, in gardening, are rows of
trees planted about a whole garden or
plantation, or in hedges, so as to inclofe
quarters or separate parts of a garden;
and are trained up regularly to a lattice
of wood-work in a clofe hedge, for the
defence of tender plants against the in-
juries of wind and weather. They are
of admirable use and beauty in a kitchen-
garden, serving not only to shelter the
tender plants, but screen them from the
fight of persons in the walks.

The trees chiefly planted for espaliers,
are apples, pears, and some plums: some
plant apples grafted upon paradise-stocks;
but, as these are of short duration, it is
better to plant those grafted upon crab-
stocks, or upon what the gardeners call
dutch-stocks; which will both caufe them
to bear sooner, and prevent their grow-
ing too luxuriant. The best kind of
apples for this purpose, are the golden
pippin, nonpareil, rennette, &c. and the
best sorts of pear, are the jargonne, blan-
quette, &c. These last, if designed for
a strong moist foil, should be grafted upon
quince-stocks; but, if for a dry foil, upon
tree-stocks.

While the trees are young, it will be suf-
cient to drive a few stakes into the
ground on each side of them; fattening
the branches to these in an horizontal po-

dition, as they are produced. This me-
thod will do for the three first years;
after which an espalier should be made of

afh-poles, whereof there must be two
forts, larger and smaller; the former to
be driven upright into the ground a foot
afunder, and the latter, or slender poles,
to be nailed across these, at about nine
inches. Some prefer to this another fort
of espalier, made of square timber cut to
any size: these are, indeed, more tightly,
but withal vaftly more expensive.

When the espalier is thus framed, the
branches are to be fattened to it with ofter-
twigs; observing to train them in an ho-

dizontal position, and at equal distances.

Fruit-trees thus managed, are preferable
to any others; not only as bearing better
tafted fruit, but as taking up very little
room in a garden, so as to be left hurtful
to plants which grow in the quarters.

ESPAILER, in the french gardening, de-
notes a wall-tree. See WALL TREE.

ESPAULE and ESPAULEMENT. See the
articles EPAULE and EPAULEMENT.

ESPERIE, a city of Hungary, forty miles
north of Tockay: it is remarkable for
its salt mines.

ESPINAL, a town of Lorrain on the Mo-
selle, thirty-five miles south-eaft of Nancy.

ESPLANADE, in fortification, the flop-
ing of the parapet of the covered way to-
wards the campaign. See PARAPET and
CAMPAIGN.

It is the fame with glacis, but begins to
be antiquated, and is more properly the
empty space between a citadel and the
houses of a town, commonly called a
place of arms. See the articles FORTIF-
ICATION, COVERT WAY, GLACIS,
and CITADEL.

ESPLEES, in law, the general products
which lands yield, or the profit or com-
modity that is to be taken or made of a
thing; as of a common, the taking of
grafts by the mouths of the beams that
common there; of an advowson, taking
of tythes by the parson; of wood, the
selling of wood; of an orchard, selling
the fruit growing there; of a mill, the
taking of toll, &c.

These and such-like issues are termed ef-
plees. In a writ of right of land, ad-

vowson, &c. the demandant must allege
in his count, that he or his ancestors took
the esplees of the thing demanded, other-
wise the pleading is not good.

ESPOUSALS, in law, signify a contract
or promife made between a man and a
woman, to marry each other; and in
cases where marriage may be consum-
med, espousals go before. Marriage is
termed an espoual de praesenti.

ESQUI-
ESQUINANCY, in medicine. See the article QUINZY.

ESQUIRE, armiger, was antiently the person that attended a knight in time of war, and carried his shield.

This title has not, for a long time, had any relation to the office of the person, as to carry arms, &c. Those to whom the title of esquire is now of right due, are all noblemen's younger sons, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons; the officers of the king's courts, and of his household; counsellors at law, justices of the peace, &c. though these latter are only esquires in reputation: besides, a justice of the peace holds this title no longer than he is in commission, in case he is not otherwise qualified to bear it: but a sheriff of a county, who is a superior officer, retains the title of esquire during life, in consequence of the trust once reposed in him: the heads of some antient families are said to be esquires by descent, or constitution of substances, on that title by creation, wherein there is the nominal right due, are such as have preserved the same with a bridge five miles over: it lies about eighty miles north-west of Belgrade.

ESSEK, a town of Hungary, near the confluence of the rivers Drave and Danube, with a bridge five miles over: it lies about eighty miles north-west of Belgrade.

ESSEN, a town of Westphalia, about ten miles north-east of Dusseldorp.

ESSENCE, in philosophy, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others; being nothing but that abstract idea to which this name is affixed; so that every thing contained in it, is essential to that particular kind.

This Mr. Locke calls the nominal essence, in contradistinction to the real essence, or constitution of substances, on which this nominal essence depends: thus the nominal essence of gold, is that complex idea the word gold stands for; let it be, for instance, a body, yellow, weighty, malleable, fusible, and fixed: but its real essence is the constitution of its inelastic parts, on which these qualities and all its other properties depend, which is wholly unknown to us.

That essence, in the ordinary use of the word, relates to sorts, appears from hence, that, if you take away the abstract ideas by which we sort individuals, and rank them under common names, then the thought of any thing essential to any of them instantly vanishes. We have no notion of the one without the other, which plainly shews their relation. No property is thought essential to any individual whatsoever, till the mind refers it to some sort or species of things; and then preyently, according to the abstract idea of that sort, something is found essential; so that essential, or not essential, relates only to our abstract ideas, and the names annexed to them.

Substances are distinguished into sorts and species, by their nominal essence; and the species of things are nothing to us, but the ranking them under distinct names, according to the complex ideas in us, and not according to precise distinct real essences in them.

We cannot rank and sort things by their real essences, because we know them not.

a pattern in this way. Mr. Locke calls his treatise on the human understanding, an Essay; and Mr. Pope calls his four ethic epistles, an Essay on Man.

ESSAY-HATCH, is the miner's term for a little trench or hole, which they dig to search for shoad or ore.

ESSE, in the schools, the same with essence. See the article ESSENCE.

ESSECK, a town of Hungary, near the confluence of the rivers Drave and Danube, with a bridge five miles over: it lies about eighty miles north-west of Belgrade.

ESSEN, a town of Westphalia, about ten miles north-east of Dusseldorp.

ESSENCE, in philosophy, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others; being nothing but that abstract idea to which this name is affixed; so that every thing contained in it, is essential to that particular kind.

This Mr. Locke calls the nominal essence, in contradistinction to the real essence, or constitution of substances, on which this nominal essence depends: thus the nominal essence of gold, is that complex idea the word gold stands for; let it be, for instance, a body, yellow, weighty, malleable, fusible, and fixed: but its real essence is the constitution of its inelastic parts, on which these qualities and all its other properties depend, which is wholly unknown to us.

That essence, in the ordinary use of the word, relates to sorts, appears from hence, that, if you take away the abstract ideas by which we sort individuals, and rank them under common names, then the thought of any thing essential to any of them instantly vanishes. We have no notion of the one without the other, which plainly shews their relation. No property is thought essential to any individual whatsoever, till the mind refers it to some sort or species of things; and then preyently, according to the abstract idea of that sort, something is found essential; so that essential, or not essential, relates only to our abstract ideas, and the names annexed to them.

Substances are distinguished into sorts and species, by their nominal essence; and the species of things are nothing to us, but the ranking them under distinct names, according to the complex ideas in us, and not according to precise distinct real essences in them.

We cannot rank and sort things by their real essences, because we know them not.
Our faculties carry us no farther in the knowledge of substances, than a collection of thofe fensible ideas we obferve in them. But the internal constitution whereon thofe effences depend, is utterly unknown to us. This is evident when we come to examine but the ftones we tread on, or the iron we daily handle; we foon find that we know not their make, and can give no reafon of the different qualities we find in them; and yet how infinitely thofe come short of the fine contrivance, and unconceivable real effences of plants and animals, every one knows.

But though the nominal effences of substances are made by the mind, they are not yet made fo arbitrarily as thofe of mixed modes. To the making of any nominal effence, it is neceffary, 1. That the ideas whereof it consists, have fuch an union as to make but one idea, how compounded ever. 2. That the particular idea so united be exactly the fame, neither more nor lefs: for if two abstract complex ideas differ, either in number or forts of their component parts, they make two different, and not one and the fame effence. In the firft of thofe, the mind, in making its complex ideas of substances, only follows nature, and puts none together which are not fuppofed to have an union in nature; for men obferving certain qualities always joined and exift­ing together, therein copy nature, and if of ideas so united make their complex ones of substances.

Though the nominal effences of substances are all fuppozed to be copied from nature, yet they are all, or molt of them, very imperfected; and fince the composition of these complex ideas is in feveral men very different, we may conclude that thofe boundaries of species are in men and not as nature makes them; if, at leaft, there are in nature any fuch prefixed bounds. If the firft lorting of indi­viduals depends upon the mind of man, vairiously collecting the fimple ideas that make the nominal effence of the loweft species, it is much more evident that the more comprehensive classes called genera, do fo in forming more general ideas that may comprehend different forts: the mind leaves out thofe qualities that dif­tinguifh them, and puts into its new collection only fuch ideas as are common to feveral forts: thus by leaving out thofe qualities that are peculiar to gold, silver, &c., and by retaining a complex idea made up of thofe that are common to each species, there is a new genus con­fifted to which the name metal is annexed.

**ESSENCE.** In chymiftry, signifies the bafi­fic part of any thing, separated from the thicker matter; fo that wherever this is done by means of extraction, the bafi­fic part is called effence by way of eminence; fometimes thickened juices are called effences, but it is better to call these by their own name, to avoid con­fusion.

**ESSENS, or ESSENIANS,** in Jewifh an­ti­quity, one of the three antient fects among that people, who outdid the Pharifees in their molt rigorof observances. They allowed a future fate, but denied a re­furrection from the dead. Their way of life was very singular: they did not marry, but adopted the children of others, whom they bred up in the institutions of their fect: they defpifed riches, and had all things in common; and never changed their cloaths, till they were entirely worn out. When initiated, they were ftrictly bound not to communicate the myfteries of their fect to others; and if any of their members were found guilty of enormous crimes, they were expel­led.

Pliny tells us, that they dwelt on the weft fide of the lake of Alphalites; that they were a folidary kind of men, living with­out women or money, and feeding upon the fruit of the palm-tree: he adds, that they were constantly recruited by new comers, whom the farges of ill fortune had made weary of the world; in which manner the fect was kept up for feveral thousands of years, without any being born among them. The reafon why we find no mention made of them in the New Teftament, may be their reclude and retired way of life, no lefs than their great simplicit and honestly, whereby they lay open to no cenfure or repro­of.

**ESSENTIA, ESSENCE.** See the article ESSENCE.

**ESSENTIAL,** something neceffarily be­longing to the effence or nature of a thing, from which it cannot be conceived dif­tinct: thus the primary qualities of bodies, as expansion, figure, number, &c. are effential or insepafable from them in all their changes and alterations. See the article QUALITY.
ESSENTIAL OIL, that procured from plants by distillation. See the article OIL.

ESSENTIAL SALTS, those obtained from vegetable juices by crystallization. See the article SALT.

ESSEX, a county of England, bounded by Suffolk, on the north; by the German sea, on the east; by the river Thames, which divides it from Kent, on the south; and by Middlesex and Hertfordshire, on the west.

ESSLISORS, or ESISORS. See the article ESSLISORS.

ESSOIN, in law, an excuse for a person summoned to appear and answer to an action, on account of sickness or other just cause of his absence.

There are divers essoins, as de ultra mare, when the defendant is beyond sea, whereby he is allowed forty days; in an expedition to the holy land, a year and a day; infirmity, called common essoin, when he is sick in bed; and, lastly, in the king's service.

ESSOIN-DAY, is regularly the first day of every term, though the fourth day after is also allowed by way of indulgence.

ESSOIN DE MALO VILLE, is where the defendant appears in court, but before pleading, falls sick in a certain village: this is also allowed, if found true.

ESSOINS and PROFFERS. See PROFFER.

ESSORANT, in heraldry, denotes a bird standing on the ground with its wings expanded, as if it had been wet, and were drying itself.

ESTABLISHMENT of dower, in law, an assurance of dower made to the wife by the husband, or some friend of his, on marriage. See the article DOWER.

ESTAMPS, a town of France, twenty-five miles south of Paris.

ESTAPLES, a port-town of Picardy, in France, twelve miles south of Boulogne.

ESTATE, in law, signifies the title or interest that a person has in lands, tenements, or other effects; comprehending the whole in which a person hath any property, and will pass the same.

Estates are either real or personal; otherwise distinguished into freeholds, which descend to heirs; or chartels, that go to executors or administrators. See the articles FREEHOLD, &c.

A fee simple is the amplyest estate our law admits of. See the article FEE.

Estates are obtained several ways, as by descent from a father to a son; by conveyance or grant, from one person to another; by gift or purchase; or by deed or will. See the articles HEIR, CONVEYANCE, GRANT, &c.

ESTATES, in a political sense, is used either to denote the dominions of some prince, or the general classes into which the people are divided.

In Britain, the estates are the king, lords, and commons; or rather the lords and commons, who meet the king in parliament, for reforming abuses, and establishing good and wholesome laws. See the articles STATUTE, PARLIAMENT, &c.

In France, there are three estates, viz. the clergy, the nobility, and the people, who make the third estate.

ESTATES GENERAL, in the polity of Holland. See STATES-GENERAL.

ESTE, a town of Italy, fifteen miles south-west of Padua, and subject to Venice.

ESTELLA, a town of Navarre, in Spain, twenty miles south-west of Pampeluna.

ESTEPAA, a town of Spain, in the province of Gianada, forty-five miles north of Malaga.

ESTERLING, or STERLING. See the article STERLING.

ESTETE, in heraldry, denotes the heads of beasts torn off by main force. See the articles ARACHE and ERASED.

ESTHER, a canonical book of the Old Testament, containing the history of a jewish virgin, dwelling with her uncle Mordecai at Shushan, in the reign of Ahauerus, one of the kings of Peria. The great beauty of this maid raised her to the throne of Peria, whereby she had an opportunity to save her countrymen, whose destruction was plotted by Haman, a favourite of that prince. The learned are not agreed who this Ahauerus was. Archbishop Usher supposes him to be Darius Hittaspe, and Artytona to be Esther. Scaliger makes him the same with Xerxes, and his queen Hameltris to be Esther. Jofephus, on the contrary, positively afferts, that the Ahaueerus of the scriptures, is the Artaxerxes Longimanus of profane story; and the septuagint, throughout the whole book of Esther, translate Ahaueerus by Artaxerxes. Most people subscribe to this last opinion; and, indeed, the extraordinary kindness shewed by Artaxerxes to the Jews, can scarce be accounted for otherwise, than by supposing that they had so powerful an advocate as Esther to sollicite for them.

ESTIVAL,
ESTIVAL, or ÆSTIVAL. See the article ÆSTIVAL.

ESTOILEE, or CROSS ESTOILÉE, in heraldry, a star with only four long rays in form of a cross; and, accordingly, broad in the center, and terminating in sharp points.

ESTONIA, a province subject to Russia, on the north of Livonia.

ESTOPPEL, in law, an impediment or bar to an action, which arises from a person's own fault; or rather, where he is forbid by law to speak against his deed, which he may not do, even to plead the truth. Thus where a person is bound in a bond by such a name, and being afterwards sued by that name on the obligation, he shall not be allowed to say he is misnamed, but shall answer according to the bond, though it be wrong. Hence the parties in all deeds are estopped from saying anything against them. However, a plaintiff is not estopped from saying anything against what he had said in his writ or declaration; and though parties be estopped, yet juries are not so, who may find things out which three are comprehended under reasonable estovers.

ESTOVERS, in law, is most generally taken for certain allowances of wood made to tenants, as house-bote, hedge-bote, and plough-bote; which three are comprehended under reasonable estovers.

ESTRANGELE, estrangulus character, in the syrian grammar, a particular species or form of syrian letters, serving as the majuscule letters of that language, and by several supposed to be the true antient chaldee character.

ESTRAPADE, in the manage, the defence of a horse that will not obey, who, to get rid of his rider, rides mightily before; and, while his forehead is yet in the air, yerks furiously with his hind legs, striking higher than his head was before; and during this counter-time, goes back rather than advances.

ESTRAY, in law, any beast not wild that is found within a lordship, and owned by nobody: in which case, being cried according to law in the two next market towns adjacent, and not claimed in a year and a day by the owner, it becomes the property of the lord of the manor, or liberty wherein it was found. If the beast proclaimed stray to another lordship within the year, the first lord cannot retake it; and where the estray was never duly proclaimed, the owner may take it again, at any time.

paying the lord for keeping thereof: likewise the owner may seize an estray, without telling the marks or proving his property, which may be done at the trial, if contested: and here the tendering of amends is good, without shewing any particular sum.

ESTREAT, in law, a true copy, note, or duplicate of an original writing or record, especially fines, amercements, penalties, &c. set down and impos'd in the rolls of a court, to be levied by the bailiff, or other officer.

Estreats relate generally to fines for crimes and offences, defaults and omissions of persons concerned in suits, and likewise of officers. Non-appearance of defendants and jurors, &c. and before process iss'd to levy forfeitures on recognizances to the king's use, the recognizances must be first estreated into the exchequer by sheriffs of counties. Fines, poft fines, and forfeitures, are to be estreated twice a year on pain of sol. and it is the course of the king's bench to send their estreats into the exchequer on the last days of the two iuliable terms.

ESTREMADEURA, a province of Spain, bounded by Leon, on the north; by the two Castiles, on the east; by Andalusia, on the south; and by the province of Alentejo, in Portugal, on the west.

Estremadura is also a province of Portugal, lying north of Alentejo, and westward of Spanish Estremadura. Lisbon is its capital, as also of the kingdom.

ESTREMOS, a town of Alentejo, in Portugal, eighty-five miles south-east of Lisbon.

ESTREPEMENT, in law, any spoil made by tenants for life on any lands, &c. to the prejudice of the reverfoner: it is also taken to signify the making land barren, by continual plowing and fowing, and thereby drawing out the heart of the ground without manuring, or rather good husbandry, by which means it is impaired.

It may likewise be applied to the cutting down of trees, or lopping them farther than the law allows.

There is also a writ of eftrepement that lies in two cafes, viz. the one is where a person having an action depending, as a formedon or writ of right, &c. sues to prohibit the tenant from making wale. The other is for the demandant, who is adjudged to recover feisin of the land, before execution, fixed out by the writ habere facias
ETC

ESULA, in botany, a kind of spurge, comprehended under the euphorbia of Linnaeus. It is one of the sharpest and most acrid spurges, and therefore hardly safe: it purges violently, both by vomit and focol. Some recommend it in dropsies, but it should be used with great caution; and it is a good method to macerate it a day or two in vinegar, before it is used.

ESURINE SALTS, such as are of a corroding, fretting, and eating nature; abound- ing chiefly in places near the sea-side, and where great quantities of coals are burnt, as appears from the speedy rusting of iron bars in the windows of houses built in such places.

ESWEGEN, or ESCHWEBE, a town of Germany, twenty-five miles south-east of the city of Caffel.

ETALPE, a term used, in the French armies, for the provisions and forrage allowed an army in their route through a kingdom, whether going into winter-quarters, or returning to take the field. Hence, etapier is the undertaker or person who contracts with the country or territory, for supplying the said provisions.

ETCHING, a method of engraving on copper, in which the lines or strokes, instead of being cut with a tool or graver, are eaten in with aquafortis. Etching is done with more ease and expedition than engraving: it requires fewer instruments, and represents most kind of subjects better and more agreeable to nature, as landscapes, ruins, grounds, and all small, faint, loose, remote objects, buildings, &c. See ENGRAVING.

The method of etching is as follows: choose the copper-plate as directed for engraving, and furnish yourself with a piece of ground, tied up in a bit of thin silk, kept very clean, to be laid upon the plate when both have been warmed; proper needles to hatch with on the ground; a pencil or brush, to wipe away the bits of ground which rise after hatching; a polisher; two or three gravers; a pair of compasses, to measure distances and draw circles; a ruler, to hatch straight lines; green wax, to make the wall round the edges of the plate, to contain the aquafortis; an oil-flone; a bottle of aquafortis; some red lead, to colour the back-side of the copy; a knife, and a hand-vice, to hold the plate over the candle. See the articles NEEDLE, GRAVER, POLISHER, COMPASS, &c.

To make the ground, take three ounces of asphaltum, two ounces of clean rosin, half an ounce of burgundy-pitch, three ounces of black wax, and three ounces of virgin's wax; let all these be melted in a clean earthen pipkin over a flow fire, stirring it all the time with a small flick; if it burn to the bottom, it is spoiled. After the ingredients are well melted, and it boils up, put it into a pan of fair water; and before it be quite cold, take it out, and roll it into small lumps to be kept from dust: this ground is what others call the varnish. The next thing is to clean the plate to receive the ground: take a piece of lifting, roll it up as big as an egg, tie it very tight, so as to make it a rubber, and having dropped a small quantity of sweet oil, and added a little powder of rotten-flone on the plate, rub it with this ball, till it will almost throw your face. Then wipe it all off with a clean rag, and after that, make it quite dry with another clean rag, and a little fine whiting. The next thing is to lay on the varnish; to do which aright you must take a hand-vice, and fix it at the middle of one part of the plate, with a piece of paper between the teeth of the hand-vice and the plate, to prevent the marks of the teeth: then laying the plate on a chaffing-dish, with a small charcoal fire in it, till the plate be so hot, that, by spitting on the backside, the wet will fly off: rub the plate with the ground tied up in silk, till it be covered all over; and after that, when the plate has a piece of cotton wrapped up in silk till the ground be quite smooth, keeping the plate a little warm all the time. The varnish being thus smoothed upon the plate, it must be blacked in the following manner: Take a thick tallow candle that burns clear, with a short snuff, and having driven two nails into the wall, to let it rest upon, place the plate against the wall, with the varnish side downward, and take care not to touch the ground with your fingers: then taking the candle, apply the flame to the varnish as close as possible, without touching the varnish with the snuff of the candle, and guide the flame all over it, till it become perfectly black. After this is done, and the plate dry, the design is traced with a needle through the varnish, and a rim or border...
border of wax is raised round the circumference of the plate; and then the artist has a composition of common varnish and lamp-black, made very thin, whereunto he covers the parts that are not to be bitten, by means of a hair pencil. And he is ever now and then covering or uncovering this or that part of the design, as occasion may require; the conduct of the aquafortis being the principal concern, on which the effect of the print very much depends. The operator must be attentive to the ground, that it does not fail in any part, and where it does, to stop up the place with the above composition. The plate is defended from the ENGRAVING, by copper through which the water eats into the all the poured hard, the aquafortis being the part, and where it does, to much depends. The operator stops everywhere, the aquafortis every where, the plate washed, and the copper, through which the water eats into the all the filed: otherwise it will make the work very hard, and sometimes break up the ground: the aquafortis having done its part, the ground is taken off, and the plate washed and dried: after which nothing remains for the artist but to examine the work with his graver, to touch it up, and heighten it where the aquafortis has missed. And, lastly, it is to be remembered, that a fresh dip of aquafortis is never given, without first washing out the plate in fair water, and drying it at the fire.

ETERNITY, an attribute of God, expressing his infinite or endless duration. See the article GOD.

According to Mr. Locke, we come by reasons of things, and yet be wholly in- to the idea of eternity, by being able to repeat any part of time, as a year, as often as we will, without ever coming to an end.

ETHILING, or ATHELING. See the article ATHELING.

OTHER and ETHERIAL. See the articles AETHER and AETHERIAL.

ETHICS, or MORALITY, the science of manners or duty, which it traces from man's nature and condition, and flowed to terminate in his happiness; or, in other words, it is the knowledge of our duty and felicity; or the art of being virtuous and happy.

Moral philosophy inquires, not how man might have been, but how he is constituted; not into what principles or dispositions his actions may be artfully resolved, but from what principles and dispositions they actually flow; not what he may, by education, habit, or foreign influence, come to be or do, but what by his nature, or original frame, he is framed to be and do. From a view, therefore, of man's faculties, appetites and passions, it appears, that the health and perfection of man must be in the supremacy of conscience and reason, and in the subordination of the passions and affections to their authority and direction; and virtue or goodness must conflict in all agreeably to this order and sequence. See the articles APPETITE, CONSCIENCE, REASON, HAPINESS, &c.

It is true, some eminent philosophers, have attempted to lay the founda- tions of morals much deeper, and on a more large and firm bottom, viz. the natures and reasons, the truth and fitness of things. Senses and affections, they tell us, are vague and precarious; and though they were not, yet irrational principles of ac- tion, and consequently very improper foundations, on which to rest the eternal and immutable obligations of moral- ity. Hence they talk much of the ab- stract natures and reasons of things, of eternal differences, unalterable relations, fitness and unfitness resulting from those relations; and from these eternal reasons, differences, relations, and their consequent fitnesses, they suppose moral obligation to arise. A conduct agreeable to them, or, in other words, to truth, they call virtue; and the reverse, vice. See the articles VIRTUE and VICE.

But the truth is, that we might perceive all the possible relations, differences, and reasons of things, and yet be wholly in- different to this or that conduct, unless we were endowed with some sense or affection, by which we approved and loved the one, and disapproved and disliked the other conduct. Reason may perceive a fitness to a certain end, but without some sense or affection we cannot propose, or indeed have any idea of an end; and, without an end, we cannot conceive any inducement to action. Therefore, be- fore we can understand the natures, reasons, and fitnesses of things, which are said to be the foundation of morals, we must know what natures are meant, to what ends they are fitted, and from what principles or affections they are prompted to act; otherwise we cannot judge of the duty required, or of the conduct becoming that being whom we suppose under
moral obligation. But let the natures be once given, and the relations which subsist among them be ascertained, we can then determine what conduct will be obligatory to such natures, and adapted to their condition and economy. And to the same natures, placed in the same relations, the same conduct will be eternally and invariably proper and obligatory.

Besides, to call morality a conformity to truth, gives no idea, no characteristic of it, but what seems equally applicable to vice. For whatever propositions are predicative of virtue, as that it flows from good affections, or is agreeable to the order of our nature, tends to produce happiness, is obedient with approbation, and the like; the contrary propositions are equally true, and may be equally predicative of vice.

Another set of philosophers establish morals upon the will or positive appointment of the Deity, and call virtue a conformity to that will, or appointment. All obligation, they say, supposes one who obliges, or who has a right to prescribe, and can reward the obedient, and punish the disobedient. This can be none but the Creator. His will, therefore, is our law, which we are bound to obey. And this, they tell us, is only sufficient to bind or oblige such imperfect and corrupt creatures as we are, who are but feebly moved with a sense of the beauty and excellency of virtue, and strongly swayed by passion, or views of interest.

This scheme of morality entirely coincides with that deduced from our inward structure and condition, since these are the effects of the divine will. Whatever therefore is agreeable, or correspondent to our inward structure, must likewise be agreeable, or correspondent to the will of God. So that all the indications, or sanctions of our duty, which are declared or enforced by our structure, are, and may be, considered as indications or sanctions of the will of our Creator. If these indications, thro' inattention to, or abuse of our structure, prove insufficient to declare; or if these sanctions, thro' the weaknesses or wickedness of men, prove insufficient to enforce obedience to the divine will, and the Deity is pleased to add new indications, or new sanctions; these additional indications and sanctions cannot, and are not supposed, by the assertors of this scheme, to add any new duty, or new moral obligation; but only a new and purer promulgation of our duty, or a new and stronger sanction or motive from interest, to perform that duty, and to fulfil that obligation to which we were bound before. It makes no difference, as to the matter of obligation, after what manner the will of our Creator is enforced, or declared to us, whether by word or writ, or by certain inward notices and determinations of our own minds, arising according to a necessary law of our nature. Again, if the scheme of duty, as deduced from moral perceptions, and the affections of our nature, be thought too flight a foundation on which to rest morality, because these are found insufficient to bind, or rather to compel men to their duty, we fear the same objection will militate against the scheme of conformity to the divine will, since all the declarations and sanctions thereof have not hitherto had their due effect, in producing a thorough and universal reformation.

When some speak of the will of God, as the rule of duty, they do not certainly mean a blind, arbitrary principle of action, but such a principle as is directed by reason, and governed by wisdom, or a regard to certain ends in preference to others: for unless we suppose some principle in the Deity analogous to our sense of obligation, some antecedent affection, or determination of his nature, to prefer some ends before others, we cannot assign any sufficient reason why he should will one thing more than another, or have any election at all. Whatever therefore is the ground of his choice, or will, must be the ground of obligation, and not the choice or will itself. That this is the case, appears farther from the common distinction which divines and philosophers make between moral and positive commands and duties. The former they think obligatory antecedent to will, or at least to any declaration of it; the latter, obligatory only in consequence of a positive appointment of the divine will. But what foundation can there be for this distinction, if all duty and obligation be equally the result of mere will?

Before we conclude this article, it will be proper to say something of the extraordinary hypothesis of Hobbes, concerning the foundation of morality. This philosopher, who saw his country involved
volved in all the distraction and misery of a civil war, seems to have taken too narrow and partial a view of our nature, and has therefore drawn it in a very odious and uncomfortable light. Next to the desire of self-preservation, he makes the love of glory and of power to be the governing passions in man; and from these, by an arbitrary, unnatural, and unsupported hypothesis, contrary to common experience, and common language, he attempts to deduce all the other passions which inflame the minds, and influence the manners of men. According to him, all men are equal, all desire and have a right to the same things, according to him, all men are equal, all
guage, he attempts to deduce all the
to
render, and of this mutual
violation of his promise. But one may
agreement, they are secured against
laws, or to common judges or
peaceable behaviour; so that it is no
tual hostilities, and bound or obliged to
moral tie that
has raised on it no less so.

ETHIOPIA, or ÆTHIOPIA, a very extensive country of Africa, comprehending Abyssinia, Nubia, and Abex: it is bounded by Egypt, and the defart of Barca on the north, by the Red sea, and indianocean on the east, by Anian, and the unknown parts of Africa on the south, and by other unknown countries on the west. See ABEX and NUBIA.

ETHIOPIAN YEAR. See the article YEAR.

ETHMOIDAL, in anatomy, one of the common futures of the skull, which goes round the òs ethmoides, from which it derives its name, separating it from the bone in contact with it. See the articles SUTURE and ETHMOIDES.

ETHMOIDES òs, in anatomy, the same with cribrosum òs, or cubiciforme. See the article CRIBROSUM.

ETHNARCH, ETHNARCHA. See the article ETHMALOTARCHA.

ETHNOPHRONES, in church history, heretics of the seventh century, who, professing christianity, joined thereto all the ceremonies and follies of paganism, such as judicial astrology, divinations of all kinds, &c. and who observed all the feasts, times, and feations of the Gentiles.

ETHPOEIA, or ETHOLOGY, in rhetoric, a draught, or description, expressing the manners, passions, genius, tempers, aims, &c. of any person. Such is that noted picture of Catalinè, as drawn by Sallust: fuit magnà vi & animi, &c.

"he was a man of great vigour both of body and mind; but of a difpo- position extremely profigate and de- praved. From his youth he took pleasure in civil wars, massacres, depredations, and infults, broils; and in these he employed his younger days. His body was formed for en- during cold, hunger, and want of reft; to a degree indeed incredible: his spirit was daring, subtle, and changeable: he was expert in all the arts of simulation and diffimulation, covetous of what belonged to others, lavish of his own, violent in his passions: he had eloquence enough, but too high to be attainable."

ETHUSA, FOOL's PARSLEY, in botany, a genus of the pentandria-digynia class of plants, the general corolla of which is commonly uniform; the partial one consists of five inflexo-cordated, unequal petals: the fruit is naked, of a roundish oval figure, and separable in two parts: the seeds are two, roundish, striated, and thence a third part plane.

ETNA, or mount GIBELLO, a vulcano, or burning mountain of Sicily, situated fifty miles south-west of Messina, and twenty west of Catania. See VULCANO.

ETRUSCA TERRA, TUSCAN EARTH, a species of bole. See the article BOLE.

ETYMOLOGY, that part of grammar which considers and explains the origin and derivation of words, in order to arrive
EU, a port town of Normandy, in France, fifteen miles north-east of Dieppe.

EVACUANTS, in pharmacy, are properly such medicines as diminish the animal fluids, by throwing out some morbid or redundant humour, or such as thin, attenuate, and promote the motion and circulation thereof. See the article ATTENUANTS, &c.

Evacuating medicines are prejudicial in intermitting fevers; are prejudicial as they weaken, exhaust the most fluid juices, and disturb the conceotions and digestions which are here more especially necessary.

EVACUATION, in medicine, the art of diminishing, emptying, or attenuating the humours of the body.

Evacuations are, by Dr. Pringle, much recommended in the bilious fever and dysentery: but this sort of medicine is to be sparingly used in malignant fevers: in wounds of the head the best evacuations are plentiful bleeding and purging of the bowels; both which are to be made at one and the same time, as plentifully as the patient's strength will permit; and to be repeated again as often as necessary, if you find the symptoms relieved after their administration.

Evacuations are bad in nnaeas, from a disturbance of the spirits; but are of great use in curing the delirium in fevers: the provoking the menstria in women, is to be attempted by such remedies as mollify and relax, and not by those called emmenagogés, most of which increase the impetus of the circulation, except in women of a cold and lax habit: blood-letting likewise supplies the deficiency of the piles, or menstrual discharge in men, by making this artificial evacuation of blood in a part the most remote from the head. But all these evacuations are only of use where the vessels are distended with too great a quantity of blood, or when the force of the circulation is too great. In intermitting fevers evacuations are very imprudent. In inflammatory disorders, where the chief intention should also be to diminish the force of the blood, to thin it, and to relax the fibres, evacuations, such as bleeding, purging, vomiting, attenuants, and diaphoretics, are the chief remedies.

EVANGELIST, a general name given to those who write, or preach the gospel of Jesus Christ. The word is of greek origin, signifying one who publisheth glad tidings, or is the messenger of good news.

According to Hooker, evangelists were presbyters of principal sufficiency, whom the apostle sent abroad, and used as agents in ecclesiastical affairs, wherefore they law need. The term evangelist, however, is at present confined to the writers of the four gospels. See the article GOSPEL.

EVANID, a name given by some authors to such colours as are of no long duration,
EVASION, among the ancients, the priests of Bacchus, thus called, by reason, that in celebrating the orgia, they ran about as if distracted, crying, evas, evan, of evan. See BACCHANALIA.

EVAPORATION, in chemistry, setting a liquor in a gentle heat to discharge its superfluous humidity, reduce it to a proper consistence, or obtain its dry remainder. Evaporation may be accounted for from its evanescent form of a lighter body, if the person who gives the kiss is killed, it is murder; and such is the act of one who gives the kiss to each other. Thus, the kiss is an action which an ancient druid, or soothsayer, divided into two equal parts; and thus will seem to have the sanction of the law, for no person shall evade the justice of the law, by any such pretense to forestall his malice.

EVALES, a branch or division of the druids, or antient celtic philosophers. Strabo divides the Britsh and Gaulish philosophers into three sects, druids, evates, and evates, evates, and evates, druids, evates, druids.

EYERARD'S

As to the manner of celebrating the eucharist, among the antient Christians, after the customary oblations were made, the deacon brought water to the bishop and presbyters, standing round the table, to wash their hands, according to that of the psalmist, “I will wash my hands in innoceney, and so will I compass thy altar, O Lord.” Then the deacon cried out aloud, “Mutually embrace each other;” which being done, the whole congregation prayed for the universal peace and welfare of the church, for the tranquility and repose of the world, for the prosperity of the age, for wholesome weather, and for all ranks and degrees of men. After this followed mutual salutations of the minifter and people; and then the bishop, or presbyter, having sanctified the elements, by a solemn benediction, he brake the bread, and delivered it to the deacon, who distributed it to the communicants; and after that the cup. Their sacramental wine was usually diluted, or mixed with water. During the time of administration, they sang hymns and psalms, and having concluded with prayer and thanksgiving, the people saluted each other with a kiss of peace, and so the assembly broke up.

EUCHITRES, in church-history, heretics, otherwise called Meffalians. See the article MESSALIANS.

EUCHOLOGIUM, εὐχολογίω, in the greek church, the ritual, or book of common-prayer of that church. See RITUAL.

EUDISTS, a congregation of missionary priests, in France, associated under the name and title of Jesus and Mary. It is governed by a superior, who receives his power from the bishops of each dioctes, where they have an establishment.

EUDOXIANS, in church-history, a branch of Arians. See ARIANS.

EVE, the same with vigil. See VIGIL.

EVECTIO OF THE MOON, the same with libration. See the article LIBRATION.

EVEN NUMBER, in arithmetic, that which can be divided into two equal parts: such are 4, 10, 40, &c.

A number is said to be evenly even, when being even itself, it is measured by an even one, an even number of times: such is 32, as being measured by the even number 8, an even number of times 4. Evenly odd number is, that which an even number both measure by an odd one: such is 30, which 2 or 6, both even numbers, do measure by 15 or 5, odd ones.
EVERARD's SLIDING-RULE. See the article SLIDING-RULE.

EVERDING, a town of Austria, in Germany, situated on the Danube, twelve miles west of Lints.

EVER-GREEN, in gardening, a species of perennials, which continue their verdure, leaves, &c. all the year: such are hollies, phillyria's, lauretinus's, bay's, pines, firs, cedars of Lebanon, &c.

EVERLASTING-FLOWER, in botany, a name given to the amaranthoides.

EVERLASTING-PEA, a genus of plants, otherwise called lathyrus.

EVESDROPPERS, in law persons who stand under the eves, walls, or windows of a house, by day or by night, to listen after news, and carry it to others, thereby raising strife and contention in the neighbourhood. They are punishable in the court-leet, or quarter-sessions.

EVESHAM, a borough-town thirteen miles south-east of Worcester, which sends two members to parliament.

EUGENIA, the SILVER-TREE, in botany, a genus of the icofandria-monogynia class of plants, the corolla whereof consists of four oblong, obtuse, concave petals, twice as large as the cup: the fruit is a quadrangular, coronated drupe, containing only one cell: the seed is a roundish, smooth nut.

EUGUBIO, a town and bishop's see of Italy, in the duchy of Urbino, and thirty-five miles south of that city.

EVIAN, a town of Savoy, situated twenty-five miles north-east of Geneva, on the south side of the lake of Geneva.

EVICTION, in law, signifies a recovery of lands, or tenements by law.

When lands, &c. are evicted before rent reserved upon a lease becomes due, the lessee is not liable to pay any rent. Likewise, if on an exchange of lands, either of the parties is evicted of the land given in exchange, the party evicted may, in that case, re-enter his own lands. And a widow being evicted of her thirds, shall be endowed in the other lands of the heir.

EVIDENCE, according to the Epicureans, is nothing else than that kind of certitude obtained by the senses, which, in the opinion of these philosophers, are the primary criterion of truth.

By evidence of sense the epicureans mean that species, or image, exhibited by the sense, or phantast, which, when all impediments to a just judging, as distance, motion, medium, &c. are removed, can not be contradicted, or gainst: wherefore the question being put, whether or no a thing be just as it appears; the answer is not given till it has been tried and examined all the ways, and by all the senses that it can be an object of. Some distinguishing evidence into objective and formal.

Objective evidence, they say, consists in the clearness or perspicuity of the object; or the object itself so constituted as that it may be clearly and distinctly known. An object may be clearly known, either immediately from the bare explication of the terms of a proposition; or meditately, that is, we may arrive at a clear and distinct knowledge of it, by means of some medium; thus space, according to the Epicureans, becomes evident by reason of motion, because there can be no motion where there is no space.

Formal evidence is the act of the intellect considered as clear and distinct; and this is also immediate, or such as consists or depends upon the primary principles; or it is mediate, and requires some medium whose attribute agrees with the subject of the proposition. The former consists in a certain natural light of the intellect, which is acquired without any study or pains: the latter is found no where but in the conclusion of demonstration, and is therefore termed mediate evidence. See the article Demonstration.

Others divide evidence into moral, physical, and metaphysical; that is, by how many means the truth appears, by so many is the evidence said to arise: thus, a thing is said to be morally evident, so far as I have a distinct knowledge or notion thereof by unexceptionable witnesses. See the article Certitude.

Physically, so far as natural sense and reason, pointing out any thing, convinces me thereof. Metaphysically, when I enter so fully and clearly into the essence of any thing that nothing can be clearer.

But whatever may be the sentiments of these philosophers concerning evidence, says Chaucinus, this should at least be granted, that the evidence of human knowledge, of what kind ever it be, is not absolute, but comparative: that is, that there is no act in human knowledge quite void of all confusion.

The primary sign of evident knowledge requires that the object known should strike the intellect violently, in like manner...
Evidence, in law, any proof, whether it be by testimony of men on oath, or by writings and records so called, because hereby the point in issue is made evident to the jury. As to evidence, the common law requires no certain number of witnesses, though in some cases the statute-law does. The testimony of one single evidence is sufficient for the crown in all causes, except treason, where there must be two: sometimes violent presumption will be admitted as evidence, without witnesses, as where a person is run through the body in a house, and one is seen to come out of that house with a bloody sword. In general, a party interested in a suit, a wife for or against her husband, unless in cases of treason, an alien infidel, perjury, &c. may not be evidence in the cause: but kinship, though never so near, also tenants, servants, masters, attorneys for their clients, one of the jurors upon trial, and all others that are not infamous, and who want not understanding, or are no parties in interest, may be allowed to give evidence; tho' the credit of servants is left to the jury.

In cases of crimes, as of robbery on the highway, in an action against the hundred, and, rapes of women, &c. a man or woman may be 'an evidence' in their own cause; so likewise in private notorious cheats, where none else can be witness of the circumstances of the fact, but he that suffers. When any person is served with a process, and refuses to appear to give evidence in a criminal cause, the court may put off the trial, and grant an attachment against him; whereupon he shall be committed to prison and fined; and in a civil cause an evidence refusing to appear on being tendered his reasonable charges, and he having no lawful excuse, action of the case lies against him, and thereupon 10l. damages shall be recovered, and other recouperation to the party.

Evidence by writings and records is where acts of parliaments, statutes, judgments, fines and recoveries, proceedings of court, and deeds, &c. are admitted as evidence. And here it is to be observed, that the printed statute-book is good evidence upon a general act of parliament, which need not be pleaded; but in the case of a private act, it is otherwise: for there it must be pleaded and examined by the records of parliament, before it can be admitted in evidence. Records and enrolments prove themselves, and a copy of a record sworn to may be given as an evidence. A record of an inferior court has been rejected in evidence, and the proceedings in county-courts, courts-baron, &c. may be denied, and then tried by a jury. A copy of copyhold-lands shall be an evidence where the rolls are lost. An antient deed proves itself: the counterpart of a deed is no evidence, when the original is in being, and can be procured.

Although a witness swear to the hand and contents of a letter, if he never saw the party write, it will not be good evidence. And a shop-book may not be given in evidence for goods sold, &c. after one year, before the action brought, except there be a bill, &c. for the debt: but this does not extend to any buying or selling, or trading between one tradesman and another: here to make books evidences, there must be the hand of the person to them who delivered the goods, which is to be proved. In debt, a release may be given in evidence, so may any matters of fact, tampering with witnesses, or fraud.

EVIL, malum, in philosophy, &c. is either moral or natural.

Moral evil is the disagreement between the actions of a moral agent, and the
rule of those actions, whatever it be. See the articles Ethics and Good. Moral good and evil coincide with right and wrong, since that cannot be good which is wrong, nor that evil which is right. See Right and Wrong.

Some make the essence of moral evil consist in the disarray of our manners to the divine will, whether known by reason or revelation; others, in being contrary to reason and truth; and others, in being inconsistent with the nature, faculties, affections, and situation of mankind. See the article Ethics.

Be this as it will, no act can be deemed morally evil, unless the agent be capable of distinguishing, choosing, and acting for himself; or, more briefly, is an intelligent and free agent. See the articles Agent and Action.

Natural Evil, whatever destroys, or any way disturbs the perfection of natural beings: such are blindness, diseases, death, &c. See the articles Blindness, Disease, Death, &c.

King's Evil, in medicine, the same with the scrophula. See Scrophula.

Hungry Evil. See Bulimy.

Eulogy, in church history, a name by which the Greeks call the panis benedictus, or bread over which a blessing is pronounced, and which is distributed to those who are unqualified to communicate. The name Eulogiae was antiently given to the consecrated pieces of bread, which the bishops and priests sent to each other, for the keeping up a friendly correspondence: these presents likewise which were made out of respect or obligation, were called eulogiae.

St. Paulinus, bishop of Nola, about the end of the sixth century, having sent five eulogiae, at one time, to Romanian, says, "I send you five pieces of bread, the ammunition of the warfare of Jesus Christ, under whose standard we fight."

Eumenides, furies, in antiquity. See the article Furies.

Eunomians, in church history, Christian heretics, in the fourth century. They were a branch of Arians, and took their name from Eunomius, bishop of Cyzicus, who was instructed byÆtius, in the points which were then controverted in the church, after having at first followed the profession of arms. Eunomius so well answered the designs of his master, and declared so vehemently against the divinity of the Word, that the people had recourse to the authority of the prince, and had him banished; but the Arians obtained his recall, and elected him bishop of Cyzicus. The manners and doctrines of the Eunomians were the same with those of the Arians.

Eunuch, έυνόχεας, a castrated person. See the article Castration.

In Britain, France, &c. Eunuchs are never made, but upon occasion of some disease, which renders such an operation necessary: but in Italy, they make great numbers of children, from one to three years of age, eunuchs, every year, to supply the opera's and theatres of all Europe with fingers: though it is not one in three, that, after having lost their virility, has a good voice for a recollection. In the eastern parts of the world, they make eunuchs in order to be guards or attendants on their women. The seraglio of the eastern emperors are chiefly served and guarded by eunuchs; and yet, from good authority, we learn, that the rich eunuchs in Persia and other countries keep seraglio's for their own use. Those who, out of an imprudent zeal to guard themselves from sensual pleasures, made themselves eunuchs, were, by the council of Nice, condemned and excluded from holy orders. There are several severe prohibitions in Germany against the making of eunuchs; and in France an eunuch must not marry, not even with the consent of the woman.

Eunuchs, in church history, a sect of heretics, in the third century, who were mad enough to castrate, not only those of their own persuasion, but even all others that they could lay hold of; they took their rise from the example of Origen, who, misunderstanding the following words of our Saviour, --- "And eunuchs who made themselves eunuchs for the kingdom of heaven," castrated himself.

Evocation, evocatio, in Roman antiquity, a solemn invitation preferred by way of prayer, to the gods and goddesses of a besieged town, to forfake it and come over to the Romans; who always took it for granted that their prayers were heard, provided they could make themselves masters of the place.

Evolute, evoluta, in the higher geometry, a curve, which, by being gradually opened, describes another curve. Such is the curve B C F; (plate XCIV.
EVO

XCIV. fig. 4.) for if a thread FCM be wrapped about, or applied to, the said curve, and then unwound again, the point M thereof will describe another curve AMM, called by Mr. Huygens, a curve described from evolution. The part of the thread, M, C, is called the radius of the evolute, or of the oscillatory circle described on the center C with the radius MC.

Hence, 1. when the point B falls in A, the radius of the evolute MC is equal to the arch BC; but if not, to AB and the arch BC. 2. The radius of the evolute CM is perpendicular to the curve AM.

3. Because the radius MC of the evolute continually touches it, it is evident from its generation, that it may be described through innumerable points, if the tangents in the parts of the evolute are produced until they become equal to their corresponding arches. 4. The evolute of the common parabola is a parabola of the second kind, whose parameter is 2/3 of the common one. 5. The evolute of a cycloid is another cycloid equal and similar to it. 6. All the arches of evolute curves are rectifiable, if the radii of the evolute can be expressed geometrically. Those who desire a more particular account of these curves, may consult Huygens's Horologium Oscillatorium, Sir Isaac Newton's and Mac-Laurin's Fluxions, and Wolfius.

EVOLUTION, in algebra, the extraction of roots. See the article EXTRACTION.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preserve a post, or occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better.

It consists in doublings, counter-marches, conversions, &c. A battalion doubles the ranks, when attacked in front or rear, to prevent its being flanked, or surrounded; for then a battalion fights with a larger front. The files are doubled either to accommodate themselves to the necessity of a narrow ground, or to refresh an enemy which attacks them in flank; but if the ground will allow it, conversion is much preferable, because after conversion the battalion is in its first form, and opposes the file-leaders, which are generally the best men to the enemy; and likewise, because doubling the files in a new, or not well disciplined regiment, they may happen to fall into disorder. See DOUBLING.

EUONYMOIDES, in botany, a name used by Ione for the celastrus. See the article CELASTRUS.

EUONYMUS, the spindle-tree, in botany, a genus of the tetrandria monogynia class of plants, the corolla whereof consists of four ovated, plane, and patent petals, longer than the cup: the fruit is a succulent, coloured capsule, of a quadrangular figure, formed of four valves, terminating in four points, and forming four cells: the seeds are single, of an oval figure, and covered with a calyptra. See plate XCIV. fig. 5.

The fruit of this plant provokes vomiting, is a stomachic, and purges by stool: however, it is dangerous, and should be taken cautiously.

EVORA, or EBORA, a city of Portugal, seventy miles south-east of Lisbon. It is an archbishopric and university, and is situated in one of the pleasanter and most fruitful countries of that kingdom. See the article PORTUGAL.

EUPATORIOPHALACRON, in botany, the same with the verbesina. See the article VERBEsINA.

EUPATORIUM, hemp-agrimony, in botany, a genus of the jymenea-polymisia equalis class of plants, the compound corolla of which is uniform and tubulose; the hermaphrodite flowers are equal; the partial flower is infundibuliform: the fruit is naked, only covered by the cup: the seeds are oblong, and crowned with a plumose down.

This plant is hepatic and vulnerary; but the principal use of it is in cachexies, catarrhs, and in suppressions of urine and the menses: the root purges just in manner of the white hellebore.

EUPHEMIA, a port-town of the further Calabria, in Naples, fifty miles north-east of Reggio.

EUPHEMISM, euphemism, in rhetoric, a figure which expresses things in themselves disagreeable and shocking, in terms implying the contrary quality: thus, the Pontus, or black sea, having the epithet άτοπη, i.e. inhospitable, given it, by reason of the savage cruelty of those who inhabited the neighbouring countries, this name, by Euphemism, was changed into that of Euxinus. Thus Onid Trif. lib. iii. el. 15.

Dum me terrarum pars pené novissima

Ponti

7 F 2

Euxinus
EUPHONY, EUPHRASI, in grammar, an easiness, smoothness, and elegance in pronunciation.

Euphony is properly a figure, whereby we suppres a letter that is too harsh, and convert it into a smoother, contrary to the ordinary rules: of this there are abundance of examples in all languages.

EUPHORIA, in botany, a genus of the polyandria-monogynia class of plants, comprehending the tithymalus or spurge, the euphorbium properly so called, the tithymaloïdes, and the eufula of authors. The flower consists of four or five petals, which are thick, gibbous, turbineated and truncated: the fruit is a roundish trilocular capsule, containing a single roundish seed.

The euphorbium has a fleshy or angular stalk, and the petals in some species are trifid; the tithymalus has leaves on the stalk, which the others have not; and the tithymaloïdes has the calyx gibbous on the under side. See the article EUHORBIUM, &c.

EUPHORBIUM, in pharmacy, a gum refin brought us always in loose, smooth, and glossy gold-coloured drops or granules. It is the produce of the euphorbium antiquorum verum, which grows to ten or twelve feet high. Its principal use is externally in sinapisms, and internally in large doses, served by Avifenna, that when taken internally in large doses, it has been found to exacerbat the intestines, and bring on death itself, after the most terrible symptoms.

EUPHRASTIA, EYE-BRIGHT, in botany, a genus of the didynamia-angiopermia class of plants, the corolla of which consists of a single ringent petal; the tube is of the length of the cup; the upper lip is concave and emarginated; the lower one is patent, and divided into three segments; the fruit is an ovo-oblong, compressed capsule, forming two cells: the seeds are numerous, very small, and of a roundish figure.

This plant is an ophthalmic and cephalic, and good for a weak memory.

EUPHRATES, the finest river in Turky in Asia, has two sources, northward of the city of Erzerum, in 40° north latitude. After passing through Armenia, it divides Syria from Diar-beck or Assyria, runs through Eyraca or Chaldea; and uniting with the Tygris, it passes by the city of Baffori, fifty miles below which it falls into the gulph of Persia.

EUPHROSYNUM, in botany, a name used by the antients for borage.

EUREUX, a city of Normandy in France, twenty-five miles south of Rouen.

EURIPUS, a strait between the island of Negropont, and the continent of Greece, remarkable for its irregular tides. The term euripus is sometimes used, in a more general sense, for any straits, where the water is much agitated.

EUROPE, the leaf of the four grand divisions of the earth, is situated between 36° and 72° north latitude; and between 10° degrees west longitude, and 65° east longitude; being about 3000 miles long from north to south, and 2500 miles broad from east to west. It is bounded by the frozen ocean on the north, by Asia on the east, by the Mediterranean, which separates it from Africa, on the south, and by the Atlantic ocean on the west.

Europe is commonly subdivided into three grand divisions, north, middle, and south. The north or upper division comprehends Russia or Muscovy, Sweden, Denmark, and Norway, and the islands of Britain, Iceland, Greenland, and those of the Baltic. The middle division contains Poland, Germany, and the hereditary dominions of the house of Austria, the Low Countries, or Netherlands, and France. The southern division comprehends Turky in Europe, the antient Greece chiefly, Switzerland, Italy, Spain and Portugal, and the islands of Sicily, Sardinia, Corsica, Majorca, Minorca, Ivera, and those of the Archipelago. See the articles RUSSIA, SWEDEN, DENMARK, &c.

EURYTHMY, in architecture, painting, and sculpture, is a certain majesty, elegance, and easiness, appearing in the composition of diverse members, or parts of
of a body, painting or sculpture, and resulting from the fine proportion of it. Vitruvius ranks the eurythymia among the essential parts of architecture: he describes it as confiding in the beauty of the construction, or assemblage of the several parts of the work, which renders its aspect, or its whole appearance, grateful; e.g. when the height corresponds to the breadth, and the breadth to the length. Evelyn, in his account of architecture, says, that from these three ideas, or designs, viz. orthography, scenography, and profile, it is, that the same eurythymia, majestic and beautiful appearance of an edifice does result, which creates that agreeable harmony between the several dimensions, i.e. between the length, breadth, and height of each room in a fabric, so that nothing seems disproportional, too long for this, or too broad for that, but correpsons in a just and regular symmetry and concert of all the parts with the whole.

EUSEBIANS, a name given to the arians. See the article ARIANS.

EUSTATHIANS, the same with the catholics of Antioch, in the IVth century, so called from their refusing to acknowledge any other bishop beside St. Eustathius, who was deposed by the arians.

EUSTACE, or EUSTATIA, one of the Caribbee-islands, four miles west of St. Christophers, and subject to the Dutch.

EUSTYLE, in architecture, a sort of building in which the pillars are placed at the most convenient distance one from another, the intercolumniations being just two diameters and a quarter of the column, except those in the middle of the face, before and behind, which are three diameters distant.

EUTYCHIANS, in church-history, heretics in the IVth century, who embraced the errors of the monk Eutyches, maintaining that there was only one nature in Jesus Christ. The divine nature, according to them, had so entirely swallowed up the human, that the latter could not be distinguished; inomuch, that Jesus Christ was merely God, and had nothing of humanity but the appearance. This hereby was condemned in a council held at Constantinople in 448, which sentence was confirmed by the general council of Chalcedon, in 451.

EUXINE, the same with the Black-sea. See the article BLACK-SEA.

EWAGE, a toll paid for the passage of water, and otherwise called aquage.

EWE, the English name of a female sheep. See the articles OVIS and SHEEP.

EWRY, in the British customs, an office in the king's household, which has the care of the table-linnen, of laying the cloth, and serving up water, in silver ewers, after dinner.

EXACERBATION, the same with paroxysm. See the article PAROXYSM.

EXACHORD, or HEXACHORD. See the article HEXACHORD.

EXACTION, in law, a wrong done by an officer, or a person in pretended authority, in taking a reward or fee, that is not allowed by law. A person guilty of exaction may be fined and imprisoned. It is often confounded with extortion. See EXTORTION.

EXACTIS, in zoology, a species of flat-fish, with fix rays. See STAR-FISH.

EXACTOR REGIS, is sometimes taken for the sheriff, though more generally it denotes any person that collects the public monies, &c.

EXACUM, in botany, a genus of the Te-trandra-mongyna class of plants: the flower is monopetalous, patent, and divided into four segments at the limb; the fruit is a bilocular capsule, marked with two deep furrows, opening at the top, and containing numerous seeds.

EXAGON, or HEXAGON. See the article HEXAGON.

EXÆRESIS, in surgery, the operation of extracting or taking away something that is hurtful to the human body.

EXAGGERATION, in rhetoric, a kind of hyperbole, whereby things are augmented or amplified, by saying more than the truth, either as to good or bad. There are two kinds of exaggeration, the one of things, the other of words. The first is produced, 1. By a multitude of definitions. 2. By a multitude of adjuncts. 3. By a detail of causes and effects. 4. By an enumeration of consequences. 5. By comparisons. And, 6. By the contrart of epithets and rational inference. Exaggeration by words is effected, 1. By using metaphors. 2. By hyperboles. 3. By synonymous terms. 4. By a collection of splendid and magnificent expressions. 5. By periphrasis. 6. By repetition. And, lastly, by confirmation with an oath; as for example, Parietes, medius fidiis, gratias tibi agere goftitunt. See METAPHOR and HYPERBOLE.

EXAGGERATION, in painting, a method by which the artist, in representing things, charges
EXAMINATION, an exact and scrupulous disquisition or enquiry, in order to find out the truth of any thing.

Self-Examination, by way of preparation to repentance, is reduced by divines to five points: 1. A returning thanks to God for his benefits. 2. A begging of grace and light, to know and distinguish our fins. 3. An enquiry into all our words, thoughts, and actions, in order to learn what has been offensive to God. 4. A begging of pardon, and conceiving a sincere sorrow for having displeased him. 5. Making a firm resolution not to offend him any more; and taking the necessary precautions to preserve ourselves from it.

EXAMILION, or HEXAMILION. See the article HEXAMILION.

EXAMINERS, in chancery, two officers of that court, who examine, upon oath, witnesses produced in causes depending there, by either the complainant or defendant, where the witnesses live in London, or near it. Sometimes parties themselves, by particular order, are examined. In the country, above twenty miles from London, on the parties joining in commission, witnesses are examined by commissioners, being usually counsellors or attorneys, not concerned in the cause. See the article CHANCERY.

EXAMPLE, in rhetoric, is a way of reasoning, by which a particular fact is produced, or cleared up, by another that is similar to it.

EXANNUAL ROLL, that wherein, according to the old way of exhibiting sheriffs accounts, the illegible fines and desperate debts were transcribed. This roll was yearly read over to the sheriffs, to see what might be gotten thereby.

EXANTHEMA, εκανθέμα, among physicians, denotes any kind of effusion or eruption, as the measles, purple spots in the plague, or malignant fevers, &c.

EXARCH, εκαρχ, in antiquity, an officer sent by the emperors of the east, into Italy, in quality of vicar, or rather praefect, to defend that part of Italy which was yet under their obedience, and particularly the city of Ravenna, against the Lombards. The exarch resided at Ravenna, which place, with Rome, was all that was left to the emperors, of their italian dominions. The first exarch was under Justin the younger, in the year 567, after Belisarius and Narés had driven the barbarians out of Italy. The last was Eutychius, defeated by Adolphus king of the Lombards, in 752. But Pepin, king of France, deprived him of the exarchate, and made a gift of it to the pope, ordering his chaplain to lay the keys of all the towns on the altar of St. Peter and Paul at Rome.

EXARCH of a diocefe was the same with primate. See the article PRIMATE.

EXARCH also denotes an officer still subsisting in the greek church, being a kind of visitor, or one deputed by the patriarch into provinces, to see whether the bishops do their duty, and whether the rest of the clergy observe the canons of the church. There is another officer also of this name under the patriarchs of the greek church, who has the care and inspection of the patriarchal monasteries, or such as depend immediately on the patriarch.

EXARCHOS is a name given by Homer, Philo, and other antient writers, for the choragus, or he who sung first in the antient chorus. See the articles CHORAGUS and CHORUS.

EXARTICULATION, in surgery. See the article LUXATION.

EXAUCTORATION, exauétoratio, in roman antiquity, corresponded, in some measure,
EXCMEASURE, to our keeping soldiers or sailors in half-pay; but differed in this, that the auxiliori milites were deprived of their pay and arms, without being absolutely discharged. Sometimes, indeed, it signifies a full, but ignominious discharge.

EXCALCULATION, among the Hebrews, was a particular law, whereby a widow, whom her husband's brother refused to marry, had a right to sumon him to a court of justice, and, upon his refusal, might excalcule him, that is, pull off one of his shoes, and spit in his face; both of them actions of great ignominy.

EXCAMBIATORS, in our old customs, persons employed in exchanging lands, much the same as our brokers are between merchants. See the article Broker.

EXCELLENCY, a title antiently given to kings and emperors, but now to embassadors or ministers in half-pay; but differed in this, that it was a legal title, to our keeping soldiers or sailors in half-pay; but differed in this, that it was a particular law, whereby a widow, whom her husband's brother refused to marry, had a right to sumon him to a court of justice, and, upon his refusal, might excalcule him, that is, pull off one of his shoes, and spit in his face; both of them actions of great ignominy.

parallax at the same distance from the zenith, and from the sun's being observed to continue longer in the northern than in the southern hemisphere.

EXCENTRICITY, in the new astronomy, is the distance of the center of the orbit of a planet from the center of the sun, that is, the distance between the center of the ellipsis and the focus thereof.

It is also called simple or single excentricity.

To find the Excentricity of the earth's orbit, and the place of the apsides. Take an observation of mars when he is in opposition with the sun, and then, if mars be in M (plate XCIIV. fig. 3.) the sun in S, and the earth in T, they will be all in the same right line MTS. When mars, after 687 days, returns again to the same point M, and the earth not reaching the same till after 210½ days, in which time the completes two revolutions in her orbit, is found in the point A, observe the place of the sun seen from the earth by the right line AS, and the place of mars seen by the right line AM. We have, therefore, by means of the sun's place in E, at the time of the second observation, and his place in F, at the time of the first observation, the angle ESF given, to which the angle MSA is equal.

And by knowing the place of the fun and mars in the second observation, we have the distance of mars from the sun, or the angle MAS. In the same manner may be found the angle MSB, and BS the distance of the earth from the sun in decimal parts of MS, when mars returns a second time to M, and likewise the angle MSC, and the right line SC, when mars returns a third time to M. Wherefore since the focus of the earth's orbit is in S, and A, B, and C are points in that orbit, the line of the apsides will be determined, the orbit will be described, and consequently the excentricity will be known. The excentricity of all the primary planets, and the position of the line of apsides may be found in the same manner, if three heliocentric places of the planet, together with its true distance from the sun are known. But it must be observed, that we suppose that the planet, in the same point of its orbit, has the same distance from the sun, which we may easily suppose on account of the slowness of the motion of the aphelia.

The excentricities of the several orbits of the planets are as follow; supposing the distance of the earth from the sun, 9000 equal parts.

The excentricity of mercury's orbit is about 80 parts.
Venus's
The earth's
Mars's
Jupiter's
Saturn's

The excentricity of the moon's orbit is about 3.3 of the semi-diameter of the earth, and now and then it grows greater and now and then it diminishes. It is greatest when the line of the apsides is coincident with the lyzygia, or is in the line which joins the centers of the sun and earth. And the excentricity is least when the line of the apsides cuts the other at right angles. The difference between the greatest and least excentricity is so considerable, that it exceeds the half of the least excentricity.

Double Excentricity, is the distance between the two foci in the ellipsis, which is equal to twice the single excentricity.

EXCEPTION, in law, denotes a fllop or stay to an action, and is either dilatory or peremptory, in proceedings at common law: but in chancery it is what the plaintiff alledge against the sufficiency of an answer, &c.

An exception is no more than the denial of what is taken to be good by the other party, either in point of law, or pleading. The counsel in a cause are to take all their exceptions to the record at one time, and before the court has delivered any opinion of it.

EXCEPTION to evidence, is where a demurrer is offered in any civil cause, for the insufficiency of the evidence given, and the court does not agree to it; in such case, the court, upon request, is to seal a bill of exceptions to the evidence, which may be heard on a writ of error. A plaintiff or defendant may also alledge any exception to the judge's opinion, praying the same to be allowed; and if the judge refutes it, then the party concerned is to write it down, and when signed by counsel, require the judge to seal the same; to be heard afterwards.

EXCEPTIONS in deeds and writings, is the vacating a particular thing out of a general one granted by deed, as a room, floor, or cellar out of a house; a field, or timber trees, out of land, &c.

Exceptions of this kind must be something servicable, and if they cross the grant, or are repugnant thereto, they are void of
EXCHANGE, in commerce, implies the trade of money, carried on between one place and another, by means of bills of exchange. See the article BILL.

The original traffic of mankind becoming troublesome, necessity led them to the invention of some more easy manner of continuing their commerce, for which end money was thought the most commodious medium, and consequently this was, many ages since, adopted to carry on their trade; and still, for a greater convenience of foreign trade, they not only made coins of the most valuable metals, but, by degrees, fell into an improvement even of this, and sublimated remittances and exchange, by bills, to save the expense and risque which the portage of money from one kingdom to another occasioned.

But as commerce varied, so did exchange too, though long ago they were generally reduced in Europe into four, viz: cambio commune, cambio real, cambio fisco, and cambio feticito.

Cambio commune, in England, was that which was constituted by the several kings, who, having received monies in England, would remit the like sum by exchange, to be paid in another kingdom, according to the value of the different coins current in these countries. Cambio real was when monies were paid to the exchanger, and bills were drawn without naming the species, but according to the value of the several coins; and was no more than the payment of money in England, with a proviso to be paid the just value in specie, in another country, according to the price agreed on between the exchanger and deliverer, to allow or pay for the exchange of the money and the loss of time. Cambio fisco, or dry exchange, is when a merchant has occasion for 500 l. for a certain time, and would pay interest for it; but the lender, being defirous to take more than the statute allows, and yet willing to avoid its penalty, offers the 500 l. by exchange for Cadiz, to which the merchant agrees; but having no correspondent there, the lender defires him to draw his bill on the paid place, payable at double or triple usance, by any feigned person, as the exchange shall then govern, with which the merchant complies; and on receipt of the bill, the banker pays the money and remits the bill to some friend at Cadiz, which, with the exchange and interest, the merchant is to pay his creditor; these expenses formerly were very considerable. Cambio feticito is when a merchant hath occasion for goods, but cannot spare money for their payment; and the owner of them, to secure his advantage, and avoid the penalty of the law, acts as the usher in the former cafe, and obliges the buyer to defray the expenses of re-exchange, &c.

The just and true exchange for monies, that is at this day used both in England and other countries, by bills, is par pro passi, or value for value. Thus the English exchange is grounded on the weight and fineness of our own money, and the weight and fineness of those of each other country, according to their several standards, and proportionable to their valuations, which, being truly and justly made, ascertains and reduces the price of exchange to a sum certain for the exchange of monies to any country whatever. As money is the common measure of things between man and man within the realm, so is exchange between merchant and merchant both within and without the realm; the which is properly made by bills, when money is delivered; simply here in England, and bills received for the repayment of the same in some other country, either within or without the realm, at a price certain, agreed on between the merchant and the deliverer; for there is not at this day any peculiar or proper money to be found in specie, whereby on outland exchanges can be grounded; therefore, all foreign coins are called imaginary.
As the monies and species of almost every nation differ not only in their current prices, but also in their intrinsic value, there is a just and certain par established between them, according to the real and effective worth of each species, without any regard to their currency in the countries where they are coined; and the par is, by some authors, supposed to be of two sorts, viz. the one of real monies, the other of exchanges, or imaginary species, though both seem to be the same thing, as having a necessary dependence on each other. See the article PAR.

The relative abundance and scarcity of species in different countries, form what is called the course of exchange. This scarcity or plenty, from whence results the mutability of the course of exchange, is not the real, but a relative scarcity or plenty; for example, when France has greater occasion for funds in Holland, than the Dutch of having funds in France, species is said to be common in France, and scarce in Holland; and vice versa. See BALANCE of trade.

In order to judge of the scarcity or plenty of species, we must know, for example, that if there are more bills from Holland than there are from France, then species is scarce in France, and common in Holland. It then becomes necessary that the exchange should rise, and the Dutch give more for species of the same value in France, than the French for that of an equivalent value in Holland. When money of the same standard and weight in France, yields money of the same standard and weight in Holland, it is said that the exchange is at par. In the actual state of species, which was in 1744, the par was nearly at 54 gros to the French crown of three livres. When the exchange is above 54 gros, the French say it is high; when beneath, they say it is low.

In order to know the loss and gain of a state in a particular situation of exchange, it must be considered as debtor and creditor, as buyer and seller. When the exchange is below par, it loses as debtor, and gains as creditor; it loses as buyer, and gains as seller. It is obvious it loses as debtor. Suppose, for example, France owes Holland a certain number of gros, the greater number of gros there are in a crown, the more crowns she has to pay. On the contrary, if France is creditor for a certain number of gros, the less number of gros there are in a crown, the more crowns she will receive. The state loses al least as a buyer; for there must be the same number of gros to buy the same quantity of merchandise; and while the exchange is low, every French crown is worth fewer gros: for the same reason, the state gains as seller; you sell your merchandise in Holland for a certain number of gros: you receive then more French crowns, when for every 54 gros you receive a crown, than you would do if you received the same crown for every 48. The contrary to this takes place in the other state. If the Dutch are indebted a certain number of crowns to France, they will gain; if they are owing to them, they will lose; if they fell, they lose; if they buy, they gain.

Again, when the exchange between France and Holland is below par; for example, if it should be at 48 instead of 54, it should follow, that France, on sending bills of exchange to Holland for 54,000, could buy merchandizes only to the value of 50,000; and that, on the other hand, the Dutch sending the value of 50,000 to France, might buy 50,000 crowns, which makes a difference of 6, that is, a loss of more than 7; so that France would be obliged to send to Holland 7 more in specie or merchandise, than she would do was the exchange at par; and as the mischiefs must consequently increase, because a debt of this kind would bring the exchange still lower, France would in the end be ruined.

It items, we say, as if this should certainly follow; and yet it does not, because states constantly lean towards a balance, in order to preserve their independence. Thus they borrow only in proportion to their ability to pay, and measure their buying by what they sell; and taking the example from what has been said, if the exchange happens to fall in France from 54 to 50, the Dutch, who buy merchandizes in France to the value of a thousand crowns, for which they used to pay 54,000 gros, would now only pay 50,000, if the French would consent to it. But the merchandize of France will rise infensibly, and the profit will be shared between the French and the Dutch; for when a merchant can gain, he easily shares his profit; there then arises a communication of profit between the French and the Dutch.

In the same manner, the French who bought merchandizes of Holland for 54,000 gros, and who, when the exchange was at 54, paid for them 1000 crowns,
E X C [1143] E X C

erowns, will be obliged to add more in french crowns, to buy the same mer-
chandies. But the french merchant, be-
ing sensible of the loss, he suffers, will take
up less of the merchandie of Holland: the
french and the dutch merchant will
then be both losers, the
french and the dutch merchant will
will not be attended
with these inconveniences we had reason
to
fear.

A merchant may send his flock into a
country, when the exchange is
below par, without injuring his fortune,
because when it returns, he recovers what
he had lost; but a prince, who sends
only specie into a foreign country, which
can never return, is always a loser.

When the merchants have great dealings
in any country, the exchange there infal-
libly rises. This proceeds from their
finance, great quantities of
merchandises
for them.

The exchange of all places constantly
tends to a certain proportion, and that in
the very nature of things. If the course of
exchange from Ireland to England is
below par, that of Ireland to Holland
will be still lower: that is, in a compound
ratio of that of Ireland to Eng-
land, and that of England to Holland:
for a dutch merchant, who can have his
specie indirectly from Ireland, by the way
of England, will not choose to pay dearer,
by having it the direct way.

This, we say, ought naturally to be the
case; but, however, it is not exactly so:
there are always circumstances which
vary these things; and the different profit
of drawing by one place, or of drawing
by another, constitutes the particular art
and dexterity of the foreign bankers. See
the article Banker.

This is what in a great measure con-
stitutes what is called arbitration in ex-
changes, which is defined to be a truck,
which two bankers mutually make of
their bills upon different parts, at a con-
ditional price, and course of exchange.
This is the most beneficial; as well as the
most delicate branch of exchange to be
thoroughly informed of.

1. Before any one applies himself to the
study of this subject, it is necessary that
he should be well skilled in the practical
operations, in regard to the reducing of
the sterllng money of England into the
foreign monies of exchange and of ac-
count of all places throughout Europe,
according to the direct courses of ex-
change established for these purposes, and
vice versa.

2. That he should be acquainted with
the methods of converting sterllng money
into the monies of exchange and of ac-
count of all other places of commerce,
wherewith England has no direct esta-
blished courses of exchange, but is under
the necessity of making use of the inter-
mediate exchanges of other places; to-
gether with the nature of the agios, and
the manner of converting their bank
monies into current, and the reverse.

See the article Agio.

3. The manner of calculating all the
foreign monies of Europe into those of
every other distinct country, either ac-
cording to the direct or intermediate ex-
change, which makes a much greater
variety of cafes than those who are not
acquainted with this extensive subject can
imagine.

4. It is necessary also to know the in-
trinsic value of foreign monies, accord-
ing to the most accurate annals which
have been made for that purpose; and
this the reader will find done to his hand
under the article Coin. See Coin.

5. Lastly, it is requisite to understand
the general natural causes of the rise
and fall of the courses of exchange be-
tween nation and nation, or between one
trading city and another in the same na-
tion; which depends upon the balance
of trade being either in favour of, or
against a nation, or trading city.

Another method of considering the arbi-
tration of exchanges, is founded upon
comparing the various occasional prices
of exchange between nation and nation,
in order to discover at all times, whether
certain courses continue in an equality of
proportion, or how far they deviate there-
from; by which means the advantage to
be made by such a comparison of ex-
changes may be exactly ascertained, for
the government of the merchant or re-
mitter, to take his measures accordingly,
and not to let the advantageous occasion
7 G 2
EXCHANGE. And this must necessarily prove the cause, provided a person is not accomplished in this branch of the exchanges; and here it will be proper to observe, that in a comparison or combination of the courses of exchange of several places together, it is rare that they happen to ebb and flow in an exact equality of proportion; the reason whereof must be obvious to every one who considers, that the balance of trade differs between different nations; which being the case, the judgment of the exchange-negotiator consists in vigilantly observing, from a due comparison of the courses, where the greatest inequality of proportion lies; for there lies the greatest profit to be made, by drawing and remitting to certain places preferably to others.

But the greatest profit to be made this way, does not always happen to arise from a comparison of these courses only, where the general currency of a trader's business lies; on the contrary, from the nature and circumstances of the trade of such countries, the rise and fall of the courses may generally continue in such an equality of proportion, as only occasionally, or seldom, to admit of any extra-profit by the exchange. When the exchange is lower than the specie of a country, a profit may be made by sending it abroad; when it is higher than the specie, there is a profit in calling it to return: but there is a case in which profit may be made by sending the specie out of the kingdom, when the exchange is at par; that is, by sending it into a foreign country, to be coined over again. When it returns, an advantage may be made of it, whether it be circulated in the country, or paid for foreign bills.

EXCHANGE signifies also a place in most considerable trading cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet on certain days, and at certain times thereof, to confer and treat together of matters relating to exchanges, remittances, payments, adventures, assurances, freightments, and other mercantile negotiations, both by sea and land. These assemblies are held with so much exactness, that the absence of a merchant, &c. makes him suspect of drawing to a failure or bankruptcy, as not being able to stand the change.

The most considerable exchanges in Europe, are those of Amsterdam, and that of London, called the royal-exchange. See the article ROYAL-EXCHANGE.

EXCHANGE, in law, signifies a mutual grant of lands or tenements, the one in exchange for the other. This word, in our law, is peculiarly used for that compenstation which the warrantor must make to the warrantee, value for value, in case the land warranted be taken, or recovered from the warrantee. Exchanges are made of lands in fee, tail, or for term of life, &c. where a person is feid of certain lands or tenements, and another is feid of other lands, &c. these two persons may exchange their lands, so that each of them shall have the other's lands so exchanged. But in this exchange the eftates granted must be equal; for should one have an eftate in fee in his land, and the other an eftate in the other land only for term of life, or in tail, such exchange is void, on account of the inequality; though, if the eftates are equal, as eftate in fee for another in fee, tail for tail, &c. the exchange will be good, if the lands be not of equal value.

EXCHANGERS, are such as return money by bills of exchange. See the articles BILL and EXCHANGE.

EXCHEQUER, in the British jurisprudence, an antient court of record, in which all caufes concerning the revenues and rights of the crown are heard and determined, and where the crown-revenues are received. It took this name from the cloth that covered the table of the court, which was party-coloured or chequered. This court is said to have been erected by William the conqueror, its model being taken from a like court established in Normandy long before that time. Antiently its authority was so great, that it was held in the king's palace, and the acts thereof were not to be examined or controlled in any other of the king's courts; but, at present, it is the laft of the four courts at Westminster. In the exchequer, some reckon seven courts, viz. those of pleas, accounts, receipts, exchequer-chamber, (which is an assembly of all the judges on difficult matters in law) errors in the exchequer, errors in the king's bench, and, lastly, the court of equity in the exchequer. But the exchequer, for dispatch of business,
nefs, is generally divided into two parts; one of which is chiefly conversant in the judicial hearing and deciding of all causes relating to the king's coffers, formerly termed the exchequer of accounts: the other is called the receipt of the exchequer, as being principally employed in receiving and payment of money. Officers of the receipt may take one penny in the pound, as their fee for sums issued out; and they are obliged, without delay, to receive the money brought thither; and the money received is to be put in chests under three different locks and keys, kept by three several officers. All sheriffs, bailiffs, &c. are to account in the exchequer; and in the lower part, termed the receipt, the debtors of the king, and persons in debt to them, the king's tenants, and the officers and ministers of the court, are privileged to sue one another, or any stranger, and to be sued in the like actions as are brought in the courts of king's bench and common pleas.

The judicial part of the exchequer, is a court both of law and equity. The court of law is held in the office of pleas, according to the course of common law, before the barons: in this court, the plaintiff ought to be a debtor or accountant to the king; and the leading process is either a writ of subpoena, or quo warranto, which last goes into Wales, where there also lies a puisne-baron, who administers the oaths to high sheriffs, bailiffs, auditors, receivers, controllers, surveyors and searchers of all the customs, &c. See the articles Baron, chancellor, &c. The exchequer in Scotland, has the same privileges and jurisdiction as that of England; and all matters competent to the one, are likewise competent to the other.

Black book of the exchequer, a book containing a description of the court of England in 1175, and its officers, with their ranks, wages, privileges, perquisites, &c. also the revenues of the crown, both in money and cattle.

ExciPient, in pharmacy, denotes the ingredient, which, in compound medicines, receives all the rest; as the conservator in electuaries, the syrup in boluses, &c.

Excise, a certain duty or impost charged upon liquors, as beer, ale, cyder, &c. malt, and several other commodities, within the kingdom of Great Britain, and town of Berwick upon Tweed. The excise is one of the most considerable branches of the king's revenue. It was formerly farmed out, but is now managed for the king by commissioners in both kingdoms, who receive the whole product of the excise, and pay it into the exchequer. These commissioners are nine in number in England, and four in Scotland. The former have a salary of 1000l. a year, the latter, 500l. They are obliged by oath to take no fee or reward but from the king himself; and from them there lies an appeal to five other commissioners, called commissioners of appeals. The duty of excise was first granted to king Charles II. by act of parliament in the year 1660, during the life of that monarch. 1. It was 15d. per barrel upon every barrel of beer or ale above 6 g. the barrel, and 3d. per barrel for every barrel of 6 g. or under, brewed for retail; 1d. for every hoghead of cyder or perry sold by retail, 1d. for every gallon of making of which he may call in any person interested in the cause, or any officers, or others, to instruct him, that the king be not prejudiced thereby, and his answer is to be put in without oath. But besides the business relating to debtors, farmers, receivers, accountants, &c. all penal punishments, intrusion, and forfeitures upon popular actions, are matters likewise cognizable by this court; where there also lies a puisne-baron, who administers the oaths to high sheriffs, bailiffs, auditors, receivers, collectors, controllers, surveyors and searchers of all the customs, &c. See the articles Baron, chancellor, &c.
of strong water, aqua viva, &c. 2. A
new excise was granted for ever by the
fifth money act of Will. and Mary, be-
ing for every barrel of beer or ale above
6s. the barrel, 9d. and for every barrel
of 6s. or under, 3d. for every hoghead
of cyder or perry, 1s. per hoghead.
In this excise, the price of the liquor is to
be reckoned exclusive of the duty. 3. An
excise was granted of 6d. a bushel on
malt in the reign of king William, which
by subsequent statutes has been continued
yearly every since. But such malt as shall
be made for exportation, and be so en-
tered and kept separate from other malt,
is exempted from the payment of this
duty. 4. Another new excise upon
home-made liquors was granted in queen
Anne's reign; being an additional ex-
cise upon every barrel of beer or ale brew-
ed for sale above 6s. the barrel, 3d. ex-
clusive of the duties; and for every bar-
rel at 6s. or under, 1d. for every hog-
head of cyder or perry, 5d. for every
gallon of strong waters or aqua viva, 1d.
This excise was not laid upon any such
liquors imported. 5. An excise on can-
dles was first granted in the reign of queen
Anne, and continued for ever, being a
duty of 4d. a pound on wax and a half-
penny the pound on tallow-candles, made
in Great Britain for sale or not for sale;
but makers for their own use may com-
pound for 1s. a head for every person in
their family. An additional excise on
candles was afterwards granted, being
the same with the former in every re-
spect. 6. An excise upon hides and skins tan-
ned in Britain, first granted in queen
Anne's reign, was an excise of seventeen
different kinds, upon so many different
kinds of hides and skins particularly
named, and upon all others not named,
31. per cent. ad valorem. An addi-
tional excise was afterwards granted, be-
ing an additional duty of different kinds,
upon so many different sorts of hides and
skins particularly named, and on all others
not named, 31. per cent. on the value.
7. An excise on home-made vellum and
parchment, first granted by the same act,
being 1s. per dozen on vellum, and 6d.
the dozen on parchment. And after-
wards an additional excise on vellum, &c.
was granted, being an additional duty
of 2s. the dozen on vellum, and 1s. the
dozen on parchment. 8. An excise on
hops of home growth was first granted
in queen Anne's reign, being 1d. per
pound. 9. An excise on paper, palette-
boards, milled-boards, and scale-boards,
was first granted in the reign of queen
Anne, being a duty of eleven different
kinds on so many different sorts of paper
particularly named, made in Great Bri-
tain; on palette-boards, &c. 3s. the hun-
dred weight, and on all sorts of paper not
named, 12l. per cent. on the value. An
additional duty on paper, &c. was grant-
ed of eleven different kinds, &c. on palette-
board, 1s. 6d. the hundred weight, and
on all sorts of paper not named, 6l. per
cent. on the value; and on painted paper
for: angings, a halfpenny the yard square.
10. An excise of 1d. per pound on soap
made in Great Britain, was granted by
the same act; to which an additional ex-
cise has been added of a halfpenny per
pound. 11. An excise upon printed
silks, callicoes, linnens and stuffs made
in Great Britain, and printed, painted,
stained or dyed here, was first granted in
queen Anne's reign, being a duty of 3d.
on silks and callicoes, and 1½d. on linnen
and stuffs the yard square, excepting silk-
handkerchiefs, linnens and fulltains dyed
of one colour, and stuffs made of woollen,
or the greatest part in value of woollen.
And an additional excise was granted of
6d. the yard of half-yard broad silks;
1d. the yard square of silk handkerchiefs;
3d. the yard square of callicoes, and 1½d.
the yard square of linnens and stuffs, ex-
ccepting, as before, callicoes, &c. dyed of
one colour, and woollen stuffs. 12. An
excise on starch was first granted for 1d.
the pound; and afterwards an additional
excise of 1d. the pound. 13. The ex-
cise on gilt and silver wire made in Great
Britain, is 8d. the ounce on gilt wire,
and 6d. the ounce on silver wire.
If any brewers do not make true entries
of their liquors brewed, once a week at
the excise-office, they forfeit 10l. but this
is subject to mitigation, 10 as not to be
less than double the duty; and the re-
tailers of beer and ale and strong waters,
neglecting to make their entries once a
month of what liquors they retail, are
liable to 40s. penalty. In cafe any brewer
creets or alters any back, copper, cooler,
&c. or keeps a private store-house, or if
any malter keeps any private vessel for
steeping barley, without giving proper
notice to the officers of excise, fuch brewer
or malter forfeit 50l. and where they
bribe a gauger, it is 70l. The officers
of excise may go on board ships, and
search for any excisable liquors, as offi-
cers of the customs do, and seize commo-
ties.
E X C [ 1147 ] E X C

E X C L U S I O N, or Bill of Exclusion, a bill proposed about the close of the reign of king Charles II. for excluding the duke of York, the king's brother, from the throne, on account of his being a papist.

EXCLUSION, in mathematics, is a method of coming at the solution of numerical problems, by previously throwing out of our consideration such numbers as are of no use in soling the question. Mr. Fre- nicle gives an account of it in the Ouvra- ges de Mathematique, &c.

EXCLUSIVE, is sometimes used adjecti- vely, thus. A parent carries with it an exclusive privilege; and sometimes adver- bially, as, he sent him all the numbers from \( n^1 \) to \( n^2 \) exclusive; that is, all between these two numbers, which themselves were excepted.

EXCLUSIVE PROPOSITIONS, in logic, are those where the predicate agrees with its subject, as to exclude every other. Thus, virtue alone constitutes nobility, is an exclusive proposition.

EXCOMMUNICATION, an ecclesiasti- cal penalty or censure whereby such per- sons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication among the Jews, according to Eliahou; a German rabbin, was distingukshed into three kinds, 1. Niddui, which was a separation of but a few days. 2. Cherem, a separation attended with execration and malediction. And, 3. Shammathah, which was the last and greater excommunication. But Selden

says, that niddui and shammathah are the same thing, and therefore that there were but two kinds of excommunication among the Jews, viz. the greater and the lesser. They made also another distinction in ex- communication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular person in conver- sation might exclude another, and himself likewise; and this excommuni- cation, if well grounded, was of force: nay, if a man dreamed that he was ex- communicated by himself or another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.

As to the effects of the Jewish excommu- nication, the lesser excluded the excommu- nicated person from the society of men; that is, he was not to come nearer than four cubits, neither he, his wife, children, or domestics, according to Buxtorf. The greater absolutely sequestered the person from the conversation of others; and sometimes he was shut up in a small chamber or prison, where he lived alone. Baroniou.s and Beza pre- tend, that the greater excommunication excluded men from the use of sacred things. Selden, on the contrary, affirms, that they were allowed to be present in the temple, and partake of the public worship. Buxtorf, who is of the same opinion, adds, that whereas others came into the temple at the right hand, and went out at the left, the excommunicated were obliged both to go in and out at the left.

Excommunication among the modern Jews, is attended with the most terrible con- sequences. The excommunicated person is refused all human assistance: if there be a worse in his house, or a child to be circumcised, none must help him. He is turfed by the book of the law, by the curse of Joshua against Jericho, by that of Eliezer against the children, by heaven and earth, and God is besought that a whirlwind may dash him to pieces. He is pelted with stones if he appear, in the streets; and if he obtains abolution, it is upon the most mortifying condi- tions; for he is publicly tied to a post and whipped, after which he lays him-
EXC [1148] EXC

In the ancient Christian church, the power of excommunication, as well as other acts of ecclesiastical discipline, was lodged in the hands of the clergy, who distinguished it into the greater and lesser. The lesser excommunication simply called ἀπορρίσεως, separation or suspension, consisted in excluding men from the participation of the eucharist, and the prayers of the faithful. But they were not expelled the church; for they had the privilege of being present at the reading of the scriptures, the sermons, and the prayers of the catechumens and penitents.

This excommunication was inflicted for minor crimes, such as neglecting to attend the service of the church, misconduct in it, and the like.

The greater excommunication, called συνάντησις: ἀπορρίσεως, total separation and anathema, consisted in an absolute and entire exclusion from the church and the participation of all its rites. When any person was thus excommunicated, notice was given of it by circular letters to the most eminent churches all over the world, that they might all confirm this act of discipline, by refusing to admit the delinquent to their communion. The consequences of this latter excommunication were very terrible. The excommunicated person was avoided in civil commerce and outward conversation. No one was to receive him into his house, nor eat at the same table with him; and when dead, he was denied the solemn rites of burial. It has been a question, whether the ancient church used to add excommunication to her censures. Grotius thinks this was done, though very seldom, as in the case of Julian the apologist, for whose destruction the ancient Christians absolutely prayed to God. St. Chrysostom was utterly against this practice, affirming that we ought not to pray against the sinner, but against his opinions or actions.

The Roman pontifical takes notice of three kinds of excommunication. 1. The minor, incurred by those who have any correspondence with an excommunicated person. 2. The major, which falls upon those who disobey the commands of the holy see, or refuse to submit to certain points of discipline; in consequence of which they are excluded from the church militant and triumphant, and delivered over to the devil and his angels. 3. Anathema, which is properly that pronounced by the pope against heretical princes and countries. In former ages, these papal fulminations were most terrible things; but at present, they are formidable to none but a few petty states of Italy. See Anathema and Fulmination.

Excommunication in the Greek church, cuts the offender off from all communion with the 318 fathers of the first council of Nice, and with the saints; confines him over to the devil and the traitor Judas; and condemns his body to remain after death as hard as a flint or piece of steel, unless he humbles himself and makes atonement for his sins by a sincere repentance. The form abounds with dreadful imprecations; and the Greeks assert, that if a person dies excommunicated, the devil enters into the lifeless corpse; and therefore in order to prevent it, the relations of the decedent cut his body in pieces, and boil them in wine.

It is a custom for the patriarch of Jerusalem annually to excommunicate the pope and the church of Rome; on which occasion, together with a great deal of idle ceremony, he drives a nail into the ground with a hammer, as a mark of malediction.

The form of excommunication in the church of England, intently ran thus: "By the authority of God the Father, the Son and Holy Ghost, and of Mary the blessed mother of God, we excommunicate, anathematize, and excommunicate with us, are contempt of the bishop's court, hereby, neglect of public worship and the sacraments, incontinency, adultery, simony, &c. It is published in the church, and if the offender does not submit in forty days, the civil magistrate interposes, and the excommunicated person is imprisoned till he submits and obtains abolution. Excommunication disabling a person from doing any judicial act, as sitting in an action at law, being a witness, &c. See Excommunicato Capiendo, &c.

Excommunication, among the pagans, excluded the person from the sacrifices and the temples, and delivered him over to the furies, which was called exsiccavat and diris deseruere. When Marcus Cæsarius set out on his expedition against the Parthians, Atteius, tribune of the people,
people, not being able to prevent him, ran to the gate of the city through which the general was to pass, and setting a charging-dish in the middle of the way with fire in it, when Craufs drew near, he threw some perfumes into the charging-dish, and pronounced curses against Craufs with great exclamation, and thus excommunicated him.

EXCOMMUNICATO CAPIENDO, a writ issued from the chancery upon the bishop's certifying an excommunication. This writ is directed to the sheriff to take the body of the person excommunicated, and imprison him until he has made satisfaction to the church for the contempt or wrong done. See EXCOMMUNICATION. In the certificate of an excommunication, the cause is to be particularly expressed, that the judges may see whether the ecclesiastical court has cognizance of the cause; and if the ordinary excommunicate a person for a thing of which he hath no cognizance, the party may bring an action against him, and in some cases may be delivered by habeas corpus, or by prohibition.

EXCOMMUNICATO DELIBERANDO, a writ directed to a sheriff for the delivery of an excommunicated person, upon the bishop's certifying to the king, that he hath conformed to the ecclesiastical jurisdiction.

EXCOMMUNICATO RECIPIENDO, a writ where excommunicated persons being committed to prison, and afterwards illegally delivered, are commanded to be re-taken and imprisoned again.

EXCORIATION, in medicine and surgery, the galling or rubbing off of the cuticle, especially of the parts between the thighs, and about the anus. In adults, it is occasioned by riding, much walking, or other vehement exercise, and may be cured by vulnerary applications. In children, there is often an excoriation not only of the parts near the pudenda, chiefly of the groin and scrotum, but likewise in the wrinkles of the neck, under the arms, and in other places; proceeding from the acrimony of the urine and sweat, and occasioning itching pains, crying, watching, and ruffledness.

To remedy this, the parts affected may be washed often with warm water, and sprinkled with drying powders, as chalk, hartshorn, but especially tuff, lapis calaminaris, and cerufs, which may be tied loosely in a rag; and the powder hook out on the disordered places. If the parts tend to a real ulceration, it will be proper to add a little sugar of lead to the powder, or to anoint the place with ungent. alb. camphor. Likewise a little white vitriol, dissolved in spring-water, and daubed upon the part, will dry and heal it very powerfully.

EXCORIATION, the same with bark- ing of trees. See the article BARKING.

EXCREMENT, whatever is discharged out of the body of animals after digestion, or the fibrous parts of the aliment, mixed with the bile, saliva, and other fluids. Urine and the faces are the gross excrements that are discharged out of the bladder or belly. Other excrements are the various humours that are secreted from the blood through the various strainers in the body, and which serve for several uses, such as the saliva, sweat, bile, the pancreatic juice, lymph, the semen, nails, the hair, the horns and hoofs of animals. The ejection of excrements is an evacuation by urine, stool, spittle, &c. Unless the excretions are regular, health cannot be maintained, and therefore, if they are too plentiful, defective, or suppressed, they will occasion various disorders: hence, if a person be colitive, it is generally the forerunner of some disease. As a man generally takes more aliment than is necessary to generate blood and serum, and the common excrements are not sufficient to carry off superfluous humours, extraordinary ones sometimes happen, at stated times; as the piles, haemorrhages, &c. See more upon this under the articles DISEASE and EXCRETION.

EXCRESCEENCE, in surgery, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or tubercle. If they are born with a person; as they frequently are, they are called nasvi materni, or marks from the mother; but if the tumour is large, so as to depend from the skin like a fleshy mass, it is then called a farcoma. Excrences arise in all parts of the body, but more especially the head, face, eye-brows, neck, breast, abdomen, anus, legs, and arms. Their size and figure are various; with regard to their colour, some resemble that of the skin, others are inclined to black or red; and, with respect to their figure, they resemble strawberries, mulberries, grapes, figs, pears, mice, and the like.

As to the general treatment of them, they may be removed either by ligature, the knife, or actual and potential cauterities, according as the patient's habit of body
body and other circumstances may require. However, it is to be observed, that if these excrescences have a very large root, if there are large arteries or veins near the root, or if it be firmly joined to the bone, in these cases, the surgeon should remove them with great caution; or, in cases of great danger, wholly neglect them. When these tumours lie near large blood-vessels, it is proper to have flypotics, bandages, and often actual cauteries in readiness to stop the hemorrhage, especially if they are removed by abscission.

EXCRETION, or SECRETION, in medicine, a separation of some fluid, mixed with the blood, by means of the glands. Excretions, by which we mean those that evacuate superfluous and heterogeneous humours, purify the mass of blood: the humours which are generated in the blood are excreted by the glands, and are replaced by a sufficient quantity of aliment. This, in adults, keeps the body of an equal weight, and consequently preserves life and health; therefore the secretions ought neither to be disturbed or diminished, suppressed or increased: the extraordinary excretions, such as the bleeding piles, and hemorrhages of the nose, also large sweats, loofeins, running at the nose, coughs, catarrhs, plentiful spitting, all promote health; and if these are defective or suppressed, dangerous diseases may arise: whereas it is highly hazardous to suppress secretions of this kind. See the article EXCREMENT.

EXCRETORY, in anatomy, a term applied to certain little ducts or vessels, destined for the reception of a fluid, secreted in certain glandules, and other viscera, for the excretion of it in the appropriated places. See the preceding article.

All the glands are usually furnished with an excretory duct. See GLAND.

EXCURSION, in astronomy, is used in a synonymous sense with elongation. See the article ELONGATION.

Circles of Excursion. See the preceding article.

EXCUTIA VENTRICULI, in surgery, the stomach-broth. See STOMACH.

EXECRATION, excretio, in antiquity, a kind of punishment, consisting of direful curfes and marks of infamy: such was that used against Philip king of Macedon, by the Athenians. A general assembly of the people being called, they made a decree, that all the statues and images of that king, and of all his ancestors, should be demolished, and their very names razed; that all the festivals, sacred rites, priests, and whatever else had been instituted in honour of him, should be proclaimed; that the very places where there had been any monument or inscription to his honour, should be detestable; that nothing should be set up, or dedicated in them, which could be done in clean places: and, lastly, that the priests, as often as they prayed for the athenian people, allies, armies, and fleets, should as many times detest and excrurate Philip, his children, kingdom, land and sea forces, and the whole race and name of the Macedonians.

At the taking and demolishing a city, it was frequent to pronounce dreadful curses and executions upon whoever should endeavour to rebuild it; which some imagine was the reason that Troy could never be railed out of its ashes, though several persons attempted it, being devoted to eternal and irreparable ruin by Agamemnon. We find Joshua at the destruction of Jericho, fix an imprecation upon the person who should endeavour to rebuild it, which was accomplished in Hiel the Bethelite, many ages after.

EXECUTION, in a general sense, the act of accomplishing, finishing, or achieving anything to be done.

EXECUTION, in law, the compleating or finishing some act, as of judgment, deed, &c. and it usually signifies the obtaining possession of any thing recovered by judgment of law. See JUDGMENT.

Sir Edward Coke observes, that there are two sorts of executions: the one final, and the other a quoique, that tends to an end. An execution final, is that which makes money of the defendant's goods, or extends to his lands, and delivers them to the plaintiff, who accepts the fame in satisfaction; and this is the end of the suit, and the whole that the king's writ requires to be done. The writ or execution with a quoique, though it tends to an end, yet is not final, as in the case of a capias ad satisfaciendum. where the defendant's body is to be taken, in order that the plaintiff may be satisfied for his debt. See the article CAPIAS.

Executions are either in personal, real, or mixed actions. In a personal action, the execution may be made three ways, viz. by the writ of capias ad satisfaciendum, against the body of the defendant; fieri facias, against his goods; or elegit, against his lands. See FIERI FACIAS and ELEGIT.
In a real and mixed action, the execution is by writ of habere facias seisinam, and habere possessionem. See Habere. Writs of execution bind the property of goods only from the time of delivery of the writ to the sheriff; but the land is bound from the day of the judgment obtained: and here the sale of any goods for valuable consideration, after a judgment, and before the execution awarded, will be good. It is otherwise as to lands, of which execution may be made, even on a purchase after the judgment, though the defendant fell such land before execution. Likewise, sheriffs may deliver in execution all the lands whereof others shall be seised in trust for him, against whom execution is had on a judgment, &c.

When any judgment is signed, the execution may be taken out immediately thereon; but if it be not issued within a year and a day after, where there is no fault in the defendant, as in the case of an injunction, writ of error, &c. there must be a fiere facias to revive the judgment; though, if the plaintiff sues out any writ of execution within the year, he may continue it after the year is expired. After judgment against the defendant, in an action wherein special bail is given, the plaintiff is at liberty to have execution against such defendant, or against his bail: but this is understood where the defendant does not render himself, according to law, in safeguard of the bail: and execution may not regularly be sued forth against a bail, till a default is returned against the principal: also, if the plaintiff takes the bail, he shall never take the principal. It is held that an execution may be executed after the death of the defendant; for his executor, being privy thereto, is liable, as well as the testator. The execution is an entire thing, so that he who begins must end it: therefore, a new sheriff may distrain an old one, to sell the goods seised on a distingas, and to bring the money into court.

Execution of judgments, in criminal cases. This must be pursuant to the judgment, and the king may not alter it, for this reason, that no execution can be warranted by law, but where it is according to the judgment given; yet the king may par­don part of the execution in judgment for treason, viz. all but beheading. The execution of criminals is to be made by the proper officer; and if the sheriff, or other officer empowered to do it, alters the execution, or any other executes an offen­
another. If he appoints executors only for a certain number of years, after they are elapsed, the ordinary may grant administration of the goods; as he may do, till the power of executors take place. It is also observable, that where there is no executor, there is properly no will; and where there is no will, there can be no executors: but this only regards goods; for where lands in fee are devised, it is a good will, though no executor be named therein.

An executor may either accept or refuse the executorship; but after he has accepted the office, he shall not refuse the same, nor take it up after refusal. If any one of several executors prove the will, it will serve for all; so that the residuary estate is held to be the estate of all the executors, and most of them may not administer. Such a person is chargeable to refund.

The particular duty of an executor, is to bury the testator in a decent manner, according to his rank and circumstances, and with a due regard to the estate left; for whatever the executor lays out in funeral charges extravagantly, if there be not enough to pay debts, he must bear it at his own expense. He is to make an inventory of all the goods and chattels of the deceased, with their value; and then, or before, if requisite, where there is enough to pay the testator's debts and legacies, he ought to prove the will before the ordinary in common form, either by his own oath, or by witnesses, if required by those who have a right to question it; and when exhibited in the registrar's office of the ecclesiastical court, a copy thereof in parchment is delivered to the executor under the ordinary's seal, which is called the probate.

The executor is next to pay all debts, before legacies, in the order following, viz. the charges of the funeral being first paid, the king's debt is to be preferred before all others; then debts on judgments, and statutes or recognizances, those due upon mortgages, bonds, and other specialties; after them, rent on leases, servants wages, debts on notes, and shop-books: for if he pays the debts in any other order, he is liable to the payment of debts of a higher degree, though out of his own estate; yet, among debts of equal degree, an executor may pay himself first: and such as are first funded for, shall be first paid; and if no suit be commenced, he may pay the whole debt to any one creditor, although there should be nothing left to pay another any part of his. In case the testator is bound in several bonds, his executor has the privilege to pay which bond he pleases, unless an action of debt is actually prosecuted against him upon some of the other bonds; and in such a case, if while an action of this kind is depending, another bond-creditor brings another action, before any judgment is obtained, he may prefer which he will by confessing a judgment to one, and paying him; which judgment may be pleaded in bar to the other action.

After the debts, an executor is to pay the legacies; and he may prefer a legacy to himself, though there should not be enough to pay any of the rest. He may likewise pay what legacies he pleases first, or give to each legatee a part, in proportion, if there is not enough to pay the whole. However, if there be a specific legacy of some particular thing, as a horse, or silver-cup, it must be delivered before any other legacy.

In case an executor pays out the affairs in legacies, and afterwards debts appear, of which he had no notice, which he is obliged to pay; he may, by a bill in chancery, compel the legatees to refund.

After the debts and legacies are paid, whatever remains, it is laid, belongs to the executor by the common law; but this has been construed, where the executor is a relation of the deceased, and had no legacy or other provision by the will. Hence, where a person made a will, and an executor, without dispoising of the residue of his personal estate, it has been adjudged, that the remainder should not go to the executor, but be distributed among the relations of the testator by administration.

Executor de son tort, or an executor of his own wrong, a person that takes upon him the office of an executor by intimation, without being so constituted by the testator, or appointed by the ordinary to administer. Such a person is chargeable to the rightful executor, as also to
EXE

all the testator's creditors and legatees, so far as the goods amount to which he wrongfully pollised.

EXECUTORY, in law, is where an estate in fee, that is made by deed or fine, is to be executed afterwards by entry, livery or writ. Leaves for years, annuities, conditions, &c. are termed inheritances executory.

EXECUTORY DEVISE, is when the fee by devise is vested in any person, and is to be vested in another upon contingency. In all cases of executory devises, the estates descendent until the contingencies happen. The remainder of a fee may not be limited by the rules of law after a fee simple, unless such estate depends upon a contingency or is conditional, when it may take place as an executory devise. Executory devises of terms for years, ought to arise within the compass of one life.

EXEDRA, in church-history, a name sometimes given to the ambo. See the article AMBO.

EXEDRAE, in antiquity, a general name for such buildings as were distinct from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the exedrae the chief was the baptistery. See the article BAPTISTERY.

Exedrae were also halls or little academies with several feats, upon which philosophers, rhetoricians, &c. sat, when they met for conversation or disputations. Vitruvius speaks of them as places very open and exposed to the sun.

EXEGESIS, a discourse by way of explanation or comment upon any subject. In the Scotch universities, there is an exercise among the students in divinity called an exegesis, in which a question is stated by the respondent, who is then opposed by two or three other students in their turns; during which time the professor moderates, and solves the difficulties which the respondent cannot overcome.

EXEGETICA, a term used by some for the method of extracting the roots of equations. See the articles EXTRACTION and EQUATION.

EXEMPLARY, denotes much the same with model. See the article MODEL.

EXEMPLIFICATION of letters patent, a transcript or duplicate of them, made from the enrolment thereof, and sealed with the great seal.

These exemplifications are by statute equally effectual, and may be pleaded as well as the originals. One may exemplify a patent under the great seal in chancery; also any record, or judgment, in any of the courts at Westminster, under the seal of each court; which exemplifications may be given in evidence to a jury. It is held, that nothing but matter of record ought to be exemplified.

EXEMPLIFICATION, in law, a writ granted for the exemplification of any original record. See the articles EXEMPLIFICATION and RECORD.

EXEMPTION, in law, a privilege to be free from some service or appearance; thus, barons and peers of the realm are, on account of their dignity, exempted from being sworn upon inquests; and knights, clergymen, and others, from appearing at the sheriff's turn. Persons of seventy years of age, apothecaries, &c. are also by law exempted from serving on juries; and justices of the peace, attorneys, &c. from parish-offices.

EXEMPTION, in the church of Rome, a privilege granted by the pope to the clergy, and sometimes to the laity, to exempt or free them from the jurisdiction of their respective ordinaries. Thus monasteries, and even private priests, for a small charge, formerly procured exemptions from the jurisdiction of their bishops. In this, however, the council of Trent made a small reformation, by abolishing the exemption of particular priests, and monks not living in cloysters, and that of chapters in criminal matters.

EXERCISE, among physicians, such an agitation of the body as produces salutary effects in the animal economy. Exercice may be said to be either active or passive. The active is walking, hunting, dancing, playing at bowls, and the like; as also speaking, and other labour of the body and mind. The passive is riding in a coach, on horseback, or in any other manner. Exercice may be continued to a beginning of weariness, and ought to be used before dinner, in a pure light air; for which reason, journeys and going into the country contribute greatly to preserve and re-establish health.

Exercice increases the circulation of the blood, attenuates and divides the fluids, and promotes a regular perpiration, as well as a due secretion of all the humours; for it accelerates the animal spirits, and facilitates their distribution into all the fibres of the body, strengthens the parts, creates an appetite; and helps digestion. Whence it arises, that
Those who accustom themselves to exercise are generally very robust, and seldom subject to diseases.

Boerhaave recommends all bodily exercises in diseases of a weak and lax fibre. By riding on horseback, says his commentator, the pendulous viscera of the abdomen are shaken every moment, and gently rubbed as it were one against another, while in the mean time the pure air acts on the lungs with greater force. But it is to be observed, that a weak man should not ride on a full stomach, but either before dinner, or after the digestion is near finished; for when the stomach is distended, weak people do not bear these concussions of the horse, without difficulty; but when the prime viæ are near empty, the remaining facces are discharged by this concussion. Sailing in a ship is also an exercise of great use to weak people. If the vessel moves with an even motion, by increasing perspiration it usually excites a wonderful alacrity, creates an appetite, and promotes digestion. These exercises are more especially serviceable to weak people; but in order to corroborate the body by muscular motion, walking, running, and bodily exercises are to be used. In these we should begin with the most gentle, such as walking, and increase it by degrees till we come to running. Those exercises of the body are more especially serviceable which give delight to the mind at the same time, as tennis, fencing, &c. for which reason the wisdom of antiquity appointed rewards for those who excelled in these gymnastic exercises, that by this means the bodies of their youth might be hardened for warlike toils. See the article Gymnastics.

As nothing is more conducive to health than moderate exercise, so violent exercise dissipates the spirits, weakens the body, destroys the elasticity of the fibres, and exhausts the fluid parts of the blood. No wonder then, that acute and mortal fevers often arise from too violent exercise of the body; for the motion of the venal blood towards the heart being quickened by the contraction of the muscles, and the veins being thus depleted, the arteries more easily propel their contained humours through the smallest extremities into the new left reffilling veins, and therefore the velocity of the circulation will be increased through all the vessels. But this cannot be per-
formed without applying the humour oftener, or in a greater quantity to the secretary organs in the same time, whence the more fluid parts of the blood will be dissipat'd, what remains will be inspiflated, and by the greater action of the vessels upon their contained fluids, and of the reffiling fluids upon the vessels, the blood acquires an inflammatory density. Add to this, that by the violent attrition of the solidus and fluids, together with the heat thence arising, all the humours will incline to a greater acidity, and the salts and oils of the blood will become more acid and volatile. Hence, says Boerhaave, those fevers which arise from too much exercise or motion, are cured by rest of body and mind, with such aliments and medicines as moiften, dilate, and soften, or alloy acidity.

The exercise of a soldier in camp, considered as conducive to health, Dr. Pringle distinguishes into three heads, the first relating to his duty, the second to his living more commodiously, and the third to his diversions. The first consisting chiefly in the exercise of his arms, will be no less the means of preferring health, than of making him expert in his duty, and frequent returns of this early; and before the sun grows hot, will be made more advantageous than repeating it seldom, and paying out long at a time; for a camp affording little convenience for refreshment, all unnecessary fatigue is to be avoided. As to the second article, cutting boughs for flading the tents, making trenches round them for carrying off the water, airing the straw, cleaning their cloaths and accoutrements, and assifting in the business of the més, ought to be no difagreeable exercise to the men for some part of the day. Lastly; as to diversions, the men must be encouraged to them either by the example of their officers, or by small premiums to those who shall excel in any kind of sports, as shall be judged most conducive to health; but herein great caution is necessary not to allow them to fatigue themselves too much, especially in hot weather, or sickly times; but above all, that their cloaths be kept dry, wet cloaths being the most frequent causes of camp diseases.

Exercise, in military affairs, is the ranging a body of soldiers in form of battle, and making them perform the several motions and military evolutions with
EXH [ 1155 ] EXH

Nitrous and sulphureous exhalations are the chief matter of which thunder, lightening, and other meteors are generated in the air. True air is also generated by, or rather set at liberty along with, these exhalations, which it serves to buoy up in the atmosphere. See the articles AIR and ATMOSPHERE.

Mr. Boyle informs us, that the exhalations from mines are hot; as are those ascending from some wells. See the article AIR-PUMP.

Exhaustions, in mathematics, a method in frequent use among the antient mathematicians, as Euclid, Archimedes, &c. that proves the equality of two magnitudes, by a deduction ad absurdum, in supposing that, if one be greater, or less than the other, there would follow an absurdity.

This is founded upon what Euclid faith in his tenth book, viz. "That those "quantities, whole difference is less "than any assignable one, are equal." For if they were unequal, be the difference never so small, yet, it may be so multiplied, as to become greater than either of them: if not so, then it is really nothing. This he assumes in the proof of the 1st proposition of book 10, which is, "That if from the greater of "two quantities, you take more than "its half, and from the remainder "more than its half, and so continually, "there will, at length, remain a quanti-"ty less than either of those pro-"posed."

On this foundation they demonstrate, that if a regular polygon of infinite sides be inscribed in, or circumscribed about, a circle; the space that is the difference between the circle and the polygon will, by degrees, be quite exhausted, and the circle be equal to the polygon.

Exheredation, exheridatio, in the civil law, the exclusion of a son by the father from inheriting his estate; termed, among us, disinheritting.

Exhibit, in law, is where a deed, or other writing, being produced in a chancery suit, to be proved by witnesses, the examiner, or commissioner appointed after the examination of any such, certifies on the back of the deed, or writing, that the same was shewn to the witnesses,
EXHIBITION, a benefaction settled for the benefit of scholars in the universities, that are not on the foundation.

EXHIBITION was antiently an allowance for meat and drink, such as the religious appropriators made to the poor depending vicar.

EXHORTATION, in rhetoric, differs only from suasion, as being more directly addressed to the passions.

EXHUMATION, the digging up of a body interred in holy ground, by the authority of a judge. By the French law the exhumation of a dead body is ordered, upon proof that he was killed in a duel; and a parish may demand the exhumation of any of his parishioners, when interred out of the parish, without his consent.

EXIGENT, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or distrained.

This writ is directed to the sheriff, to proclaim and call the defendant five county-court days, one after another, charging him to appear under the pain of outlawry. Where a person indicted of felony, &c. absents himself so long, that the writ of exigent is awarded against him, such a withdrawing will be deemed a flight in law, whereby he is liable to forfeit his goods, and though he afterwards renders himself on the exigent, and is found not guilty, 'tis said the forfeiture shall stand; but if the party was in prison, or beyond the seas, he, or his executors, may recover the award of the exigent, by writ of error. Upon all exigents, a proclamation shall be issued out to make proclamations in the county where the defendant dwells, for him to yield himself, &c.

EXIGENTERS, four officers in the court of Common-Pleas, who make all exigents and proclamations, in all actions where process of outlawry lies. Writs of superfluous, as well as the prothonotaries upon exigents, were likewise drawn up in their office.

EXILE, the same with banishment. See the article BANISHMENT.

EXILISM, in law, signifies a spoiling; but seems to be restrained to the injury done to tenants by altering their tenure, ejecting them, &c.

EXILLES, a strong fortress on the frontiers of Dauphine and Piedmont, about ten miles west of Suza, and twenty-five north-west of Turin: east long. 7°, north lat. 45° 5'.

EXISTENCE, that whereby any thing has an actual existence, or is said to be. See the article ESSENCE.

Mr. Locke lays, that we arrive at the knowlege of our own exisitence, by intuition; of the existence of God, by demonstration; and of other things, by sensation. As for our own existence, continues that great philosopher, we perceive it so plainly, that it neither needs, nor is capable of, any proof. I think, I reason, I feel pleasure and pain; can any of these be more evident to me than my own existence? If I doubt of all other things, that very doubt makes me perceive my own existence, and will not suffer me to doubt it. If I know I doubt, I have as certain a perception of the thing doubting, as of that thought which I call doubt: experience then convinces us, that we have an intuitive knowlege of our own existence.

From the knowlege of our own existence, Mr. Locke deduces his demonstration of the existence of a God. See the article GOD.

It has been a subject of great dispute whether external bodies have any existence but in the mind, that is, whether they really exist, or exist in idea only: the former opinion is supported by Mr. Locke, and the latter by Dr. Berkley. The knowledge of the existence of other things, or things without the mind, we have only by sensation: for there being no necessary connection of real existence with any idea a man hath in his memory, nor of any other existence, but that of God, with the existence of any particular man; no particular man can know the existence of any other being but only, when, by operating upon him, it makes itself be perceived by him. The having the idea of any thing in our mind no more proves the existence of that thing, than the picture of a man evidences his being in the world; or the visions of a dream make a true history. It is therefore the actual receiving of ideas from without, that gives us notice of the existence of other things, and makes us know that something does exist at that time without us, which cauks that idea in us, though perhaps
we neither know nor consider how it does it. This notice, which we have by our senses of the existence of things without us, though it be not altogether so certain as intuition and demonstration, yet deferves the name of knowledge, if we persuade ourselves that our faculties act, and inform us right concerning the existence of those objects that affect us; but besides the assurance we have from our senses themselves, that they do not err in the information they give us of the existence of things without us, we have other concurrent reasons; as, first, It is plain these perceptions are produced in us by external causes affecting our senses, because those that want the organs of any sense never can have the ideas belonging to that sense produced in their minds. Secondly, because we find sometimes that we cannot avoid the having those ideas produced in our minds. When my eyes are shut, I can, at pleasure, recall to my mind the ideas of light, or the sun, which former sensations had lodged in my memory; but if I turn my eyes towards the sun, I cannot avoid the ideas which the light or the sun then produces in me; which shews a manifest difference between those ideas laid up in the memory, and such as force themselves upon us, and we cannot avoid having: besides, there is nobody who doth not perceive the difference in himself between actually looking on the sun, and contemplating the idea he has of it in his memory; and therefore he hath certain knowledge that they are not both memory or fancy. Thirdly, add to this, that many ideas are produced in us with pain, which we afterwards remember without the least offence: thus the pain of heat, or cold, when the idea of it is revived in our minds, gives us no disturbance, which when felt, was very troublesome; and we remember the pain of hunger, thirst, head-ach, &c. without any pain at all, which would either never disturb us, or else constantly do it, as often as we thought of it, were there no more but ideas floating in our minds, and appearances entertaining our fancies, without the real existence of things affecting us from abroad. Fourthly, our senses in many cases bear witness to the truth of each other's report concerning the existence of sensible things without us: he that doubts when he sees a fire, whether it be real, may, if he pleases, feel it too, and by the exquisite pain, may be convinced that it is not a bare idea, or phantom. Locke.

Dr. Berkeley on the other hand contends, that external bodies have no existence but in the mind perceiving them; or that they exist no longer, than they are perceived: his principal arguments, which several others, as well as himself, esteem a demonstration of this system, are as follow. That neither our thoughts, passions, nor ideas formed by the imagination, exist without the mind, is allowed; and that the various sensations impressed on the mind, whatever objects they compose, cannot exist otherwise than in a mind perceiving them, is equally evident. This appears from the meaning of the term exist, when applied to sensible things: thus, the table I write on, exists, i.e. I see and feel it; and were I out of my study, I should say it existed, i.e. that were I in my study, I should see and feel it as before. There was an odour, i.e. I smelt it, &c., but the existence of unthinking beings without any relation to their being perceived is unintelligible: their esse is percipi, then to shew that the notion of bodies is grounded on the doctrine of abstract ideas, What, he asks, are light and colours, heat and cold, extension and figure, in a word, the things we see and feel, but so many sensations, notions, ideas, or impressions on the sense; and is it possible to separate, even in thought, any of these from perception? The several bodies then, that compose the frame of the world, have not any subsistence without a mind: their esse is to be perceived or known; and if they are not perceived by me, nor by any other thinking being, they have no shadow of existence at all: the things we perceive are colour, figure, motion, &c. that is, the ideas of those things; but has an idea any existence out of the mind? To have an idea is the same thing as to perceive; that, therefore, wherein colour, figure, &c. exist, must perceive them. It is evident, therefore, that there can be no unthinking subsistence, or substratum of those ideas. But you may argue, if the ideas themselves do not exist without the mind, there may be things like them, whereof they are copies or resemances, which exist without the mind. It is answered, an idea can be like nothing but an idea, a colour or figure can be nothing else but another colour
colour or figure. It may be farther asked, whether those supposed originals or external things, whereof our ideas are the pictures, be themselves perceivable or not? If they be not, I appeal to any one whether it be sense to say, a colour is like somewhat which is invisible; hard or soft, like somewhat untangible, &c. Some distin-
guish between primary and secondary qualities, the former, viz. extension, solidity, figure, motion, rest, and number, have a real existence out of the mind; for the latter, under which come all other sensible qualities, as colours, sounds, tastes, &c. they allow the ideas we have of them are not resemblances of any thing without the mind, or unperceived, but depend on the size, texture, motion, &c. of the minute particles of matter. Now it is certain, that those primary qualities are insepably united with the other secondary ones, and cannot even in thought be abstrated from them; and, therefore, must only exist in the mind. Again, great or small, swift or slow, are allowed to exist no where without the mind, being merely relative, and changing, as the frame or position of the organ changes: the extension, therefore, that exists without the mind, is neither great nor small; the motion, neither swift nor slow, i.e. they are nothing. That number is a creature of the mind is plain (even though the other qualities were allowed to exist) from this, that the same thing bears a different denomination of number as the mind views it with different respects: thus the same extension is 7, 3, or 58, as the mind considers it, with reference to a yard, a foot, or an inch. In effect, after the same manner, as the modern philosophers prove colours, tastes, &c. to have no existence in matter, or without the mind, the same thing may be proved of all sensible qualities whatever: thus they say, heat and cold are only the affections of the mind, not at all patterns of real beings existing in corporeal substances, for that the same body which seems cold to one hand seems warm to another. Now why may we not as well argue that figure and extension are not patterns or resemblances of qualities existing in matter, because, to the same eye, at different stations, or to eyes of different structure, at the same station, they appear various. Again, sweetness, it is proved, does not exist in the thing itself, because the thing remaining unaltered, the sweetness is changed to bitterness, as in a fever, or by an otherwise vitiated palate. Is it not as reasonable to say, that motion does not exist out of the mind, since if the succeffion of ideas in the mind become smaller, the motion, it is acknowledged, will appear slower, without any external alteration. Again, were it possible for solid figured bodies to exist out of the mind, yet it were impossible for us ever to know it: our senses, indeed, give us sensations of ideas, but do not tell us that any thing exists without the mind, or unperceived, like those which are perceived; this the materialists allow. No other way, therefore, remains, but that we know them by reason's inferring their existence from what is immediately perceived by sense: but how should reason do this, when it is confused, there is not any necessary connection between our sensations and these bodies. It is evident from the phenomena of dreams, phrenises, &c. that we may be affected with the ideas we now have, though there were no bodies existing without them; nor does the supposition of external bodies at all forward us in conceiving how our ideas should come to be produced. As to the existence of spirits, Mr. Locke says, that our having ideas of them does not make us know that any such things do exist without us, or that there are any finite spirits, or any other spiritual beings but the eternal God. We have ground from revelation, and several other reasons, to believe with assurance that there are such creatures; but our senses not being able to discover them, we want the means of knowing their particular existence; for we can no more know that there are finite spirits really existing by the idea we have of such beings, than by the ideas any one has of fairies or centaurs, he can come to know that things answering those ideas do really exist. EXIT, exitus, in law, properly signifies issue or offspring; but is also applied to issues, annual rents, and profits of lands. EXIT, in a theatrical sense, the action of a player in going off the stage, after he has played his part. To do this with propriety, or in a manner suitable to the occasion, is by no means the least difficult part of a player’s office.
Fig. 1. Exocētus, the Flying-Fish.

Fig. 2. Extremer.

Fig. 3. Excentricity.

Fig. 4. Evolute.

Fig. 5. Euonymus, the Spindle-Tree.
EXLEGALITUS, among lawyers, the same with an outlawed person. See the article OUTLAW.

EX MERO MOTU, a formula used in the king's charters and letters patent, signifying that he grants them of his own will and motion.

It is intended to bar all exceptions that might be taken to the charter or patent, by alleging the king, in granting them, was abused by false suggestions.

EXOCATACOELI, in church history, a general name by which several great officers in the church of Constantinople were called, as the grand master of the chapel, the grand steward, &c.

They were of great authority in public assemblies, and even had the precedence of bishops.

EXOCIONITES, or EXACIONITES, names given to the Arians of the IXth century. See the article ARIANS.

EXOCETUS, the Flying-Fish, in ichthyology, constitutes a distinct genus of fishes of the malacoptygious or soft-finned order; it has ten small bones in the membrane of the gills; the pectoral fins are extremely long, and situated just below the extremity of the covering of the gills on the sides, but elevated towards the back; they almost equal the whole body of the fish in length, which greatly resembles an herring, both in shape and colour. See plate XCIV.

fig. 1.

It is caught in the Mediterranean, and other seas, and is called by different authors exocetus, exochinus, hirundo pilcis, and mugil alatus.

When pursued by any fish of prey, it throws itself into the air, where it not only suspends itself, but moves very nimbly forward by means of its long fins, so long as they continue wet.

EXODIARY, exodiarius in the ancient Roman tragedy, was the person who after the drama or play was ended, sung the exodium. See the article EXODIUM.

EXODIUM, in the ancient Greek drama, one of the four parts or divisions of tragedy, being so much of the piece as included the catastrophe and unravelling of the plot; and answering nearly to our fourth and fifth acts. See EPILOGUE.

EXODIUM, among the Romans, consisted of certain humorous verses reheard by the exodiarius at the end of the Fabula Atellana.

EXODIUM, εξοδιούμ, in the Septuagint signifies the end or conclusion of a feast. Particularly it is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the Exodus, or departure out of Egypt.

EXODIUM was also the name of a song sung at the conclusion of a feast.

EXODUS, a canonical book of the old Testament; being the second of the pentateuch, or five books of Moses.

It is so called, from the Greek ἔξοδος, going out, or departure of the children of Israel from the land of Egypt; the history of which is delivered in this book, together with the many miracles wrought on that occasion.

EX OFFICIO, among lawyers, signifies the power a person has, by virtue of his office, to do certain acts without being applied to. Thus a justice of peace may ex officio, at his discretion, take security of the peace, without complaint made by any person whatsoever.

There was formerly an oath ex officio, whereby a supposed offender was compelled in the ecclesiastical court to confess, accuse, or clear himself of a crime; but this law is repealed.

EXOMPHALUS, ἐξομφαλος, in surgery, called also omphalocele, and herma umbilicalis, is a preternatal tumor of the abdomen at the navel from rupture, or diaphragm of the parts which invest that cavity. These ruptures differ by their size and figure, some being small, especially when recent, others large and sometimes monstrous. Some are of a round figure, others acuminate, and Heister mentions an exomphalos in a woman with child, which resembled the size and figure of the penis.

Umbilical ruptures are again distinguished according to their contents, as if from the intestines, enteromphalocele; from the omentum epiploemphalocele; and if from air or wind, pneumatomphalocele: Some of these tumours are again distinguished by their consistence into hard or soft, returnable or not, painful or incarcerated.

An exomphalos arises from various causes; but the immediate cause is always some force exerted upon the abdomen, especially near the navel, such as a violent and sudden motion, a fall, a violent blow, or leap, strong coughing or freezing, straining to lift great weights, difficult labour in women, &c. by which causes the peritoneum at the navel is either dilated, or as it sometimes happens,
EXORCISM, EXONERATION, EXCEPT

happens, entirely broke off. The method of cure is twofold, according as the intestines are returnable into the abdomen or not. If the fist can be practised, it should be done without any delay, and the parts secured against a future relapse by a girdle or bandage. But if the intestine cannot be returned through the straitness of the aperture in the peritonenum, and the patient is tortured with violent pain in the part affected, with vomiting, and other bad symptoms, to apply the bandage in that case would not only be useless, but pernicious: the patient should rather be treated with emollient Clysters and cataplasm, to relax the parts and facilitate their return; and if he is inclined to be feverish, it may then be proper to bleed, as in other inflammatory distempers, by which means the distended vessels of the intestine will be contracted, and probably afterwards returned by a gentle pressure of the hands, to be then secured with compres, bandage, and a proper instrument. If the disorder becomes still worse, after bleeding and the use of other medicines, the surgeon should then proceed to the operation, which consists chiefly in dilating the wound of the abdomen so as to make it large enough to return the intestine: for this purpose he makes a transverse incision through the integuments, and if the tumour be large, a crucial incision, taking great care not to injure the intestine; then the peritonenum, which immediately invests the intestine, may be diluted with as small an incision as possible, and the intestine afterwards returned into the abdomen. See the article HERNIA.

EXONERATIONE sectae, in law, a writ which formerly lay, to free the king's ward from all suits to courts. See the article WARD.

EXORCISM, εξοριεσθαι, among ecclesiastical writers, the expelling demons from persons possessed, by means of conjurations and prayers. See CONJURATION. Exorcism makes a considerable part of the superintendence of the church of Rome, the rituals of which forbid the exorcising any person without the bishop's leave. The ceremony is performed at the lower end of the church, towards the door. The exorcist first signs the possessed person with the sign of the cross, makes him kneel, and sprinkles him with holy water. Then follow the litanies, psalms, and prayer; after which the exorcist asks the devil his name, and adjoins him by the mysteries of the Christian religion, not to afflict the person any more: then, laying his right hand on the demoniac's head, he repeats the form of exorcism, which is this: "I exorcise thee, unclean spirit, in the name of Jesus Christ: tremble, O Satan! thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who hast deprived men of life, and hast rebelled against justice; thou seducer of mankind, thou root of evil, thou source of various discords and envy." The Romanists likewise exorcise houses and other places, supposed to be haunted by unclean spirits; and the ceremony is much the same with that for persons possessed.

EXORCISTS, in church-history, an order of men, in the ancient church, whose employment it was to exorcise or cast out devils. See the preceding article.

EXORDIUM, in rhetoric, is the preamble or beginning, serving to prepare the audience for the rest of the discourse. Exordiums are of two kinds, either just and formal, or vehement and abrupt. The last are most suitable on occasions of extraordinary joy, indignation, or the like.

All exordiums should be composed with a view to captivate the good will, or attract the attention of the audience. The first may be done by paying them some compliment: thus St. Paul, I think myself happy, king Agrippa, because I shall answer for myself this day before thee, teaching all the things whereof I am accused of the Jews especially because I know thee to be expert in all customs and questions which are among the Jews. Attention is procured by promising to treat some weighty, useful, pleasant, or surprising subject: and thus Horace, Ode i. lib. 3.

Pauete linguis: carmina non prius Audita, ministarum facerdos, Virginibus puerisque canto.

The requisites in an exordium are, 1. Propriety, whereby it becomes of a piece with the subject, and matches it as a part does a whole: in this the Greeks were very defective. 2. Modesty, which very much recommends the orator to the favour of his audience. And, 3. Brevity, not amplified or dwelt on with a detail of circumstances. The style should not be too much raised, nor should it run into bombast: and, above all things, the vain-glory should be
EXORISTOS, in ichthyology, a name given to the petromyzon, or lampern.
EXOS, the same with the holo, or iling-glia's fifth. See the article HUso.
EXOSTOSIS, in surgery, a preternatural eminence or excrecence of a bone, whether attended with an erosion or not. When an exostosis is attended with no bad symptoms, it is best to let it alone, as the remedy will be worse than the disease. But if it occasions great deformity, impedes any action, or produces pain or other mischief, it may be removed in the manner directed under the article SPINA VENTOSA.
EXOTIC, an appellation denoting a thing to be the produce of foreign countries. Exotic plants of the hot climates are very numerous, and require the utmost attention of the gardener to make them thrive with us. See the articles STOVE and GREEN-HOUSE.
EXPANSION, among metaphysicians, denotes the idea we have of falling distance, all whose parts exist together.
EXPANSION, in physiology, the swelling or increafe of the bulk of bodies when heated. See the article Heat.
Dr. Halley found boiling water to expand one twenty-fifth part of its former bulk; but with a moderate heat, its expansion was imperceptible. Mercury, with a very gentle heat, expanded one seventy-fourth of its usual bulk, when cold. Spirit of wine, with a heat much less than that of boiling water, expanded itself to a twelfth part of its bulk, when cold, and then fell a boiling and emitting bubbles copiously. Mr. Boyle, in his book Of Cold, tells us, he found the expansion of water by freezing to be about a tenth part of a space more than the water usually takes up. See FREEZING.
Dr. Gregory faws, that if a globule of air, only one inch in diameter, had so great an expansion as it would have at a semi-diameter of the earth from its surface, it would fill all the planetary regions, as far as, and even beyond the sphere of Saturn. See the article Air.
But besides fluids, the most solid bodies are expanded by heat, though not in the inverse ratio of their specific gravities or cohesion, nor even in the ratio compounded of both. The degree of expansion seems rather to depend on the different arrangement, magnitude, and figure of their component parts. According to professor Mulchenbroek, the expansions of metals in the same degree of heat, are as follows, viz. silver 78, iron 80, copper 89, brass 110, tin 153, lead 155. As to the time of their beginning to expand, it is found to be in the following order, viz. tin first, then lead, silver, brass, copper, and, last of all, iron; the reason of which is thought to depend upon the different structures of their pores, and their being more or less fitted to admit the influence of the fire.
For the expansion of the mettalline rods of pendulums, and how remedied. See the article PENDULUM.
EXPANSUM FOLIACEUM. See the article FOLIACEUM.
EX PARTE, a term used in the court of chancery, where a commission is taken out and executed by one side or party only, upon the other party's neglecting or refusing to join therein.
When both the parties proceed together, it is called a joint commission.
EX PARTE TALIS; a writ that lies for a bailiff or receiver, that having auditors assigned to pass his accounts, cannot procure from them reasonable allowance, but is cast into prison; in which case the practice is to file this writ out of the chancery, directed to the sheriff to take the four mainporners to bring his body before the barons of the exchequer, at a certain day, and to warn the lord to appear at the same time.
EXPECTANT, in law, signifies having relation to, or depending on: thus, where land is given to a man and his wife, and to their heirs, they have a fee simple estate; but if it be given to them and the heirs of their bodies begotten, they have an estate tail, and a fee expectant, which is opposed to fee simple.
EXPECTATIVE, in the canon-law, an expectation grounded on the promise of having the next benefice that shall become vacant; or a right to the reversion of the next benefice. See BENEFICE.
EXPECTATIVE GRACES, gratia expectativa, bulls antiently given by the popes, for obtaining some benefices that should become vacant. These bulls were very mortifying to bishops, because they encroached on their
EXP [1162] EXP

their privileges: besides, they were odious as they induced people to wish the death of others. The council of Trent annulled all expeptatives; but the canons relating thereto were never admitted in France, where the right of conferring expeptative graces is one of the king's prerogatives.

EXPEKTORANTS, in pharmacy, medicines which promote expectoration. See the next article.

These medicines are very numerous: the most considerable in the vegetable kingdom are the roots of elecampane, arum, florentine orris, and liquirice; the herbs paul's betony, chervil, fesbicious, mouse-ear, germander, hyssop, and tarragon; the flowers of violets, mallows, red poppies, and saffron; the seeds of anise and fennel; the bark of fassafras; and among resinous gums, benjamin and gum ammoniac: among fruits, figs, jujubes, and pine-kernels; among mineral substances, sulphur, among animal substances, gum ammoniac: among fruits, liquorice-juice, asafoetida, and skirnys, among flowers. Thefe medicines are very numerous: when we premeditately and deignedly perceive the phenomena of natural things, without any direct observation, the mind perceives the simple phenaena of natural things, without any direct attention thereto, or making any application thereof. The second is that preceded by a foreknowledge, or, at least, an apprehension of the event, and determines whether the apprehension were true or false.

EXPERIMENT, in philosophy, is the trial of the effect or effect of the applications and motions of certain natural bodies, in order to discover something of their motions and relations, whereby to ascertain some of their phenomena, or causes. See the article EXPERIMENTAL PHILOSOPHY. Torricellian EXPERIMENT. See the article TORRICELLIAN.

EXPERIMENTAL PHILOSOPHY, that philosophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to enquire into and to investigate the reasons and causes of the various appearances or phenomena of nature, and to make the truth or probability thereof obvious and evident to the senses, by plain, undeniable, and adequate experiments.
EXPERIMENTUM CRUCIS, a capital, leading, or decisive experiment; thus termed, either on account of its being like a cross, or direction post, placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are enquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is as it were extorted by force.

EXPIATION, a religious act, by which satisfaction, atonement, or amends is made for the commiission of some crime, the guilt done away, and the obligation to punishment cancelled.

The method of expiation, among the Jews, was chiefly by sacrifice, whether for sins of ignorance, or to purify themselves from certain pollutions; as a woman after child-birth, a leper after cleansing, &c. See the articles SACRIFICE and PURIFICATION.

Great day of Expiation, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answers to our September,
September. On this occasion the high priest laid aside his breast-plate and embroidered ephod, as being a day of humiliation. He first offered a bullock and a ram for his own sins, and those of the priests; then he received from the heads of the people two goats for a sin-offering, and a ram for a burnt offering, to be offered in the name of the whole multitude. It was determined by lot which of the goats should be sacrificed, and which let at liberty. After this he performed the sanctuary with incense, and sprinkled it with blood; then, coming out, he sacrificed the goat, upon which the lot had fallen. This done, the goat, which was to be set at liberty, being brought to him, he laid his hands upon its head, confessed his sins, and the sins of the people, and then sent him away into some distant place: it was called azazel, or the scape goat. See the article scape-goat.

As to the expiations among the heathens, they were of several kinds, as sacrifices and religious washings.

Expiation, in a figurative sense, is applied by divines to the pardon procured to mens sins, by the merits of Christ's death.

Explication, among civilians, the carrying off, or sequestration, something belonging to an inheritance, before the heir had intermeddled therewith.

Explication also denoted a robbery committed by night, and so called from the robbers stripping people of their cloaths.

Explication, in physic, that part of respiration whereby the air is expelled, or driven out of the lungs. See the article respiration.

Expiration, in chemistry, is applied to all sorts of evaporation, and fublimate effluvia, that go off into the air.

Expiration is also used for the end of any term agreed upon. It likewise signifies death.

Exples, or Esplees, in law. See the article esplees.

Explicit, in the schools, something clear, distinct, formal, and unfolded.

Explosion, in physics, is properly applied to the going off of gun-powder and the report made thereby. Hence it is used to express such sudden actions of bodies, as generate air instantaneously: thus, half a dram of carraway-feed, poured upon a dram of the compound spirit of nitre, in an empty receiver, produces such a prodigious quantity of air as to blow up with an explosion a receiver of six inches in diameter and eight inches deep; the pressure, therefore, of the atmosphere on the exhausted receiver, which it overcomes, is above 400 lb reckoning 15 lb to a square inch. From the experiments in Mr. Robins's New Principles of Gunnerie, it appears, that the force of fired gun-powder, at the instant of its explosion, is the same as that of an elastic fluid of a thousand times the density of common air. See Gun-powder.

Exponas venditiones. See the article venditiones.

Exponent, in algebra, is a number placed over any power or involved quantity, to shew to what height the root is raised: thus, a is the exponent of \( x^a \), and \( a \) the exponent of \( x^a \) or \( xx^n \).

We have observed, under the article division, in algebra, that the rule for dividing powers of the same quantity, is to subtract the exponents, and make the difference the exponent of the quotient; if, therefore, a lesser power is divided by a greater, the exponent of the quotient must, by this rule, be negative: thus, 

\[
\frac{a^4}{a^6} = a^4 - 6 = a^{-2} \text{. But } \frac{a^4}{a^6} = \frac{1}{a^2} \text{; and hence } \frac{1}{a^2} \text{ is expressed by } a^2, \text{ with a negative exponent. It is also obvious that }\]

\[
a - a^2 = a^{1-2} = a^{-1} \text{; but } \frac{a}{a} = 1, \text{ and therefore } a^{1} = a \text{. After the same manner, }\]

\[
\frac{1}{a} = a^{-1} \div a = a^{-1} - 1 = a^{-2}; \frac{1}{a} = a^0 = a^a = a^a - 2 = a^{-2}; \frac{1}{a} = a^{0-3} = a^{-3}; \frac{1}{a^2} \text{. So that the quantities, } a, a, a, \frac{1}{a}, \frac{1}{a^2}, \frac{1}{a^3}, \frac{1}{a^4}, \text{ &c. may be expressed thus, } a^0, a, a^{-1}, a^{-2}, a^{-3}, a^{-4}, \text{ &c. These are called the negative powers of } a, \text{ which have negative exponents; but they are at the same time positive powers of } \frac{1}{a}, \text{ or } a^{-1}. \text{ See the articles power and involution of quantities.}\]

Exponent of a ratio, is the quotient arising from the division of the antecedent by the consequent: thus, in the ratio of 5 to 4, the exponent is \( \frac{5}{4} \); but the exponent of 4:5 is \( \frac{4}{5} \).

If the consequent be unity, the antecedent itself is the exponent of the ratio: thus the exponent of the ratio 4:1 is 4.

Wherefore
Wherefore the exponent of a ratio is to unity as the antecedent is to the consequent. Altho’ the quotient of the division of the antecedent by the consequent is usually taken for the exponent of a ratio, yet in reality the exponent of a ratio ought to be a logarithm. And this seems to be more agreeable to Euclid’s definition of duplicate and triplicate ratios, in his fifth book. For \( 1, \frac{2}{3}, 9 \) are continual proportionals; now if \( \frac{2}{3} \) be the exponent of the ratio of \( 1 \) to \( 3 \), and \( \frac{2}{3} \) or \( \frac{1}{2} \) the exponent of the ratio of \( 3 \) to \( 9 \); and \( \frac{3}{2} \) the exponent of the ratio of \( 1 \) to \( 9 \); and since, according to Euclid, if three quantities be proportional, the ratio of the first to the third is said to be the duplicate of the ratio of the first to the second; therefore according to this, \( \frac{3}{2} \) must be the double of \( \frac{1}{2} \), which is very false. But it is well known, the logarithm of the ratio of \( 1 \) to \( 9 \), that is, the logarithm of \( 9 \), is the double of the ratio of \( 1 \) to \( 3 \), or of \( 3 \) to \( 9 \), that is the logarithm of \( 3 \). From whence it appears that logarithms are more properly the exponents of ratios, than numerical quotients; and Dr. Halley, Mr. Cotes, and others, are of the same opinion.

Exponent is also used in arithmetic, in the same sense as index or logarithm. See Index and Logarithm.

**Exponential Calculus.** See the article Calculus Exponentialis.

**Exponential Curve.** is that whole nature is expressed by an exponential equation. The area of any exponential curve whose nature is expressed by this exponential equation \( x^n = y \) (making \( 1 + \frac{1}{\nu} \)

\[
\begin{align*}
1 & = x^0 \\ 1 & = x^1 \\ 1 & = x^2 \\ 1 & = x^3 \\ 1 & = x^4 \\ 1 & = x^5 \\ 1 & = x^6 \\
&= \frac{1}{\nu} \cdot 1.2.3.4.5.6
\end{align*}
\]

See the article Calculus Exponentialis.

**Exponential Equation** is that where in there is an exponential quantity. See the next article.

**Exponential Quantity** is a quantity whose power is a variable quantity, as \( x^a \), \( a^x \). Exponential quantities are of several degrees and orders, according as the exponents themselves are more or less involved. If the exponent be a simple quantity, as \( a \), it is called an exponential of the first or lowest degree; but when the exponent itself is an exponential of the first degree, as \( x^x \), it is called an exponential of the second degree. In like manner, if the exponent itself be an exponential of the second degree, as \( x^{x^x} \), it is called an exponential of the third degree, &c.

**Exportation.** The shipping and carrying out of the kingdom wares and commodities, for other countries. Exportation is part of foreign commerce, distinguished by the appellation active or selling part, in opposition to importation, which is called the passive, or buying part. Belloni observes, that commerce, when active, must produce a vast flow of riches, the balance being always received in money; whereas, if it be passive, the most immense treasures will be soon exhausted, as the balance of trade must be continually made good out of the remaining coin. Hence plenty of money in any place, implies that the quantity of goods exported far exceeds that of goods imported; and wherever we see money scarce, we may conclude that greater quantities of goods have been imported than exported, See the articles Commerce, Money, and Exchange.

**Exposition,** in general, denotes the setting a thing open to public view: thus it is the Romanists say, the hoist is exposed, when shewn to the people.

**Exposition of Children,** among the ancients, a barbarous custom of laying down children by the sides of highways, and other places most frequented, where they were left at the mercy of the public, and must unavoidably perish, unless taken up and educated by charitable and compassionate persons. Many exposed their children merely because they were not in a condition to educate them; and as for those who exposed them for other reasons, they commonly did it with jewels, with a view no doubt to encourage those who found them to take charge of their education if alive, or give them human burial, if dead.

**Exposition,** in a literary sense, the explaining an author, passage, writing, or the like, and setting their meaning in an obvious and clear light. Exposition of deeds, of all kinds, ought to be according to the true intent thereof, and reasonable and equal. See Deed.
EXPOSITOR, or EXPOSITORY, a title given to small dictionaries, serving to explain the hard words of a language.

EX POST FACTO, in law, something done after another: thus an estate granted may be good by matter ex post facto, that was not so at first, as in case of election.

EXPOSITION, in rhetoric, a warm address to a person, who has done another some injury, representing the wrong in the strongest terms, and demanding redress.

EXPOSURE, in gardening, the situation of a garden, wall, or the like, with respect to the points of the compass, as south; for the points of the compass are so ordered as not to have one point to the east-ward of the south; by reason these will enjoy the benefit of the morning sun, and be less exposed to injuries from the west and south-west winds, than walls directly facing the south. The next best aspect is due south, and the next to that south-east, which is preferable to the south-west, for the reasons before assigned. However, as there will, for the most part, be south-west and west walls in every garden, these may be planted with such sorts of fruit as do not require so much heat to ripen them; and wherever there are north walls, they are only fit for baking-pears and plums, morello-cherries for preserving, or some duke-cherries may be thus continued longer in the season. See GARDEN, PLANTING, &c.

EXPRESS, something that is determinate and precise, or in such formal terms as leaves no room for doubt.

EXPRESS also denotes a courier. See the article COURIER.

EXPRESSED OILS, in chemistry, such oils as are obtained from bodies only by pressing. See the article OIL.

EXPRESSED SPECIES. See SPECIES.

EXPRESSION, in chemistry, or pharmacy, denotes the act of expressing out the juices or oils of vegetables, which is one of the three ways of obtaining them; the other two being by infusion and decoction.

Oils obtained by means of fire, are called billiations.

EXPRESSION, in rhetoric, the elocution, diction, or choice of words in a discourse. Beautiful expression is the natural and true light of our thoughts: it is to this we owe all the excellencies in discourse; which gives a kind of vocal life and spirit. As the principal end of discourse is to be understood, the first thing we should endeavour to obtain, is a richness of expression, or habit of speaking so well as to make our thoughts easily understood. See STYLE, TROPE, RHETORIC, &c.

EXPRESSION, in painting, a natural and lively representation of the subject, or of the several objects intended to be shown. The expression conflicts chiefly in representing the human body and all its parts, in the action suitable to it: in exhibiting in the face the several passions proper to the figures, and observing the motions they impress on the external parts. See the article ATTITUDE.

The term expression is frequently confounded with that of passion, but they differ in this, that expression is a general term, implying a representation of an object agreeably to its nature and character, and the use or office it is to have in the work; whereas passion, in painting, denotes a motion of the body, accompanied with certain dispositions or airs of the face, which work an agitation in the soul: so that every passion is an expression, but not every expression a passion.

The law of Expression. Expression being a representation of things according to their character, may be considered either with respect to the subject in general, or to the passions peculiar thereto.

First, with respect to the subject, it is to be observed, 1. That all the parts of the composition are to be transformed or reduced to the character of the subject, so as they may concur to impress the same sentiment, passion, or idea. 2. In order to this, if any circumstance occur in history or description, that would avert or take from the idea, it must be suppressed, unless essential to the subject. 3. To this end the history or fable is to be well studied in the authors who describe it, in order to conceive its nature and character truly, and impress it strongly on the imagination, that it may be diffused and carried through all the parts of the subject. 4. A liberty may be taken, to choose favourable incidents, in order to diversify the expression, provided they are not contrary to the principal image of the subject, or the truth of history.

5. The harmony of the tout ensem ble ought to be particularly regarded, both with respect to the actions and the light and colour. See CLARO-OBSCURO. 6. The modes and customs are to be observed, and every thing made conformable to time, place, and quality. 7. The three unities of time, place, and action ought
to be observed; that is, nothing should be represented in the same picture, but what is transcended or past at the same time, and may be seen at the same view.

Secondly, with respect to the particular passions and affections of the subject, the rules are, 1. That the passions of brutes be few and simple, and have almost all an immediate respect either to self-preservation or the propagation of the species: but in the human kind there is a greater variety, and accordingly more marks and expressions thereof. 2. Children not having the use of reason, act much after the same manner as brutes, and express the motions of their passions directly, and without fear or disguise. 3. Though the passions of the soul may be expressed by the actions of the body, it is in the face they are generally shewn, and particularly in the turn of the eye, and motions of the eye-brows. 4. There are two ways of lifting up the eye-brows, the one at the middle, which likewise draws up the corners of the mouth, and argues pleasent motions; the other at the point next the nose, which draws up the middle of the mouth, and is the effect of grief or sadness. 5. The passions are all reducible to joy and sadness, each of which is either simple, or mixed and passionate. 6. Joy causeth a dilatation of the parts: the eye-brows rife in the middle; the eyes half open, and smiling; the pupil sparkling, and moist; the nostrils a little open; the cheeks full; the forehead smooth and even, the eye-brows a little elevated on the side the pupil is turned to, the eyes sparkling and open, the head inclined towards the object, the air of the face smiling, and the complexion lively. That proceeding from desire shews itself by the body, the arms extending towards the object in certain and unquiet motions. 8. Simple sadness is expressed by the body being cast down, the head carelessly hanging aside, the forehead wrinkled, the eye-brows raised to the middle of the forehead, the eyes half-closed, and the mouth a little open, the corners downwards, the under lip pointing and drawn back, the nostrils swelled and drawn downwards. That mixed with fear causes the parts to contract and palpitate, the members to tremble and fold up, the visage to be pale and livid, the point of the nostrils elevated, the pupil in the middle of the eye, the mouth opened at the sides, and the lip drawn back. In that mixed with anger, the motions are more violent, the parts all agitated, the muscles swelled, the pupil wild and sparkling, the point of the eye-brows fixed to the nose, the nostrils open, the lips big and prefixed down, the corners of the mouth a little open and foaming, the veins swelled, and the hair erect. That with despair resembles the last, only more excessive and disordered. 9. The hand has a great share in the expression of the sentiments and passions; the raising of the hands, conjoined, towards heaven, expresses devotion; wringing the hands, grief; throwing them towards heaven, admiration; painting and defected hands, amazement and despair; folding hands, idleness; holding the fingers indented, musing; holding forth the hands together, yielding and submission; lifting up the hand and eye to heaven, calling God to witness; waving the hand from us, prohibition; extending the right hand to any one, pity, peace, and safety; scratching the head, thoughtfulness; laying the hand on the heart, solemn affirmation; holding up the thumb, approbation; laying the fourth finger on the mouth, bidding silence; giving with the finger and thumb, a giving sparingly; and the fore-finger put forth and the rest contracted, to shew and point at, as much as to say, this is he. 10. The sex of the figure is to be regarded; and man, as he is of a more vigorous and resolute nature, ought to be expressed in all his actions freer and bolder than women, who are to be more reserved and tender. 11. So also as to the age, the different states whereof incline to different motions both of body and mind. 12. The condition or honours a person is invested with, renders their actions more refined, and their motions more grave, contrary to the populace, who observe little conduct or restraint, giving themselves up, for the most part, to their passions; whence their external motions become rude and disorderly.

Lastly, in spirits, all those corruptible things must be retrenched, which served only for the preservation of life, as veins, arteries, &c. only retaining what may serve for the form and beauty of the body. In angels particularly, as symbolical figures, their offices and virtues are to be marked out, without any draught of sensual.
fual passions, only appropriating their characters to their functions of powers, activity and contemplation, *Diff. Poligr.*

**EXPULSION**, in a general sense, the act of violently driving a person out of any city, society, &c.

**EXPULSION**, in medicine, the act whereby any thing is forcibly driven out of the place in which it is: thus we say, the expulsion of the fetus in delivery. See the article *DELIVERY.*

**EXPURGATION**, in astronomy, a term used by some authors for emersion. See the article *EMERSION.*

**EXQUIMA**, in zoology, a species of guinea monkey, of a reddish brown, spotted with white on the upper part of the body, and the under part white, with a beard of a beautiful snow-white colour. See the article *MONKEY.*

**EXTASY**, a transport which suspends the function of the senses, by the intense contemplation of some extraordinary or supernatural object, or when God impresses on the imagination the extraordinary ideas of any thing he would reveal.

**EXTASY**, in medicine, a species of catalepsy, when a person perfectly remembers, after the paroxysm is over, the ideas he conceived during the time it lasted. In an extasy there must be an unusual tension of the senory, as is common in deliriums, &c.

**EXTEND in law**, signifies to value the lands or tenements of a person bound by a statute, &c. who has forfeited the fame, at such an indifferant rate, that by the yearly rent the creditor in time may be paid his debt. See *EXTENT.*

**EXTENDI FACIAS**, a writ to extend lands, &c. See the preceding article.

**EXTENSION**, in philosophy, one of the common and essential properties of body, or that by which it poiffeles or takes up some part of univeral space, which is called the place of that body. See the articles *BODY* and *SPACE.*

Extension is threefold, 1. Either into length only, and then it is called a line. Or, 2. Into length and breadth, which is called a superficies. Or, 3. Into length, breadth, and depth, which is called a solid; being the three dimensions according to the quantity of which the magnitude or bulk of bodies are estimated. See *LINE, SUPERFICIES, and SOLID.*

Extension, according to Mr. Locke, is space considered between the extremities of matter, which fills up its capacity with something solid, tangible, and moveable. Space, says that philosopher, may be conceived without the idea of extension, which belongs to body only.

**EXTENSION of fractured limbs**, in surgery, ought to be performed in the following manner: 1. The patient is to be kept firm and steady. The posture of body to be observed at this time differs, according to the circumstances of the case; sometimes the patient should fit, either upon a stool, or upon the floor. 2. An affilant should support the limb with his hands, both above and below the fractured part. 3. The affilant, who holds the lower part of the limb, should extend it strongly and equally, till the fractured bone can be replaced: if his hands alone are not sufficient to make the required extension, he must use a cord, or rather a napkin: if one man has not strength enough for this office, there must be two or more employed.

You must be careful not to use too great roughness in this operation, lest you give your patient unnecessary pain. If the tumour and inflammation is come on before the extension, it is best to defer it till these symptoms are removed. When the fractured bones maintain their natural situation, you are under no necessity of extending or replacing the limb; but when the fractured parts recede from each other, some degree of extension is necessary, which must be always suited to the distortion of the limb: the greater distance there is between the extremities of the divided parts of the bone, so much shorter will the limb be, from the contraction of the muscles; therefore the extension in this place ought to be so much the greater. See the article *FRACTURE.*

The extension in luxated bones is to be performed much in the same manner with that in fractures, viz. the outer or lower part of the dislocated limb is to be extended till the head of the disordered bone be reduced exactly into the sinus from whence it was luxated.

**EXTENSOR**, an appellation given to several muscles, from their extending or stretching the parts to which they belong: such are, 1. The common extensor of the fingers, which has its origin at the external condyle of the humerus, and the posterior part of the radius and ulna: it afterwards divides into four tendons, which pass under the ligament of the carpus, and terminate in the posterior surface of all the phalanges of the fingers, where they are gibbous. 2. The exten-
EXT [1169] EXT

for of the thumb, called also bicornis and tricornis, arises in the posterior and middle part of the radius and ulna, and terminates in two or three tendons in the first, second, and third phalanx of the thumb. 3. The proper extensors of each finger, which are a part of, or at least have their origin with the common extensor. 4. The long extensor of the toes, which has its origin in the upper part of the tibia, and in the anterior part of the ligament, between the tibia and fibula: it afterwards divides into five tendons, four of which are inserted into the four phalanges of the toes, and the fifth into the outer metatarsal bone. 5. The short extensor of the toes, arises from the upper part of the calcaneum, and dividing into tendons, is inserted into the toes.

Besides these, there are proper extensors of the toes; also the long and short extensors of the great toe, and the common extensor of the back and loins, which is divided into three. If these act only on one side, they draw the parts obliquely sideways.

EXTENT, in law, is used in a double sense; sometimes it signifies a writ or command to the sheriff for the valuing of lands or tenements; and sometimes the act of the sheriff, or other commissioner, upon this writ: but most commonly it denotes an estimate or valuation of lands; and hence come our extended value and verdia, without which the same order of all the coefficients, prefixed to the same unknown quantity, coefficients of the same order: such are $a$, $d$, $g$, in theorem 2, as being prefixed to the same quantity $x$: such also are $b$, $e$, $b$; and $c, f, k$. But he calls those opposite coefficients, that are taken each from a different equation, and from a different order of coefficients, as $a$ and $e$, and $d$ and $b$, in the first theorem; and $a$, $e$, $k$; $a$, $b$, $f$, $d$, $b$, $k$, in the second theorem.

Theorem 1. Suppose two equations given involving two unknown quantities, as

\[
\begin{align*}
ax + by &= c \\
dx + ey &= f
\end{align*}
\]

Then shall

\[
y = \frac{af - de}{ae - db}
\]

Where the numerator is the difference of the products of the opposite coefficients, in the orders in which $y$ is not found; and the denominator is the difference of the products of the opposite coefficients, taken from the orders that involve the unknown quantities. For from the first equation it appears that $ax = c - by$, and $x = \frac{c - by}{a}$; and from the second equation, that $dx = f - ey$, and $x = \frac{f - ey}{d}$.

Therefore, $\frac{c - by}{a} = \frac{f - ey}{d}$; and $cd - dby = af - aey$, whence $aey - db = af - cd$; and $y = \frac{af - cd}{ae - db}$. Q.E.D.

To exemplify this theorem, suppose $a = 5$, $b = 7$, $c = 100$, $d = 3$, $e = 8$, and $f = 80$. Then

\[
y = \frac{5 \times 80 - 3 \times 100}{5 \times 8 - 3 \times 7} = \frac{5}{19}
\]

and $x = \frac{240}{19} = \frac{12}{9}$.

Theorem 2. Suppose now that there are three unknown quantities, $x, y, z$, and three equations: thus,

\[
\begin{align*}
ax + by + cz &= m \\
dx + ey + fz &= n \\
gx + hy + kz &= p
\end{align*}
\]

Then shall

\[
z = \frac{an - afj - adm + dcz}{ae - db}
\]

and

\[
y = \frac{am - afj - adm + dcz}{ae - db}
\]

for exterminating and forestalling or commanding something. In algebra, pluses, minuses, fractions, and unknown quantities are exterminated by the rules for reducing equations. See the article EQUATION.

We have two curious theorems in Mr. Maclaurin's algebra, for exterminating unknown quantities of given equations; and here it is proper to observe, that he calls all the coefficients, prefixed to the same unknown quantity, coefficients of...
The existence of an external world, that is, of bodies and objects out of the mind, was absolutely denied by Dr. Berkeley. See the article Existence.

External angles, are the angles on the outside of any right-lined figure, when all the sides are severally produced, and they are all, taken together, equal to four right angles. See the article Angle.

External ear. See the article Ear.

Extinction, in general, denotes the putting out or destroying something, as a fire or flame. See Fire and Flame.

Various engines have been contrived for extinguishing accidental fires, for which see Engine and Water-bomb.

Extinction, in chemistry, is when a metal, mineral, &c. after having been heated red hot, is plunged into some fluid; either to soften and temper its acrimony, as tarry in role-water; or to communicate its virtue to the liquor, as iron or steel to common water, &c.

Extinguishment, in law, is a consolidation or union, as where one has due to him a yearly rent out of lands, and afterwards purchases the lands out of which the rent arises: in this case, both the property and the rent being united in one possessor, the rent is paid to extinguished. Likewise where a person has a lease for years, and he afterwards buys the property of what is leased, the lease becomes thereby extinguished.

There is, however, a difference on purchasing part of the lands, and the several parts of rents: thus if a person has a rent-charge granted to him and his heirs, issuing out of land, and he purchases any part of that land to him and his heirs; as this rent is entire, and issuing out of every part of the land, the whole rent-charge is extinguished. Yet if such person has a rent-service, and he does purchase part of the lands where-out it issues, this shall not extinguish all the rent, but only for the land purchased.

Extinguishment of common, is by purchasing all the lands which have interest therein: also if a commoner releases his common in one acre, it is an extinguishment of the whole; but where he aliens part of his lands, to which the common belongs, the common is not extinguished thereby, but shall be divided.

Extinguishment services. If the lord purchases or accepts any part of the tenancy, out of which an entire service is to be paid, the service becomes thereby extinguished; unless it be for the public good,
or homage and fealty, which are not subject to extinguishment.

Extinguishment of ways, is where a person has a highway as appendant, and he makes a purchase of the land in which the way is, then the way is extinct: tho' it is held, that a way of necessity, to a market or church, is not so.

Extermination, the same with extermination. See Extermination.

Extermination in law, a judicial writ that lies against a person, who, after a verdict found against him for land, &c. maliciously overthrows a house, or extirpates any trees upon it.

Extirpex, in antiquity, the person who drew prefigures from viewing the entrails of animals offered in sacrifice. See the articles Sacrifice, Haruspex, and Divination.

Extorsion, in law, is an illegal manner of wresting any thing from a man either by force, menace, or authority. It is also the execution of unlawful ultries, winning by unlawful games, and taking more than is due under pretence of right, as excessive tolls in millers, &c.

At the common law, extortion is punishable by fine and imprisonment; and the statute of 3 Eliz. c. 30, has enacted, that officers of justice guilty of extorsion for the expedition of business, &c. shall render to the party treble value. There are likewise divers other statutes for punishing extorsions of sheriffs, bailiffs, gaolers, clerks of the affile and of the peace, attorneys, solicitors, &c.

Extra, a latin preposition signifying without, and used in composition with other words, as for instance, 1. Extra-judicial, where judgment is given in a cause that is not depending in the court where the same passed; or whereon the judgment has no jurisdiction. 2. Extraparochial, which is paid of places out of the bounds of any parish, or freed from the duties of a parish. The greatest part of the forests in England are extra-parochial.

Extract, in pharmacy, is a solution of the purer parts of a mixed body inspissated, by distillation or evaporation, nearly to the consistency of honey. Extracts may be made almost of every part of the materia medica, or from any medicine, whether simple or compound, that is suited to give a tincture to any menstruum, in which it is eutomerably infused. They make a principal part of modern pharmacy, and with great reason too; for the different elements of many compound bodies have qualities and powers, when separate and pure, which they are incapable of exerting when their force is suppreft by the quantity, or counteracted by the repugnant qualities of other species with which they are conjoined, as in the inferences of acid spirits, teetaceous earths, calces of metals, gums or resins of vegetables, and many others. The directions given by the college of physicians for making extracts, are these. Take the matter from which the extract is to be prepared, cut, bruile, or otherwife manage it, as its nature requires, for infusion. Pour upon it spirit of wine, or any distilled waters, most accommodated to the prescriber's intention. Let it continue in infusion in a bath, or any other flow heat, for two days, or more, according as the hardnes or softness of the matter requires, until the liquor is impregnated with the tincture of the thing infused. Then let the tinged liquor be separated by inclination, pouring on a fresh menstruum, infusing and separating, as before, as long as any tincture can be obtained. Let all the tinctures be put together and filtered through ap-paper, and then in a bath-heat evaporate the humidity, until the matter left is of the consistence of honey, which must be kept for sale. And to this extract, for the sake of preferring it molli, may be added some portion of salt, or some other thing suitable to the main intention.

The most remarkable extracts of the London dispensatory are, 1. Extracts of the roots of elecampane, gentian, black hellebore, of the leaves of rue and savine, 2. Extract of liquorice. 3. Of logwood. 4. Of peruvian bark, both soft and hard. 5. Of lignum vitae, both soft and hard. 6. Of jalap. And 7. The cathartic extract which is prepared from proof spirit poured upon a proper quantity of succotain aloes, the pith of coloquintida, scammony, and the lefer cardamom-seeds husked.

The thebaic extract consists only of opium dissolved in water, strained and evaporated to a consistence. Let it be remarked, that all watery extracts should be moistened or sprinkled with a little spirit of wine, to prevent their growing mouldy.

Extract, in matters of literature, is something copied or collected from a book or paper.
EXT [II72] EXT

Extracts of writings or records, are notes upon them. See Extrat.

Extracta curie, are the issue or profits of holding a court arising from the customary dues, fees and amerce-
ments.

Extraction, in chemistry and pharmacy, the operation by which offences, tinctures, &c. are drawn from natural bodies. See the article Extraction.

Extraction, in surgery, is the drawing any foreign matter out of the body by the hand, or by the help of instruments. In extracting arrows and such like beard-
ed weapons used by barbarous nations, the whole business consists in drawing out the head, so as that its protuberant beard or hooks may not wound and lacerate the contiguous parts. If it appears to be lodged but superficially under the integuments, it will be best to draw it out the same way it entered, provided the wound be first sufficiently dilated by incision, in order to prevent the laceration of the adjacent parts; otherwise it must be thrust forwards, and drawn out in the direction of its point in the opposite side, if possible, an incision being first made to meet it. This last method is most eligible, when the weapon has descended very deep; so that there is much less space for it to pass onward, than to be drawn back again; and also when it has passed beyond any large blood-vessels or nerves, so that it would induce a laceration of them to draw it back.

In extracting foreign bodies from the ear, you must first be informed by the account of the patient, and by searching with a probe, of what nature the offending body is; and if it happen to be a lump of dried indurated wax, it will be proper to inject some warm milk, or oil of olives or almonds, ordering the patient to hold the glutinous ear-wax, excites an intolerable pruritus and tickling, which in time turns to acute pain. When the in-

fect can be perceived, it may be drawn out by a probe, &c. but if that fails, you must inject warm oil, or spirit of wine, which will quickly kill the insect; and then you may wash it out with the fame or some other liquor, and afterwards cleanse the cavity of the ear with a bit of cotton or lint upon the end of your probe.

To extract bodies fallen into the eyes, the first and most easy method is by agita-
tating and extending the eye-lids with one's fingers, holding the head down at the same time, by which means the increased flux of tears excited by the vellici-

tating body, very often washes it out of the eye without much difficulty. But if this method does not succeed, the next remedy is to blow some levigated pearl or crab-claws through a quill under the eye-

lid, that as these are washed out by tears, they may also take the foreign body with them, otherwise the surgeon must take the small round head of a slender probe, or the end of a tooth-pick, and extending the eye-lids gently from the eye, care-

fully extract the offending body. Lime or any acid salt may be washed from the eyes by a pencil brush of soft feathers, or a bit of fine sponge wetted in a quill, dipped in warm water.

The method of extracting small bones of fish, needles, pins, &c. sticking in the fauces or gula, is as follows. When the offending body cannot be removed by taking a large draught of some liquor, or swallowing a large mouthful of bread, &c. recourse must be had to some instru-

ment. The tongue is first to be depressed with a spatula, in order to observe whether the obstacle can be seen; and if it appears near the upper part of the oeso-

phagus, it should be cautiously extrated with a pair of piers, or some such instru-

ment. But if it is lodged deep in the oesophagus, the surgeon may then give the patient a piece of sponge to swal-

low, that has first been dippt in oil, and well fastened to a strong cord, by which it is to be pulled up again, after it has been swallowed by the patient as far as it will go; by which means the body sticking in the oesophagus, will be either forced down into the stomach, or else drawn up into the mouth.

For the extraction of bullets, &c. from wounds. See Gun-shot wounds.

Extraction,
Extraction, in genealogy, implies the stock or family from which a person is descended.

Extraction of roots, in algebra and arithmetic, the method of finding the root of any power or number. See the articles Root, Square, Cube, &c.
The reader will perceive by the articles Involution and Power, that the extraction of roots, or the resolving of powers into their roots, is the reverse of Involution, and consequently that the roots of single quantities are easily extracted by dividing their exponents by the number that denominates the root required; for the powers of any root are found by multiplying its exponent by the index that denominates the power; and therefore, when any power is given, the root must be found by dividing the exponent of the given power by the number that denominates the kind of root that is required. Thus the square root of $a^8$ is $a^{8 \div 2} = a^4$; and the square root of $a^b \cdot b^c$ is $a^{b \cdot c}$. The cube root of $a^b$, is $a^{b \div 3} b^2$; and the cube root of $a^b \cdot y^2 \cdot z^2$, is $a^b \cdot y^2 \cdot z^2$. It will also appear from what we shall lay of Involution, that any power that has a positive sign, may have either a positive or negative root, if the root is denominated by an even number. Thus the square root of $a^2$ may be $+a$ or $-a$, because $+a \times a = -a \times -a$ gives $+a^2$ for the product. But if a power have a negative sign, no root of it denominated by an even number can be affigned, since there is no quantity that multiplied into itself an even number of times can give a negative product. Thus the square root of $-a^2$ cannot be affigned, and is what we call an impossible or imaginary quantity. See the article Root.

But if the root to be extracted is denominated by an odd number, then shall the sign of the root be the same as the sign of the given number whose root is required. Thus the cube root of $-a^3$ is $-a$, and the cube root of $-a^3 \cdot b^3$ is $-a^3 b$. If the number that denominates the root required is a divisor of the exponent of the given power, then shall the root be only a lower power of the same quantity. As the cube root of $a^{12}$ is $a^4$, the number $3$ that denominates the cube root being a divisor of $12$. But if the number that denominates what fort of root is required is not a divisor of the exponent of the given power, then the root required shall have a fraction for its exponent: thus the square root of $a^\frac{5}{2}$ is $a^{\frac{5}{2}}$, the cube root of $a^\frac{5}{3}$ is $a^{\frac{5}{3}}$, and the square root of $a$ itself is $a^{\frac{1}{2}}$. These powers that have fractional exponents, are called imperfect powers or surds, and are multiplied and divided, involved and evolved, after the same manner as perfect powers. Thus the square of $a^{\frac{1}{2}}$ is $a^{\frac{1}{2}} \times a^{\frac{1}{2}} = a^2$; and the cube of $a^{\frac{1}{3}}$ is $a^{\frac{1}{3}} \times a^{\frac{1}{3}} \times a^{\frac{1}{3}} = a^2$. The square root of $a^{\frac{1}{2}}$ is $a^{\frac{1}{2}}$, and the cube root of $a^{\frac{1}{3}}$ is $a^{\frac{1}{3}}$. See the article Surd.

The square root of any compound quantity, as $a^2 + 2ab + b^2$, is discovered after this manner. First take care to dispose the terms according to the dimensions of the alphabet, as in division then find the square root of the first term $aa$, which gives $a$ for the first member of the root. Then subtract the square from the proposed quantity, and divide the first term of the remainder $2ab + b^2$, by the double of that member, viz. $2a$, and the quotient $b$ is the second member of the root. Add this second member to the double of the first, and multiply their sum $2a + b$ by the second member $b$, and subtract the product $2ab + b^2$ from the forefayd remainder $2ab + b^2$, and if nothing remains, then the square root is obtained. The manner of the operation is thus:

$$\frac{a^2 + 2ab + b^2}{a^2} = \frac{2a + b}{2ab + b^2} \times b = \frac{2ab + b^2}{x^b}$$

But if there had been a remainder, you must have divided it by the double of the sum of the two parts already found, and the quotient would have given the third member of the root. Thus if the quantity proposed had been $a^2 + 2ab + 2ac + b^2 + 2bc + c^2$, after proceeding as above you would have found the remainder $2ac + 2bc + c^2$, which divided by $2a + 2b$ gives $c$ to be annexed to $a + b$ as the third member of the root. Then adding $c$ to $2a + 2b$, and multiplying their sum $2a + 2b + c$ by $c$, subtract the product $2ac + 2bc + c^2$ from the forefayd remainder; and since nothing now remains, you conclude that $a + b + c$ is the square root required.

7. L
The operation is thus:
\[
a^2 + 2ab + 2ac + b^2 + 2bc + c^2 = (a + b)^2 + 2ac + 2bc + c^2
\]
\[
x^2 - (2a)
\]
\[
x^2 - (2a) - ax + 2aa
\]
\[
x - (2a) - ax + 2aa
\]

The square root of any number is found out after the same manner. If it is a number under 100, its nearest square root is found by the following table, by which also its cube root is found, if it be under 10000, and its biquadratic, if it be under 100000.

<table>

But if it is a number above 100, then its square root will consist of two or more figures, which will be found by different operations by the following rule. Place a point above the number that is in the place of units; pass the place of tens, and place again a point over that of hundreds; and go on towards the left hand, placing a point over every second figure, and by these points the number will be distinguished into as many parts as there are figures in the root. Then find the square root of the first part, and it will give the first figure of the root; subtract its square from that part, and annex the second part of the given number to the remainder. Then divide this new number (neglecting its last figure) by the double of the first figure of the root; annex the quotient to that double, and multiply the number thence arising by the said quotient; and if the product is less than your dividend, or equal to it, that quotient shall be the second figure of the root. But if the product is greater than the dividend, you must take a less number for the second figure of the root than that number. Much after the same manner may the other figures of the quotient be found, if there are more points than two placed over the given number.

To find the square root of 99856, I first point it thus, 9, 9, 8, 5, 6, then I find the square root of 9 to be 3, which therefore is the first figure of the root. I subtract 9 the square of 3 from 9, and to the remainder I annex the second part of the given number (56) and dividing 3756 (neglecting the last figure) by the double of 3 or 6, and I place the quotient after 6, and then multiply 61 by 1, and subtract the product 61 from 98. Then to the remainder, I annex the last part of the proposed number (56) and dividing 3756 (neglecting the last figure) by the double of 31, that is by 62, I place the quotient after, and multiplying 625 by the quotient 6, I find the product to be 3756, which subtracted from the dividend, and leaving no remainder, the exact root must be 316.

Examples.

\[
\times 3 \div 129
\]

In general, to extract any root out of any given quantity: first range that quantity according to the dimensions of its letters, and extract the said root out of the first term, and that shall be the first member of the root required. Then raise this root to a dimension lower by unit than the number that denominates the root required, and multiply the power that arises by that number itself; divide the second term of the given quantity by the product, and the quotient shall give the second member.
Raife the part already found of the root, and multiplying by 5, I find that the root of the fifth power out of \(a^5\), gives 5; which I raife to the fourth power, and raifing \(a + b\) to the fifth power and subtracting it, there being no remainder, I conclude that \(a + b\) is the root required. If the root has three members, the third is found after the same manner from the root required. Thus to extract the root of the fifth power out of \(a^5 + 5a^4b + 10a^3b^2 + 10a^2b^3 + 5ab^4 + b^5\), I find that the root of the fifth power out of \(a^5\), gives 5; which I raife to the fourth power, and raifing \(a + b\) to the fifth power and subtracting it, there being no remainder, I conclude that \(a + b\) is the root required. If the root has three members, the third is found after the same manner from the root required.

Thus the square root of \(a^2 + x^2\) is found to be \(a + \frac{x^2}{2a}\), the square root of \(a^3 + x^3\) will be found to be \(a + \frac{x^3}{3a^2}\), the cube root of \(a^3 + x^3\) will be found to be \(a + \frac{x^3}{3a^2}\), the fourth power of \(a^4 + x^4\) will be found to be \(a + \frac{x^4}{4a^3}\), the fifth power of \(a^5 + x^5\) will be found to be \(a + \frac{x^5}{5a^4}\), and so on.

The reader will find a general theorem for extracting the root of any binomial under the article Binomial. The roots of numbers are to be extracted as those of algebraic quantities. Place a point over the units, and then place points over every third, fourth, or fifth figure towards the left hand, according as it is the root of the cube, of the fourth or fifth power that is required; and if there be any decimals annexed to the number, point them after the same manner, proceeding from the place of units towards the right hand. By this means the number will be divided into so many periods, as there are figures in the root required. Then enquire which is the greatest cube, biquadrate, or fifth power in the first period, and the root of that power will give the first figure of the required root. Subtract the greatest cube, biquadrate, or fifth power from the first period, and to the remainder annex the first figure of your second period, which shall give your dividend. Raise the first figure already found to a power less by unit than the power whole root is sought, that is, to the second, third, fourth, or fifth power, according as it is the cube root, the root of the fourth, or the root of the fifth power that is required, and multiply that power by the index of the cube, fourth or fifth power, and divide the dividend by this product, and the quotient will be the second figure of the root required.

Raise the part already found of the root, to the power whole root is required, and if that power be found less than the two first periods of the given number, the second figure of the root is right; but if it be found greater, you must diminish the second figure of the root, till that power be found equal to or less than those periods of the given number. Subtract it, and to the remainder annex the next period, and proceed till you have gone through the whole given number; finding the third figure by means of the two first, as you found the second by the first, and afterwards finding the fourth figure (if there be a fourth period) after the same manner from the three first.
Thus to find the cube root of $13824$, point it $13824$; find the greatest cube in $13$, viz. $8$, whose cube root $2$ is the first figure of the root required. Subtract $8$ from $13$, and to the remainder annex $8$, the first figure of the second period; divide $58$ by triple the square of $2$, viz. $2$, and the quotient is $4$, which is the second figure of the root required, since the cube of $24$ gives $13824$, the number proposed.

Operation.

\[
\begin{align*}
13824 &= 24 \times 2 \times 2 \\
3 \times 4 &= 12 \\
58 &= 2 \times 2 \times 2 \\
\text{Subtract} &= 24 \times 2 \times 2 \times 2 = 13824 \\
\text{Rem.} &= 0
\end{align*}
\]

After the same manner the cube root of $13312053$, is found to be $237$.

Operation.

\[
\begin{align*}
13312053 &= 237 \times 2 \times 2 \\
12 &= 2 \times 2 \times 2 \\
\text{Subtract} &= 2 \times 2 \times 2 = 12167 \\
3 \times 23 \times 23 &= 138711450 (7) \\
\text{Subtract the cube of} &= 237 = 13312053 \\
\text{Rem.} &= 0
\end{align*}
\]

In extracting of roots, after you have gone through the number proposed, if there is a remainder, you may continue the operation by adding periods of cyphers to that remainder, and find the true root in decimals to any degree of exactness required.

For the method of extracting the root of any affected equation, See the article Quadratic Equation, &c.

**EXTRACTOR**, in midwifery, an instrument, or forceps, for extracting children by the head. See Delivery.

**EXTRAVAGANTES**, those decrætal epistles, which were published after the Clementines. See Clementines. They were so called because, at first, they were not digested, or ranged, with the other papal constitutions, but seemed to be, as it were, detached from the canon law. They continued to be called by the same name when they were afterwards inserted in the body of the canon law. The first extravagantes are those of John XXII. succéssor of Clement V. the last collection was brought down to the year $1483$, and was called the common extravagantes, notwithstanding that they were likewise incorporated with the rest of the canon law. See the article Decretal.

**EXTRAVASATION**, in contusions, fissures, depressions, fractures, and other accidents of the cranium, is when one or more of the blood-vessels that are distributed on the dura mater, is broke or divided, whereby there is such a discharge of blood as greatly oppresses the brain, and disturbs its offices; frequently bringing on violent pains, and other mischiefs; and at length, death itself, unless the patient is timely relieved. See the articles Contusion, Fissure, and Fracture.

If the extravasated quantity of blood be ever so small, it will certainly corrupt, and affect the meninges, and the brain itself, with the same disorder: from hence will proceed violent inflammations, deliriums, ulcers, &c. and even death itself, sooner or later. And this will frequently be the case, after a violent blow upon the cranium, though the bone should escape without any injury. In this case the blood is split either between the cranium and dura mater, or between the dura mater and pia mater, or between the pia mater and the brain, or lastly, between the sinuses of the brain. Each of these cases are attended with great danger, but the deeper the extravasation happens, so much greater will the danger be. See the article Wound.

You may suspect that blood is extravasated in the cavity of the cranium, from the violence of the symptoms which succeed, if the patient lies still without sense or motion, if blood flows from the mouth or nose, if the eyes are much inflamed and swelled, if vomiting succeeds; and when upon the remission of these symptoms the patient complains of a remarkable heaviness of the head, a sleepiness, vertigo, blindness, spasms, &c. When the quantity of extravasated blood is very considerable, the patient dies on the spot.

If no fissure or contraffure in the cranium, nor any external injury appear on the head after a violent blow, then, in order to find out in what part of the head the extravasation is seated, it will be proper to shave the head all over, and if no mark of a flagellation of blood appears, cover the head with an emollient plaster, laying over it medicated bags well heated, which will, in a few hours, produce
produce tumour, and softness upon the injured part. See the article CONTRA-
FISSURE.

When the seat of the injury is discovered, the first intention is to discharge the extravasated blood, for which intent many advise the use of the trepan: but as that should not be attempted, unless in a case of absolute necessity, 'tis best to try first the use of attenuating and dividing medicines. See the articles TREPAN and ATTENUANTS.

With this intention, open a vein, and draw away as much blood as the strength of the patient will admit; prescribe a brisk purge, or sharp clysters; foment the head with medicated bags, and apply a melilot plaster to it; give frequently attenuating warm fluids; the operation of bleeding must be repeated, especially if the patient is young and athletic.

EXTRAVASATION of blood between the flesh and the skin, in phlebotomy, the same with ecchymosis. See ECCHYMOSIS.

EXTREMES, in logic, the terms expressing the two ideas whose relation we enquire after in a syllogism. See the article SYLLOGISM.

EXTREME and MEAN PROPORTION, in geometry, is when a line AB, (plate XCIV. fig. 2.) is so divided in F, that the rectangle under the whole line AB, and the lesser segment FB, is equal to the square of the greater segment AF.

Let a square be formed upon the line AB, and one of its sides AC be equally divided in the point D; draw DB, and take the line DG equal to the line BD; then the square AGHF will be equal to the rectangle FE.

For since the line AC is equally divided in the point D, and is lengthened by the line AG, the rectangle CH, together with the square of the line AD, will (by § 2. of each) be equal to the square of the line DG or DB. But the square AE, with the square of the line AD, is also equal (§ 47. § 1.) to the square of the line DB. Therefore the square AE is equal to the rectangle CH. Taking then away from both the rectangle CF, the rectangle FE will be equal to the square FG.

But no number can be so divided into two parts, as is well demonstrated by Clavis, in his commentaries upon lib. 9. of Euclid; which is evident enough thus: Let a be the number, and x the greater part; then the lesser part will be $a - x$, and so $a - a\sqrt{5} = xx$, and thence $x = \frac{a + a\sqrt{5}}{2}$.

Since the square root of 5 cannot be had in numbers exactly, it is plain that the value of $x$ partly consisting of the square root, multiplied by $a$, cannot be had exactly in numbers neither.

EXTREME UNCTION. See UNCTION.

EXTREMUM clausi diem, in law. See the article DIEM.

EXTRINSIC, among metaphysicians, is taken in various senses: sometimes it signifies a thing's not belonging to the essence of another; in which sense, the efficient cause and end of a thing are said to be extrinsic. Sometimes it signifies a thing's not being contained within the capacity of another; in which sense these causes are called extrinsic, which introduce something into a subject from without, as when a fire introduces heat. Sometimes it signifies a thing's added or applied to another, in which sense accidents and adherents are said to be extrinsic to the subjects to which they adhere. Sometimes the vision is said to be extrinsic from some form which does not exist in that thing, but is adjacent to it, or by some means or other without it. See the article INTRINSIC.

EXULCERATION, in surgery. See the article ULCER.

EXUVIAE, among naturalists, denote the cast off parts, or coverings, of animals, as the skins of serpents, caterpillars, and other insects. See the articles SERPENT and CATERPILLAR.

Mr. Reaumur is very particular in describing the manner in which the caterpillar tribe throw off, or extricate themselves from, their exuviae. See vol. 1. of his History of Insects, and the article CATERPILLAR.

The crab, as is well known, can even throw off its limbs at pleasure, which are again replaced by new ones. See the articles CANCER and CRAB.

EXUVIE is also used for the remains of sea-animals, found fossil, and more properly called extraneous, or marine fossils. See the article FOSSILS.

EYE, oculus, in anatomy, the organ of sight; or that part of the body, whereby visible objects are represented to the mind.

With regard to the eyes, we are to observe first, their situation, which is in the upper part of the face, to the end that we
we may be able to see at a greater distance than otherwise we could. Secondly, their figure, which, excepting for the internal parts, is globular; and thirdly, their colour, which in the human species is variable; some being black, others greyish, and others bluish. The parts which do not enter into the composition of the eye, but are defined for the assistance of seeing, are the eyebrows, the eyelids, and the muscles of the eyes.

The eyelids, palpebrae, are the integuments of the eyes: there are two of them to each, an upper, and an under-lid; and, at their joining, there are formed two corners, called canthi, an interior and larger; and an exterior and smaller; they are capable of closing and opening at pleasure, by means of muscles. They are composed of the epidermis, the cutis, which is there very thin, and an arched cartilage, called the tarsus of the eye-lid; and are lined on the inner surface with a fine and delicate soft membrane, very sensitive and continuous to the perioptoeum, and to the albumen of the eye.

The eye-lashes, cilia, are certain rigid hairs, situated on the arch or tarsus of the eyelids, and bent in a very singular manner; they are defined for keeping external bodies out of the eye, and for moderating the influx of light.

The glandulae sebaceae are situated in the interior surface of the eye-lids: they serve for the secretion of an oleaginous fluid, which is of great use in preventing the attrition of the eye-lids, from their continual motion. See the articles SEBACEAE GLANDULAE.

After this we observe the caruncula lachrymalis. See the article CARUNCULA.

The glandula lachrymalis is situated in the orbit, above the smaller angle, with its excretory ducts under the upper eyelid. See the article LACHRYMALIS.

The puncta lachrymale are two. See the article LACHRYMALIA PUNCTA.

The use of the eye-lids is to cover and defend the eye; to wipe off fowths from the cornea; to moderate the influx of light, at pleasure; and, by their frequent motion, to occasion a secretion of a necessary fluid from the glands.

The muscles of the eyes, serving to their motions, are in the human frame six in number: four straight, viz. the attollens, deprimens, adductor, and abductor; and two oblique, the superior and inferior. See the articles MUSCLE and ATTOLLENS, &c.

Between, and among these, there is a considerable quantity of fat serving for various very important purposes.

The proper parts of the eye, which form its globe, or bulb, are its coats, or tunics, the humours and the vessels.

The coats of the eye are several. 1. The albucineae, adnata, or conjunctiva. 2. The cornea. 3. The sclerotic, in which what is called the aquæductus Nuck are to be observed. 4. The choroides.

5. The uveæ, wherein we are to observe. 1. Its anterior coloured surface, called the iris, which is intirely vascular, and from which arises the variety of colours in the human eyes. 2. The pupil or foramen, which is round in the human eye, is nearly in the middle of the iris, and is capable of dilatation and contraction. 3. Its posterior surface, which is black, and in which, when this blackness is cleared away, there appears the sphincter of the pupil, formed of circular fibres for contraction; the ciliary fibres, or processae for the dilatation of the pupil; the ciliary ligament for the motion of the vitreous and crystalline humours; the arterial and venal circles, from which the vessels are in a wonderful manner distributed over the uveæ; the choroides; the ligamentum ciliare; and the vitreous and crystalline humouræ, the ductus nigræ, so called from their black colour, placed between the processae and the legamentum ciliare; the space between the uveæ and the cornea, called the anterior camera of the eye; and that between the uveæ and the crystalline, called its posterior camera, which is either much smaller or entirely wanting. Many authors have attributed glands to the uveæ, but they are very difficult to be distinguished, if there be any. See the articles ALBUCINEA, CORNEA, SCLEROTIC, &c.

Finally, we are to mention the retina, which is a very delicate, tender, and, as it were, mucous coat of the eye; pr, more properly, it is only an expansion of the optic nerve at the bottom of the eye: it is a primary part of the eye, and the great organ of vision, for the sake of which all the rest were formed. See the article RETINA.

The humours of the eye are generally establihed to be three; their office is to serve
serve for the expansion of the coats, and for the refraction of the rays of light, they are distinguished by the name of aqueous, vitreous, and crystalline. See the articles Aqueous, Vitreous, and Crystalline.

After these three humours of the eye, we observe the tunica arachnoides: this is an extremely thin and fine vafculous membrane, which surrounds the crystalline and the vitreous humour, and by the afflance of which the crystalline lens is lodged in the fovea of the vitreous humour. On the cutting or breaking of this membrane, the crystalline falls out.

The blood-vessels are next to be considered; these are distributed in an amazing manner through the internal parts of the eye. Arteries from the internal and external carotids go to the eye in many different parts. There are also numbers of extremely minute ones, which convey only a lymph thither, by which means the blood back to the finus of the dura mater, and partly to the jugulars.

Besides these vessels, Vallalva assures us, that he discovered a number of true and proper lymphatics in the eye of an ox.

The nerves of the eye are very numerous: besides the optic nerve, which, by its expansion forms the retina, and enters the eye from the side of the nose, there are the third and fourth pair of the brain, and a fifth and sixth branch distributed about the muscles, membranes, eyelids, and lacrimal fasciculus and gland.

See the article Nerve.

Motions of the Eye are either external or internal. The external motion is that performed by its four straight and two oblique muscles, whereby the whole globe of the eye changes its situation or direction. The spherical figure of our eyes, and their foole connection to the edge of the orbit, by the tunica conjunctiva, which is soft, flexible and yielding, does excellently dispose them to be moved this, or the other way, according to the situation of the object we would view. By the membranes already described, the eye is connected to the edge of the orbit, which being soft and flexible, they do in such a manner, as not in the least to impede its necessary motions; and that great quantity of fat placed all round the globe, betwixt it and the orbit, lubricates and softens the eye, and renders its motions more easy: hence arise the three following remarkable observations. 1. When nature has denied the head any motion, it is observable, that she has, with great care and industry, provided, for this defect. To this purpose belongs the surprizing beautiful and curious mechanism observable in the inmoveable eyes of flies, wasps, &c.

They nearly resemble two protuberant hemispheres, each consisting of a prodigious number of other little segments of a sphere, all which segments are perforated by a hole, which may be called their pupil, in which this is remarkable, that every foramen, or pupil, is of a lenticular nature, so that we see objects through them topy-turvy, as through so many convex glaftes: yet, they become a small telescope, when there is a due focal distance between them, and the lens of the microscope by which they are viewed. Leuwenhoek's observations make it probable, that every lens of the cornea supplies the place of the crystalline humour, which seems to be wanting in those creatures, and that each has a distinct branch of the optic nerve answering to it, upon which the images are painted, so that as most animals are binocular, and spiders for the most part octonocular, so flies, &c. are multocular, having in effect as many eyes as there are perforations in the cornea, by which means, as other creatures but with two eyes are oblied, by the contraction of the muscles above enumerated, to turn their eyes to objects, these have some or other of their pupils always ready placed towards objects nearly all around them: whence they are so far from being denied any benefit of this noble and most necessary sense of light, that they have probably more of it than other creatures, answering to their necessities and ways of living.

II. As in man, and most other creatures, the eyes are situated in the head, because, among other reasons, it is the most convenient place for their defence and security, being compos'd of hard bones, wherein are formed two large, strong sinusses, or fockets, commonly called orbits, for the convenient lodging of these tender organs, and securing them against external injuries; so in these creatures whose head, like their eyes and the rest of their body, is soft and without bones, nature hath provided for this...
this necessary and tender organ, a wonderful kind of guard, by enduing the creature with a faculty of withdrawing his eyes into his head, and lodging them in the same safety within his body. We have a very beautiful example of this in the Als, whose eyes are lodged in four horns, like atramentous spots, one at the end of each horn, which they can retract at pleasure, when in any danger. Here it may be also observed, that the hardness of the cornea in all animals that want eyelids, as fishes, exactly resembles the horn of a lantern; and therefore is not hurt by such particles as their eyes are commonly exposed to. And in the mole, because this animal lives under ground, it was necessary its eyes should be well guarded and defended against the many dangers and inconveniences to which its manner of living exposes it; this is the reason why its eyes are so small, and that they are situated so far in the head, and covered so strongly with hair; and besides they can protrude, and retract them at pleasure.

III. The third and last reflection we shall make upon the external motion of our eyes, is what regards a problem which has very much perplexed both physicians and philosophers, viz. What is the cause of the uniform motion of both eyes. In some creatures, such as fishes, birds, and among quadrupeds, the hare, camelion, &c. the eyes are moved differently; the one towards one object, and the other towards another. But in man, sheep, oxen, and dogs, the motions are so uniform, that they never fail to turn both towards the same place: hence in operations upon the eye that require it to be kept immovable, sometimes it is necessary to tie up the found eye with a comprese, by which means the other is easier kept fixed and immovable.

The final cause of this uniform motion is, 1. That the sight may be thence rendered more strong and perfect; for since each eye apart impresses the mind with an idea of the same object, the impression must be more strong and lively, when both eyes concur; and that both may concur, it is necessary that they move uniformly; for though the retina, or immediate object of vision, be expanded upon the whole bottom of the eye, as far as the ligamentum ciliarum, yet nothing is clearly and distinctly seen, but what the eye is directed to. 2. A second advantage we reap from the uniform motion of the eyes, which is more considerable than the former, consists in our being thereby enabled to judge with more certainty of the distance of objects. See the article Vision. There is yet another advantage, full as considerable as any of the former, that is thought to arise from the uniform motion of our eyes, and that is, the single appearance of objects seen with both our eyes; which, though at first view it does not appear probable, is true: for if in looking at an object, you impress one of your eyes aside with your finger, and alter its direction, every thing will be seen double.

By the internal motions of the eye, we understand those motions which only happen to some of its internal parts, such as the crystalline and iris; or to the whole eye, when it changes its spherical figure, and becomes oblong or flat. The internal motions of our eyes are either such as respect the change of conformation, that is necessary for seeing distinctly, at different distances, or such as only respect the dilatation and contraction of the pupil.

That our eyes change their conformation, and accommodate themselves to the various distances of objects, will be evident to any person, who but reflects on the manner and most obvious phenomena of vision.

Authors are very much divided in their opinions with regard to the mechanism by which this change is introduced, as well as what parts it consists in: for some are of opinion, that the whole globe changes its form, by being lengthened into an oblong figure, when objects are near, and by becoming flat, when they are removed to a greater distance; and others are of a quite contrary opinion.

With regard to the change of the crystalline, and the mechanism by which it is produced, some maintain, that according as objects are at different distances, this humour becomes more or less convex, which does indeed very well account for distinct vision at all distances; for objects painted on a sheet of white paper, by means of a lens placed in the hole of a window-shutter, in a dark room, have their images always distinct, at whatever distance they be from the window, provided that the lens be of a convexity
convexity answerable to that distance. See the article Lens, &c.

Others again are of opinion that the crystalline never changes its figure, but that it is moved to and from the retina, according to the distance or proximity of the object in view, and this also does equally well account for the distinct appearance of objects at all distances, as is evident from the laws of optics. See the articles Vision and Optics.

Diseases of the Eye are, an ophthalmia, or inflammation of the eyes; the gutta serena, or amaurosis; a luffusion, or cataract; an ecropium; a glaucoma; an amblyopia, or obscurity of sight, containing the myopia, the presbytopia, the nyctalopia, and the amaurosis; the strabismus, or squinting; an unguis, pannus, or pterygium of the membrane of the eye; the albugo, leucoma, or spot in the eye; the gutta serena; in the beginning they may be forerunners of a venerum in the eyes, and the gutta serena, or rheum in the eyes, and the respective name. See the article EYE.

Atoms and flies appea ing before the Eyes. These images, or appearances, arise before the eyes from an obstruction of the optic nerve, from the fine fibres of the retina, or from the small veins contained therein, that is, they seem to be too much dilated, and are cured with difficulty; especially if they are intemperate, because they are not seldom the forerunners of a gutta serena; in the beginning they may be cured with such things as open obstructions, especially those medicines mentioned in the cure of the gutta serena. See GUTTA SERENA.

Defluxion on the Eye. For a watery eye, if it arises from a weakness of the lachrymal gland, it will be proper to use strengtheners externally, as spirit of wine, Hungary water, spring water, fennel, or Valerian water, whereupon the parts adjoining are to be washed. Internally the abounding ferum must be evacuated, or revulsed: if it be too sharp, it must be corrected by balsamicks, and medicines against catarrhs, such as essence of amber, and decoction of the woods. The revulsion must be made by blisters and influes.

Wounds in the Eyes. If the eye is wounded, but not so as to let out the vitreous or crystalline humour, the following method will be of great service. The wound should be anointed, two or three times in a day, with a feather, or fine rag, well dipped in Unguentum alabastrinum; and afterwards, a small compress laid over it, being well saturated with a collyrium, made of the whites of two eggs, two ounces and a half of rose water, half a drachm of oil of roses, and three grains of camphor, well mixed together. The bowels should also be kept loofie for some days, with cooling and opening medicines: if the patient is of a plethoric habit, blood should be drawn from the neck or feet; all warm or sharpe things should be thrown out of the patient's diet, and great care taken to keep him quiet. When the crystalline humour flicks in the orifice of the wound, it should be pulled out, that it may not bring on any deformity, or other mischief. When the vitreous and crystalline humours are fallen out of the eye, not only the figure but figure of the eye must be entirely destroyed, therefore, at first, it should be dressed with compresses dipped in warm wine, and afterwards with some vulnerary balsam. See the article EYE-BROW.

Contusions of the Eye. When the eye is contused by any accident, it will be entirely deprived of sight, except the contusion is very small, and proper remedies are instantly applied. If the eye therefore has received a flight contusion, you may wash it frequently, for the first day, with cold spring water, covering it with linen rags, wet with the fame. On the next day, rub it externally with camphorated spirit of wine, covering it with flups wrung out of vinous decoctions of eye-bright, speedwell, hyssop, fage, camomile flowers, and fannel feeds. If you cannot get these herbs, apply bolsters dipped in warm wine, renewing them often. If the contusion is large, or the patient of a plethoric habit, you must open a vein. See the article SCARIFICATION.

To extrac objects fallen into the Eye. See the article EYE.

Scarification of the Eyes. See the article SCARIFICATION.

Falling out of the Eye. See the article PROLAPSUS OCULI.

EYE-BROW. See the article BROW.

Artificial Eye, a kind of camera obscura. See CAMERA OBSCURA.

EYE, in architecture, is used to signify any round window, made in a pediment, an attic, the ruins of a vault, or the like.

EYE of a dome, an aperture at the top of a dome, as that of the Pantheon at Rome, or of St. Paul's at London: it is usually covered with a lantern.
Eye of the volute, in architecture, is the center of the volute, or that point in which the helix, or spiral of which it is formed, commences: or it is the little circle in the middle of the volute, in which are found the thirteen centers for describing the circumvolutions of it.

Eye-brow, in architecture, is used in the same sense as lid or fillet. See Fillet.

Eye, in agriculture and gardening, signifies a little bud, or shoot, inflected into a tree, by way of graft.

Eye of a tree, a small pointed knot to which the leaves flock, and from which the shoots or sprigs proceed.

Eye-bright. See Euphrasia.

Eye of a pear, the extremity opposite to the stalk.

Eye-flap, in the manège, a little piece of leather, that covers the eye of a coach-horse.

Eye of the branch of a bridle, the uppermost part of the branch, which is flat, with a hole in it, for joining the branch to the head-stalk, and for keeping the curb flat.

Eye of a bean, in the manège, a black speck or mark in the cavity of the corner-teeth, which is formed there about the age of five and a half, and continues till seven or eight. See Teeth.

Eye of the anchor, on board a ship, the hole wherein the ring of the anchor is put into the shank.

Eye of the strap, on board a ship, the ring or round which is left of the strap to which any block is seized. See Strap.

Eye, in printing, is sometimes used for the thickness of the types; or more properly, it signifies the graving in relief on the top of the letter, otherwise called its face: the eye of the e is the small opening at the head of that letter, which distinguishes it from the c.

Eye, among jewellers, is used for the lustre and brilliancy of precious stones, more commonly called the water. See Water.

Bull's Eye, in astronomy, the fame with aldebaran. See Aldebaran.

Eye-glass, in the microscope. See the article Microscope.

Cat's Eye, in natural history, the fame with afteria. See the article Asteria.

Crab's Eye. See the article Crab's Eyes.

Goat's Eye, the same with Ægias. See the article Ægias.

Hare's Eye. See Lagophthalmia.

Eye-mouth, or Aymouth, a port-town of Scotland, about six miles north of Berwick.
the fifth letter of the alphabet, and fourth consonant, is by some reckoned a mute, and by others a semi-vowel: it has much the same sound with the greek φ, or ph in English words, and is only written in words of Latin origin, ph being used instead of it in those derived from the Greek.

Suetonius tells us, that the emperor Claudius invented the f, and two other letters; and that it had the force of ω consonant, and was wrote inverted.

As a numeral, F denotes 40, and with a dash over it thus, F, 40000: in music, it stands for the bass clef; and frequently for forte, as ff does for forte forte. See the articles CLEF and FORTE.

F, in medicine, stands for fiat, let it be done: thus F. S. A. stands for fiat secundum artem, let it be done according to art.

As an abbreviation, F stands for filius, fellow, and the like: thus F. R. S. signifies fellow of the Royal Society.

FA, in music, one of the syllables invented by Guido Aretine, to mark the fourth note of the modern scale, which rises thus, ut, re, mi, fa. See the articles NOTE and GAMUT.

Musicians distinguish two fa's vis: the flat, marked with a b, or b; and the sharp or natural, marked thus f, and called quadro. See BQUADRO.

FAINTO, a feigned F, or a joint upon that note: this is the caes of every note that has the mark b before it; but more especially mi and f, or our E and B, and is what we commonly call the flat of any note. See the article FLAT.

FABA, the bean, in botany, is comprehended by Linnaeus among the Vicieae. See the articles VICIA and BEAN.

FABA ÆGYPTIACA, an Egyptian bean, a kind of nymphaea, the root of which is accounted stomachic and astringent.

FABA BENGALENSIS: in the materia medica, a roundish compressed substance, about an inch in diameter, brought from Bengal, and thought to be a vitiated fruit of the myrobalsan-kind. It is a very good astringent, and therefore prescribed with great success in fluxes and hemorrhages.

FABA STI. IGNATII, St. Ignatius's bean, in the materia medica, a dry and hard fruit, or rather kernel, prescribed with good success in vertigos, lethargies, epilepsies, affinmas, quartan agues, and worms, but should be used with great caution. It is given in powder, 10 to 12 grains being the dose, when intended to vomit the patient. In smaller quantities it acts as a sudorific. Its tincture is safe even for children, and is said to be one of the best medicines for their convulsions, and other disorders arising from obstructions of the prime vae.

FABA PURGATRIX, the fruit of a species of ricinus. See the article RICINUS.

FABAGO, in botany, the same with the zygophyllum. See ZYGOPHYLLUM.

FABARIA, in botany, a name given to the telephium or opirine. See TELEPHIUM.

FABER, in ichthyology, a fish of the zeus-kind, called in English doree, or John Dory. See the article ZEUS.

It is distinguished from the other species of zeus by its prickly belly, and ragged appearance. Its usual length is from six to ten inches, and its breadth nearly half its length. See plate XCV. fig. 1.

FABIONS, fabit, in Roman antiquity. See the article LUPERCALIA.

FABLE, fabula, a tale or feigned narration, designed either to instruct or divert, disguised under the allegory of an action, &c.

Fables were the first pieces of wit that made their appearance in the world, and have been still highly valued, not only in times of the greatest simplicity, but among the most polite ages of the world. Jotham's fable of the trees is the oldest that is extant, and as beautiful as any that have been made since. Nathan's fable of the poor man is next in antiquity, and had so good an effect as to convey instruction to the ear of a king. We find Æsop, in the most distant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeased by the fable of the belly and the members. As fables had their rise in the very infancy of learning, they never flourished more than when learning was at its greatest height; witness Horace, Boileau, and Fontaine. See APOL.OLUGI.
FABLE is also used for the plot of an epic or dramatic poem, and is, according to Aristotle, the principal part, and, as it were, the soul of a poem. See the articles DRAMA and EPIC.

In this sense the fable is defined to be a discourse invented with art, to form the manners by instruction, disguised under the allegory of an action. Aristotle divides the fable into simple and compound: the simple having no change of fortune; and the compound having a turn from bad fortune to good, and from good to bad. The contrivance of each fable must have two parts, the intrigue and the discovery. The compound fable, according to Aristotle, pleases most, as having most variety.

Lord Baron observes that the use of allegorical poetry is to envelope things, whose dignity deserves a veil, as when the secrets and mysteries of religion, policy, and philosophy are wrapped up in fables and parables. Others are of opinion that fable is so essential to poetry, that there is no poetry without it; the fable being as much the form and distinction of a poem, as the figure is to a piece of marble to denominate it a statue. It is requisite towards the perfection of a fable, that it be admirable and probable; however admirable the fable is, it can have no effect if it is not probable; and probability alone is too taint and dull for poetry, as what is only admirable is too extravagant and dazing. It is, therefore, of the utmost importance to be able to know how to mingle these in such a just temperament as may please the fancy, without shocking the reason. The admirable is all that which is against the ordinary course of nature; the probable is whatever suits with the common opinion; but the most part of poets, by too great a passion to create admiration, take not sufficient care to temper it with probability. Almost all the ancient poets, however judicially otherwise, have been guilty of this fault, not to speak of the moderns.

FABRIC, in general, denotes the structure or construction of any thing; but particularly of buildings, as a church, hall, house, &c. See BUILDING.

FABRIC-LANDS, those formerly given towards rebuilding or repairing of cathedrals and other churches; for antiently almost every body gave more or less, by his will, to the fabric of the parish-church where he dwelt.

FABULOUS, something consisting of, or connected with a fable. See FABLE.

FABULOUS AGE, among ancient historians. See the article AGE.

FAC, an abbreviation of facciata.

FACADE, in architecture. See FACCIA.

FACCIATA, among Italian musicians, signifies a shortened page.

FACE, facies, or vultus, in anatomy, comprehends all that part of the head which is not covered with the common long hair. See the article HEAD.

Of the parts common to the whole face are, 1. The epidermis and cutis, or skin, the colour and fineness of which constitutes the principal beauty of the face. 2. The fat, which being in considerable quantity, and frequently covered with a feathery panicle, adds much to the beauty of the face. The parts proper to particular parts of the face are the muscles and bones, which are described in their proper places: besides which, we may likewise refer to the face, the organs of the senses of seeing, hearing, tasting, and smelling. See the articles EYE, EAR, NOSE, PALATE, MOUTH, TONGUE, &c.

To these may be added the forehead, cheeks, temples, &c. See FOREHEAD, CHEEKS, &c.

The chin is nothing but the angle of the lower jaw, with its feathery integuments. See the article MAXILLA.

FACE, or FACADE, in architecture, the front of a building, or the side which contains the chief entrance. Sometimes, however, it is used for whatever side presents to the street, garden, court, &c. or is opposite to the eye.

FACE of a stone, in masonry, that superficies of it which lies in the front of the work. The workmen generally choose to make one of those sides the face, which, when in the quarry, lay perpendicularly to the horizon, and consequently the breaking, not the cleaving way of the stone.

FACE, in fortification, an appellation given to several parts of a fortres, as the face of a bastion, &c. See BASTION.

The face of a place is the front comprehended between the flanked angles of two neighbouring bastions, being composed of a curtain, two flanks, and two faces; and is likewise called the tenaille of a place. In a siege, the attacks are carried on against both bastions, when the whole tenaille is attacked.

Prolonged FACE, that part of the line of defence-razant, which is between the angle of the shoulder and the curtain, or the
the line of defence-razant, diminished by the length of the face.  

**FACE of a gun**, the superfcies of the metal at the extremities of the muzzle of the piece.  

**FACE, in the military art, a word of command**, intimating to turn about: thus, *face to the right,* is to turn upon the left heel a quarter-round to the right; and, *face to the left,* is to turn upon the right heel a quarter-round to the left.  

**FACE of plants, among botanists, signifies their general appearance, which, being nearly the same in plants of the same genus, serves to distinguish them at first sight.** See **BOTANY, PLANT, &c.** The same term, *face, facies,* is used by other naturalists to denote the like resemblance among other objects, as fishes, birds, &c. However, it is proper to remark, that this resemblance is too fallacious to serve as a general character; since things, belonging to very different genera, are sometimes found to be very like each other in external appearance.  

**FACET, or FACETTE, among jewellers, the name of the little faces or planes to be found in brilliant and rose diamonds.** See the article DIAMOND.  

**FACETANUS LACERTUS, the same with the tarantula.** See **TARANTULA.**  

**FACIA, or FASCIA.** See FASCIA.  

**FACIES, face.** See the article FACE.  

**FACK, or FAKE.** See the article FAKE.  

**FACTION, a cabal or party formed in a state, city, or company.**  

**FACTION, in antiquity, a name given to the different companies of combatants in the circus. They were four, viz. the white, the red, the green, and the blue; to which Domitian added another of purple colour. They were so denominated from the colour of the liverys they wore, and were dedicated, according to M. Aur. Caffiodorus, to the four seasons of the year, the green being consecrated to spring, the blue to winter, the red to summer, and the white to autumn. It appears from ancient inscriptions, that each faction had its procurators and physician; and from history, that party-rage ran so high among them, that in a di@ension between two factions, in the time of Julius, almost forty thousand men lost their lives in the quarrel.**  

**FACTITIOUS, any thing made by art, in opposition to what is the produce of nature. Thus, factitious cinnamon is opposed to native cinnamon.** See the article CINNABAR.
advice of his proceedings, admits them according to his first intention. A factor that sells a commodity under the price he is ordered, shall be obliged to make good the difference; and if he purchases goods for another at a price limited, and afterwards they rise, and he fraudently takes them for his own account, and sends them to another part, in order to secure an advantage that seemingly offers, he will, on proof, be obliged, by the custom of merchants, to satisfy his principal for damages. If a factor, in conformity with a merchant's orders, buys with his money, or on his credit, a commodity he shall be directed to purchase; and, without giving advice of the transaction, sells it again to profit, and appropriates to himself the advantage, the merchant shall be amerced for his fraud. When factors have obtained a profit for their principal, they are responsible: and if a merchant remits goods to his factor, having money in his hands, accepts the bill, then the principal breaks, and the factor must answer the bill notwithstanding, and come in a creditor for so much as he was obliged, by reason of his acceptance, to pay. A factor who enters into a charter-party with a master for freight, is obliged by the contract; but if he loads aboard generally, the principal and the lading are liable for the freightment, and not the factor. If a factor, having money in his hands belonging to his principal, neglect to insure a ship and goods, according to order, if the ship miscarries, the factor, by the custom of merchants, shall make good the damage; and if he make any composition with the insurers after insurance, without orders so to do, he is answerable for the whole insurance.

As fidelity and diligence are expected from the factor, so the law requires the like from the principal; if, therefore, a merchant remits counterfeit jewels to his factor, who sells them as if true; if he receive loss or prejudice by imprisonment or other punishment, the principal shall not only make full satisfaction to the factor, but to the party who bought the jewels.

What is here said of factors, is meant of such as reside abroad to act for merchants, and may be applied to supercargoes, who go a voyage to dispose of a cargo, and afterwards return with another to their principals; but it is also the custom of the merchants of the highest credit throughout the world, to act mutually in the capacity of factors for each other. The business so executed is called commissioneer-buliness, and is generally desirable by all merchants, provided they have always effects in their hands, as a security for all the affairs which they transact for the account of others. And this class of traders of established reputation, have current as well as commissioneer account, constantly between them, and draw on, remit to, and send commissions to each other only by the interchange of letters which, among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

Factor, in multiplication, a name given to the multiplier and multiplicand, because they constitute the product. See the article Multiplication, &c.

Factorage, called also commissioneer, is the allowance given to factors by the merchant who employs them. The gain of factorage is certain, however the voyage or sale prove to the merchant: but the commissions vary; at Jamaica, Barbadoes, Virginia, and most of the western parts of the world the commissione runs at 8 per cent. generally through Italy, 2 ½; in France, Spain, and Portugal, &c. 2; and in Holland, and other places near home, 1 ½ per cent.

Factory is a place where a considerable number of factors reside, to negotiate for their matters or employers. See the article Factor.

The most considerable factories belonging to the British are those established in the East-indies, Portugal, Turkey, &c.

Factum, in arithmetic, the product of two quantities multiplied by each other.

Facule, in astronomy, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed upon or about the surface of the sun: they are but very seldom seen. See the article Sun.

Faculty, in law, a privilege granted to a person, by favour and indulgence, of doing what, by law, he ought not to do.

For granting these privileges, there is a court under the archbishop of Canterbury,
bury, called the court of the faculties, the chief officer whereof is styled master of the faculties; who has a power of granting dispensations in divers cases, as to marry without the bans being first published; to eat flesh on days prohibited; to ordain a deacon under age; for a son to succeed his father in his benefice; a clerk to hold two or more livings, &c.

**Faculty**, in the schools, a term applied to the different members of an university, divided according to the arts and sciences taught there: thus in most universities there are four faculties, viz. 1. Of arts, which include humanity and philosophy. 2. Of theology. 3. Of physic. And, 4. Of civil law. The degrees in the several faculties in our universities are those of bachelor, master, and doctor. See the articles Degree, Bachelor, &c.

**Faculty of advocates**, a term applied to the college or society of advocates in Scotland, who plead in all actions before the court of seccion. They meet in the beginning of every year, and choose the annual officers of the society, viz. dean, treasurer, clerks, private and public examinators, and a curator of their library. The manner of admission into the faculty of advocates is by a trial in the civil law, and Scotch law: the person desiring to be admitted, having, upon petition, obtained a recommendation to the dean of the faculty, he giveth a remit to the private examinators, who are nine in number, and who, after their election, having divided the body of the civil law into nine parts, each taking one, appoint a diet for examination: in this diet there must be at least seven present, each of whom examines the candidate; and the question being afterwards put, Qualified, yea or no? they give their opinion by balloting, upon which the candidate is either admitted by signing his petition, or remitted to his studies. After the private trial, the dean of the faculty assigns the candidate a title of the civil law, for the subject of a thesis, which being distributed among the advocates, the faculty meet on a day appointed, when three at least of fifteen public examinators dispute against the thesis; and afterwards the faculty give their opinions by balloting, as in the private trial. If the candidate is found qualified, the dean assigns him a law for an harangue before the lords, which harangue being made, he is admitted a member of the faculty, upon paying the fees, taking the oaths to the government, and an oath to be faithful in his office.

**Faculty** is also used to denote the powers of the human mind, viz. understanding, will, memory, and imagination. See the articles Understanding, &c.

The doctrine of the use and objects of the mental faculties, says lord Bacon, has two parts well known, viz. logic and ethics, the one producing resolutions and the other actions. The imagination, indeed, on both sides performs the office of agent or embassador, and afflicts alike in the judicial and ministerial capacity. Wolfius, in his Analytical Psycholog, after establishing the existence of the soul, considers it with respect to its faculty of understanding, which he distinguishes into superior and inferior. The inferior comprehends perception, the source of ideas, thought, imagination, the power of feigning, memory, forgetfulness, and recollection. The superior part of the faculty of understanding consists in attention and reflection, in understanding in general, and its three operations in particular, and in the natural dispositions of the understanding. The second general faculty of the soul, is that of desiring an object, considered as a good; from whence results the contrary determination, when it is looked upon as an evil. This faculty he also distinguishes into inferior and superior: the first is nothing else than the sensori appetite, the desire or aversion we entertain for objects, when we allow ourselves to be guided by the confused ideas of our senses; hence arise the passions; the superior part is the will, considered so far as it is determined by distinct ideas, exempt from all mechanical impressions; and the use we make of this power of determining, is liberty.

**Fæces**, in chemistry, the gross matter, or sediment, that settles at the bottom after distillation, fermentation, and the like.

The fæces of wine are more generally known by the name lees. See Lees.

**Fæces**, in medicine, the excrements voided by stool. See Excrement.

**Fæcula**, in pharmacy, a form of medicine, consisting of the fæces of vegetable juices, principally those of roots; the manner of making which may be gathered from the following example, as ordered in the college dispensatory. To make a faecula of bryony, take the roots of that plant, any quantity; let them be scraped small with a knife, and squeeze out
FOENUGREEK, or FOENUGREEK. See the article FOENUGREEK.

FAENZA, a city and bishop's see of Italy, situated in the pope's territories, about thirty miles east of Bologna: east long. 14° 38', and north lat. 44° 30'.

FAETE or FOETOR. See FOETOR.

FAGGAR, in the materia medica, a fruit brought from the East-indies, much resembling the cubeb. This fruit is a berry, the exterior bark whereof is black resembling the cubeb. This berry, when ripe, being cut open, exhibits a dark, shining, solid seed, and the seeds when ripe, being cut open, exhibits a dark, shining, solid seed, and the seeds are two, roundish, attached to the by inclination.

The article FAETE or FOETOR. See FOETOR.

FAGGOTTO, in music, is a single curtail, a musical instrument something like the bafoon. See the article BASSOON.

FAGUŚ, the beech, in botany, a genus of the monacia-polyandria class of plants, having no corolla; the stamens are generally twelve hairy filaments of the length of the cup; the anther is oblong; the fruit is a roundish capsule, very large, surrounded with soft prickles, composed of four valves, and containing only one cell; the seeds are two, roundish, acuminate, and three-cornered. This genus comprehends the common chestnut-tree.

FAILURE, a species of bankruptcy, commonly called breaking, or stopping payments. See BANKRUPTCY.

Failure of record, in law, is where an action is brought against a person, who alleges, in his plea, matter of record in bar of the action, and avers to prove it by the record; to which the plaintiff replies, Nulla tali record, voce. There is no such record: whereupon the defendant has a day given him by the court to bring it in; and if he fails to do it, he is then said to fail of his record, and the plaintiff shall thereon have judgment. Where the tenor only of a record, &c. is brought in, or is no bar to the plaintiff's action, the party likewise fails of his record; but small variances in a record may be amended, and are no failure of record.

FAINT-ACTION, in law, a feigned action, or such as, although the words of the writ are true, yet, for certain causes, the plaintiff has no title to recover thereby.

FAINT-PLEADER, in law, a covinous, false, or collusive manner of pleading, to the deceit of a third person.

FAINTING. See LIPOTHYMIA.

FAIR,
FAIR, a greater kind of market, granted to a town, by privilege, for the more speedy and commodious providing of such things as the place stands in need of. See the article Market.

It is incident to a fair, that persons shall be free from being arrested in it for any other debt or contract than what was contracted in the same; or, at least, promised to be paid there. These fairs are generally kept once or twice a year, and, by statute, they shall not be held longer than they ought, by the lords thereof, on the time of the fair is ended, on forfeiture to be paid there. By statute, they are held without the pain of their being seized into the king's hands, &c. The proclamation is to be made, how long they are to continue; and no person shall sell any goods after the time of the fair is ended, on forfeiture of double the value, one fourth to the king, &c. Also, the sale of things, and for stallage, may be made, how long they are to continue; and no person makes, whether natives or aliens, without licence, not only on account of the great trade, but the vast concourse of princes of the empire, nobility, and people, who come to them from all parts of Germany to partake of the diversions to be had.

FAIRFIELD, a town of New-England, in the province of Connecticut, about an hundred miles south-west of Boston; west long. 72°, and north lat. 41°. FAIRFORD, a market-town, about nineteen miles south-east of Gloucester.

FAIRY, in antient traditions and romances, signifies a sort of deity, or imaginary genius, conversant on earth, and distinguished by a variety of fantastical actions, either good or bad. The fairies are a peculiar species of divinities, that have but little relation to any of those of the antient Greeks or Romans; unless perhaps to the latter: though others, with great reason, will not have them ranked among gods, but suppose them an intermediate kind of beings, neither gods, angels, men, nor devils. They are of oriental extraction, and seem to have been invented by the Persians and Arabs, whose religion and history abound with relations concerning them: thefe have a particular country which they suppose the fairies to inhabit, called Fairy-land.

Spencer's Fairy Queen is an epic poem, under the pertons and characters of fairies. In this sort of writing, the poet loves sight of nature, and entertains the reader's imagination with the characters of fairies, witches, magicians, demons, and departed spirits. It requires an odd turn of thought, and a peculiar cast of fancy, with an imagination naturally fruitful and superstitious.

This sort of poetry raises a pleasing kind of horror in the mind of the reader, and amuses his imagination with the strangeness and novelty of the persons who are represented in it; but the judicious object to it, as not having probability enough to affect the imagination.

FAIRY-CIRCLE, or RING, a phenomenon pretty frequent in the fields, &c. supposed, by the vulgar, to be traced by the fairies in their dances: there are two kinds of it, one of about seven yards in diameter, containing a round bare path,
a foot broad, with green grass in the middle of it. The other is of different bigness, encompassed with a circumference of grass, greener and ftrether than that in the middle. Meff. Jeflop and Walker, in the Philofophical Tranfaet, acribe them to lightening, which is confirmed by their being moft frequently produced after forms of that kind, as well as by the colour and brittleness of the grass-roots, when firft observed. Lightening, like all other fires, moves round, and burns more in the extremity than in the middle: the second circle arifes from the firft, the grass burnt up growing very plentifully afterwards. Others maintain that these circles are made by ants, which are frequently found in great numbers therein. 

FAIT, in law, the fame with deed. See the article DEED.

FAITH, fides, in antiquity, was defityed by the Romans, and had a temple in the capitol. 

Public faith is represented on medals sometimes with a basket of fruit in one hand, and three ears of corn in the other; and sometimes holding a turtle-dove. But the moft usual fymbol, is with her two hands joined together.

FAITH, in divinity and philofophy, the firm belief of certain truths upon the testimony of the perfon who reveals them. The grounds of a rational faith are, 1. That the things revealed be not contrary to, though they may be above natural reafon. 2. That the revealer be well acquainted with the things he reveals. 3. That he be above all fufpicion of deceiving us. Where these criterions are found, no reaonable perfon will deny his affent: thus, we may as well doubt of our own eflence, as of the truth of a revelation coming from God, who can neither be deceived himself, nor deceive others by proposing things to be believed, that are contradictory to the faculties he has given us. Whatever propositions, therefore, are beyond reafon, but not contrary to it, are when revealed, the proper matter of faith.

Confession of FAITH. See Confession.

FAITHFUL, an appellation assumed by the mahometans. See Mussulmen.

1AKE, among failors, signifies one round or circle of a cable or hawfer, coyled up out of the way.

TAKEHAM, a market-town of Norfolk, about sixteen miles north-weft of Norwich.

FAKIR, in pagen theology, a kind of Indian monks, who even outdo the mortification and severities of the antient christian anchorrets. See Anachoret. Some of them mangle their bodies with scourges and knives; others never lie down; and others remain all their lives in one posture. There are alfo another kind of fakirs, who do not praife much severities: thefe flock together in companies, and go from village to village, prophesying and telling fortunes. It is said that even perfons of fortune, in India, become fakirs, and that there are more than two millions of them.

FALCAIS, a town of lower Normandy, in France, sixteen miles south of Caen.

FALCADERE, in the manage, the motion of a horse when he throws himself upon his hanches two or three times, as in very quick corvets; which is done in forming a ftop and half stop. See the article STOP.

FALCATED, something in the form of a fickle: thus, the moon is faid to be falcated when she appears horned. See the articles MOON and PHASIS.

FALCARIA, in botany, a name used by Rivinus for a species of fium. See the article SIUM.

FALCATA, a name used by the fame botanift for the medicago. See the article MEDICAGO.

FALCINELLUS, a bird supposed to be of the heron-kind, with a long crooked bill, and called by some the black heron. See plate XCV. fig. 2. It is somewhat larger than a pigeon, and is of a greenifh colour, variegated with purple.

FALCO, in ornithology, a genus of birds, of the order of the accipitres, with three toes always before, and only one behind. This genus comprehends the falcon-kind, properly fo called, the hawk, gyrfalcon, eagle, buzzard, pygargus, lanner, kite, keutil, &c. See FALCON, HAWK, &c.

FALCON, or Gentle FALCON, the yellow-legged falco, with a grey body spotted with brown, and with five or fix broad and black facies or waves on the tail. It is a very beautiful bird, and though very bold and voracious, is easily made tame and tractable.

Mr. Edwards has defcribed two falcons brought from Hudfon's Bay, both about the bigness of the common crow. One
of these is brown on the upper part of the body, and the under part is whitish, variegated with crescent-like spots of a dark colour. The other is of a black, or very dark dulky colour, on the upper part of the body; the ridge of the wing, in the upper part, is white, and the whole under side is of a dirty clay colour, with black spots at the ends of the feathers. See plate XCVI. fig. 1., which represents the first of these.

In the choice of a falcon, take one that has wide nostrils, high and large eyelids, a large black eye, a round head, somewhat full on the top; barb feathers under the clap of the beak, which should be short, thick, and of an azure colour; the breast large, round, and fleasy; and the thighs, legs, and feet large and strong, with the tear of the foot and bluish: the pounces should be black, with wings long and crossing the train, which should be short and very pliable.

FALCON, in gunnery, a piece of cannon. See the article CANNON.

FALCONER, one who tames, manages, and looks after falcons, or other hawks. See the next article.

A falconer should be well acquainted with the quality and mettle of his hawks, that he may know which of them to fly early, and which late. Every night, after flying, he should give them casting; one while plumage, sometimes pellets of cotton, and at another time physic, as he finds necessary. He ought also every evening to make the place clean under the perch, that by her casting he may know whether she wants scouring upwards or downwards. Nor must he forget to water his hawk every evening, except such days wherein she has bathed; after which, at night, she should be put into a warm room, having a candle burning by her, where she is to sit unhooded, if she be not rammage, that she may prune and pick herself.

A falconer should always carry mummy, and other medicines, into the field where a hawk frequently meets with accidents. Neither must he forget to take with him any of his hawking implements; and it is necessary he should be skilful in making lures, hooded of all sorts, jeffes, bewets, and other furniture. Neither ought he to be without his coping-irons, to cope his hawk’s beak when overgrown, and to cut her pounces and talons as there shall be occasion; nor should his cautling-irons be wanting.

FALCONRY, the art of training all manner of hawks, but more especially the larger sort, called falcons, to the exercise of hawking. See HAWKING.

When a falcon is taken, she must be fed in such a manner, that as the feeling slackens, she may see what provision lies before her; but care ought to be taken, not to feel her too hard. A falcon or hawk newly taken, should have all new furniture, as new jeffes of good leather, mailed leathes with buttons at the end, and new bewets. There should also be provided a small round stick, to stroke the hawk; because the oftener this is done, the sooner and better will she be manged. She must also have two good bells, that she may be found when she scatters; her hood should be well fashioned, raised and banded against her eyes, deep, and yet strait enough beneath, that it may fasten about her head without hurting her; and her beak and talons must be a little coped, but not so near as to make them bleed.

If it be a soar-falcon, which hath already passed the seas, she will indeed be harder to reclaim, but will prove the best of falcons. Her food must be good and warm, and given her twice or thrice a day, till she be full gorged: the best for this purpose is pigeons, larks, or other live birds; because the must be broken off by degrees from her accustomed feeding. When she is fed, you must hoop and lure, as you do when you call a hawk, that she may know when you intend to give her meat. On this occasion the must be unhooded gently, and after giving her two or three bits, her hood must be put on again, when the is to get two or three bits more. Care must be taken that she be close seeled, and after three or four days, her diet may be livened; the falconer letting her every night to perch by him, that he may awake her often in the night. In this manner he must proceed, till he find her to grow tame and gentle; and when he begins to feed eagerly, he may give her a sheep’s heart. He may now begin to unhood her in the day-time, but it must be far from company, first giving her a bit or two, then hooding her gently, and giving her as much more. When she is sharp let, he may now unhood her, and give her some meat just against his face and eyes, which will make her lets a raid of the countenances of others. She must be borne continually on the fift, till she is properly
properly manned, causing her to feed in company, giving her in the morning, about fun rie, the wing of a pullet; and, in the evening, the foot of a hare or coney, cut off above the joint, head and laid in water, which being squeezed, is to be given her with the pinion of a hen's wing. For two or three days give her wafted meat, and then plume in more or less quantity, as she is thought to be more or less foul within. After this, being hooded again, she is to get nothing till she has gleamed and caft, when a little hot meat may be given her in company; and, towards evening, she when you intend with her, give her a little reaching of meat on both sides and give her a bit or two. Then unwind the creance, and draw it after she is grown familiar to this way, let somebody on foot hold the hawk, and he on horeback must call and caft the lure about his head, the holder taking off the hood by the taffel; and if she seize eagerly on the lure without fear of man or horse, then take off the creance, and lure her at a greater distance. And if you would have her love dogs as well as the lure, dike dogs when you give her her living or plumage. See the article HAWKING.

FALDAGE, an antient privilege referred to lords, of letting up folds for sheep in any fields within their manors, for the better manurance of the same; and this, in former times, was usually done as well with their tenants sheep, as with their own.

FALDFEY, or FALDFEE, a rent or fee paid by some customary tenants, for liberty to fold their sheep on their own lands.

FALKIRK, a town of Scotland: well long, 5° 48', north lat., 56° 20'.

FALL, the descent of a heavy body towards the center of the earth. See the articles DESCENT, GRAVITY, ACCELERATION, &c.

FALLS is also the name of a measure of length used in Scotland, and containing six ells of that country. See MEASURE and ELL.

FALL, in the sea-language, that part of the rope of a tackle, which is hauled upon.

Also when a ship is under sail, and keeps not to near the wind as she should do, they say the falls off; or when a ship is not flush, but has risings of some parts of her decks more than others, it is called falls.

FALLACY, a deception, fraud, or false appearance.

The epicureans deny that there is any such thing as a fallacy of the senses: for according to them, all our sensations and perceptions, both of sense and phantasy, are
are true: whence they make sense the primary criterion of truth. See the article Evidence.

The cartellans, on the other hand, maintain, that we should suspect as false, or, at most, dubious, every thing that present themselves to us by means only of our external senses, because they do frequently deceive us. They add, that our senses, as being fallacious, were never given us by nature for the discovery of truth, or the contemplation of the principles of things, but only for pointing out to us what things are convenient or hurtful to our bodies. See Existence.

The peripatetics keep a middle course: they lay, that if a tenible object be taken in its common or generical view, the senfe cannot be deceived about it; but that if the object be taken under its specific view, the senfe may be mistaken about it, from the want of the dispositions necessary to a just sensation, as a disorder in the organ, or any thing uncommon in the medium: thus in some disorders of the eye, all objects appear yellow; a fick in water appears broken or crooked, &c.

Fallacy, or sophistical Fallacy, in logic, a captious argument, which, on account of its apparent goodness and defect, is made use of to deceive a respondent not well versed in the art of sophistry. See the article Sophism.

Fallacies either arise from words or things. The foundation of all fallacy in words, is an ambiguity; but that of fallacy in things, is very numerous.

Falling-sickness, the same with epilepsy. See the article Epilepsy.

Fallopiian tubes, two canals of a tortuous figure, but approaching to a conic form, joined to the fundus of the uterus, one on each fide.

They are connected closely and continuously to the uterus, and more laxly to the ovaries by the alæ vespertilionem, and finally to the offa ilei, by the ligamenta lata: their length is different, fix, feven, or eight fingers breadth, and sometimes more: their thickness about the middle is equal to that of one's little finger; their extremities are smaller, that next the uterus is very small; it opens into its cavity, and may be inflat ed by blowing into the uterus: or a small style may be thrust up into it: their small extremity is connected to the uterus, the other is free, and fluctuates about the abdomen: this is larger and is fimbriated, or fringed round the edges; and when there is occasi on, this extremity applies itself to the ovary, embracing it with those muscular segments or fringes.

Their substan ce is membranaceous and cavernous: they are composed of a double membrane, the exterior one seem to be continuous with the peritoneum, and the interior with the interior membrane of the uterus. They are wrinkled on the inner surface, and are imbued with a lubricous humour; but they are not cellulous in the human body as in beasts. They are furnished with a great number of vessels, and have a cavernous subfance between their membranes, by means of which they are rendered rigid in applying their mouths to the ovary. They are also moistened on their inner surface by these vessels.

Their use in generation is very great; they become erect in the time of the coitus, from the influx of the blood and spirits, and at that time, by a natural motion, they apply their loose fringed extremities to the ovaries, which are surrounded and imbraced by them. In this state they convey to them the prolific matter of the male semen injected into the womb: and after one of the ovula is impregnated, they receive and convey it to the womb. The fallopian tubes are easily discovered in hens and other birds, and are called oviducts. See Oviduct.

See a representation of one of them in plate XCVII. fig. 1.

Fallow, a pale red colour, like that of brick half burnt: such is that of a fallow-deer. See the article Deer.

Fallow-field, or Fallow-ground, land laid up, or that has lain untilled for a considerable time.

Fallow-finch, or Fallow-smich, a bird otherwise called oenanthe. See the article Oenanthe.

Fallowing of land, a particular method of improving land.

The great benefit of fallowing, appears by the common practice of landlords, who every where take care to oblige their tenants to a strict observance of it once in three years; few lands being able to bear two crops without it.

It appears that none will find a year's fallowing a loss to them, let their land be what it will; but, more particularly, the advantage of fallowing consists in, first, its laying of the land in ridges, and its exop ing it to the frost, wind, sun and dews, all which sweeten and mellow the land very much; the often flipping of it,
and breaking the clots, disperse it for the bearing of good crops. Secondly, it kills the weeds, by turning up the roots to the sun and air; and kills not only the weeds that grew with the last corn, but wild oats, darnel, and other weeds that sow themselves, and that as soon as they begin to peep out of the ground; so that they have no time to hack out any of the heart of the land.

The way of ordering fallow-lands is, after the crop is off, to let the land lie all understanding representing a thing other-giving in many places, ought to be very rare. The crimen falsi, in the civil law, is fraudulent subornation or concealment with design to darken or hide the truth, and make things appear otherwise than they are. The crimen falsi is committed, 1. By words, as when a witness swears falsely. 2. By writing, as when a man antedates a contract, or the like. 3. By deed, as when he sells by false weights and measures.

The falsifying a record, is where a person purchases land of another, who is afterwards outlawed for felony; in this case, he may falsify the record as to the time when the felony is supposed to have been committed, and also as to the point of the offence. But in the case where a person is found guilty by verdict, such purchaser shall only falsify the time.

To falsify a recovery, may be done by the issue in tail, where it is suffered by a tenant for life.

False judicium. See the article False Judgment.

False return breviurn, a writ that lies against a sheriff for false returning of writs he had got to execute.

False bordone, in music, denotes the burden or ground bass of a song when it is not exact to the rules of harmony. It is also applied by the Italians to a certain harmony produced by the accompaniments of several sixths following one another, which make several fourths between two higher parts, because the third part is obliged to make tierces with the bas.

Falx, in anatomy, a process of the dura mater placed between the two hemispheres of the brain, and resembling a reaper's sickle.

FALX, in ichthyology, a species of tænia, so called from its bending itself into the form of a sickle. See the article Tænia.
FAMAGOUSTA, a city of Asiatic Turkey, situated on the east end of the island of Cyprus.

FAMOUS CANNA, an excefsive appetite. See the article BULIMY.

FAMILIARS of the inquisition, are people that affift in the apprehending of such persons as are accused, and to carry them to prison; upon which occasion, the unhappy person is surrounded by such a number of these officious gentlemen, that there is no possibility of escaping out of their hands. As a reward of this base employ, the familiars are allowed to fituated on the east end of the island of

FAMILY, family, families.

FAN is employ, the familiars are allowed to

fituated on the east end of the island of

mit the most

their hands. As a

there is no

to

happy

persons as are accused, and to carry them

bauch, affafinate, and kill, with

impunity. See the article INQUISITION.

FAMILY, familia, denotes the persons that live together in one house, under the direction of one head or chief manager. It also signifies the kindred or lineage of a person, and is used by old writers for a hide or portion of land sufficient to maintain one family. See the article HIDE.

FAMILY, in natural history, a term used by authors to express any order of animals, or other natural productions of the same class. See CLASS and ORDER.

FAMILY of curves. See CURVE.

FAN, a machine used to raise wind and cool the air by agitating it. The custom which now prevails of wearing fans, was borrowed from the East, where they are almost indispensably necessary for keeping off the sun and the flies. Fans are made of a thin skin or piece of paper, taffaty, or other light stuff, cut semi-circularly, and mounted on several little sticks of wood, ivory, tortoise-shell, or the like. The paper, &c. is usually painted, and in mounting is plaited in such a manner, as that the plaits may be alternately inward and outward. That this machine was known to the antients, we may infer from what Terence says, cape boc flabellum, & ventulum buic sic facito. It was composed of different materials, but the most elegant were made of peacocks feathers, or perhaps were fo painted as to represent a peacock's tail.

FAN is also an instrument used in winnowing corn.

Fans for corn pay on importation 15. 3 40 d.

and draw back on exportation, 13. 1 63 d.

India fans pay for every 100 l. gros value

at the sale 26 l. 14 s. 2 2 d. The draw-

back on exportation is 25 l. 25 s. 5 1 2 d. 

100

FANANO, a town of Italy, twenty-five miles south of Modena.

FANATICS, wild, enthuhaftic, visionary persons, who pretend to revelation and inspiration.

The antients called those fanatici who passed their time in temples (fana) and being often seized with a kind of enthu- saism, as if inspired by the divinity, threwed wild and antic gestures. Prudentius represents them as cutting and flashing their arms with knives; shaking the head was also common among the fanatici; for Lampridius informs us, that the emperor Heliogabalus was arrived to that pitch of madness, as to shake his head with the gaited fanatices. Hence the word was applied amongst us to the anabap-tists, quakers, &c. at their first rile, and is now an epithet given to the modern prophets, muggletonians, &c.

FANATIO, a term used for the fawning feaon in forests.

FANCY, or IMAGINATION. See the article IMAGINATION.

FANIONS, in the military art, small flags carried along with the baggage.

FANO, a bishop's fee and port-town of Italy, situated on the gulf of Venice, in 14° east long. and 44° north lat.

FANTASIA, in music, the fame with caprice. See the article CAPRICE.

FANUM, TEMPLE. See TEMPLE.

FAPESIO, a form of syllogism, wherein the major or first proposition is an universal affirmative, the minor an universal negative, and the conclusion a particular negative.

FAQUIR, or FAKIR. See FAKIR.

FAR, in horsemanship, an appellation given to any part of a horse's right side; thus the far foot, far shoulder, &c. is the same with the right foot, right shoulder, &c.

FARCE, was originally a droll or petty shew exhibited by mountebanks and their buffoons in the open streets, to gather the people together. At present it is of more dignity: it is removed from the street to the theatre, and instead of being performed by merry-andrews to amuse the rabble, is acted by comedians, and become the entertainment of a polite audience. Poets have reformed the wildness of the primitive farces, and brought them to the taste and manner of comedy. The difference between the two on our stage is, that comedy keeps to nature and probability, and therefore is confined to certain laws prescribed by ancient critics, whereas
whereas farce disallows of all laws, or rather lets them aside on occasion. Its end is purely to make merry, and it flicks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is usually low, the persons of inferior rank, the fable or action trivial or ridiculous, and nature and truth every where heightened and exaggerated.

FAREWELL, the most loutishly promontory of Greenland, in 50° west long. and 60° north lat.

FARM, or FARM, signifies the chief meal or flour.

FARMHAM, a market-town of Hampshire, ten miles east of Southampton.

FARING-DEAL, the fourth part of an acre of land. See the article ACRE.

FAREHAM, a market-town of Hampshire, twenty-five miles north-west of Reading.

FARLEY, or FARLEY, signifies the chief meal or flour, which is used for a voyage, or passage by water; but, in London, it is what petitions pay for being conveyed from one part of the town to another in a coach or chair. See the articles COACH, WATERMEN, &c.

FARO, most commonly signifies the money paid for a voyage, or passage by water; but, in London, it is what petitions pay for being conveyed from one part of the town to another in a coach or chair. See the articles COACH, WATERMEN, &c.

FARINA FOECUNDANS, signifies the proper addition of a farm to his family to live on.

FARLIEU, money paid by tenants in the west of England, in lieu of a heriot. See the article HERIOT.

FARM, or FARM, signifies the chief meal or flour, which belongs to the landlord, another for the charges of cultivating it, and the third for the farmer and his family to live on.

In different parts of the country, a farm is called by different appellations: in Lancashire, it is termed farm-hold; in Essex, a wicke; and in the north, a tark. According to some, a farm should make three rents, or its produce shoul amount to three times the rent, one for the landlord, another for the charges of cultivating it, and the third for the farmer and his family to live on.

FARMER, the person who occupies or is lessee of a farm, whether for life or years. See the articles FARM and LEASE.

FARMER, among miners, signifies the lord of the field, or the person who farms the lot and cope of the king.

FARNHAM, a market-town in the county of Surry, ten miles west of Guilford, remarkable for its large plantations of hops.
FASCIA, FASCES, FASCE, FARS, F.
FARRIER'S POUCH, FARRIER, FARREATION, or FARRA, in ichthyology, ASCETS, and but a small member having a an architrave, in order to convey them the only give terwar.

decemviri, it was the only authority: in after times they after the hch carried by the badge of governors. The article FE feme with ward of the gulph of the leaft that has a leather-bag, in which the antient albula nobilis. See ALBULA.

FARO, a sea-port to vn of Portugal, in the province of Algarve: we long; 9°, north lat. 36° 56'.

FARRA, in ichthyology, the same with the albula nobilis. See ALBULA.

FARREATION, or CONFARREATION, in antiquity. See CONFARREATION.

FARRIER, one whole employment is to shoe horses, and cure them when diseased or lame.

FARRIER'S POUCH, a leather-bag, in which are contained nippers, drivers, shoes for all sizes of feet, good sharp nails, and all the implements for new shoeing a horse that has lost his shoe upon the road.

A gentleman on a journey ought to have one of these pouches well provided, and a groom that knows how to drive nails.

FARRIERY, the art of trimming the feet, and curing diseased horses. See HORSE.

FARS, or FARSISTAN, the antient Peris, being a province of Persia lying northward of the gulph of Persia. Its chief town is Schiras.

FARTHELLING, among seamen, the name with furling. See FURLING.

FARTHING, the least copper-coin used in Britain, being half of the half-penny. See the article COIN.

FASCE, or FESSE, in heraldry. See the article FESSE.

FASCIÉ, in anatomy, called also musculus membranous, is a muscle of the tibia or leg, arising flieby from the anterior part of the anterior and superior spine of the ileum. Soon after its origin it becomes entirely membranaceous, and closely surrounds the muscles of the thigh; after which it is inserted in the upper part of the tibia, near the head of the fibula, and from thence sends out an aponoeurosis almost over the whole tibia.

The fascia lata serves to draw back the thigh, and to elevate both this and the leg; it is therefore, as well as some other of the adjacent muscles, common to both the thigh and the leg.

FASCIAE, in astronomy, certain parts on jupiter's body resembling belts or swaths. They are more lucid than the rest of that planet, and are terminated by p rafel lines, sometimes broader and sometimes narrower. Mr. Huygens observed a fascia in mars much broader than those of jupiter, and poftefing the middle part of his disk, but very obscure.

FASCIALIS, in anatomy, a muscle of the leg called alfo sartorius. See the article SARTORIUS.

FASICULUS, in medicine, denotes a handful, or according to some, as much as can be taken up between the finger and the thumb.

FASCINATION, a kind of witchcraft or enchantment fuppoled to operate by the influence either of the eye or tongue. To the firfl kind of fascination, Virgil alludes in his third eclogue, nejica quis teneros oculus mibi fascinan agnos. To the fecond, in his leventh eclogue, in these lines. Aut, fi ultra placitum landarit, baccare frontem

Cingite, ne vati nocet malo lingua futuro.

FASCINES, in fortification, faggots of small wood of about a foot diameter and fix feet long, bound in the middle and at both ends. They are used in rafing batteries, making chandelers, in filling up the moat to facilitate the passage to the wall, in binding the ramparts where the earth is bad, and in making parapets of trenches to screen the men.

Fascines
FAST-DAYS, those appointed, by public authority, to be observed in fasting and humiliation.

FAST-GROUND, or FAST-COUNTRY, among miners, denotes the same with shelf. See the article SHELF.

FASTERMANS, among our saxon ancestors, were pledges or bondmen, who were answerable for each others good behaviour.

FAST, in roman antiquity, the calendar wherein were expressed the several days of the year, with their feasts, games, and other ceremonies.

There were two sorts of fast, the greater and les; the former being distinguished by the appellation fafti magiftrales, and the latter by that of fafti calendares.

The greater fasti contained the feasts, with every thing relating to religion and the magiftrales.

The lesser were again distinguished into the city and country faft, each adapted to the people for whom they were designed. In all these fasti, the court-days, or those whereon caufes might be heard and determined, were marked with the letter F; these days were called fafti, from fari, to speak or pronounce; and the other days, not marked with this letter, were called nefatti.

FASTI CONSULARI, was also a tablet or chronicle, wherein the several years were denoted by the respective confuls, with the principal events that happened during their confulship. And hence, the term fasti is still applied to the archives and public registers of a nation.

FASTIGIUM, in architecture, the same with pediment. See PEDIMENT.

FAST, in anatomy, an oleaginous or butyraceous matter, secreted from the blood, and filling up the cavity of the adipose cells. Fat, properly and distinctly so called, is not secreted from glands, but from the little arteries of the adipose membrane. Authors distinguish it into two kinds, which they express by the words seum and pinguedo. See the articles SEVUM and PINGUEDO.

According to this distinction, there is no such thing as seum or hard fat in the human body, its fat being all of that fort expressed by pinguedo, or soft and oily. That this oleaginous matter has a circulatory motion, or an egress into the veins, is very evident from the sudden consumption of it in many diseases, and from its vast diminution by exercise or labour.
The uses of fat are, 1. To serve as a kind of covering to the body, in order to defend it from cold and other injuries. 2. To defend the more tender and sensible parts from being too strongly vellicated by the salts. 3. To preserve in good order the flexion of the muscles, of the cutis, and of the other parts between and about which it is placed. 4. To facilitate the motions of some parts, as the eyes, jaws, &c. 5. To fill up a number of empty interstitial spaces, and by that means to add greatly to the symmetry and beauty of the parts; as is evidently the case in the face, the neck, and to facilitate the distention of the parts, the spaces between which it thus fills up. There is evidently a great use of the fat about the vagina, the anus, the olla ichii, and pudenda; which filling up many large spaces there, gives way greatly in the distension of those parts in the exclusion of the faeces, and even of the harder excrements. 6. To prevent the painful presssure and attrition of the parts, particularly in the soles of the feet, the nates, and other the like parts; in all which the fat is copiously disposed, and serves in the place of a cushion for the muscular flesh to rest upon. 7. And, finally, there is great reason to suppose, that when the body does not receive nourishment in the usual way, the regres of the fat into the veins supplies that defect.

The fat of several animals, as a goose, dog, viper, bear, and even that of mankind, are met with prescribed in the intention of suppuratives and digestives; for being of a penetrating nature, they are supposed to dissolve and rarify the inclosed humours, and bring them to what is called maturity. See Suppuratives and Ripeners.

The best way of preparing fat for medicinal use, is to free it from skins, veins, fibres, &c. and after washing it till it becomes unbloody, to melt, strain, and preserve it from air.

Fat, in the sea-language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the truffling in or tuck of her quarter be deep.

Fat is also used for several utensils, as, 1. A great wooden vessel, used for the measuring of malt, and containing a quarter or eight bushels. 2. A large brewing-vessel, used by brewers to run their wort in. 3. A leaden pan or vessel for the making of salt at Droitwich.

Fat likewise denotes an uncertain measure of capacity. Thus a fat of tingleh contains from 3½ hundred weight to 4 hundred weight; a fat of unbound books, half a maund or four bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

Fate, fatum, denotes an inevitable necessity depending upon a superior cause. The Greeks called it συμφατον, as it were a chain or necessary series of things indissolubly linked together. It is also used to express a certain unavoidable designation of things, by which all agents, both necessary and voluntary, are swayed and directed to their ends. See the article Necessity.

In this last sense, fate is distinguished into, 1. Astrological, arising from the influence and position of the heavenly bodies, which (it is supposed) give laws both to the elements and mixed bodies, and to the will of men. 2. Stoical fate, defined by Cicero an order or series of causes, wherein cause being linked to cause, each produces another, and thus all things flow from one prime cause. To this fate, the Stoics subject even the gods.

Fate is divided by later authors into physical and divine. Physical fate, is an order and series of natural causes appropriated to their effects. By this fate it is that fire warms, bodies communicate motion to each other, &c. and the effects of it are all the events and phenomena of nature. See Nature.

Divine fate, is what is more usually called providence. See Providence.

Fates, parce, in mythology. See the article Parcae.

Father, a term of relation denoting a person who hath begot a child. By the laws of Romulus, a father had an unlimited power over his children. Amongst the Lacedæmonians, as we learn in Aristotle's politics, the father of three children was excused from the duty of mounting guard for the security of the city; and a father of four children, was exempted from every public burden. The poppean law amongst the Romans, granted many noble privileges to the fathers of three children, amongst which one was, that he should be excused from civil offices, and that the mother should have liberty, in her father's life-time, to make a will, and manage her estate without the authority of tutors.

Natural Father, is he who has illegitimate children.
FAV
[1200]

FAU

FATHER IN LAW, is a person who has
married a woman, who has children by
a former marriage.

GRAND-FATHER. See GRAND-FATHER.

FATHER, in theology, is used in speaking
of the first person of the trinity. See the
article TRINITY.

FATHER is also used in speaking of spiritual
and moral things. Thus, Abraham is
called the father of the faithful.

FATHER in church-history, is applied to
antient authors who have preserved in
their writings the tradition of the church.
Thus St. Chrysoldom, S. Basil, &c. are
called Greek fathers, and St. Augustine
and St. Ambrose Latin fathers. No au-
thor who wrote later than the twelfth
century is dignified with the title of
FATHER.

FATHER is also a title of honour given to
prelates and dignitaries of the church, to
the superiors of convents, to congrega-
tions of ecclesiastics, and to persons
venerable for their age or quality. Thus
we say the right reverend father in
God, the father general of the bene-
diction, the fathers of the council of
Nice, father of his country, &c.

FATHER-LASHER, a name given by the
people of Cornwall to a fish of the cottus-
kind, with the upper jaw longeit, and a
prickly head. See COTTUS.

FATHOM, a long measure containing
fix feet, chiefly used at sea for measur-
ing the length of cables and cordage.

FATTENING of oxen, horse, swine,
&c. See the article CORPULENCY.

FAVORITO, in music, as choro favorito,
a chorus, in which are employed the
best voices and instruments, to sing the
recitatives, play the ritornella's, &c.
this is otherwise called the little chorus,
or choro recitante. See RECITANTE.

FAVUQUEMONT, in geography. See the
article VALKENBURG.

FAUSSE-BRAYE, as such things as
are surrounded with a wet ditch,
for lying low, it cannot be
provided it
faulfe-braye, such
places surrounded with a wet ditch,
a faulfe braye is more useful, provided it
be made only before the curtin and
flanks; for lying low, it cannot be
easily hurt by the enemies cannon,
and it defends the fosse better, because of its
low situation, than the true rampart, which
on account of its height cannot so well
discover the fosse: faulfe-brayes ought
never
FAWN, among sportmen, a buck, or doe, of the first year; or the young one of the buck's breed in its first year.

FAYAL, one of the Azores-islands. See the article AZORES.

FE, or St. Fe, the capital of New Mexico: west long. 109°, north lat. 36°.

St. Fe de Bogota, the capital of the kingdom of New Granada: west long. 73°, north lat. 4°.

It is an archibishopric and the seat of the governor of the province, &c.

St. Fe is also a town of Spain, in the province of Granada, situated on the river Xemil: west lon. 3° 45', north lat. 37° 20'.

St. Fe is also the capital of a province of the same name, in Terra firma in South America, situated on the river of St. Martha, 200 miles south of Carthagena: west long. 77°, north lat. 7° 24'.

FEALTY, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land: by this oath the tenant holds in the freest manner, on account, that all who have fee, hold per fidem & fiduciam, that is, by fealty at the leaf.

This fealty, at the first creation of it, bound the tenant to fidelity, the breach of which was the loss of his fee. It has been divided into general and special: general, that which is to be performed by every subject to his prince; and special, required only of such as, in respect of their fee, are tied by oath to their lords.

To all manner of tenures, except tenancy at will, and frank-almoign, fealty is incident, though it chiefly belongs to copyhold estates, held in fee and for life. The form of this oath by Stat. 17 Ed. II. is to run as follows. "I A. B. will be to you my lord D. true and faithful, and bear to you faith for the lands and tenements which I hold of you, and I will truly do and perform the customs and services that I ought to do to you. So help me God."

FEAST, or FESTIVAL, in a religious sense, is a day of feasting and thanksgiving.

Among the antients, feasts were instituted upon various accounts, but especially in memory of some favourable interposition of providence. Thus, the Jews had their feasts of passover, pentecost, and tabernacles; the Greeks, their cerealia, panathenaea, &c. and the Romans, their saturnalia, ambarvalia, &c. See PASSOVER, CERIALIA, &c.

In the ancient Christian church, besides the high festivals of Christmas, Easter, Pentecost, Annunciation, &c. there were others instituted in honour of the apostles and martyrs: all which are retained by the church of England. See the articles CHRISTMAS, EASTER, &c.

In the church of Rome, there are double, half-double, and simple feasts almost without number. The name of double feasts is given to such whose service is fuller and more solemn than the rest, which likewise constitutes the difference between the others; the churches being embellished, and the altars adorned, according to the rank which each saint holds in his respective church. All high festivals have an octave, consisting of the feast itself, and the seven following days.

In Italy, certain festivals are celebrated solely by the lovers of that country. When a lover wants to give his mistress the highest testimony of his gallantry, he immediately makes her the idol of his devotion; procuring vespers, and even masses, to be said in her honour. For this purpose he makes choice of the festival of some saint whose name the bears; and though the saint has the same name, they manage matters so, that the devotion of the festival is plainly relative to the lover's mistress.

The four quarterly feasts, or stated times, whereon rent on leaves is usially referred to be paid, are Lady-day, or the annunciation of the blessed virgin Mary, or 25th of March; the nativity of St. John the Baptist, held on the 24th of June; the feast of St. Michael the archangel, on the 29th of September; and Christmas, or rather of St. Thomas the apostle, on the 29th of December. See the article ANNUNCIATION, &c.

FEATHER, in physiology, a general name for the covering of birds; it being common to all the animals of this class.
to have their whole body, or at least the greatest part of it, covered with feathers or plumage.
There are two sorts of feathers found on birds, viz. the strong and hard kind, called quills, found in the wings and tail; and the other plumage, or soft feathers, serving for the defence and ornament of the whole body. All birds, so far as yet known, moult the feathers of their whole body yearly.
Feathers make a considerable article of commerce, as serving for beds, writing-pens, &c. Those for beds pay, on importation, 1l. 3s. 1½d. and draw back 1l. 8s. 3d. Ostrich-feathers, if dressed, pay 7s. 8½d. the pound, but if undressed only 5s. 10½d.; drawing back in the former case, 6s. 9d. and in the latter, 3s. 4½d.
Feather-bed. See the article Bed.
Feather-beds, whether old or new, pay, on importation, each 10s. 3½d. and drawback 9s. on exporting them.
Feather, in the manège, a sort of frizzling of the hair, which in some parts rises above the rest, resembling the tip of an ear of corn. This happens most frequently, between the eyes; and if lower, it is a sign of a weak sight.
A feather upon a horse's neck, is called a roman feather; being a row of hair turned back, and forming a mark like a sword-blade near the mane.
Mid-feather, in the salt-works, the partition in the middle of the furnace, which it divides into two chambers. See the article Salt-making.
Feather-edged, among carpenters, an appellation given to planks or boards, which have one side thicker than the other.
Feather, or Cat a Feather. See Cut.
Prince's Feather, a plant otherwise called amaranth. See the article Amaranth.
Feazing, in the sea-language, signifies the ravelling out of any great rope, or cable, at the end.
Febrifuge, in medicine, an appellation given to such medicines as mitigate, or remove a fever. These medicines are otherwise termed antifebrilia. Febrifuge is also a name for the centaurium minus.
Febris, Fever, in medicine. See the article Fever.
February, in chronology, the second month of the year, reckoning from January, first added to the calendar of Romulus by Numa Pompilius.

February derived its name from Februa, a feast held by the Romans in this month, in behalf of the manes of the deceased, at which ceremony sacrifices were performed, and the last offices were paid to the shades of the defunct.
February in a common year, consists only of twenty-eight days, but in the bisesse
tile year, it has twenty-nine, on account of the intercalary day, added that year. See the article Bissextile.
Feclaies, or Poeclaeas, a college of preists instituted at Rome by Numa, consisting of twenty persons, selected out of the best families. Their business was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith. It is probable that they were ranked among the officers of religion, to procure them the more deference and authority, and to render their persons more sacred among the people. If the commonwealth had received any injury from a foreign state, they immediately dispatched their officers to demand satisfaction, who, if they could not procure it, were to advert the Gods against the people and country, and to denounce war: otherwise they confirmed the alliance, or contracted a new one, which they ratified by sacrificing a hog.
Fecula, or Fæcula, in pharmacy. See the article Fæcula.
Feculent, or Fæculent. See the article Fæculent.
Fecundity, or Foecundity, the same with fertility. See Fertility.
Fee, in law, signifies a certain allowance to physicians, barristers, attorneys, and other officers, as a reward for their pains and labour.
If a person refuse to pay an officer his due fees, the court will grant an attachment against him, to be committed till the fees are paid; and an attorney may bring an action of the case for his fees, against the client that retained him in his cause.
Fee also denotes a settled perquisite of public officers, payable by those who employ them.
The fees due to the officers of the custom-house, are expressly mentioned in a schedule, or table, which is hung up in public view in the said office, and in all other places where the said fees are to be paid or received. And, if any officer shall offend, by acting contrary to the regulations therein contained, he shall
FEE

shall forfeit his office and place, and be for ever after incapable of any office in the customs-house.

The other public offices have likewise their settled fees, for the several branches of business transacted in them.

FEE-ESTATE, that held by the benefit of another, and for which some service, rent, or acknowledgment is paid to the chief lord, or superior, in whom the mere propriety of the soil always continues.

Fee is generally divided into absolute and conditional. Absolute, otherwise termed fee-simple, is where a person is feized of lands or tenements, to him and to his heirs for ever; whereas, fee-tail, or conditional fee, is where a person is feized of lands, with a limitation to him and the heirs of his body. A fee-simple is the largest estate a person can have, and can be conveyed by no other expression, but heirs for ever; yet, in a will, which is more favoured than a grant, the intention of the testator is more considered than the literal meaning of the words.

FEE-FARM, a kind of tenure without homage, fealty, or other service, except that mentioned in the feoffment; which is usually the full rent, or at least a fourth part of it. The nature of this tenure is, that if the rent be behind, and unpaid for two years, then the feoffor and his heirs may have an action for the recovery of the lands.

FEE EXPECTANT. See EXPECTANT.

FEEDING of fish. See Fish.

FEELERS, in natural history, a name used by some for the horns of insects. See the article HORN.

FEELING, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities. This sense is the coarsest, but at the same time, the surest of all others: it is besides the most universal. We see and hear with small portions of our body, but we feel with all. Nature has bestowed that general sensation wherever there are nerves, and they are everywhere, where there is life. Were it otherwise, the parts diversified of it might be destroyed without our knowledge. It seems that upon this account nature has provided, that this sensation should not require a particular organization. The structure of the nervous papillae is not absolutely necessary to it. The lips of a fresh wound, the periosteum, and the tendons, when uncovered, are extremely sensible without them. These nervous extremities serve only to the perfection of feeling, and to diversify sensation.

Feeling is the basis of all other sensations. All the nervous solids, while animated by their fluids, have this general sensation; but the papillae in the skin, those of the fingers in particular, have it in a more exquisite degree, so perfectly, that they convey some notice of the figure of the bodies which they touch.

The object of feeling is every body that has consistency or solidity enough to move the surface of our skin. It was necessary to perfect feeling, that the nerves should form small eminences, because they are more easily moved by the impression of bodies, than an uniform surface. It is, by means of this structure, that we are enabled to distinguish not only the size and figure of bodies, their hardness and softness, but also their heat and cold.

Feeling is so useful a sensation, that it supplies the office of the eyes, and in some fenses indemnifies us for their loss.

FEELING a horse, in the manage, is of two sorts: 1. To feel a horse in the hand, is to observe, that the horse be under subjection, by obeying the bit. 2. To feel a horse upon the haunches, is to observe, that he plies or bends them.

FEINT, in music, the fame with diefe. See the article DISSIS.

FEINT, in fencing, a shew of making a thrust at one part, in order to deceive the enemy, that you may really strike him in another. A simple feint is a mere motion of the wrist, without stirring the foot.

FELAPTON, in logic, one of the six moods of the third figure of syllogisms, wherein the first proposition is an universal negative, the second an universal affirmative, and the third a particular negative.

FELIN, a town of Livonia, about an hundred miles north east of Riga.

FELIS, in zoology, is used by Linnæus, as the name of a large genus of quadrupeds, of the order of the fere; the characters of which are these: the fore-teeth are small, obtuse, and equal; the tongue is furnished with prickles, all pointing backwards; and the feet are formed for climbing, with claws which may
FELLEING of timber. See Timber.

FELLOWS, in fortification, are fixe pieces of wood, each whereof form a piece of an arch of forty degrees, and joined all together, by dulleges, make an intire circle; which with the addition of a nave, and twelve spokes, make the wheel of a gun carriage. Their thicknes is usually the diameter of the ball of the gun they serve for, and their breadth something more.

FELLOWSHIP, or Company, in arithmetic, is when two or more join their flocks, and trade together, dividing their gain, or loss, proportionably. Fellowship is either with or without time. Questions without time, or in the single rule of fellowship, as it is frequently called, are wrought by the following proportion.

As the whole flock to the whole gain or loss, so is each man's particular flock to his particular share of gain or loss.

Example I. A, B, and C make a joint flock: A puts in 4601. B 5101. and C 4801. they gain 3401. what part of it belongs to each?

In order to the solution of this question, find the total of their joint flock, viz. A's flock 4601. + B's flock 5101. + C's flock 4801. = 14501. the total flock.

Then 1. To find A's share of the gain, state as follows: If 14501. : 3401. :: 4601. which being worked by the rule of three, the answer will be 1791. 175. 24d. for A's share of the profit.

2. B's share of the gain, by facting thus, if 14501. : 3401. :: 5101. and working by the rule of three, will be found to be 1191. 115. 83d.

3. C's share will appear 1121. 11s. 62d. when worked as before, after having facted thus. If 14501. : 3401. :: 4801.

Ex. II. Suppofe three partners, A, B, and C make a joint flock in this manner: A puts in 24l. B 32l. and C 40l. in all 96l. with which they trade, and gain 12l.

required each man's true share of that gain? The first operation for A's part of the gain will stand thus,

96l. : 12l. : 12l. : 3l. = A's gain.
96l. : 12l. : 32l. : 4l. = B's gain.
96l. : 12l. : 40l. : 5l. = C's gain.

Proof 3l. + 4l. + 5l. = 12l. the whole gain. That is, if the total of all their particular gains amounts to the whole gain, the work is true; if not, some mistake has been committed.

FELLOWSHIP with time, usually called the Double Rule of Fellowship, because every man's money is to be considered with relation to the time of its continuance in the joint flock. It is worked thus, multiply each man's flock by the respective time he puts it in for, and add all the products; the total of which must be your first number thro' all the flatings: the gain or loss the second, as before; and each man's particular flock, multiplied by its time, the third.

Note, all the particular times (if not so given) must be reduced into one denomination, i.e. all years, all months, all weeks, or all days; &c. See REDUCTION.

Ex. 1. A put into company 5601. for eight months, B 2791. for ten months, and C 731. for six months; they gained 1001. What share of it must each have?

For the solution of this question, proceed as follows. A's flock 5601. × 8 its time = 4480, B's flock 2791. × 10 its time = 2790, C's flock 731. × 6 its time = 4410. Then 4480 + 2790 + 4410 = 11680. Now, 1. To find A's share of the profit, state as follows. If 11680l. : 1000l. :: 4480l. which being worked by the rule of three, the answer will be 3831. 115. 24d. for A's share of the gain.

2. For finding B's share, state thus, if 11680l. : 1000l. :: 2790l. and working as before directed, the answer will be 2381. 175. 43d.

3. To find C's proportion of the gain, say, if 11680l. : 1000l. :: 4410l. then working it by the rule of three, the true amount of his share will appear to be 1771. 115. 43d.

Ex. II. Three merchants, A, B, and C, enter into partnership thus: A puts into the flock 65l. for eight months; B puts in 78l. for twelve months; and C puts in 84l. for six months. With this joint flock they traffic, and gain 1661. 12s. 'Tis required to find each man's share of the gain proportional to his flock and time of employing it.
WORT, wool and hair. Those of French make.

Then, and whether by hanging, drowning, stabbing, riving all its

FELON, FELONY, felony, of which infants, without either spinning or weaving.

It is a species of felony, of which idiots, lunatics, and persons
diseased, and favourable interpretation, that it is im-

The whole gain = 1661. 12s.

FELT, in commerce, a sort of stuff, deriving all its confidence merely from be-
ing full, or wrought with lees and size, without either spinning or weaving.

Felt is made either of wool alone, or of wool and hair. Thole of French make, 3½ yards long, and 1½ broad, for cloaks, pay each 2l. 14s. 1½d. on importa-
tion, and draw back 1l. 12s. 3d. on exporting them again.

FELTRI, a town of Italy, subject to Venice, thirty-five miles north of Padua.

FELUCCA, in sea-affairs, a little vessel with six oars, frequent in the Medi-

terranean, which has this peculiarity, that its helm may be applied either in the head or stern, as occasion requires.

FEMALE, femina, a term peculiar to animals, signifying that sex which con-

ceives and generates its young within it-

self. See Sex and Generation.

Females differ in many respects, besides sex, from males: in most quadrupeds they are smaller and weaker; but, in birds of prey, the reverse of this generally holds. See the article MALE.

FEMALE is also applied, figuratively, to things without life, from the resemblance they bear to the females of animals: thus we say, a female screw, female flower, etc. See SCREW, FLOWER, etc.

FEMME COVERT, in law, a married woman. See the article COVERTURE.

FEMME SOLE, an unmarried woman, whose debts, contracted before marriage, be-

come thes of her husband after it. A femme sole merchant, is where a wo-

man, in London, uses a trade alone, without her husband, on which account she shall be charged without him.

FEMININE, or FOEMININE, in gram-

mar, one of the genders of nouns. See the article GENDER.

The feminine gender serves to intimate that the noun belongs to the female. In Latin, the feminine gender is most com-

monly
monly distinguished by the article hæc, as it is in the greek by the article το. In the French the article la commonly denotes this gender; but we have no such distinction by articles in the English language.

FEMUR, os femoris, in anatomy, the thigh-bone.

This is the longest and strongest bone in the whole human frame. In its upper extremity is to be observed a very large head, and in this head a cavity defined for the ligamentum rotundum, by means of which it is fixed in the acetabulum, and itsluxation upwards prevented. To its neck is affixed a robust annular ligament, which contains the head and neck of the bone as it were in a case; it is observable, that the progress of this neck is not straight but oblique, nearly horizontal, and turning somewhat outward, being the contrivance of nature for keeping the thighs atunder, by which means we tread the firmer; and, by this situation of the neck of this bone also, several muscles have a much more commodious insertion than could otherwise have been possible.

Next, may be remarked the spongy cavernous structure of this extremity of the bone, by reason of which it is less liable to fractures, especially in this part: the apertures for the ingress of several vessels are also observable; and there are two apophyses, called trochanters, which serve for the insertion of the muscles of the thigh, and which, together with the head, become, before puberty, distinct epiphyses. In the lower extremity of the femur we observer two heads, with a cavity between them, for the articulation with the tibia; also a posterior cavity intended to give safe passage to the vessels of the tibia: there is, besides, an interior cavity, for the placing of the patella; and lastly, two condyles, or tubercles, placed near the heads, and serving for a fixed point to the origin of the muscles, which are to move the foot. In the exterior part of these we observe a peculiar depression, and often a single feamaide bone; and sometimes there is also found another of these in the other tubercle: this usually, however, happens in old subjects. The whole extremity of the femur, is seen, quite to the age of puberty, a perfectly distinct epiphysis. In the body of the thigh-bone it is remarked that the anterior surface is convex, but the posterior somewhat concave: the obliquity of this part of the body is singular: its spine is remarkable, as is also its great cavity for containing the marrow. The strength and firmness of this bone are surprizingly great; hence the use of the thigh-bone is to support and sustain the weight of the whole body, and its moveable articulation at the head gives way to the easy motion of the body, while the feet are unmoved.

FEN, a place overflowed with water, or abounding with bogs. See the articles Bog and Draining.

Fens are either made up of a congeries of bogs, or confist of a multitude of pools or lakes with dry spots of land intermixed, like so many little islands.

Several statutes have been made for the draining of fens, chiefly in Kent, Cambridgeshire, Bedfordshire, and Lincolnshire; and by a late act, 11 Geo. II. commissioners shall be appointed for the effectually draining and preferring of the fens in the isle of Ely, who are authorized to make drains, dams, and proper works thereon; and they may charge the landholders therein with a yearly acre-tax, and in default of payment fell the defaulter's lands.

FENCE, in country-affairs, a hedge, wall, ditch, bank, or other inclosure, made around gardens, woods, corn-fields, &c. The chief reason why woodlands and plantations so seldom prosper, is in a great measure owing to the neglect of fencing them round, to keep out the cattle. This neglect prevails much in the northern parts of this island, though the use of fenses is certainly more necessary there than in the south, as the lands require more shelter and warmth. There are several ways of fencing lands, but the usual is that of hedging it with either white or black thorn, crab, holly, alder, or furze, &c. See Hedge.

But the best, and probably the cheapest, considering the duration and goodness of it, where flat fones are not to be had, is, in a grassy place, to dig turf, a spit or near a spit deep, the breadth of your spade, and about four or five inches thick: lay these turf with the grass outward, even by a line on one side, and on the backside of these lay another row of turf, leaving a foot space of solid ground on the outside, to prevent the bank from slipping in, if the ground should any way be faulty: on the outside of which you may make a ditch of what breadth or depth you please; or you may lower the ground on each side with a small slope, two feet deep, by which means you will have no loss of pasture by the fence, because it will bear grass on both sides. Then, with the
the earth that comes out of the ditches or floped places, fill the middle of the bank level with the turf on each side, and then lay two more rows of turf upon the first, and then fill it again as before: this do, till your bank be four feet high, or of what height you please; only your foundation must be always broader the higher you raise it. You must observe on each side to give a small slope to the bank, so as to make the top about three feet wide, upon which plant quick, making on the top a little hollow, to keep as much of tangling of words, and then fill it again as before: this do, enemy, as for defending one's self. monsennelleed and the sweetfenel-feed. In Devonshire they build two stone walls, first setting two edgeways, and then one between, and as it rises filling the interval or coffer with earth, to any height and breadth at pleasure. This is the neatest and most saving fence whatever, where they can be supplied with abundance of flatty flones. Upon these banks they not only plant quick-frets, but timber trees that thrive exceedingly. In Cornwall the husbandmen secure their woods and lands with high mounds, on which they plant acorns, to that the roots fenellra. The flapes. The fenellra rotunda leads to the cochlea, and is closed by a membrane. See the articles Ear, Stapes, Cochlea, &c.

FENESTRA, in anatomy, a term applied to two openings or foramina within the ear, distinguished by the names of the oval and the round fenestra. The fenestra ovalis leads to the vestibule on which flands the flapes. The fenestra rotunda leads to the cochlea, and is closed by a membrane. See the articles Ear, Stapes, Cochlea, &c.

FENESTRELS, a town and fort of Piedmont, fifteen miles from Turin.

FENNEL, fennelcum, in botany. See the article Foeniculum.

Here are kept two very different sorts of fennel-seeds in the shops, called the common fennel-feed and the sweet fennel-feed. The common kind is of a sharp, biting, and pungent taste; whereas the sweet kind is not only larger and more beautiful, but of a pleasant aromatic sweetish taste, with nothing of the pungency of the other. Sweet fennel-feed is accounted carminative and attenuant, and considerably diuretic and sudorific, and recommended as a specific in the measles, small-pox, and malignant fevers. It is also an ingredient in many of the offinall compositions
compositions, and in the decoctions for clysters.
Fenell-roots are of the number of the five opening ones of the shops, and prescribed in the same intentions with the seeds. They are likewise said to be great anti-nephritics.

Fenell-Flower, a plant known among botanists by the name of nigella. See the article Nigella.

Fenell-Giant, a plant also called serula. See the article Ferula.

Hog's Fenell, the English name of the peucedanum. See Peucedanum.

Sweet Fenell, in botany. See the article Finochia.

Scorching Fenell, a name given to the thapsia. See the article Thapsia.

Fenugreek, or Foenugreek. See the article Foenugreek.

Feod, feodum, the name with fee. See Fee.

Feodal and Feudatory. See the articles Feudal and Feudatory.

Feoffment, in law, is a gift or grant of any manors, meffuages, lands, or terms to another in fee, that is, to him and his heirs for ever, by delivery of seisin, and possession of the estate granted. A deed of feoffment is the most antient conveyance of lands, and is said in some measure to exceed the conveyance by fine and recovery, because it clears all disputed terms, abatements, intrusions, and other wrongful estates, which neither a fine, recovery, nor bargain and sale by deed from the seoffer destroys. A seffment however supplies the place of any, and his heirs for ever, by delivery of seisin in honour of the manes of their deceased ancestors.

Feoffment is always applied to fome corporeal and immoveable thing, and usually consists of the following parts, viz. the names and additions of the parties, the consideration, the granting part, the thing granted, the habendum or clause explaining for what estate or use it is granted, a covenant that the seoffer is freed in fee and has good right to grant, that the seoffee shall quietly enjoy the premises free from incumbrances; and, lastly, a covenant for making further assurance with a letter or power of attorney to make livery and seisin.

Feralia, in antiquity, a festival observed among the Romans, on Feb. 21, or, according to Ovid, on the 17th of that month, in honour of the manes of their deceased friends and relations. During the ceremony, which consisted in making presents at their graves, marriages were forbidden, and the temples of the divinities shut up; because they fancied that during this festival, the ghosts suffered no pain in hell, but were permitted to wander about their graves, and featt upon the meats prepared for them.

Fer de Fourchet, in heraldry, a crois having at each end a forked iron, like that formerly used by soldiers to rest their musquets on. It differs from the crois fourchete, the ends of which turn forked, whereas this has that fork fixed upon the square end. See plate XCVI. fig. 2.

Fer de Moulin, milinda, in kel de moulin, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone.

Ferdin, or Verden, a city of Germany, subject to Hanover; it is situated in lower Saxony, on the river Aller, twenty-six miles south-east of Bremen; east lon. 90, and north lat. 53° 24'.

Ferdwit, a term formerly used to denote a freedom from going forth upon any military expedition; or, according to some, the being quit of manslaughter committed in the army.

Fere, a town of Picardy, in France, forty-two miles south-east of Amiens.
Fere is also a town of Champaign, about thirty miles north of Troyes.

FERENTARIUM, in Roman antiquity, were auxiliary troops, lightly armed; their weapons being a sword, bow, arrows, and a sling.

There were another kind of Ferentarii, who carried arms after the armies, and were ready to supply the soldiers in time of battle.

FERETINO, a city and bishop's see of Italy, about fifty miles east of Rome: east lon. 1° 5', and north lat. 41° 45'.

FERETTE, a town of Alsace, subjected to France, fifty-five miles south of Strasbourg.

FERIAE, in Roman antiquity, holidays, or days upon which they abstained from work.

It was a pollution of the feriae, according to Macrobius, if the rex sacrificium or flamines saw any work done on them, and therefore they ordered proclamation to be made by the herald, that every one might abstain from work, and whoever transgressed the order, was fined. Nay, the same author informs us, that Mutius Scaevola, the pontiff, was of opinion, that the breaking the feriae was an unpardonable crime, unless it was done inadvertently, and in this case an expiation was to be made by sacrificing a hog. The Romans had two kinds of feriae:

1. The public, common to all the people in general.
2. The private, which were only kept by some private families.

The public feriae were four-fold: 1. Statio feriae, holidays which always fell out upon the same day of the month, and were marked in the calendar; of these the chief were the agonalia, carmentalia, and lupercales. See the articles Agonalia, Carmentalia, &c.

2. Conceptivae feriae, holidays appointed every year upon certain or uncertain days by the magistrates, or the pontiff; such were the laticins, paganalia, compitalia, &c. See the article Paganalia, &c.

3. Imperativae feriae, holidays commanded or appointed by the authority of the consuls or pretors; of this kind we may reckon the lecisternium. See Lectisternium.

4. Nundinæ, the days for fairs. See Nundinæ.

The private feriae were either confined to private families or particular persons, as birth-days; and those expiations upon the tenth day after a person died in a house, called feriae denicales.

FERIAE LATINÆ were instituted by Tarquinius Superbus, who having overcome the Tuscan, made a league with the Latins, and proposed to them to build a temple in common to Jupiter Latiaris, in which both nations might meet, and offer sacrifice for their common safety. At this festival a white bull was sacrificed, and each town, both of the Latins and Romans, provided a certain quantity of meat, wine, and fruits. At first the solemnity continued but one day; after the expulsion of the kings, the senate added a third, a fourth, and so on to ten days.

FERIA, in the Roman breviary, is applied to the several days of the week; thus Monday is the feria secunda, Tuesday the feria tercia; though these days are not working days, but holidays. The occasion of this was, that the first Christians were used to keep the Easter-week holy, calling Sunday the prima feria, &c. whence the term feria was given to the days of every week. But besides these, they have extraordinary feriae, viz. the three last days of Passion-week, the two days following Easter-day, and the second feria of Rogation.

FERIAL DAYS, according to the statute 27 Hen. VI. cap. v. are taken for all days of the week except Sunday.

FERM, or FARM. See Farm.

FERMANAGH, a county of Ireland, in the province of Ulster, the chief town of which is Inniskilling.

FERMENT, any body which being added to another, produces fermentation. See the article Fermentation.

Ferments are either matters already in the act of fermentation, or that soon run into this act. Of the first kind are the flowers of wine, yeast, fermenting beer, or fermenting-wine, &c. and of the second are the new expressed vegetable juices of summer-fruits.

Among distillers, ferments are all those bodies which, when added to the liquor, only correct some fault therein, and by removing some obstacle to fermentation, forward it by secondary means; as also such as being added in time of fermentation, make the liquor yield a larger proportion of spirit, and give it a finer flavour. See the article Addition.

It appears that ferments are of use not only in beginning, but in regulating and determining the species of fermentation; thus fresh yeast determines the fermentation of wheat-flour, to make our common bread, which would prove of another kind with the flowers or lees of vinegar; and thus specific or determinate ferments...
ferments have their correspondent effects. If sugar, honey, manna, treacle, or new wine be added to vinegar, themselves are soon changed into vinegar without stop- ing to make wine; because the acetoous fer- ment or vinegar over-rules them; and so vinegar is soonest made in a cask that has before contained the same liquor. And if the best wine were put into a cask that had held putrid vinegar, the wine would not now make vinegar, but immediately run into corruption. So great and over- ruling a power have specific ferments; the use of which may afford considerable rules in chemistry, practical philosophy, and arts.

We recommend, therefore, to distillers to be careful in pitching upon a proper ferment, and also to consider its quantity, quality, and manner of operation. The quantity must be proportioned to that of the liquor, to its tenacity, and the degree of flavour it is intended to give, and to the dispatch required in the operation. As to the quality, it must be chosen perfectly sweet and fresh, for all ferments are liable to grow musty and corrupt; and if in this state they are mixed with the fermentable liquor, they will communicate their nauseous and filthy flavour to the spirit, which will scarce ever be got off by any subsequent refining. If the ferment be sour, it must by no means be used to any liquor; for it will give it an acetoine instead of a vinous ten- dency. The ferment is to be put to the fermentable liquor in a state barely tepid, or scarce lukewarm. For the ferments most generally used, see the articles WINE-LEES, YEAST, &c.

FERMENTARIANS, fermentarii, an ap- pealation which those of the Latin church have given to the Greeks, on account of their using leavened or fermented bread in the eucharist. The greek church, on the other hand, call the Latins azymites. See the article AZYMITES.

FERMENTATION, may be defined a sensible internal motion of the constituent particles of a moist, fluid, mixt or com- pound body; by the continuance of which motion, these particles are gradually re- moved from their former situation or combi- nation, and again, after some visible sepa- ration is made, joined together in a different order and arrangement. The whole process then of fermentation, con- sists of two different operations, viz. an analytical one, whereby the particles are resolved; and a synthetical one, whereby they are new ranged. And whenever these two different effects are found to be produced in direct sequence, the opera- tion may be called by the name of fer- mentation, whether it happen in the blood or other animal, vegetable, or mineral substances. All separable, mixt, or com- pound bodies, may be the subjects of this operation; but the easier they are separ- able by means of water, air, and heat, the more readily they ferment. Thus the sweet or saccharine part of malt more readily dissolving in warm water, fer- ments easier than unmalted corn, which is more clammy, and will not dissolve so soon.

Fermentation, according to our later philo- sophers, arises from an inequality in the attractions of cohesion of the constit- uent particles of bodies. They distin- guish it into two kinds, the one is that which happens when a solid is dissolved by a fluid; the other is, when two fluids being mixed together, ferment with each other. Dr. Friend and Keill are of opinion, that in order to cause a fermentation between a solid and a fluid, it is ne- cessary, 1. That the particles of the solid attract those of the fluid with a greater force, than the particles of the fluid at- tract one another. 2. That the pores of the solid be not too small to admit the particles of the fluid into them. 3. That the body be of so loose a contexture, that the force of impact, with which the par- ticles of the fluid rush into its pores, may be sufficient to disintegrate its parts. 4. That the elasticity of the particles tend to pro- mote and augment the fermentation. Dr. Boerhaave makes also four conditions re- quire, 1. That there be a due propor- tion between the size of the particles of the fluid, and the pores of the body to be dissolved. 2. That the figure of the par- ticles of the fluid, have a determinate re- lation to that of the pores of the solid. 3. That the particles of the fluid be suf- ficiently solid, that their momentum or force of action may not be too weak. 4. That there be a fit disposition of the particles of the fluid, when received into the pores of the solid, to make some stay there and not immediately to pass through, but to act every way upon the solid, as they move towards the external surface thereof. Mr. Rowing thinks there is no occasion to have recourse to so many suppositions: if the particles of the solid (says he) attract those of the fluid with a greater degree of force than either those of
of the fluid or of the solid attract one another, it is sufficient, and there will follow a diffusion of the body, as may clearly be demonstrated from the laws of mechanics, whatever the other circumstances relating to the figure or magnitude of pores, &c. may be. See Row. Syst. of Nat. Phil. part II. Diff. VIII.

Fermentation is divided by chemists into many distinct species, particularly into vegetable, animal, and mineral. The vegetable kind again may be distinguished into vinous, acceous, and putrefactive; the vinous again into mucilaginous, mouldy, and putrefactive, and so of the acceous.

Of vinous Fermentation. The juice of the grape being chemically examined, proves to be no more than a large proportion of real sugar dissolved in water, with the addition only of a certain flavour in the juice of the grape, according to the nature of the vine; whence we may lay it down as an axiom, that a saccharine substance is the basis of wines; and indeed whoever would thoroughly enquire into the nature and means of improving vinous and acceous fermentation, cannot perhaps do better than to choose sugar for his subject; a chemical analysis of which will shew the principles necessarily required in this operation. These principles appear to be an acid salt, an oil, and earth so united together, as to be capable of dissolving perfectly in water. Experience shews us, that all fermentable bodies do not require ferments to begin their motion of fermentation. Raisins, we know, require none, much less does the fresh expressed juice of the grape, or other vegetable juices in the summer season, or in a warm air. But all sweet vegetable juices that have felt much of the fire, as treacle, wort high boiled, rob of malt, rob of elder, or the like, usually require a considerable proportion of vinous ferments to make them work. Water, we find, is absolutely necessary to begin and procure a fermentative motion in vegetable substances; for raisins and sugar being kept dry, will never ferment; and this holds universally of all the subjects of vinous and acceous fermentation. Whence water is an instrument that must be necessarily employed in these kinds of fermentation, whether natural or artificial. Warmth, with the free admission of the external air, is necessary to expedite the actions of vinous fermentation; for if raisins and water were to stand either in a very cold place, or be kept entirely from the access of the common atmospheric air, either no fermentation, or a very slow and small one, would ensue, as has been often experienced. The lees remaining at the bottom of a cask where wine has fermented, will set any lees fermentable subject at work, and determine its fermentation for the vinous kind. Whence it appears, that vinous fermentation consists, first, in an intestine struggle or commotion of the fluid; and, secondly, in a separation of a groffer part, which did not appear in that form before.

Of acceous Fermentation. The whole process of making vinegar being attentively considered, it is observable, that if wine were not bunged down when arrived at its vinous state, but suffered still to remain open and exposed to a warm air, it would spontaneously become vinegar; and the sooner, if a somewhat greater degree of heat than served for the making of wine, were employed. Acceous fermentation then requires a stronger heat than the vinous; and wines having once finisht their fermentation, as wines do not naturally stop there, but unless prevented, proceed directly on to vinegars; where again they make no stop, but unless prevented here also, spontaneously go on to vapidity, ropinefs, mouldinefs, and putrefaction; from which observation we would deduce this axiom, that, to speak philosophically, the intention and tendency of nature is to proceed from the very beginning of vinous fermentation directly in a continued series to putrefaction, and thence again to a new generation. See Putrefaction, &c.

If we examine the changes wrought upon vegetable subjects by vinous and acceous fermentation, we shall find that an inflammable spirit is produced by the action of vinous fermentation, from a vegetable subject and water, wherein no signs of any such spirit appeared before; info much, that this may be justly esteemed the criterion or inseparable effect of vinous fermentation; but that acceous fermentation, on the other hand, has a very different effect, and that it either conceals, alters, exhales, destroys, or some ways abolishes the inflammable spirit produced by the vinous fermentation. A part of this spirit is unquestionably exhaled by the heat employed in accification, yet part also remains bound under a
a different modification, so as to be recovered by art in an inflammable form, as we find covered by art in an inflammable form, fermentation, as before we which is only lead diffolved in spirit of vinegar. Having thus a criterion of acetous fermentation, as before we quor comes this will determine that fermentation to nOils, negar. Having thus a criterion of acetous fermentation is a vegetable kinds of fermentation in the same vegetable subject, and we make no doubt that some other species may be found upon due enquiry.

It has been disputed, whether animal bodies naturally undergo a fermentation after death; but supposing this not a dispute about words, it should seem that there is a proper species of fermentation peculiar to the animal subjects, as there is one peculiar to vegetables; and till this point be settled, we should not lay down vegetable fermentation as the test and standard of fermentation in general. For want of distinguishing in this case, all true fermentation seems denied to the blood and juices circulating in a living animal body, and, again, to the sap of vegetables. But, perhaps, were the enquiry into fermentation prosecuted in its full latitude, and not arbitrarily confined to any single species, many natural and artificial operations would prove to be actual fermentation. To say that there is no fermentation in the blood, because it affords no inflammable spirit upon distillation, is to say, in effect, that blood is not wine; whereas the question is not, whether there be a vegetable fermentation in the blood, but whether there be not an animal one; the criterion of which is the production of a volatile urinous salt, as the production of an inflammable spirit is the criterion of vinous fermentation.

Some of the processes in chemistry seem to prove, that fermentation is not confined to animal and vegetable substances, but that minerals are also liable to something of it. If an ounce of lead, and an ounce of bismuth be melted together in an iron ladle, and an ounce of quicksilver be heated in another ladle, and all three mixed together, this makes an amalgam, which appears perfectly uniform or homogeneous, and paffes thro’ leather in a running form. But this mixture being suffered to cool and stand quiet for some hours, a gross matter will separate from it by degrees, and float upon the reft, which will now run easily through leather, and leave the gross metallic matter behind. Here then appears all the requisites of fermentation, a fluid form, an uniform matter, an intemperate motion, and an actual separation of a grosser matter, leaving a thinner behind. There are many more instances of an apparent fermentation in mineral bodies; but this suffices to evince, that in a proper sense, there is an actual fermentation exercised not only in the vegetable and animal, but also in the mineral kingdom.

Upon the whole we may infer, 1. That the degrees of fermentation differ with the degrees of heat employed: thus vinous fermentation requires a less degree of heat than the acetous, the acetous less than the putrefactive, which last may conflict with a degree of ignition. 2. That a particular kind of fermentation may be carried on in the bodies of living animals and vegetables, which are largely supplied with the requisite instruments of fermentation, viz. water, air, and heat; and in fact both animals and vegetables appear to have an intemperate motion in all their circulating fluids, which continuously deposite a grosser matter in the canals and parts they move through. 3. That when vegetables and animals die, there soon begins a different kind of fermentation in all their parts, tending not now to the repair, but to the entire destruction of their organical vessels. 4. That dry or solid substances, cannot in that state undergo a proper fermentation; for they may in that state be separated into minute particles, yet they cannot range themselves together in any order, nor deposite a grosser matter without being agitated by some fluid, or, for some time, suspended therein.

We observed before, that heat, with a free admission and emission of the common air, were necessary to promote fermentation; the things which check or hinder it, are these: 1. The acid fume of burning sulphur, received in a large quantity at several times, and shut up along with the air, remaining on the top of the fermenting liquor. 2. Alkaline salts, if added in a large quantity to fermenting liquors, immediately excite a greater effervescence, which presently ceasing, all farther fermentation is stopped. But, in both these cases, the fermenting
FERNED, in general, something, that nothing may burst; that with fermentation, than excites and promotes a violent compression of the same air, the ninety degrees rather dissipates and less than thirty-six degrees of heat. Fermented liquors are esteemed great to corruption. It also, in a great measure, gives them that aromatic refreshing and restorative virtue, and the freihing and restorative virtue, and the fermented matter, entirely prevents the origin, and stops the progress of fermentation.

FERMENTED, in general, something that has undergone a fermentation. See the preceding article.

Fermented liquors are esteemed great antidotes to putrefaction; accordingly the abstinence from them is alligned as one cause why the Turks are more subject to putrefaction; and, lastly, a violent compreßion of the same air with the fermentable matter, entirely prevents the origin, and stops the progress of fermentation.

In several places in the north, the inhabitants grow it green, and burning it to ashes, make those ashes up into balls, with a little water, which they dry in the sun, and make use of them to wash their linen with; looking upon it to be near as good as soap for that purpose. It is said, that the frequent treading them down by sheep, while that sort of cattle feed upon them, is an infallible method of killing them.

The antients used the root of the fern and the whole plant, in decoctions and diet-drinks, in chronic disorders of all kinds arising from obstructions of the vifera, particularly in hypochondriac cases, and in obstructions of the spleen and pancreas. There are not wanting modern authors who give it as high a character in these cases as the antients have done, but it is an ill-tasted medicine, and in no great use in the shops. The country people esteem it as a sovereign remedy for that troublesome distemper the rickets in children, and they give it also as a powder, after drying it in an oven, to destroy worms.

Sweet Fern, a name by which some call the myrrhis, or wild chervil. See the article MYRRHIS.

FERNAMBUC, the same with brasil-wood. See the article BRASIL.

Fernando, or Fernandes, an island in the Pacific ocean; west-long. 85°, south lat. 10°.

Ferra, a truttaceous fish, much resembling a salmon: its usual length is a foot or more.

Ferrara, a city and archbishop's see of Italy: east-long. 15° 6', north lat. 44° 50'.

Ferraria, a name used for two distinct plants, agrimony and ferophularia.

Ferre, or le Ferre, a city of Picardy, in France, forty miles south-east of Amiens: east-long. 3° 26', north lat. 49° 4′.

Ferre, or le Ferre, in zoology, a quadruped of the mustela-kind. See the article MUSTELA.

The head is small and depreßed; the snout sharp; the eyes look very fierce and red; the ears are short, patulous, and erect, they are considerably wide, especially towards the base; the mouth is large, and the teeth very sharp; the neck is short; the body is long and thin; the legs are short, and each divided at the foot into five toes; and there armed with sharp claws.

7 Q. This
FERULA, FERRUM, EQUINUM, HORSE-SHOE in botany, the same with the hippocrepis.

FERRETS, among glafs-makers, the iron with which the workmen try the melted metal, to see if it be fit to work. It is alfo used for thoſe irons which make the rings at the mouth of bottles.

FERRETTO, in glafs-making, a ſubstance which ſerves to colour glafs. This is made by a ſimple calcination of thirty miles of iron, or that contains particles of that metal, to fee if it be fit to work. Nothing can produce fertility in either ſex, but what promotes perfect health: nothing but good blood, ſpirits, and perfect animal functions, that is, high health, can beget perfect fecundity; and therefore, all means and medicines, all noſtrums and ſpeciſcs to procure fertility, differ from thoſe which procure good blood and ſpirits, are errant quackery. Dr. Cheyne says, that water-drinking males are very rarely infertile; and that if any thing in nature can prevent infertility and bring fine children, it is a milk and ſeed-diet perſervered in by both parents.

FERRO, well long, 19°, north lat. 28°, the moſt westerly of the Canary islands, near the african coaſt, where the firſt meridian was lately fixed in moſt maps; but now, the geographers of almoff every kingdom make their reſpective capitals the firſt meridian, as we do London.

FERRO, some little islands situatet in the northern ocean, 200 miles north-west of the Orcades, and as many south-eaſt of Iceland: well long. 7°, north lat. 63°.

FERROL, a fea-port town of Špain, in the principality of Galicia, ſituated on a bay of the Atlantic ocean, twenty miles north-eaſt of the Groyne, and fifty miles north of Compoſella, a good harbour, where the ſpaniſh squadroons frequently ſecured themſelves in the late war: well long. 8° 40', north lat. 43° 30'.

FERRUGINOUS, any thing partaking of iron, or that contains particles of that metal. It is particularly applied to certain mineral springs, whole waters are impregnated with the particles of iron, gene-

FERTILITY, that quality which denominates a thing fruitful or prolific. Nothing can produce fertility in either sex, but what promotes perfect health: nothing but good blood, spirits, and perfect animal functions, that is, high health, can beget perfect fecundity; and therefore, all means and medicines, all nostrums and specifics to procure fertility, different from those which procure good blood and spirits, are errant quackery. Dr. Cheyne says, that water-drinking males are very rarely infertile; and that if any thing in nature can prevent infertility and bring fine children, it is a milk and seed-diet persevered in by both parents.

FERULA, FENNEL-GIANT, in botany, a genus of the pentandria-digynia class of plants.
FERULA, in the antient FE
FESCENNINE VERSES,
FERULAE, a little wooden pallet or slice, reputed
the schoolmaster’s sceptre, wherewith he chastises the boys, by striking
them on the palm of the hand.
Under the eastern empire, the ferula was
the emperor's sceptre, as is seen on variety
of medals: it consisted of a long stem or
shank, and a flat square head. The use
of it is very antient among the Greeks,
who used to call their princes ferulabearers.
FERULA, in the antient eastern church, signified
a place separated from the church,
wherein the audientes were kept, as not being
allowed to enter the church;
whence the name of the place, the persons
therein being under penance or discipline.
This word was sometimes used to denote
the prelate’s crozier or staff. See the article CROZIER.
FERULÆ, in surgery, splinters or chips
of different matter, as of wood, bark,
leather, paper, &c. applied to bones that
have been disjointed, when they are set
again.
FERULA is also a word used by the antients,
to express the horns growing on
the deer or stag at the age of two years,
at which early time those horns are unbranched.
FESCENNINE VERSES, in roman antiquity, satyrical verses,
full of lewd and obscene expressions, sung by the company
who used to call their princes ferulabearers.
The profetis were those days allowed to
men for the administration of their affairs,
whether of a public or private nature:
these were divided into falli, comitiales,
compendini, flati, and prailiares. See Fasti, Comitiales, &c.
The intercilli were days common both to
gods and men, some parts of which were
allotted to the service of the one, and some
to that of the other.
FESTINO, in logic, the third mood of the
second figure of syllogism, the first proposition whereof is an universal negative,
the second a particular affirmative, and
the third a particular negative: as in the
following example:
FES No bad man can be happy,
TI Some rich men are bad men:
NO Ergo, some rich men are not happy.
FESTIVAL, the fame with fealt. See the article FEAST.
FESTOON, in architecture and sculpture,
&e. an ornament in form of a garland
of flowers, fruits and leaves, intermixed
or twisted together.
It is in the form of a string or collar,
whom biggest in the middle, where it
falls down in an arch; being extended
by the two ends, the extremities of which
hang down perpendicularly.
Festoons are now chiefly used in friezes,
and other vacant places, which want to
be filled up and adorned; being done in
imitation of the long clusters of flowers,
which the antients placed on the doors of
their temples and houses on festival occasions.
FESTUCA, in botany, a genus of grasses,
belonging to the triandria digynia class;
the flower of which is composed of two
valves, and terminated by a straight arist or awn: the seed is single, of an oblong figure, very sharp-pointed at each end, and marked with a longitudinal furrow.

7 Q. To
To this genus belong the capon’s tail grafts, wild oat grafts, or drank, &c. which are said to be drying, and good against a flinking breath.

Festuca is also a name sometimes used for the bromus. See Bromus.

Fetiour, Festa, or rather Feud, Feudatary, Feudal, or rather Castle. Grafis wild oat which are said to be drying, and good for the bromus. See againetl. Grafis which grow behind the pattern joint of many horses; for those of a low size have scarce any such tuft.

Fetus, or rather Foetus. See the article Foetus.

Feud, Feedam, the same with fee. See the article Fee. Estate.

Feudal, or Feodal, denotes any thing belonging to a fee. See the article Fee.

Feudatory, or Feodatory, a tenant who formerly held his estate by feudal service. See the article Vassal.

Feud-Bote, a recompence for being concerned in a feud or quarrel.

Fever, febris, in medicine, a disease, or rather class of diseases, whose characteristic is a preternatural heat felt through the whole body, or at least the principal parts of it. According to Sydenham, a fever is nothing else but the effort of a plethora or collection of blood and other fluids, to be free and natural; and the falutarv of the air, way of living, or drank, having injurious, in or because, perhaps, some very violent passions, expels them out of the body; thus palies, epilepsies, convulsions, fpasmodic and hypochondriac af-
If nature seems to be too acute, and the patient, exposed to a dubious event, either dies, or falls into a chronic distemper. Therefore, since nature is the physician, it is a pernicious practice to suspend, suppress, or in almost all fevers are of advantage, especially in the beginning. Even nature herself teaches us the use of sudorifics; they are most beneficial when the signs of concotion appear; and they are also useful through the whole course of the distemper; yea, even by the protMitcious use of them, fevers are often cured. Spirit of sal armoniac, or its volatile salt, is esteemed an universal febrifuge, which, being given pretty often, seldom fails of success. All sugared things are very harmful in fevers.

In acute and inflammatory fevers, but a very few medicines are required; for it will be sufficient diligently to observe the ways that nature aims to relieve herself by, and to forward the cure in those ways, by assisting her. If there be any obstructions in the bowels, we are to take care, by proper evacuations, to remove the load, and by that means take away some of the fuel of the distemper. If the blood be too furiously agitated, we are to quell such an impetuosity: if it be embarrassed with gros and coagulated humours, we are to endeavour at dissolving it, and rendering it more fluid. In the due observance of these three precepts, conflits, in a great measure, the whole cure of fevers, where the visera are found, and the peccant humours are lodged in the blood, or in the prime vix; and then, when nature tends to produce a crisis, or she has already begun it, we are altogether to refrain from the use of medicines, as much as we would avoid the plague.

They are grossly mistaken who, in acute and inflammatory disorders, make use of abundance of medicines so long, till nature, not knowing which way to turn herself, but being variously distracted to and fro, both by the violence of the distemper and the burden of the medicines, is at last forced to yield: for the orderly motion of nature being disturbed and distracted with the repetition of much medicines inmethodically given, the fever is not lefSened, and the crisis is postponed; and the patient, exposed to a dubious event, either dies, or falls into a chronic distemper.

The general signs of fevers are a pain in the back, more particularly about the loins; a coldness, especially of the extreme parts; a shivering; a shaking; trembling; a livid colour of the nails; a subdulence of the vesels of the hands and feet; a shrunk, dry skin; a yawning; a stretching; a pale livid countenance; a trembling and palpitating motion of the heart; an anxiety of the precordia; difficult breathing; inquietude, retleaffenfs, a fenfation of an ebullition of the blood about the heart; a contracted, weak, small pulse; a naufea, and an inclination to vomit; a suppression of perpiration; colicines, with thin watry urine. When the symptoms are very urgent, and very hastily make their progres, the fever is called acute; when they are more mild and gentle, it is denomninated a flow fever.

The general cure of fevers is summarily comprehended in confulting the strength of nature, in correcting and discharging the acrimony from the blood, in dissolving gros humours, and expelling them, and in mitigating the symptoms. If we perceive the symptoms run high, and nature to grow exorbitant, we must moderate it, and enjoin abstinence, a flender diet, drinking water, bleeding, cooling clysters, &c. If nature seems to be too sluggish, she is to be excited by cordials, aromatics, volatiles, &c. By how much the more acute a fever is, by so much the more sparing and flender ought the diet to be. In fevers, though the patient lies many days without eating anything, it is no matter; on the contrary, by eating and drinking, the fever would be exalpated.

If nature seems to be too ed; and the patient, exposed to a dubious event, either dies, or falls into a chronic distemper. Therefore, since nature is the physician, it is a pernicious practice to suspend, suppress,
F E V [1218]  F E V

pref, or destroy the febrile motions, which have a tendency to health. The most salutary work of nature ought rather to be promoted, which designs, by an increased progressive motion of the fluids, to correct, resolve, and at length to expel the morbid matter. And this is best performed by diluting, moistening, at- temperating, appetizing, corrodinating and nitrous medicines; as also by those which in the time of the intermission, especially tend to promote the proper evacuations. In all fevers, the drinking plentifully of warm weak liquors, is attended with many good consequencies: the patient is always refreshed by it; the febrile heat is mitigated, and res is promoted; and the proper and necessary sweats forwarded. Among these liquors, the common barley-water, teas made of fage, mint, baum, &c. with the milder alexipharmic roots, are most proper: with these, powders are to be given, composed of the abisterive and digestive salts: they should be grafted with lemon-juice, and then mixed with a little nitre, and may be given every three, four, or fix hours, as the urgency of symptoms require. Emulsions of sweet almonds, and the cooling seeds, are also very proper between whilcs.

The medicines by which the physician is to affift nature in her business of excre- tion, are the gentle diaphoretics; among which the diaphoretic antimony, when truly prepared, holds a very high place: alexipharmics, which have also a diuretic virtue, such as the mixtura simplex, when faithfully prepared and lightly camphorated, are very proper. All vio- lent medicines are to be dreaded in fevers. Acids, in general, are by many much dreaded, but there is no real ground for this; on the contrary, in sanguineous fevers, during the time of the violent heat, and immoderate thirft, they are found of the greatest use and benefit. The use of aromatic medicines, though too common, yet is extremely improper in all fevers. Nitre is an admirable remedy for fevers in general.

The general crisis of fevers. Whereas there is no fever cured without some considerable evacuation, raised either by nature or by art, the physician ought carefully to observe which way nature seems to intend the expulsion of the morbid matter, and affift her by all possible means. Now this expulsion is frequently made through several outlets of the body at a time, and an evacuation by one outlet, more or lefs, checks that by another: thus a loofenefs checks sweat, and vice verfa. Wherefore it is the physician's business to consider what evacuation is most likely to be of service, and to promote this, as to give the leaf interruption poftile to any other, for any one evacuation is not equally suitable to all persons, both on account of the difference of constitutions, and of diseases; although evacuations thro' every emunctuary, are sometime necefsary, as we find by experience in malignant fevers.

But of all solutions of the diseafe, the most defirable is by sweat; next to that, by stool and urine: the worst is by a hemorrhage, whether it proceeds from the nofe or from any other part, because it indicates that the blood is so far vitiated, that no proper separation of the humour can be made.

Lafly, some fevers terminate in abscffes, formed in the glands, which, if they happen in the decline of the diseafe, and suppurate kindly, are salutary. Wherefore the suppuration is to be forwarded by cataplaffins, or plasters; and some- times by cupping on the tumor; and then, if the absccfs don't break sponta- neously, it ought to be opened, either with a knife, or with a caufic. At this time this rule of practice is generally right, not to exhaust the patient's strength by evacuations of any kind. And yet in some cases there is a necessity for drawing a little blood, as when the hu- mours are in great commotion, and the heat excessive; for this remedy prudently administered, makes the tumor ripen kindly, because nature has always a great abhorrence of a turbulent state. But in order to give a more diftinct notion of the several kinds of fevers, it will be necefsary to treat them par- ticularly.

Bilious Fever. See the article Bilious. Burning Fever, Causus, attacks the pa- tient with great fury and rage, with an excessive burning heat, an intolerable thirft, and other symptoms demonstrating a great and remarkable inflammation of the blood: the respiration is thick, dificult, and quick; the tongue is dry, yellow, parched and rough; there is a loathing of food, a naufea and vomiting, a little cough, a delirium, a coma, convulsions, and other general symptoms already mentioned.

On the third and fourth day it often proves
FEV [1219]

FEV

proves mortal; it seldom exceeds the seventeenth, if violent.

It is often terminated by a hemorrhage, which, if small on the third and fourth day, is a fatal sign. A solution of this fever, on a critical day, may also be by vomiting, foop, sweat, urine, and spitting thick phlegm. If the exacerbation of symptoms happens on the second or fourth day, it is a bad sign, on the listh not so bad.

As to the cure of a burning fever, so far as it differs from the general treatment already prescribed, bleeding is necessary at the beginning, if there is a plethora, or signs of particular inflammation; or the heat intolerable, or the rarefaction too great, or a revulsion necessary, or the symptoms urgent, and not to be vanquished any other way.

Soft, diluting, laxative, antiphlogistic, cooling clysters, are to be repeated as oft as the heat, coffiveness and revulsion requires them; the whole body is to be moistened by receiving into the noftrils the steam of warm water, by wafhing the mouth, throat, feet, and hands with the same; and by fomenting with warm fponges the places where the feveral spots are moft numerous. Purgatives are dangerous before the crisis, but clysters may be used made of milk, honev, and a little nitre. After the crisis, which is known by the fefement of the urine, laxatives made with tamarinds, manna, rhubarb, rafins, or cream of tartar, are neceffary.

If a phrenzy happen, caufe bleeding of the nofe, by thrufing up a straw, or with a scarifying knife: ufe alfo frictions of the feet and legs, with hot cloths.

Catarhal Fever may be reckoned in the clafs of slow fivers, which, in the beginning, is attended with a catarrh, a corryza, cough, hoarieness, &c. These fevers are moft commonly gentle and slow by day-time, generally somewhat worse in the evenings: they are attend- ed with a great coffiveness of the limbs, the symptoms continue with an increafe of the corryza and cough, until the diftemper arises to its higheft pitch, when the matter of the catarrh is ripened, and the mucus, becoming thicker, is discharged, and the fever ceases: the feat of this diftemper is in the conglomate glands.

In a catarhal fever a decoction of faffra- fras wood is convenient, with liquorice roots and rafins, on account of the acrimony of the humours. Also the ex-
markable in this disease, for it is generally low, quick and unequal.

Gilchrist makes this state previous to the fever, and says, that for a fortnight, or three weeks, before they are laid down, they shall be low-spirited, inappetent, loaded, sleep ill, sigh frequently, groan involuntarily, and feel unexpressible dis-order, accompanied with fear, concern, and dejection, and perhaps flight alienations of mind. The same author says, that this disorder is frequently occasioned by people exposing themselves indiscreetly to the sun, or by being fatigued in it; by eating largely of fruit, or drinking hot; by wine; or by being long under a course of anxiety, care, fear, discouragement, and other enervating passions, watching, and other evacuation, together with irregularities of diet, &c. It commonly attacks people of weak nerves, and a lax habit of body, and is occasioned by an astringency that gives an universal stimulus.

The cure is to be performed with gentle volatile medicines of the cordial and disinfecting kind, in order to promote perpiration, by the application of blisters, and by a proper regimen and method of diet. In the beginning a gentle emetic may be given, or a small dose of rhubarb; when it has continued long, bleeding and sweating is very prejudicial. In giving the diarrhoeatic, we should always regard to the urine, for if that from being pale, gradually heightens to an amber colour, we are right in our dose, especially if, in bed, a gentle dew or moisture comes on, without a reflesseness. A little chicken broth is of service, both as food and drink, and its vessels and glands from obstructions: for this purpose mineral waters are proper; as are also the thermes, or hot bath waters. Where these cannot be had a decoction of thin veal broth, with the roots of succory, fennel, asparagus, dog-grass, and viper’s grass, are proper; drinking a quart a day for some weeks; and before it some preparations of steel, as the tincture of steel, or of martial flowers. If from an eruption of the stomatch and bowels, all sharp, salt, and stimulating things are as bad as poison. In this case a decoction of faffra, and the bark of Eleutherius in milk, as also chamomile flowers, and the tops of yarrow, drank about a quart a day, are of great use: as are also the root of marshmallows, or rice boiled in milk; or gum dragant, dissolved in water.

If
If from the loss of necessary fluids, and want of strength, then it may be termed a colliquative fever, and must be treated as already directed in the treatment of that fever, above.

If it proceeds from the abuse of spirituous liquors, all heating liquors should be avoided, as also analeptics and stomachics. Gruel will be proper, with succory root, red poppy flowers, and some diluted nitre. If this fever proceeds from a suppression of the menes, it requires immediate bleeding in the foot, and refolvent decoctions of succory-roots, leaves of low-thistles, dainties, and elder-flowers, for bearing all strong emmenagogues.

If from a marasmus feminis, and that the patient has been addicted to a sedentary inactive life, his appetite remaining good, and has omitted customary bleedings, or the spontaneous evacuations of blood are ceased, bleeding is indicated, and wholesome diluters must be freely drank, abstaining from food of too plentiful nourishment, and using convenient exercize: but if the disorder proceeds from a plenty of impure salt serum, not secreted thro' the skin, or otherwise, the fordes must be carried off by gentle laxatives of manna, rhubarb and raisins, and the rosid juices must be renewed by jellies and ass's milk.

Fevers of children are all owing to acidity, the primary cause of all the disorders that affect them; and the whole cure depends upon vanquishing that enemy. This is to be done two ways, the first is to prepare the acidity, and render it fit for expulsion; and then to purge it away by suitable evacuants. To prepare the acid does not require sudorifics, but absorbents; and though there are numerous, the powder of crab's claws is the chief. Purging to some may seem dangerous, but Sydenham has shewn us, that it is safe and salutarly in the fevers of adults, in so much that he depends entirely upon it for the cure of the epidemic winter-fever; and it has been found of excellent use in the fevers of children. They recommend in this case a pearl julep, made by adding a dram of prepared pearls to two ounces of the simple waters, and two drams of the compound; the dose is three spoonfuls. When there is any unusual symptoms arising from putrid humours, they prescribe about six grains of æthiops mineral the night before the purge, in a small spoonful of any agreeable syrup. After the purge, the teftaceous powders are to be given three or four times in twenty-four hours for two days and nights, and then the purge is to be repeated.

FEVERFEW, the english name of a plant, called by botanists matricaria. See the article Matricaria.

Bastard-FEVERFEW. See PARTHENIUM.

FEVERSHAM, a port-town of Kent, and one of the cinqueports. See the article Cinqueport.

It stands seven miles west of Canterbury.

FEUILLANS, an order of bare-footed monks, who observe the same rules with the bernardines. See Bernardines.

FEUVILLE DE SCIE, among the French heralds, imports that an ordinary, as a selle or a pale, is indented only on one side; so called on account of its resemblance to a saw-blade, as the words signify.

FEVILLEA, in botany, a genus of the monoecea fragifera class of plants, the flower of which is monopetalous, divided into five segments at the limb, and rotated; the fruit is a very long fleshy berry, with a hard rind, and containing compressed orbicular seeds. It is called by Pluver, nhandiroba.

FEURS, a town of France, situated on the river Loire, twenty-seven miles west of Lyons.

FEWEL, or FUEL. See the article Fuel.

FEWET, or FUMET. See Fumet.

FEZ, the capital of the empire of Fez and Morocco, in Africa: west long. 6°, north lat. 33° 30'. It is a large and populous city, and the usual residence of the emperor. See the article Morocco.

FIASCOME, a city and bishop's see of Italy, about twelve miles south of Orvietto.

FIAT, in law, a short order or warrant signed by a judge, for making out and allowing certain processes. FiaT iustitia, is where the king, on a petition to him for his warrant to bring a writ of error in parliament, writes on the top of it fiat iustitia, let justice be done; upon which the writ of error is made out.

FIBER, the beaver, in zoology, is made, by Linneaus, a species of caflor. See the article Castor.
FICUS, in anatomy, a perfectly simple body, or as least as simple as any thing in the human structure; being fine and slender like a thread, and serving to form other parts. Hence some fibres are hard, as the bony ones; and others soft, as those defined for the formation of all the other parts.

The fibres are divided also, according to their situation, into such as are straight, oblique, transverse, annular, and spiral; being found arranged in all these directions, in different parts of the body, for an account of which see Bone, Muscle, Nerve, Artery, Vein, &c.

FIBRE is also used to denote the slender filaments which compose other bodies, whether animal, vegetable, or mineral; but more especially, the capillary roots of plants. See Plant, Wood, &c.

FIBRILLA, a term sometimes used for a very minute or slender fibre.

FIBROSE, something consisting of fibres, as the roots of plants. See Root.

FIBULA, in anatomy, the outer and smaller bone of the leg, called also perone. It is nearly of a triangular figure, and stands parallel to, but distant from the tibia, or inner bone of the leg. Its upper extremity does not reach to the os femoris, but is only joined to the external side of the tibia; and its lower extremity, called malleolus externus, concurs in the articulation of the tarsus, which its eminence serves to strengthen, by rendering a luxation less easy. It has no particular motion of its own, but wholly follows that of the tibia.

FIBULÆ, a muscle of the leg, more usually called peroneus. See Peroneus.

FICARIA, in botany, the name by which Dillenius calls a species of ranunculus, called by Boerhaave chelidonium minus. See the article Ranunculus.

FICEDULA, in ornithology, a name given to several species of motacilla, particularly the brown kind, with a spotted breast, and white belly. See Motacilla.

FICHE' or FITCHE', in heraldry. See the article Fitche'.

FICOIDEA, a genus of the polyandria-pentagymia class of plants, without any flower-petals: the fruit is a ventricose, pentagonal capsule, containing five cells, wherein are contained a great many roundish seeds. The essential characteristic of the genus consists in this, that the flamina are inserted in series in the sinue of the cup, usually three in each series.

FICOIDES, a name given to several distinct plants, as the melembranythum mafa, and opuntia. See the article Melembranthum, &c.

FICTION. See the article Fable.

FICUS, the fig-tree, in botany, a genus of the cryptogamia class of plants, producing male and female flowers separate, neither of which have any flower-leaves: the flamina are three stamaceous filaments, of the length of the cup; and the fruit is large, flabby, and of a turbinate figure; being properly nothing but the common calyx or cup of the fructification. See the article Fig.

FIDA, a town on the slave-coast of Guinea: east long. 3°, and north lat. 6°.

FIDD, in the sea-language, an iron, or wooden pin, to splice and fasten ropes together. It is made taper-wise, and sharp at one end. The pin in the heel of the top-maft, which bears upon the cheffe-trees, is likewise called a fidd.

FIDD-HAMMER, one whose handle is a fidd, or made tapper-wife.

FIDDELL, or VIOLIN. See Violin.

FIDE JUSSOR, among civilians, the same with campus. See Surety.

FIDEI COMMISSUM, in roman antiquity, an estate left in trust with one person, for the use of another. See Trustee.

FIDICINALES, muscles of the fingers, otherwise called lumbicales. See the article Lumbicales.

FIEF, or FEE. See the article Fee.

FIELD, campus, in agriculture, a piece of ground inclosed, whether for tillage or pasture. See Tillage and Pasture.

The square contents, or superficies, of a field may be easily found, by the rules of surveying. See Surveying.

FIELD, in antiquity, the same with campus. See the article Campus.

FIELD, in heraldry, is the whole surface of the shield, or the continent, so called because it containeth those achievements antiently acquired in the field of battle.

It is the ground on which the colours, bearing,
FIELD, in a military sense, denotes the place where a battle was fought.

**Close Field** was antiently a place railed in with a barrier, for the performance of juts and tournaments.

FIELD, among painters, is more usually called ground. See the article GROUND.

FIELD-BOOK, in surveying, that wherein the angles, stations, distances, &c. are set down. See Surveying.

FIELD-COLOURS, in war, are small flags of about a foot and half square, which are carried along with the quarter-master general, for marking out the ground for the squadrons and battalions.

FIELD-FARE, in ornithology, the English name of the variegated turdus, with a hoary head. See the article Turdus. It is larger than the common black-bird, and with us is a bird of passage, coming over in great numbers in winter. See plate XCVII. fig. 4.

FIELD-FORT, in fortification. See Fort.

FIELD-OFFICERS, in the art of war. See the article Officer.

FIELD-PIECES, small cannons, from three to twelve pounders, carried along with an army in the field. See Cannon.

FIELD-STAFF, a weapon carried by the gunners, about the length of a halbert, with a spear at the end; having on each side, ears screwed on, like the cock of a match-lock, where the gunners fired in lighted matches, when they are upon command; and then the field-staffs are said to be armed.

FIELD-WORKS, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

ELYSSIAN FIELDS. See ELYSIAN.

FIERENZUOLO, a town of Italy, ten miles south-east of Placentia.

FIERI FACIAS, in law, a writ that lies where a person has recovered judgment for debt or damages in the king's courts against one, by which the sheriff is commanded to levy the debt and damages on the defendant's goods and chattels. This writ must be filed out within a year and a day after the judgment obtained, and where two fieri facias's against one person are delivered to the sheriff the same day, he ought to execute that first which was first delivered; but if he executes the last first, the execution will be good, though the other party in such case may have an action against him.

FIFE in music, is a sort of wind-instrument, being a small pipe. See Pipe.

FIFE, in geography, a county of Scotland bounded by the Frith of Tay on the north; by the German sea on the east; by the Frith of Forth on the south, and by Menteeth and Sterling on the west.

FIFE-RAILS, in a ship, are those that are placed on balisters, on each side of the top of the poop, and so along with hances or falls. They reach down to the quarter-deck, and to the floor of the gang-way.

FIFTEENTH, an antient tribute or tax laid upon cities, boroughs, &c. through all England, and so termed because it amounted to a fifteenth part of what each city or town had been valued at; or it was a fifteenth of every man's personal estate according to a reasonable valuation. In Domesday book, there are certain rates mentioned for levying this tribute yearly; but since, any such tax cannot be levied but by parliament.

FIFTH, in music, one of the harmonical intervals or concords. See the article Interval.

The fifth is the second in order of the concords, the ratio of the chord that affords it is $3:2$. See the articles Chord and Concord.

It is called fifth, as containing five terms or sounds between its extremes, and four degrees, so that in the natural scale of music, it comes in the fifth place or order from the fundamental. The antients called this fifth diapente. The imperfect and defective fifth called by the antients semi-diapente is less than the fifth by a lesser semitone. See the articles Diapente, Semitone, &c.

FIG, the fruit of the ficus, or fig-tree. See the article Ficus.

Figs, as well fresh as when dry, are very wholesome food: they are nutritive and emollient: they are good also in the disorders of the breast and lungs; but it is to be observed, that a too free use of them has sometimes brought on obstructions of the victure, which are very common complaints also where they are eaten as food, as they are with bread by the poor people in many parts of the Levant. They are frequently made into a preserve.
FIG

ingredients in our pectoral decoctions, and are by some greatly recommended against nephritic complaints. They are much used externally by way of cataplasms, either roasted or boiled in milk, for the ripening of tumours, and for eating the pain of the piles. Figs should be chosen large, of a pale brownish colour, soft and mellow, heavy, and when broken, with the pulpy substance yellowish and sweet, and of a soft glutinous texture.

Figs the hundred weight pay on importation 9s. 6d. the drawback on exportation is 8s. 9d. at the rate of 61. the hundred weight.

Fig, in farriery, a sort of oint on the fruits, and sometimes all over the body of a horse. The figs that appear on the fruit or allele make an evacuation of malignant thinking humours that are very hard to cure.

Fig-shell, a species of dolium. See the article Dolium.

Figwort, a plant called by the botanists Scrophularia. See Scrophularia.

Indica Fig, See Opuntia.

Infernal Fig, See Argemone.

Marygold Fig. See Mesembryantheme.

Pharaoh’s Fig. See Musa.

Fight, or Sea-Fight. See Battle.

Running-Fight, that in which the enemy are continually chafed.

Fights, in a ship, are the waste clothes hung round about a ship in a fight, to keep the men from being torn by the enemy.

Close Fights, the bulk-heads, fore and ait the ship, put up for the men to stand secure behind in case of boarding, and fire upon the enemy.

Fight-Wite, a line or mullig for fighting or creating a quarrel.

Guerre, a town of Catalonia in Spain, ten miles west of Roses.

Figural, Figurate, or Figurative, a term applied to whatever is expressed by obscure resemblances. The word is chiefly applied to the types and mysteries of the masonic law; as also to any expression which is not taken in its primary and literal sense.

Figural, or Figurate numbers, are such as do or may represent some geometrical figure in relation to which they are always considered, as triangular numbers, pentagonal numbers, pyrarnidal numbers, &c.

Figurative, among grammarians, is the same with what is otherwise called characteristic. See Characteristic.

Figurative counterpoint, in music, is that wherein there is a mixture of dissonant with the concords. See the article Counterpoint.

The French call it supposition, because the transient dissonances suppose a concord immediately following. See the article Supposition.

Figurative descant, in music. See the article Descant.

Figure, in physics, expresses the surface or terminating extremities of any body; and considered as a property of body affecting our senses, is defined a quality which may be perceived by two of the outward senses. Thus a table is known to be figure by the sight, and by the touch. The schoolmen therefore dispute whether or no the quality of figure be the same with that of form. Boethius affirms, that figure ought to be predicated of inanimate bodies, and form of animate: others again extend form to all natural bodies, and figure to all artificial ones: in the opinion of others, form and figure are applied to all sorts of bodies, but not in all relations. If only the bare circumference or circumscription be considered, they call it figure; but if the circumference be considered as ended with colour, then they call it form. See the article Form.

Figures, in arithmetic, are certain characters whereby we denote any number which may be expressed by any combination of the nine digits, &c. See the article Digit.

Figure, in architecture, and sculpture signifies the representation of things made in solid matter, as statues, &c. Daviler observes, that those representations of human bodies sitting, as popes, or kneeling, as on monuments, or lying as river-gods, &c. are more properly called figures than statues.

Figure, in astrology, a description of the disposition of the heavens at a certain hour, in which the places of the planets and stars are marked in a figure of twelve triangles, called houses. See House.

Figure, in conic sections, according to Apollonius, is the rectangle made under the latus rectum and transversum in the hyperbola and ellipsis.

Figure of the diameter; the rectangle under any diameter, and its proper parameter is, in the ellipsis and hyperbola, called the figure of that diameter.
FIGURE, among divines, is used for the mysteries represented under certain types. See the article TYPE.

FIGURE, in dancing, denotes the several steps which the dancer makes in order and cadence, considered as they mark certain figures on the floor.

FIGURE, in fortification, the plan of any fortified place, or the interior polygon, which, when the sides and angles are equal, is called a regular, and when unequal, an irregular figure.

FIGURE, in geometry, the superficies included between one or more lines, is denominated either rectilinear, curvilinear, or mixt, according as the extremities are bounded by right lines, curve lines, or both. See the articles RECTILINEAR, CURVILINEAR, &c.

EQUILATERAL FIGURE. See EQUILATERAL CIRCUMSCRIBED FIGURE. See CIRCUMSCRIBED.

Inscribed Figure. See Inscribed.

Similar Figure, &c. See Similar, &c.

FIGURE, in the higher geometry, a term applied to three mechanical curves, called the figure of the secants, figure of the tangents, figure of the femants, the difference being only that here every ordinate BC (ibid. n° 3.) answerable to the abscissa AB, is the line of the correspondent arch QS of the circle (see the former figure) instead of being its secant, as OP. This curve consists of an infinite number of parts, such as ACG, alternately rising above and falling below the abscissal line AI, which in reality make but one continued infinite serpentine line. Any space ABC of this curve is squarable. See further in Philos. Trans. n° 337.

FIGURE of the tangents, is generated like the figure of the secants, with this difference, that the ordinate BC (ibid. n° 4.) is here equal to the tangent PQ of the arch QS, to which the abscissa AB is equal; the curve consisting of an infinite number of such parts, of which EAD is one, and having a like number of parallel asymptotes at equal distances from each other.

FIGURE, in grammar, a deviation from the natural rules of etymology, syntax and profody, either for brevity, elegance or harmony.

Figure in etymology, or figure of words, is generally called metaplasmus. See the article METAPLASMUS.

Figures in syntax, or figures of sentences, are reduced to four kinds, viz. Ellipsis, pleonasmus, enallage, and hyperbaton; and the figures in profody are these, synalepha, ephithipsis, synarisis, diarisis, syfole and diafole. See each of these under its proper head.

FIGURE, in heraldry, a bearing in a shield representing a human face, as a sun, a wind, an angel, &c.

FIGURE, in logic, denotes a certain order and disposition of the middle term in any syllogism.

Figures are fourfold, 1. When the middle term is the subject of the major proposition, and the predicate of the minor, we have what is called the first figure. 2. When the middle term is the predicate of both the premises, the syllogism is said to be in the second figure. 3. If the middle term is the subject of the two premises, the syllogism is in the third figure; and lastly, by making it the predicate of the major, and subject of the minor, we obtain syllogisms in the fourth figure. Each of these figures has a determinate number of moods, including all the possible ways in which propositions differing in quantity or quality can be combined, according to any disposition of the middle term, in order
FIGURE, in painting and designing, denotes the lines and colours which form the representation of any animal, but more particularly, of a human personage. Thus a painting is said to be full of figures, when there are abundance of representations of men; and a landscape is said to be without figures, when there is nothing but trees, plants, mountains, &c.

FIGURE, in rhetoric, is a manner of speaking different from the ordinary and plain way, and more emphatical; expressing a passion, or containing a beauty. Figures, therefore, are highly serviceable to clear difficult truths, to make a style pleasant and pathetical, and to awaken and fix attention. But as, in order to obtain these ends, they are to be used with prudence and caution, the following directions ought to be observed. 1. Let the discourse always be founded on nature and facts, supported with strong reason and proof, and then add the ornaments and heightenings of figures; for a man of clear understanding will despise the flourish of figures without sense, and pomp of words that wants truth and substance of things. 2. Be sparing in the use of figures. A passion described in a multitude of words, and carried on to a disproportionate length, fails of the end proposed, and tires instead of pleasing. 3. Figures must not be over adorned, nor affectedly laboured, and ranged into new and scrupulous periods; for by affectation and shew of art, the orator betrays and exposes himself, and it is apparent, that he is rather ambitious to let off his parts and wit, than to express his sincere concern and passion.

The principal and most moving figures are exclamation, doubting, correction, omission, apostrophe, suspension, prevention, conceiision, repetition, paraphrosis, exaggeration, climax, comparison, prosopopeia, transition, sentence, epiphnema, &c. See each of these under its proper head.

FIGURED, in general, something marked with figures. See the article FIGURE. The term figured is chiefly applied to juffs, whereon the figures of flowers, and the like, are either wrought, or stamped. See the articles STUFF, WEAVING, VELVET, &c.

FIGURES STONES, in natural history, those found in the shape of shells, or other parts of animals. See STONE.

FILACER, or FILAZER. See FILAZER.

FILAGO, the name by which Vaillant calls the graphalium, or cudweed. See the article GNAPHALIUM.

FILAMENT, in physiology and anatomy, denotes much the same as fibre. See the article FIBRE.

FILAMENTs, among botanists, is particularly used for the stamens. See the article STAMINA.

FILanders, in falconry, a disease in hawks, &c, consisting of filaments, or strings of blood, coagulated; and occasioned by a violent rupture of some vein, by which the blood, extravasating, hardens into these figures, and incomodates the reins, hips, &c.

Filanders are also worms as small as thread, and about an inch long, that lie watt up in a thin skin, or net, near the reins of a hawk, apart from either gut or gorge. This malady is known by the hawk’s poverty; by ruffling her tail; by her straining the fift, or perch, with her pounces; and lastly, by croaking in the night, when the filanders prick her. The disease proceeds from bad food, and must be remedied in time, to prevent its spreading over the whole body, and destroying the bird. These must not be killed as other worms are, for fear of imposthumes from their corruption, being incapable of passing away with the hawk’s meat. They must only be starved, to prevent their being offensive; and this is done by giving the hawk a clove of garlic, after which, she will feel nothing of the filanders for forty days. It will be prudent in the falconer when he observes the hawk poor and low, to give her a clove of garlic once a month by way of prevention.

FILAZER, or FIALZER, an officer of the Common-Plas, so called from his filing those wright whereon he makes out process.

There are fourteen of these officers, who are severally allotted to particular divisions and counties, and make out all writs and processes upon original writs, issuing out of the court of Chancery, and returnable in that court. They likewise make out all appearances and special bails, upon any process issued by them, and make the first interrogatories to
on special bails, writs of habeas corpus, supererogations upon special bail; also writs of view in real actions, &c.

**FILBERT,** or **FILBERD,** the fruit of the Corylus, or hazel. See Corylus. This is the least sort of small nuts, and more nourishing than the common nuts; but it is hard to digest. They are however worthy of being propagated in orchards and gardens; which is done by sowing them in February. In order to preserve them good, they should be kept in sand, in a moist cellar, where the vermin cannot come at them to destroy them: the external air should not be kept from them, for this would occasion their turning mouldy.

**FILE,** among mechanics, a tool used in metal, &c. in order to smooth, polish, or cut. This instrument is of iron, or forged steel, cut in little furrows, with chisels, and a mattock, this and that way, and of this or that depth, according to the grain or touch required. After cutting the file, it must be tempered with a composition of chimney foot, very hard and dry, diluted, and wrought up with urine, vinegar, and salt; the whole being reduced to the consistence of mustard. Tempering the files consists in rubbing them over with this composition, and covering them in loam; after which they are put in a charcoal fire, and taken out by that time they have acquired a cherry colour, which is known by a small rod of the same steel put in along with them. Being taken out of the fire, they are thrown into cold spring water, and when cold, they are cleaned with charcoal and a rag; and being clean and dry, are kept from rust by laying them up in wheat bran. Iron files require more heating than steel ones. Files are of different forms, sizes, cuts and degrees of fineness, according to the different uses and occasions for which they are made. Those in common use are the square, flat, three square, half round, round, thin file, &c. each of which may be of different sizes, as well as different cuts.

The rough or coarse toothed files are to take off the unevenness of the work which the hammer made in the forging; and the fine toothed files are to take out of the work the deep cuts or file-strokes of the rough files: the files succeed one another in this order, first the rubber, then the bastard toothed file, next the fine toothed file, and lastly, the smooth file. Thus the files of different cuts succeed one another, till the work is so smooth, as it can be filed. After which, it may be made still smoother, by emery, tripoli, &c. See Polishing. In using all sorts of files, the rule is to lean heavy on the file in thrusting it forward, because the teeth of the files are made to cut forward; but in drawing the file back again for a second stroke, it is to be lightly lifted, just above the work, by reason it does not cut in coming back.

The file is used in pharmacy to reduce hard substances to fine particles, whose consistence will not admit of powdering.

**FILES,** the gros, containing twelve dozen, pay on importation 7s. 8d., and on exportation draw back 6s. 9d. Moreover, for every 12 lb. of the iron, the duty is 4s. 6d., and on exportation the draw-back is 4s. 8d.

**FILE, or LABEL,** in heraldry. See Label.

**FILE,** in the art of war, a row of soldiers, standing one behind another, which is the depth of the battalion, or squadron. The files of a battalion of foot are generally three deep; as are sometimes those of a squadron of horse. The files must be straight, and parallel one to another.

To double the Files, is to put two files into one, which make the depth of the battalion double of what it was in number of men.

The **File leaders,** are the foremost men in each file; the bringers up are the last men of each file, or the last rank of the battalion.

To **File off,** is the same as to defile, or to file off from a large front to march in length. See the article Defile.

**FILICULA,** the dwarf-fern. See the article **Filix.**

**FILIGRANE,** or **Filigree-work,** any piece of gold or silver-work, that is curiously done, with grains or drops on the filaments or threads.

**FILING,** in finithery, the operation of fashioning metallic bodies by means of a file. See the article **File.**

**FILIPENDULA,** dropwort, a genus of the icofandra-pentaynia class of plants, the corolla of which consists of five, or more, oblong, obtuse, plane, patent petals, inserted into the calyx: there is no pericarpium, except the crusts of the
the seed; the receptacle is globose: the seeds are oblong, acuminated, and disposed in a circular manner.

This plant is a diuretic; it is recommended against colics, flatulencies, and the fluor albus: but its chief use consists in fopping too great a flow of the lochia.

FILIX, in botany, an order of the cryptogamia class of plants, comprehending the fern, horse-tail, adder's tongue, spleenwort, polypond, &c. See the articles FERN, HORSE-TAIL, &c.

FILLET, in anatomy, the same with FILLER-HORSE.

FILLET, in heraldry, a kind of orle, or border, containing only a third or fourth part of the breadth of the common bordure. It is of a different colour from the field. It is supposed to be withdrawn inwards, and runs quite round, near the edge, as a lace over a cloak. It is also used for an ordinary drawn like a bar, from the finer point of the chief, across the shield, in manner of a scarf; though it sometimes is also seen in the situation of a bend, fesse, crois, &c. According to Guillim, the fillet is a little rule or reglet of leaf-gold, drawn over some mouldings, or on the edges of frames, panels, &c. especially when painted white, by way of enrichment.

FILLET, in the manege, the loins of a horse, which begin at the place where the hinder part of the faddle rests.

FILLER-HORSE, one yoked immediately to a cart. See the article CART.

FILLY, a term among horse-dealers, to denote the female or mare-colt. See the article FOAL.

FILM, a thin skin or pellicle. In plants, it is used for that thin, woody skin, which separates the seeds in the pods, and keeps them apart.

White Film upon the eye of a horse, may be removed by lifting up the eyelid, after the eye has been washed with wine, and stroking it gently, with one's thumb, with wheat flower; also common salt, or salt of lead, beaten fine, and put into the eye, is proper to confume a film; or you may wash the horse's eye with your little

in the morning, fasting, having first put a little salt into your mouth; but there is nothing so effectual as fal ammoniac, beaten and put into the eye, and repeated every day till the film is gone.

FILTER, or FILTRE, in chemistry, a trainer commonly made of bibulous or filtering paper in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid. See the article CLARIFICATION.

There are several filters made of flannel and linen-cloth.

FILTRATION, in chemistry, a species of clarification. See CLARIFICATION.

FIMBRIAE, denotes appendages disposed by way of fringe round the border of any thing: such are those about the thicker extremities of the fallopian tubes. See the article FALLOPIAN.

FIMBRIATED, in heraldry, an ordinary with a narrow bordure or hem of another tincture.

This, in latin, is called fimbratus, that is, edged or fringed.

FIN, pinna, in natural history, a well known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles.

The number, situation, and figure of fins, are different in different fishes. As to number, they are found from one to ten, or more; with respect to situation, they stand either on the back only, the belly only, or on both; and as to figure, they are either of a triangular, roundish, or oblong square form. Add to this, that in some they are very small; whereas, in others, they almost equal the whole body in length.

For the use of the fins in swimming. See the article SWIMMING.

Whale-Fins. See the article WHALE.

FINAL, in general, whatever terminates or concludes a thing.

FINAL CAUSE. See the article CAUSE.

FINAL LETTERS, among hebrew grammarians, five letters so called, because they have a different figure at the end of words from what they have in any other situation. These are caph, mem, nun, phe, and te, all comprehending in the word cammpharos; which, at the end of words, are written thus, א כ מ פ נ: whereas, in any other situation, their form is this, נ פ מ כ א: on which account they are likewise called biform.

FINAL, in geography, a port town of Italy, subject
FINANCES, in the French polity, signify the revenues of the King and State.

FINCH-KIND, in ornithology, an appellation given to a genus of birds, known among authors by the name of fringilla. See the article FRINGILLA.

FINE, in law, has divers significations, it being sometimes taken for a sum of money advanced and paid for the income of lands. It is likewise used in another sense, where a sum is paid as an amends, or by way of punishment for an offence committed. See MULET.

Fine denotes also a covenant made before justices, and entered upon record, for conveyance of lands and other inheritable things, in order to cut off all controversies. As this fine is a concord acknowledged before a competent judge concerning lands, tenements, and other immovable things, and for its better credit, is supposed to be made in the presence of the king, as it is levied in his court; it therefore binds women coverts, who are parties, and others whom the law generally disables to act; for this reason, because all presumption of deceit is excluded, where the King and his court of justice are deemed privy to the matter transacted. Fines, on account of their solemnity, are acknowledged in the court of common pleas. Justices of assize may also take them, though they seldom do it without a special dedimus potestatem, by virtue of which writ, fines may be also taken by commissioners in the country, and the dedimus furnishes that parties are not able to travel to Westminster; for by the common law, all fines are levied in court.

In every fine there are five parts. 1. An original writ, generally termed a writ of covenant. 2. The licentia concordandi, or the King's licence, for which a fine, called the King's silver, is paid. 3. The concord, which contains the agreement between the parties in what manner the land shall pass, and is the foundation and substance of the fine. 4. The note of the fine, or abstrait of the original contract. 5. The foot of the fine containing the day, year, and place, and before what justices the contract was made.

There are four sorts of fines. 1. *A fine sur cognizance de droit comme eoe*, which is the principal and surest kind of fine, as it gives possession, at least in law, to the cognizee, without any writ of execution. 2. *A fine sur done, grant & render*, or double fine, whereby the cognizee, after a release and warrant to him by the cognizor, grants and renders back the lands, &c. or some rent, many times limiting remainders. 3. *A fine sur cognizance de droit tautum*, and this is a fine executory, that is commonly used to pass a recovery, and sometimes by tenant for life to release to the person in reversion. 4. *A fine sur concellis*, which is made use of to grant away estates for life or years, and it is also executory; so that the cognizee must enter or have a writ of habere facias poßessionem, to obtain possession.

Fines are either with proclamation, called fines according to the statutes, or without proclamation, called fines at common law. The statutes ordain, that every fine shall be openly read and proclaimed in the common pleas, and a transcript of it sent to the justices of the assize, and another to the justices of the peace of the county where the land lies, in order to be proclaimed there; and when this is certified, privies in blood, as the heirs of the cognizor, are presently barred, but strangers to the fine have five years allowed them to enter and claim their right. The like time is given to infants, after they come to full age; to feame-coverts, not joining in fines after the death of their husbands; to prisoners, after they are set at liberty; and to persons out of the realm, after their return.

*Fine adnullando levato de tenemento quod fuit de antiquo dominico*, is a writ directed to the common pleas to disannul a fine levied of lands in antient demeine, to the prejudice of the lord.

*Fine for alienation*, was a fine paid to the king by his tenants in chief, for a licence to alien their lands. These fines are taken away by 12 Car. II. cap. 24.

*Fine capiendo pro terris*, is a writ that lies where a perfon upon conviction of an offence by jury, having his lands and goods taken into the king's hands, and his body committed to prison, obtains the favour to be remitted his imprisonment, and his lands and goods to be restored to him for a sum of money.

*Fine force*, is an expression in the statute 35 Henry VIII. c. 12. denoting that a person is forced to do that which he can no way avoid.

*Fine non capiendo pro pulchre placitando*, is a writ to hinder officers
FINES for writs, are paid in divers cafes for original writs. Thus for every writ of plea of land, if it be not of right patent, which is for the yearly value of five marks; and all original writs in debt and trespass, where the debt or damage is 40 l, a fine is due to the king of 6s. 8d. and more proportionally when any writ is forthings of greater value.

FINES of gold and silver, are those who separate these metals from coarser ores. See the article Refiners.

FINERY, in the iron-works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar. See the article Iron.

FINGERS, digit, in anatomy, the extreme part of the hand divided into five members. See the article Hand.

The names of the fingers, reckoning from the thumb, are, 1. Pollex. 2. Index. 3. Medius. 4. Anularis. 5. Aquicularis. In each of these there are three bones, which make three phalanges, the upper of which are much larger than the lower. Their exterior surface is gibbous or convex, and their interior is plane, but somewhat hollowed, for the convenience of seizing and laying hold of things. The first phalanx, in the part where they are articulated with the bones of the metacarpus at their heads, have a glenoide cavity, by means of which articulation, they have a free motion every way. In the other extremity, there are two heads with two cavities joined to the second phalanx, where the motions of flexion and extension are all that are possible; and the same is the case between the second phalanx and the third. In the upper extremities of the bones of the second and third phalanx, there is to be observed an eminence placed between two cavities: this has the same use with the olecranon. The farthest extremity of the last phalanx, has a point or apex formed narrower than the body. See the articles Phalanx and Thumb.

The muscles of the fingers are in part common and in part proper. The common are the flexors of the first, second, and third phalanx, the extensor and interossei. See the articles Extensor and Interossei.

FINO, in music, a canon or fugue is laid to be finite, when it is not perpetual, but when, at some certain place, all the parts join or unite, after having
Nature
FIRE, FIR-TREE, Scotch Fir, sweet-fennel, in botany, a species of fennel, cultivated in gardens as a fennel-herb, and as fuch much liked by fome. However, by the general notion of horifon, fo called from the horizon, fo called because it terminates the light or profound. See HORIZON.
FINLAND, a province of Sweden, lying northward of the gulf of Finland, and eastward of the bothnic gulph. It is a frontier province, bounded by Russia on the east.
FINNICKIN, the English name of a species of pigeon, remarkable for its wheeling round feveral times, whenever it courts the female.
FINNOCHIA, sweet-fennel, in botany, a species of fennel, cultivated in gardens as a fennel-herb, and as fuch much liked by fome.
FINSACLE, a name used in fome parts of the kingdom for a fuch more ufually called rudd. See the article Rudd.
FINITO, in music, a fiant, or an attempt to do feomething and not to do it; as cada­enza finto is, when having done every thing proper for a true cadence, instead of falling on the right final, another note, either higher or lower, is taken, or perhaps a paufe brought in. See the articles Inganno and Sfuggita.
FIR-TREE, abies, in botany. See the article Abies.
Scotch Fir, a name given to the mountain-pine. See the article Pine.
FIRE, ignis, in phyfiology, according to Boerhaave, is fomething unknown, which has the property of penetrating all folid and fluid bodies, and dilating them fo as to take up more space. The moft universal and fensible character of fire, and that which beft distinguishes it from every other thing, is its giving heat: whence fire may be generally defined, to be whatever warms or heats bodies. However, by the general name of fire, men feem to understand a fensation or complex notion of light, heat, burning, melting, &c.
Nature of FIRE. The doctrine of fire, as laid down by modern phyfiologists, is very different. The great and fundamental difference in refpeét to the nature of fire is, whether it be originally fuch, formed thus by the creator himfelf at the beginning of things, or whether it be mechanically producible from other bodies, by inducing fome alterations in the particles thereof. The former opinion is maintained by Homberg, Boerhaave, the younger Lemery, and s’Gravefande; the latter is chiefly supported by the English phyfiologists, lord Bacon, Mr. Boyle, and Sir Isaac Newton. Bacon, in his treatife De Forma Calidi, deduces, from a great number of particulars, that heat in bodies is no other than motion; only a motion fo and fo circum­flantiated: fo that to produce heat in a body, nothing is required but to excite a certain motion in the parts thereof. Boyle fects him in an exprefs treatife of the mechanical origin of heat and cold, and maintains the fame doctrine with new obfervations and experiments; as a fpecimen whereof, we shall here give the two following.
1. In the production, fays he, of heat, there appears nothing on the part either of the agent or patient, but motion and its natural effects. When a fmitth briskly hammers a fmall piece of iron, the metal thereby becomes exceedingly hot; yet there is nothing to make it fo, except the forcible motion of the hammer impref­sing a vehement and varioufly determined agitation on the fmall parts of the iron, which, being a cold body before, grows, by that super-induced commotion of its fmall parts, hot: firft, in a more loofe acceptation of the word, with regard to fome other bodies, compared with which it was cold before: then, fensibly hot; because this agitation furpaffes that of the points of our fingers; and in this inftance oftentimes the hammer and anvil continue cold, after the operation: which fhews that the heat acquired by the iron, was not communicated by either of thofe implements, as heat; but produced in it by a motion, great enough strongly to agitate the parts of fo fmall a body as the piece of iron, without being able to have the like effeft upon fo much greater mafles of metal as the hammer and the anvil. Though if the percu­ffions were often and briskly renewed, and the hammer were fmall, this alfo might be heated; whence it is not ne­ceffary, that a body itself be hot to give heat.
2. If a large nail be driven by a hammer into a plank of wood, it will receive feveral frokes on its head, before it grow hot: but when it is once driven to the head, a few frokes fuffice to give it a considerable heat; for while, at every blow of the hammer, the nail enters fur­ther into the wood, the motion produced is chiefly progreffive, and is of the whole nail tending one way; but when that motion ceafes, the impulse given by the
FIR [1232]

Fir, being unable to drive the nail further on, or break it, must be spent in making a various, vehement, and intense commotion of the parts among themselves, wherein the nature of heat consists.

Agreeable to this is the opinion of Sir Isaac Newton, who conceives that gross bodies may be converted into light, by the agitation of their particles; and light, again, into gross bodies, by being fixed therein.

On the other hand, M. Homberg, in his Essai du Souffre Principe, holds, as the chemical principle, or element sulphur, which is supposed one of the simple, primary, pre-existent ingredients of all natural bodies, is real fire, and consequently that fire is coeval with bodies.

Dr. s'Graveande goes on much the same principle: fire, according to him, enters the composition of all bodies, is contained in all bodies, and may be separated or procured from all bodies, by rubbing them against each other; and thus putting their fire in motion: but fire, he adds, is by no means generated by such motion.

Mr. Lemery, the younger, agrees with these two authors in afferting this abstruse and ingenious nature of fire: but he extends it farther. Not contented to confine it as an element to bodies, he endeavours to shew, that it is equally diffused through all space, and that it is present in all places; in the void spaces between bodies, as well as in the insensible interfaces between their parts.

This last sentiment falls in with that of Boehmavse, and the celebrated M. Muschenbrock. But, notwithstanding it is evident that fire, heat, flame, &c. are only the different modifications of the particles of light, and that the particles of light themselves depend entirely on velocity for their incicuous quality; since, by many experiments, we know, that the particles of bodies become lucid, or particles of light, by only producing in them a requisite degree of velocity: thus the particles in a rod of iron, being hammered very nimibly, shine and become red hot; thus, also, the violent stroke of the flint against the steel, in striking fire, puts the particles of the steel, which it takes off, into such a motion as causes them to melt and become red hot, which makes the sparks of fire produced by each stroke. As, therefore, fire consists in the great velocity of the particles, so it may be communicated from one body in which it is, to another in which it is not, after the same manner that one body in motion will communicate motion to another that has got none.

Fire differs from heat only in this, that heat is a motion in the particles of a body, with a lesser degree of velocity; and fire a motion with a greater degree of velocity, nize. such as is sufficient to make the particles shine; though we often call such a flame as will burn, fire, though it does not actually shine; and we seldom call those lucid bodies fires, which only shine, and do not burn. These are a sort of phosphorus, which, though they have no heat, yet seem to owe their lucidity to the motion of their parts. See the articles Heat and Phosphorus.

There seems to be no other difference between fire and flame, than this: that fire consists in a glowing degree of velocity in the parts of a body, while yet subsisting together in the mass; but flame is the same degree of velocity in the particles dissipated and flying off in vapour; or, to use Sir Isaac Newton's expression, flame is nothing else but a red hot vapour.

See the article Flame.

General division of Fire. Fire, in general, is divided into three kinds or species, viz. celestial, subterraneous, and culinary.

By celestial fire we principally mean that of the sun, without regard to the fire of the fixed stars, though this, perhaps, may be of the same nature. By subterraneous fire, we understand that which manifests itself in fiery eruptions of the earth, volcanoes, or burning mountains; and by any other effects it produces in mines, or the more central parts of the earth. By culinary fire, we mean that commonly employed in all chemical operations in the animal, vegetable, atmospheric, marine, and mineral kingdoms.

Considered in itself, fire seems to exist in greatest purity and perfection in the celestial regions; at least we are insensible of any considerable smoke it yields; for the rays of light come to us from the sun unmixed with any of that gross, fculent, or terrestrial matter found in culinary and subterraneous fires. And allowing for this difference, the effects of the solar fire appear the same as those of the culinary fire. To examine also the effects of subterraneous fires, we shall find them the same with those produced by the culinary fire. And thus all the three kinds of fires...
FIRE [1233] FIRE

Fires agree in giving the motion of rarefaction to bodies. All subterraneous and culinary fires require some pabulum or fuel, wherein it resides, or is collected; but whether the same is required for the subfistence of the celestial fire, is more than we know. See the article Fuel. Sir Isaac Newton is of opinion, that the fire of the sun and fixed stars, is conserved by the greatness of these bodies, and the mutual action and re-action between them and the light which they emit; that which in the universe comprises all bodies, and the vapours and exhalations which arise from their parts are kept from fuming away, interpreters betwixt the weight and density of the atmospheres incumbent upon them, and very strongly compressing them, and condensing the vapours and exhalations which arise from them.

Effects and properties of Fire. So great is the power, so extensive the action, and so wonderful the manner wherein fire acts, that it was antiently held and adored as the supreme god, by a notion reputed the wildest: wherein fire was supposed to be an uncreated being; natural heat of the body, or any form of the solar rays, being taken it for an uncreated being; natural heat of the body, or any form of the solar rays, being called the supreme god. By this notion we have a notable instance of fire, as thinkable things, &c. as to destroy the organ. Again, the effects of fire are often produced without any manifest signs of burning, melting, &c. as in evaporation, evolutions, &c.

If this method of exclusion and rejection were pursued to its due length, we should find perhaps no criterion, infallible mark, or characteristic of fire in general, but that of a particular motion struggling among the small parts of bodies, and tending to throw them off at the surface. And if this should prove the case, then such a motion will be the form or essence of fire; and which being present, makes fire also present; and when absent, makes fire also absent; whence to produce fire and produce this motion in bodies, will be the self-same thing.

But from repeated experiments we learn, 1. That, in general, both solids and fluids manifest an expansive motion upon being heated. 2. That the direct inflammable matter of fuel, is oil, or an unctuous substance. 3. That no fuel will burn or consume, without the admission of fresh air. 4. That the air which has once passed through burning fuel, is, of itself, unfit to animate fire again. And, 5. That flame exists only on the surface of fuel.
way, and consequently tend neither more
nor less to one point than another. If
fire be collected in any body so as to be
perceivable by our senses, it removes it-
self out of the flame by its own power,
and expands every way from the center
of its space or body; whence we learn
the proper conatus of fire, and that the
reception of it is spontaneous. From this
last property of fire, may be computed
its force and quantity: for the rate of
fire, as defined above, may be called its
flagination; and the powers of flagnating
fires will then be as the spaces wherein it
is contained; consequently the commu-
nication of powers will be to each other as
the spaces.
It were to be wished that the propor-
tional quantity of fire contained in a
body, could be determined; but this is
not so easy as at first sight it may seem, by
reason, that though from the discovered
effects of fire we may estimate its power,
we cannot estimate its quantity; as the
augmentation of the fire, arising from the
nearness of its particles, is hitherto
undetermined: for so long as the pro-
portion of the power of fire depending on
its density or closeness, to that depend-
ning on the quantity thereof is unknown,
so long we shall be unable to argue from
the effect of fire to the quantity thereof.
Yet fire, whilst it thus remains in a
heated body, says Boerhaave, does not
seem to unite with it into one corporeal
concrete mass; since, though greater
than before, it is not found heavier. Nei-
ther does fire diminish any thing of the
weight which the body would have had
at that time, and to which cold should
restore it. Nothing of this kind appears
from any experiment yet made.
It may be observed, that the same fire as
applied in different quantities, first com-
pounds bodies; and when raised to a
higher pitch, decomposes them again.
One and the same fire applied to the same
body, with different circumstances, will
have quite different effects, and especi-
ally as the air happens to be variously
admitted during the operation; and the
same fire, as applied in different degrees
to the same object, has very different ef-
fects, as is found by experiments.
Fire and flame are abolished or extin-
guished by suffocation, or an action con-
trary to ventilation, as being destructive
or preventive of that internal commo-
tion and discharge of the oily particles
of fuel, by means of the free air, where-
in the nature of open and consuming fire
confists. And hence fire and flame are
quenched by water, or even by spirit of
wine, or oil of turpentine, if a live coal
or lighted candle be suddenly plunged
therein below the surface of the liquor.
For the degree of heat which water, spi-
rit of wine, or oil of turpentine unfired,
are capable of receiving, is much less
than that of a burning coal or candle:
whence the greater heat is subdued by the
lefs, as fire quenched by boiling water.

FIRE, in chemistry, the great instrument
by which most of the operations in that
art are performed.
The kind, degree, direction, &c. of fire,
are things the chemist principally to
attend to. There are, in chemistry, as
many kinds of fire, as there are mediums
through which it may be conveyed, or
fuels that afford it. For common use, fire
is conveyed through ashes, sand, water,
&c. or directly through the contain-
ing vessel. Hence, fires are denomi-
nated of various kinds, as those of sand,
filings of iron, and ashes, the reverbera-
tory fire, the ignis rotæ, or fire for fu-
ision, the lamp fire, the balneum maris,
the vapour bath, and the fire of suppre-
sion. The chemists use also several other
kinds of heats, which may be clasped
among the fires, such as infolation, a
bath of horie-dung, a bath of the skins
of grapes, and the heat of quick-lime.
For the balneum arenofum, or the fires
or baths of sand, filings of iron, and
ashes, balneum maris, balneum vapo-
ris, or vapour-bath, see BALNEUM.
The reverberatory fire is made in a fur-
nace covered with a dome, that by this
means the heat or flame, which has al-
ways a tendency to make its escape at
the superior parts of the furnace, may be
reverberated, or beat back on the vessel
immediately exposed to it. To expose
a vessel to a naked fire, or to distil with
a naked fire, is when there is no inter-
mediate subsistence between the distilling
vessel and the fire.
The ignis rotæ, or fire for fusion, is when
a crucible or any other vessel containing
the matter defined for fusion, is sur-
rrounded with live-coals.
Lamp-fire, is when any matter contained
in a glafs-vessel is rendered hot by the
equable heat of a lighted lamp.
Fire of suppression, is when, in order to
distil per delcenium, the fire is laid above
the matter, so that the moisture forced
from it, by means of the heat, is precipi-
ated
pitated to the bottom of the vessel: or when the body of the retort, or other vessel, is covered over with fire.

Infotation, is when any matter designed either to be put into fermentation or dried, is exposed to the heat of the fun. The bath of horfe-dung, called also the horfe’s belly, is when a vessel containing any matter to be either digested or distilled, is placed in a large heap of horfe-dung.

Bath of the skins of grapes, like the bath of horfe’s dung, serves for digesions or distillations; the skins are to be collected after the vintage.

The heat of quick-lime moistened, may serve for some distillations. Some differences may be found in the effects produced by these different fires, applied in the same degree. But they have not, perhaps, been noted as they de­serve. In several bodies, it is evident that dry and moist heats have different effects, which we may find remarkably in the common culinary operations of boiling, roasting, baking, &c. And hence, when the same effects are required perfectly similar, the same kinds as well as degrees of fire are to be used.

The purest fire is that of alcohol, or perfectly pure spirit of wine; the next in purity is that of distilled oils; the next, that of charcoal, or charred turf; and the impurest, pit-coal: but all these have nearly the same effect, when received through the same kind of medium.

Degrees of Fire. The last thing to be considered is, how to regulate and ascertain the degrees of fire in chemical operations, so as to produce the effects required in every case. The common direc­tions of chemists about this matter are full of uncertainty; the first, second, third, and fourth degrees of heat, or fire, meaning no precise degrees, measured by any standard: however, according to Boerhaave, they are as follows.

The first degree of fire is that by which nature performs the office of vegetation in plants, and whereby chemistry imitates or does the like: this commences from the highest degree of cold, which, in Fahrenheit’s thermometer, is denoted by one, and ends at 60 degrees: since in this whole interval we find certain plants give indications of life and growth. This heat is suited to extracting of the native spirits of odoriferous vegetables with oils, as that of roses, jaffamin, &c. and again, to making the more curious infolutions, &c.

The second degree of fire may be accounted that of the human body, in a healthy state. This degree is always greater than that of the ambient air, and may be supposed to commence at the 40th degree of the thermometer, and end about the 94th. Within this compass animals may live and subsist, that is, if their juices be of any degree of heat within these bounds. This degree is adapted to vinous and acetic fermentation, putrefaction, exclusion of the chick, the finer digestions, the making of tinctures and elixirs; and the adepts have used it for the first digestion of their mercury, by carrying the including vessel constantly in their pocket.

The third degree of fire is that which extends from 94 degrees of the thermometer to 212, at which last water usually boils.

The fourth degree may be taken from 212 to 600 of the thermometer, within which latitude quicksilver or oil of vitriol boils, distils, or becomes volatile. This degree is suited to the melting of lead, tin, bismuth, &c. and the subliming of sal ammoniac and sulphur, the calcining of antimony, &c.

The fifth degree is that wherein the other metals melt, and which commences from 600 degrees of the thermometer, and ends where iron is held in a state of fusion. In this degree most bodies are destroyed; but glass, gold, silver, copper, and iron remain long unchanged; all other fixed bodies grow red-hot in this degree, and all the unvitrifiable stones are calcined.

The sixth and highest degree of fire, hitherto known, is that of the burning lens or concave, by M. Villette, Tcherinhauzen, Buffon, and others. The focus of these leaves will even volatile what is called the metalline or mercurial part of gold, and vitrify the more terrestrial. See the article Burning-glass.

The fires of sand, filings of iron, and ashes, have generally their degrees from the first to the third: the rever­baratory fire has its degrees from the first to the fourth; the ignitace serves for calcinations and fusions; and a vessel may receive different degrees of heat from a lighted lamp: the balneum maris and balneum vaporis have also their degrees, a has the fire of suppression its degrees: Initiation.
Infusion has its degrees in proportion to the heat of the sun, to which the substances are exposed: the bath of horse's dung has its degrees, according to the bulk of the heap, or the place in which it is lodged: the bath of grape-skins has also its degrees, like that of the bath of horse's dung; and the heat of quick-lime has also its degrees; for according as we desire it more or less strong, we expose it in powder longer or shorter to the open air; and when we have occasion for all its heat, we use it as quick as we possibly can.

Fire, in medicine. See Caustics.
Fire, in surgery. See Cutery.
St. Anthony's Fire, in medicine. See the article Erysipelas.
Walking Fire, in meteorology. See the article Will-with-a-whist.
Fire; in theology. See the articles Hell, Conflagration, &c.

We read of the sacred fire in the first temple of Jerusalem, concerning which the Jews have a tradition that it came down from heaven: it was kept with the utmost care, and it was forbidden to carry any strange fire into the temple. This fire is one of the five things which the Jews confesed were wanting in the second temple.
The pagans had their sacred fires, which they kept in their temples with the most religious care; and which were never to be extinguished. Numa was the first who built a temple to fire, as a goddess, at Rome, and instituted an order of priests for the preservation of it. See the article Vestals.

Fire was the supreme god of the Chaldeans; the magi were worshipers of fire; and the Greeks and Armenians still keep up a ceremony called the Holy Fire, upon a perfuasion that every easter-day a miraculous fire descends from heaven into the holy sepulchre, and kindles all the lamps and candles there. On this occasion the church of the holy sepulchre is crowded by a numerous and distracted mob, who make a solemn procession with standards, crucifixes, &c., after which the people light their candles at the sacred flame, and immediately apply it to their beards, faces, and bodoms, pretending that it will not burn like an earthly flame: they also think that if they are buried in a flapered sinned with this celestial fire, it will secure them from the flames of hell.

Fire, in the art of war, a word of command to the soldiers, to discharge their musquets; to the cavalry, to discharge their carbines or pistols; to the grenadiers, to fire their grenades; and to the gunners, to fire the guns.

Running Fire is when a rank of men, drawn up, fire one after another: or, when the lines of an army are drawn out to fire on account of a victory, each squadron or battalion takes it from another, from the right of the front line to the left, and from the left to the right of the second line.

Fire-arms are all sorts of arms charged with powder and ball, as cannon, musquets, carbines, pistols, blunderbusses, &c. See the articles Cannon, Gun, &c.

Fire-ball, in the art of war, a composition of meal-powder, sulphur, saltpetre, pitch, &c. about the biggest of a hand-grenade, coated over with flax, and primed with a slow composition of a fuse. This is to be thrown into the enemy's works in the night time, to discover where they are: or to fire houses, galleries, or blinds of the besiegers; but they are then armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are designed to have any effect.

Fire-lock. See Gun, Musquet, &c.

Fire-master, in our train of artillery, an officer, who gives the directions and proportions of ingredients for each composition required in fire-works, whether for the service of war, or for rejoicings and recreations.
His orders are given to the fire-workers and bombardiers, who must execute them.

Fire-pots, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered; then the pot is covered with a piece of parchment, and two pieces of match across lighted: this pot being thrown by a handle of match, where it is designed, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, to the end its operations may be the quicker.

Fire-workers, officers subordinate to the fire-master.

Fire-works. See Pyrotechnia.

Fire-ship, in the art of war, a vessel charged with artificial fire-works, which having the wind of an enemy's ship, grapples her, and sets her on fire.
FIRE-BARE, in our old customs, signifies a beacon, or tower, by the sea-side, where in there were kept continual lights.

FIRE-BOTE is fuel or firing for necessary use, allowed to tenants, out of the lands granted to them.

FIRE-COCKS. Churchwardens in London and within the bills of mortality, are to fix fire-cocks at proper distances in streets, and keep a large engine and hand-engine for extinguishing fire, under the penalty of 10l. Stat. 6 Anne, cap. xxxi.

On the breaking out of any fire in London and Westminster, the constables and beatles of parishes shall repair to the place with their flaves, and affift in extinguishing it, and cause the people to work for that end, &c.

FIRE-OFFICE, an office of insurance for fire. See Assurance.

FIRE-ENGINE. See the article Engine.

FIRE-KING, an English measure of capacity, for things liquid, being the fourth part of the barrel; it contains 8 gallons of ale, foap, or herring; and 9 gallons of beer. See Measure and Barrel.

FIRKIN, an English measure of capacity, for things liquid, being the fourth part of the barrel; it contains 8 gallons of ale, soap, or herring; and 9 gallons of beer. See Measure and Barrel.

FIRLOT, a dry measure used in Scotland.

The oat-firlot contains 2 1/2 pints of that country; the wheat-firlot contains about 22 1/2 cubic inches; and the barley-

firlot, 31 standard pints. Hence it appears that the Scotch wheat-firlot exceeds the English bushel by 33 cubical inches. See the article Measure.

FIRMAMENT, in the Ptolemaic astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions; a diurnal motion, given to it by the primum mobile, from east to west, about the poles of the ecliptic; and another opposite motion from west to east, which lalt it finishes, according to Tycho, in 25412 years, according to Ptolemy in 36000, and according to Copernicus in 25800, in which time the fixed stars return to the same points in which they were at the beginning. This period is commonly called the Plutonic year, or the great year. *Tredoux.*

FIRMAN is also used in divers places of scripture, to denote the middle region of the air. Several of the antients have believed, with the modern philosophers, that the firmament is a fluid matter; but certainly those who gave it the name of firmament, thought it a solid matter.

FIRMAN is a passport or permit granted by the great Mogul to foreign vessels, to trade within the territories of his jurisdiction.

FIRMNESS, firmitas, denotes the subsistence of a body, or that state wherein its sensible parts cohere in such a manner, that the motion of one part induces a motion of the rest.

Many of the cartesians maintain, that firmness consists in the mere reft of the particles of a body, and their mutual immediate contact, alleging that a separation of parts can only arise from some matter interposed between them, which matter is excluded by the notion of contiguity. But the insufficiency of this hypothesis is obvious; and the firmness of all bodies is known to depend on the connection or cohesion of their particles. See the articles Attraction, Cohesion, &c.

FIRST-FRUITs; primitiae, among the Hebrews, were obligations of part of the fruit of the harvest, offered to God as an acknowledgment of his sovereign dominion. The first of these fruits was offered in the name of the whole nation, being either two loaves of bread, or a sheaf of barley which was threshed in the court of the temple. Every private person was also obliged to bring his first-fruits to the temple, and there consigned of
of wheat, barley, grapes, figs, apricots, olives, and dates. There was another sort of first-fruits which were paid to God. When bread was kneaded in a family, a portion of it was set apart, and given to the priest or levite who dwelt in the place: if there was no priest or levite there, it was cast into the oven, and consumed by the fire. These offerings made a considerable part of the revenues of the Hebrew priesthood.

First-fruits are frequently mentioned in ancient christian writers as one part of the church-revenue. One of the councils of Carthage enjoins that they should consist only of grapes and corn, which shews that this was the practice of the african church.

First-fruits, in the church of England, are the profits of every spiritual benefice for the first year, according to the valuation thereof in the king's books. See the article Annates.

First-mover, primum mobile. See the article Primum Mobile.

Fisc, fiscus, in the civil law, the treasury of a prince. It differs from the cararium, which was the treasury of the public or people; thus, when the money arising from the sale of condemned persons goods, was appropriated for the use of the public, their goods were said publicari; but when it was designed for the support of the prince, they were called confiscari.

Fiscal, in the civil law, something relating to the pecuniary interest of the prince or people. The officers appointed for the management of the fisc, were called procuratores fisci, and advocati fisci; and among the cafes enumerated in the constitutions of the empire, where it was their business to plead, one is against those who have been condemned to pay a fine to the fisc on account of their litigiousness, or frivolous appeals.

Fis gum, a fish more usually called milgum. See the article Miegum.

Fish, in natural history, constitutes a class of animals which have no feet, but always fins; add to this, that their body is either altogether naked, or only covered with scales; and that they are aquatic animals, which live mostly, if not always, in water.

This class is subdivided by authors into five series, or orders.

1. The plagiuri or cetaceous fishes, comprehending those who have the tail not perpendicular, like all other fishes, but placed in an horizontal direction, or parallel to the horizon. 2. Chondropterygious fishes, comprehending those with perpendicular tails, and the rays of the fins not bony, but cartilaginous. 3. Branchiopterygious fishes, or those which have perpendicular tails, the rays of the fins bony, and the branchi or gills not folliculated. 4. Acanthopterygious fishes, or those with perpendicular tails, and the rays of the fins bony, and prickly at the ends. 5. Malacopterygious fishes, or such as have perpendicular tails, with the rays bony, but not prickly at their ends. See Plagiuri, &c. and plate of ichthyology, where a fish of each series is delineated, in the same order as above.

Some distinguish fishes, from the place where they are found, into sea-fish, river-fish, and lake or pond-fish. Others again divide them into cetaceous, cartilaginous, and spinose. The cetaceous, or whale-kind, called bellus marinus, have lungs, and breathe like quadrupeds; they copulate also like them, and conceive and bring forth their young alive, whom they suckle with their milk. The cartilaginous kind are produced from large eggs, like birds, which are excluded the womb also like those of birds. The spinose kind are also oviparous, but their eggs are smaller, and have spines up and down in their flesh, to strengthen it.

Wullughby thinks it would be better to distinguish fishes, first, into the cetaceous kind, or those that breathe with lungs; and those that breathe with gills: then to subdivide those that breathe with gills, not into cartilaginous and spinose, but into oviparous and viviparous; with other the like subdivisions. But the division first laid down, is that followed by the best ichthyologists, Arctedi, Linnaeus, and others.

As to the structure of fishes, it is admirably adapted to the element in which they live: their fins, tail, gills, air-bladder, eyes, figure, &c. are all such as best suit their circumstances; for the description and uses of which, see the articles Fin, Tail, &c.

Fish, in commerce. The exporter, on making oath that they were british taken, and really exported, is entitled to the following bounties, to be paid by the collector of the salt-duty, at the port of exportation, within thirty days after demand, upon a debenture prepared by the collector of the customs, viz.
Breeding

Generation of Fishes. See the article Generation.

Breeding of Fishes may be turned to great advantage; for besides furnishing your table, obliging your friends, and raising money, your land will be thereby greatly improved, so as to yield more this way than by any other employment whatever.

When fish are fed in large pools or ponds, either malt boiled, or fresh grains, is the best food; thus carp may be raised and fed like capons, and tenches will feed as well. The care of feeding them is best committed to a gardener, or the butler, who should be always at hand. In a few, any sort of grain boiled, especially peas, and malt coarse ground; also the grains after brewing, whitt fresh and sweet; but one bushel of malt not boiled, will go as far as two or three of grains. See the article Fish-pond, infra.

Royal Fishes. See the article Royal.

Fish, in a ship, a plank or piece of timber, fastened to a ship’s mast or yard, to strengthen it, which is done by nailing it on with iron-spikes, and winding or winding ropes hard about them.

Fishes, pieces, in astronomy. See the article Pisces.

Fishes, in heraldry, are the emblems of silence and watchfulness, and are borne either upright, inbowed, extended, endorsed respecting each other, surmounting one another, fretted, &c.

In blazoning fishes, those borne feeding, should be termed devouring; all fishes borne upright and having fins, should be blazoned hauminant; and those borne transverse the escutcheon, must be termed naiant.

Fish-block, in a ship. See Block.

Fish-garth, a wear or dam in a river, for catching of fish. See Wear.

Fish-shells, in husbandry. See Shells.

Fish-ponds, those made for the breeding or feeding of fish.

Fish-ponds are no small improvement of warty and boggy lands, many of which are fit for no other use. In making of a pond, its head should be at the lowest part of the ground, that the trench of the flood-gate or sluice, having a good fall, may not be too long in emptying. The best way of making the head secure, is to drive in two or three rows of stakes above six feet long, at about four feet distance from each other, the whole length of the pond-head, whereof the first row should be rammed at least about four feet deep. If the bottom is sable, the foundation may be laid with quick-lime, which blacking, will make it as hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and stakes; and when these are well covered, drive in others, as they see occasion, ramming in the earth as before, till the pond-head be of the height designed.

The dam should be made sloping on each side, leaving a walk to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed six feet, rising gradually in shoals towards the sides, for the fish to run themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a fat foil with a white fat water, as the washings of hills, commons, streets, finks, &c., is best for fattening all sorts of fish. For flooring a pond, carp is to be preferred for its goodness, quick growth, and great increase, as breeding five or six times a year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds that have marl or clay-bottoms, with plenty

| Fift of all forts, taken by foreigners, and imported in foreign ships, are forfeited, together with the ship, except stock-fish, live eels, sturgeon, herring, or cavear, and anchovies. And, by 1 Geo. I. cap. xviii. salmon taken in great rivers, and sea-fish fold, are to be of certain lengths, or the takers shall forfeit 1 l. and the sellers 20 s. besides the fifth.
plenty of weeds and grass, wherein they feed in hot months.
Your pond should be drained every three or four years, and your fish furred. If it is a breeding one, the smaller ones are to be taken out, to store other ponds with; leaving a good flock of females, at least eight or nine years old, as they never breed before that age. In feeding ponds, it is best to keep them pretty near of a size.

FISHERY, a place where great numbers of fish are caught.
The principal fisheries for salmon, herring, mackrel, pilchards, &c. are along the coasts of England, Scotland, and Ireland; for cod on the banks of Newfoundland; for whales, about Greenland; and for pears, in the East and West-Indies.

FISHERY denotes also the commerce of fish, there particularly the catching them for sale.
We are to enter into a very minute and particular consideration of fisheries, as at present established in this kingdom, this article would swell beyond its proper bounds; because to do justice to a subject of that concernment to the British nation, requires a very ample and distinct disquisition. We shall, however, observe, that since the divine providence has so eminently stocked the coasts of Great Britain and Ireland with the most valuable fish; and since fisheries, if successful, become permanent nurseries for breeding expert fishermen; it is not only a duty we owe to the Supreme being, not to deprive the wonderful plenty he hath afforded us, by neglecting to extend this branch of commerce to the utmost; but it is a duty we owe to our country, for its national security, which depends upon the strength of our royal navy. No nation can have a navy, where there is not a fund of buildings to breed and employ fishermen, without any expense to the public, and no trade is so well calculated for training up these useful members of this society, as fisheries.

The situation of the British coasts is the most advantageous for catching fish in the world; the Scotch islands, particularly those to the north and west, lie most commodious for carrying on the fishing trade to perfection; for no country in Europe can pretend to come up to Scotland in the abundance of the finest fish, with which its various creeks, bays, rivers, lakes, and coasts are replenished. King Charles I. was so sensible of the great advantage to be derived from fisheries, that he began the experiment, together with a company of merchants; but the civil wars soon occasioned that project to be set aside. King Charles II. made a like attempt, but his pressing wants made him withdraw what money he had employed that way, whereupon the merchants that joined with him, did so too. Since the union, several attempts have been made to retrieve the fisheries, and a corporation settled to that effect, intituled the Royal British Fishery. In the year 1750, the parliament of Great Britain taking the state of the fisheries into consideration, an act was passed for the encouragement of the white-herring fishery, granting a charter, whereby a corporation is created, to continue twenty-one years, by the name of the Society of the Free British Fishery, to be under the direction of a governor, president, vice-president, council, &c. who are to continue in office the space of three years, with power to make bye-laws, &c. and to raise a capital of 500,000 L. by way of subscription. And any number of persons, who, in any part of Great Britain, shall subscribe 10,000 L. into the stock of this society, under the name of the Fishing Chamber, and carry on the said fishery on their own account of profit and loss, shall be intitled to the same bounty allowed to the society. The bounty is 30s. the tun, to be paid yearly, for fourteen years, besides 3 per cent. for the money advanced by each chamber. The act contains other proper regulations relative to the nets, marks on the herring-barrels, numbers of hands, and the quantity of salt that is intitled to the bounty, &c. It is then by the encouragement given by this act, that we now see a laudable emulation prevailing all over the two kingdoms, and fishing bulks fitted out from almost every port, in order to repair to the Shetland islands, where the herring-fishery is carried on with an ardor becoming so important a branch of trade. Scotland, which suffered incredibly from the neglect of this valuable and natural produce of the seas, has not been backward to join in a scheme that tends so evidently to its own advantage; for the cities of Edinburgh and Glasgow, the towns of Montrose, Dundee, Perth, Inverness, and some other boroughs, have raised the proper sum, and chambers have been erected in each of them; the gentlemen of estates adjoining to the respective places above-mentioned, liberally contributing with merchants,
Anchovy-Fishery. Anchovies are fished on the coast of Provence, in the months of May, June, and July, at which season shoals of this fish regularly come into the Mediterranean through the sound of Gibraltar. They are likewise found in plenty in the river of Genoa, on the coast of Sicily, and on that of the island of Gorgone opposite to Leghorn; these last are reckoned the best. It is remarkable, that anchovies are seldom fished but in the night-time. If a fire be kindled on the poop of the vessels used for this fishing, the anchovies will come in greater numbers into the nets; but then it is asserted, that the anchovies taken thus by fire, are neither so good nor so firm, and will not keep so well, as those which are taken without fire. When the fishery is over, they pull off the heads of all the anchovies, gut them, and afterwards range them in barrels of different weights, the largest of which do not weigh above 25 or 26 pounds, and they put a good deal of salt in them. Some also pickle them in small earthen pots made on purpose, of two or three pounds weight more or less, which they cover with platter, to keep them the better.

Cod-Fishery. There are two kinds of cod-fish, the one green or white cod, and the other dried or cured cod, tho' it is all the same fish differently prepared; the former being sometimes salted and barrel'd, then taken out for use; and the latter having lain some competent time in salt, dried in the sun or smoke. We shall therefore speak of each of these apart, and first of

Green cod-Fishery. The chief fisheries for green cod are in the Bay of Canada, on the great bank of Newfoundland, and on the Isle of St. Peter, and the Isle of Sable, to which places vessels resort from divers parts both of Europe and America. They are from 190 to 150 tons burden, and will catch between 30 and 40 thousand cod each. The most essential part of the fishery, is to have a master who knows how to cut up the cod, one who is skilful to take the head off properly, and above all, a goodailer, on which the preserving them, and consequently the success of the voyage, depends. The best season is from the beginning of February to the end of April; the fish which in the winter retire to the deepest water, coming then on the banks, and fattening extremely. What is caught from March to June keeps well, but those taken in July, August, and September, when it is warm on the banks, are apt to spoil soon. Every fisher takes his own at a time: the most expert will take from 350 to 400 in a day, but that is the most, the weight of the fish and the great coldness on the bank fatiguing very much. As soon as the cod are taken, the head is taken off; they are opened, gutted and salted, and the salt flows them in the bottom of the hold, head to tail, in beds a fathom or two square; laying layers of salt and fish alternately, but never mixing fish caught on different days. When they have lain thus three or four days to drain off the water, they are replaced in another part of the ship, and salted again; where they remain till the vessel is loaded. Sometimes they are cut in thick pieces, and put up in barrels for the convenience of carriage.

Dry cod-Fishery. The principal fishery for dry cod, is from Cape Roche to the Bay des Exports, along the coast of Placentia, in which compass there are divers commodious ports for the fish to be dried in. These, tho' of the same kind with the fresh cod, are much smaller, and therefore fitter to keep, as the salt penetrates more easily into them. The fishery of both is much alike, only this latter is more expensive, as it takes up more time, and employs more hands, and yet scarce half so much salt is spent in this as in the other. The bait is herrings, of which great quantities are taken on the coast of Placentia. When several vessels meet and intend to fish in the same port, he whole shallops first touches ground, becomes intitled to the quality and privileges of admiral; he has the choice of his faction, and the refusal of all the wood on the coast at his arrival. As fast as the masters arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts, and in the mean time the mates provide a tent on shore, covered with branches of trees, and falls over them, with a scaffold of great trunks of pines, twelve, fifteen, sixteen, and often twenty feet high, commonly from forty to fixty feet long, and about one third as much in breadth. While the scaffold is preparing, the crew are ashore, and as fast as they catch they bring their fish ashore;
as afore; open and salt them upon moveable benches; but the main salting is performed on the scaffold. When the fish have taken salt, they wash and hang them to drain on rails; when drained, they are laid on kinds of staves, which are small pieces of wood laid across, and covered with branches of trees, having the leaves stripped off, for the passage of the air. On these staves, they are dipped, a fish thick, head against tail, with the back uppermost, and are turned carefully, four times every twenty-four hours. When they begin to dry, they are laid in heaps ten or twelve thick, in order to retain their warmth; and every day the heaps are enlarged, till they become double their first bulk; then two heaps are joined together, which they turn every day as before; lastly, they are salted again, beginning with those first salted, and being laid in huge piles, they remain in that situation, till they are carried on board the ships, where they are laid on the branches of trees dipped for that purpose, upon the ballasts, and round the ship, with mats to prevent their contracting any moisture. There are four kinds of commodities drawn from cod, vizz. the roundes, the tongues, the roes, and the oil extracted from the liver. The first is salted at the fishery, together with the fish, and put up in barrels from 6 to 700 pounds. The tongues are done in like manner, and brought in barrels from 4 to 500 pounds. The roes are also salted in barrels, and serve to cast into the sea to draw fish together, and particularly pilchards. The oil comes in barrels, from 400 to 520 pounds, and is used in dressing leather. The Scots catch a small kind of cod on the coasts of Buchan, and all along the Murray Firth on both sides; as also in the Firth of Forth, Clyde, &c., which is much esteemed. They salt and dry them in the sun upon rocks, and sometimes in the chimney. They also cure skait, and other smaller fish in the same manner, but most of these are for home-consumption.

Coral-FISHERY. See Coral-FISHERY.

Herring-FISHERY. Herrings are chiefly found in the north sea. They are a fish of passage, and commonly go in shoals, being very fond of following fire or light, and in their passage they resemble a kind of lightning. About the beginning of June, an incredible shoal of herrings, probably much larger than the land of Great-Britain and Ireland, come from the north on the surface of the sea; their approach is known by the hovering of sea fowl in expectation of prey, and by the smoothness of the water; but where they breed, or what particular place they come from, cannot be easily discovered. As this great shoal passes between the shores of Greenland and the north cape, it is probably confined, and as it reaches the extremities of Great Britain, is necessarily divided into two parts. For we find one part of the herrings, steering west, or south-west, and leaving the islands of Shetland and Orkney to the left, pass on towards Ireland, where being interrupted a second time, some keeping the shore of Britain, pass away south down St. George's channel, while the other part edging off to the south-west, coast the western ocean, till they reach the south shore of Ireland, and then steering south-east, join the reef in St. George's channel. The other part of the first division made in the north, parting a little to the east and south-east, pass by Shetland, and then make the point of Buchan-nets, and the coast of Aberdeen, filling as they go, all the bays, firths, creeks, &c. with their innumerable multitudes. Hence they proceed forward, pass by Dunbar, and rounding the high shores of St. Abbe's Head, and Berwick, are seen again off Scarborough; and even then not diminished in bulk, till they come to Yarmouth-Roads, and from thence to the mouth of the Thames, after which, passing down the British Channel, they seem to be lost in the western ocean.

The vast advantage of this fishery to our nation is very obvious, when we consider that the herrings are found upon the shores of north America, they are never seen there in such quantities as with us, and that they are not to be met with in considerable numbers in any of the southern kingdoms of Europe as Spain, Portugal, or the south parts of France on the side of the ocean, or in the Mediterranean, or on the coast of Africa. There are two reasons for herring-herring the first from June to the end of August, and the second in autumn, when the fogs become very favourable for this kind of fishing. The Dutch begin their herring-fishing on the 24th of June, and employ no less than two thousand vessels therein called buffes, being between forty-five and sixty tuns burden, and carrying three
as four small cannon. They never stir out of port without a convoy, unless there be enough together to make about eighteen or twenty cannon among them, in which case they are allowed to go in company. Before they go out, they make a verbal agreement, which has the same force as if it were in writing. The regulations of the admiralty of Holland are partly followed by the French, and other nations, and partly improved and augmented with new ones, as, that no fisher shall cast his net within a hundred fathoms of another boat: that while the nets are cast, a light shall be kept on the hind part of the vessel: that when a boat is by any accident obliged to leave off fishing, the light shall be cast into the sea: that when the greater part of a fleet leaves off fishing, and casts anchor, the rest shall do the same, &c. By the late act of parliament in Great Britain, the regulations are, that every vessel intitled to the bounty, must carry twelve Winchseffter buffers of salt in new barrels, for every hafth of fish such vessel is capable of holding; and as many more new barrels as such vessels can carry; and two fleets of tanned nets, that is, a vessel of seventy tons shall carry one fleet of fifty nets, each net to be thirty yards full upon its rope, and seven fathoms deep; and so in proportion for greater or smaller vessels; and be provided with one other fleet of fifty like nets, on board a tender, or left on shore in a proper place for the use of the said vessel, &c.

There is nothing particular in the manner of fishing. The nets wherein the fish are drawn, should regularly have their meshes an inch square to let all the lesser fry go through.

Curing and preparing Herring. The commerce of herring both white or pickled, and red, is very considerable. The white Dutch herrings are the most esteemed, being divided into four sorts, according to their sizes; and the bell are those that are fat, fleasy, firm, and white, salted the same day they are taken, with good salt and well barrelled. The British herrings are little inferior, if not equal to the Dutch, for in spite of all their endeavours to conceal the secret, their method of curing, salting, or caulsing the herrings, has been discovered and is as follows. After they have hauled in their nets, which they drag in the sterns of their vessels backwards and forwards in traversing the coast, they throw them upon the ship's deck, which is cleared of every thing for that purpose: the crew is separated into fundy divisions, and each division has a peculiar task: one part opens and guts the herrings, leaving the melts and roes: another cures and salts them, by lining or rubbing their sides with salt: the next packs them, and between each row and division they sprinkle handfuls of salt: lastly, the cooper puts the finishing hand to all by heading the casks very tight, and flowing them in the hold. It is customary with us to wash the herring in fresh water, and steep them twelve or fifteen hours, in a strong brine, before we proceed to barrel them.

Red Herrings must lie twenty-four hours in the brine, in as much as they are to take all their salt there, and when they are taken out, they are spitted, that is, strung by the head on little wooden spits, and then hung in a chimney made for that purpose. After which, a fire of brush-wood which yields a deal of smoke, but no flame, being made under them, they remain there till sufficiently smoked and dried, and are afterwards barrelled up for keeping.

Mackrel-Fishery. The mackrels are found in large shoals in the ocean, but especially off the French and English coasts. They enter the English channel in April, and proceeding as the summer advances; about June, they are on the coasts of Cornwall, Suffolk, Normandy, Picardy, &c. where the fishery is most considerable. They are taken either with a line or nets: the latter is preferable, and is usually performed in the night-time. They are pickled two ways, first by opening and gutting them, and crammimg their bellies as hard as possible with salt, by means of a stick, and then laying them in rows at the bottom of the vessel, drawing salt between each layer. The second way is putting them directly into tubs full of brine, made of salt and fresh water, and leaving them to steep till they have taken salt enough to keep. After this, they are barrelled up and pressed close down.

Pearl-Fishery. See Pearl Fishery.

Pilchard-Fishery. The chief pilchard fisheries are along the coasts of Dalmatia on the coast of Bretagne, and along the coasts of Cornwall and Devonshire. That of Dalmatia is very plentiful: that on the coasts of Bretagne employs annually about 300 ships. The pilchards caught on
on our coasts, tho' bigger, are not so much valued as those on the coasts of France, owing principally to their not being so thoroughly cured. They naturally follow the light, which contributes much to the facility of the fishery: the season is from June to September. On the coasts of France they make use of the roes of the Cod-fish, as a bait, which thrown into the sea, makes them rise from the bottom, and run into the nets. On our coasts there are porps posted ashore, who by flying by the colour of the water where the shoals are, make signs to the boats to go among them to cast their nets. When taken, they are brought on shore to a warehouse, where they are laid up in backs and sides; when dry, barrel and then sent to London, or exported up the Mediterranean. They have also in England, Scotland, a great deal of salmon for home consumption, and if properly cured and prepared, is reckoned very delicious.

Salmon-Fishery. The chief salmon fisheries in Europe are in England, Scotland, and Ireland, in the rivers, and sea-coasts adjoining to the river mouths. Those most distinguished for salmon in Scotland, are the River Tweed, the Clyde, the Tay, the Dee, the Don, the Spey, the Neth, the Bewley, &c. in most of which it is very common about the height of summer, especially if the weather happen to be very hot, to catch four or five score of salmon at a draught. The chief rivers in England for salmon are the Tyne, the Trent, the Severn, and the Thames. The fishing usually begins about January, and in Scotland, they are obliged to give over about the 15th of August, because, as it is then suppoed the fish come up to spawn, it would be quite depopulating the rivers to continue fishing any longer. It is performed with nets, and sometimes with a kind of locks or weares made on purpose, which in certain places have iron or wooden grates so disposed, in an angle, that being impelled by any force in a contrary direction to the course of the river, they may give way and open a little at the point of contact, and immediately shut again, closing the angle. The salmon, therefore, coming up into the rivers, are admitted into these grates, which open, and suffer them to pass through, but shut again, and prevent their return. Salmon are also caught with a speer, which they dart into him when they see him swimming near the surface of the water. It is customary likewise to catch them with a candle and lanthorn, or wisp of straw set on fire; for the fish naturally following the light, are struck with the spear, or taken in a net spread for that purpose, and lifted with a sudden jerk from the bottom. We make no mention of the method of catching salmon with a line or hook, because it is much the same with that explained under the article Trout Fishing.

Curing Salmon. When the salmon are taken, they open them along the back, take out the guts and gills, and cut out the greatest part of the bones, endeavouring to make the inside as smooth as possible, then salt the fish in large tubs for the purpose, where they lie a considerable time soaking in brine, and about October, they are packed close up in barrels, and sent to London, or exported up the Mediterranean. They have also in Scotland, a great deal of salmon salted in the common way, which after soaking in brine a competent time, is well pressed, and then dried in smoke; this is called kipper, and is chiefly made for home consumption, and if properly cured and prepared, is reckoned very delicious.

Sturgeon-Fishery. The greatest sturgeon-fishery is in the mouth of the Volga, on the Caspian Sea, where the Muscovites employ a great number of hands, and catch them in a kind of inclosure formed by huge stakes, representing the letter Z, repeated several times. These fisheries are open on the side next the sea, and close on the other, by which means the fish ascending in its season up the river, is embarrassed in these narrow angular retreats, and so is easily killed with a harping-iron. Sturgeons, when fresh, eat deliciously, and in order to make them keep, they are salted or pickled in large pieces, and put up in casks from thirty to fifty pounds. But the great object of this fishery is the roe, of which the Muscovites are extremely fond, and of which is made the caviar or kavia, so much esteemed by the Italians. See the article CAVEAR.
Whale-Fishery. Whales are chiefly caught in the north sea: the largest fort are found about Greenland, or Spitzbergen. At the first discovery of this country, whales not being used to be disturbed, frequently came into the very bays, and were accordingly killed almost close to the shore, so that the blubber being cut off was immediately boiled into oil on the spot. The ships in these times, took in nothing but the pure oil and the fins, and all the business was executed in the country, by which means a ship could bring home the produce of many more whales than the can according to the present method of conducting this trade.

The fishery also was then so plentiful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the situation of this trade. The ships coming in such numbers from Holland, Denmark, Hamburgh, and other northern countries, all intruders upon the English, who were the first discoverers of Greenland, the whales disturbed, and gradually, as other ships often do, forfaking the place, were not to be killed so near the shore as before, but are now found, and have been so ever since, in the openings and spaces among the ice, where they have deep water, and where they go sometimes a great many leagues from the shore.

The whale-fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away and get clear of the ice by the end of August; so that in the month of September at farthest, they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows. As soon as the fishermen hear the whale blow, they cry out *fall! fall!* and every ship gets out its long boat, in each of which there are fix or seven men: they row till they come pretty near the whale, then the harpooner strikes it with his harpoon. This requires great dexterity, for through the bone of his head there is no striking, but near his spout there is a soft piece of flesh, into which the iron sinks with ease. As soon as he is struck, they take care to give him rope enough, otherwise, when he goes down, as he frequently does, he would inevitably sink the boat: this rope he draws with such violence, that, if it were not well watered, it would by its friction against the sides of the boat, be soon set on fire. The line fastened to the harpoon is fix or seven fathoms long, and is called the fore-runner: it is made of the finest and finest hemp, that it may slip the easier: to this they join a heap of lines of go or one hundred fathoms each, and when there are not enough in one long-boat, they borrow from another. The man at the helm observes which way the rope goes, and steers the boat accordingly, that it may run exactly out before; for the whale runs away with the line with so much rapidity, that he would overfet the boat, if it were not kept straight. When the whale is struck, the other long boats row before, and observe which way the line stands, and sometimes pull it; if they feel it fliff, it is a sign the whale still pulls in strength; but if it hangs loose, and the boat lies equally high before and behind upon the water, they pull it in gently, but take care to coil it so, that the whale may have it again easily if he recovers strength: they take care, however, not to give him too much line, because he sometimes entangles it about a rock, and pulls out the harpoon. The fat whales do not sink as soon as dead, but the lean one's do, and come up some days afterwards. As long as they see whales, they lose no time in cutting up what they have taken, but keep fishing for others: when they see no more, or have taken enough, they begin with taking off the fat and whiskers in the following manner. The whale being lashed along side, they lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which together with the fins is struck off, as soon as he is taken, to keep those extremities above water. On the off side of the whale are two boats to receive the pieces of fat, utensils and men that might otherwise fall into the water on that side. These precautions being taken, three or four men with irons at their feet, to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick, and eight long, which are hauled up at the capitanle or windlass. When the fat is all got off, they cut off the whiskers of the upper jaw with an ax. Before they cut, they are all lashed to keep them firm, which also facilitates the cutting,
and prevents them from falling into the sea; when on board, five or six of them are bundled together, and properly flowed, and after all is got off, the carcass is turned adrift, and devoured by the bears, who are very fond of it. In proportion as the large pieces of fat are cut off, the rest of the crew are employed in slicing them smaller, and picking out all the lean. When this is prepared, they stow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in tubs in the hold, cramming them very full and close. Nothing now remains but to sail homewards, where the fat is to be boiled and melted down into train oil. See Train Oil.

It was in vain to speak in this place of the advantages that may be derived to Great Britain from the whale-fishery. We shall only remark, that the legislature think that trade of so great importance, as to grant a very considerable bounty for the encouragement of it; for every British vessel of 200 tons or upwards, bound to the Greenland-seas on the whale-fishery, if found to be duly qualified according to the act, obtains a licence from the commissioners of the customs to proceed on such voyage: and on the ship's return, the master and mate making oath that they proceeded on such voyage and no other, and used all their endeavours to take whales, &c., and that all the whale-fins, blubber, oil, &c., imported in their ship, were taken by their crew in those seas, there shall be allowed 40s. for every ton according to the admeasurement of the ship.

Besides their fisheries, there are several others both on the coasts of Great Britain and in the north seas, which although not much the subject of merchandise, nevertheless employ great numbers both of ships and men; as, 1. The oyster fishing at Colchester, Faversham, the Isle of Wight, in the Swales of the Medway, and in all the creeks between Southampton and Chichester, from whence they are carried to be fed in pits about Weymouth, and other places. See the article Oyster.

2. The lobster fishing all along the British channel, the firth of Edinburgh, on the coast of Northumberland, and on the coast of Norway, from whence great quantities are brought to London. And lastly, the fishing of the pot-fish, fin-fish, sea-unicorn, sea-horse, and the

feal, or dog-fish, all which are found in the same seas with the whales, and yield blubber in a certain degree; besides, the horn of the unicorn is as estimable as ivory, and the ikins of the seals are particularly useful to trunkmakers.

Fishing in general, the art of catching fish, whether by means of nets, or of spears, lines, rods, and hooks. See the articles Net, Line, Rod, &c.

By several statutes it is provided, that no persons shall fish in any pond or moat, without the owner's consent, on pain of three months imprisonment; nor shall any one take fish in a river without licence obtained from the owner, upon forfeiture of £10 to the poor, and triple damages to the party aggrieved, to be levied by justices of the peace, by distress and sale of goods. The nets, and other implements, belonging to poachers, may be seized by the owners of rivers, &c.

Fishing performed with a rod, line, and hook, is called angling. See Angling.

Carp-Fishing, requires a world of patience, by reason they seldom bite in cold weather, and, in hot, the angler cannot be too early, or too late; but when they do bite, there is no fear of the hold. The baits proper for them, are the red worm in March, the cadew in June, and the grass-hopper in July, August, and September. See Carp and Bait.

Chub-Fishing, is performed with a large bait, whether worm, snail, fly, cheese, &c., according to the season and time of the day; but the large yellow moth seems to be a favourite morrel of this fish. See the article Chub.

Cod-Fishing. See Fishery, supra.

Dace-Fishing, affords good sport, as they catch at any fly, particularly the stone-cadew, and may-fly, in the beginning of summer, and the ant-fly in June, July, August, &c. But to catch dace in winter, the bait is a white worm, with a large red head, found in ploughed lands. See the article Dace.

Eel-Fishing. The silver-eel may be caught with several sorts of baits, as powdered beef, garden-worms, lobes, minnows, garbage, &c. The night is the best time for this kind of fishing; throwing a line with good store of hooks, baited and well plumbed, into the places where eels resort, with a float to discover where the lines lie, that they may be taken up in the morning.

As to the method called bobbing and flig-
Snigling, it is only by means of a flick
thrusting a baited hook into the holes
where eels use to hide themselves. Some
fih for eels with a three-forked spear
jagged on the sides: this they strike into
the mud, and if it chance to light where
they lie, there is no fear of fecuting
them. But to take the largest eels of
all, the night hooks are to be baited
with small roaches; and the hook’s must
lie in the mouth of the fih. See EEL.

Flounder-Fishing, in the months of April,
May, June, and July, may be performed
day long, either in the stream, or
still deep-water, but the stream is best;
and the most proper baits are all sorts
of red-worms, waps, or gentles. See
the article FLounder.

Gudgeon-Fishing, may be performed with
float, the hook being on the ground;
or by hand, with a running line on the
ground, without cork or float. A small
red worm is the best bait for this fih, yet
waps, gentles, and cad-bits, will do
very well; and, in order to gather them
to the place, it may not be improper to
stir the sand and gravel, above and be-
low it, by which means they will bite
fatter, and with more eagerness. See
the article GUDGEON.

Herring-Fishing. See the articles FISH-
ERY, supra, and HERRING.

Mackerel-Fishing. See the article FISH-
ERY, supra, and MACKEREL.

Peach-Fishing. The proper baits are a
minnow, or little frog; but the best of
all is a worm called a branding. You
may allo angle for this fih with job
worms, bobs, waps, &C. If you row
for a perch with a minnow, which of all
baits yields the best sport to the
angler, it must be alive, sticking the
hook through the upper lip, or back-fin,
letting it swim about mid-water, or some-
what lower; for which end you ought
to have an indifferent large hook, with
a quill on your line; but some, with
good success, have used a strong silk-line,
and a hook armed with wire. If you fih
with a frog, the hook must be fastened
thru the skin of the leg, toward the
upper part thereof.

Pike-Fishing, is performed two ways.

1. By the ledger-bait, fixed in one certain
place; which must be a living bait of
fish or frog, as dace, roach, perch, and
yellow frogs. 2. By the walking bait,
with a troll and winch, so as to give the
fish length enough to run off with the
bait; then striking him with a smart jerk.

The rod must not be too slender at top;
and the line should be of silk two yards
and a quarter next the hook, and strongly
armed with a wire about seven inches.

Pitcher-Fishing. See FISHERY, supra,
and PILCHARD.

Rack-Fishing, is best performed, in
April, with cads or worms; and, in
summer, with white small snails, or flies;
but then the baits should be under-water,
for they will not bite at top. Some use
a may-fly with good success; and, in
autumn, a paste, made of the crumb of
fine bread, will do very well. The man-
er of fishing for rack at London is pe-
culiar. They take a strong cord, at the
end of which is fastened a three pound
weight; and a foot above the lead, a
pack-thread of twelve feet is made fast
to the cord; and to the pack-thread, at
proper distances, they add twelve strong
links of hair, with roach-hooks at them,
baited with a white snail or periwinkle.
Then holding the cord in their hands,
the biting of the fih draws the pack-
thread, and that the cord, which gives
them notice what to do. By this means,
they sometimes draw up half a dozen,
and very commonly two or three at a
draft.

Salmon-Fishing. See the articles FISHERY
and SALMON.

Sturgeon-Fishing. See FISHERY and
STURGEON.

Tench-Fishing, is best performed with
large red worms, at which they will bite
the more eagerly, if dipped in tar. Se-
veral other sorts of worms, and a paste
made of brown bread, are also used for
this purpose.

Trout-Fishing. The baits for this pur-
pose are either natural or artificial, as
earth worms, minnows, and fishing flies,
both natural or artificial. Whatever
worms are used, they answer best if
kept some time in an earthen pot, with
mois often changed in summer. If you
fih for trout with hand on the ground,
the hook is to be introduced into the
worm a little above the middle, coming
out again a little below; then draw the
worm above the arming of the hook,
making your first entrance at the tail-end,
that the point of the hook may come out
at the head-end. When you fih with min-
nows, take the whitef and middle-fixed
; and after putting the hook in at the mouth,
and out at the gills, and drawing it thro’
about three inches, flip it again into his
mouth, to as the point and beard may
come
come out at the tail. This done, tie the hook and tail together with a fine white thread, and let the body of the minnow be almost straight upon the hook.

**FISSURE of the bones**, in surgery, is when they are divided either transversely or longitudinally, not quite through, but cracked after the manner of glass, by any external force. Fissures are not easily detected, since neither the senses of seeing, feeling, or hearing can give sight enough to determine anything with certainty in this case. However, surgeons always suppose there is a fissure when there happen violent inflammations, suppurations, fistulae, and caries, with excessive pain, after any external violence. When, from these symptoms, there appears to be a fissure, it is usual to apply the plaster used in fractures, placing splints above all. When the tumour becomes soft, it is to be laid open by incision, to let out the corrupted fluid; after which a tent should be put into the wound, dipped in some vulnerary unguent, using afterwards the bandage, which is applied in fractures accompanied with a wound. Some affert, that fissures, when just made, may be cured by the application of bandages, without the assistance of other remedies. In fissures of the cranium, attended with no other bad symptoms, but white, yellow, or brown spots upon the face of the bone, it is sufficient to bore down to the diploe, and dress with some balsamic medicine; but where any violent symptoms come on, which shew that there is an extravasation of blood in the cavity of the cranium, the trepan is to be called in, without delay. See the articles CONTRA-FISSURE and EXTRAVASATION.

**FISTULA**, in the ancient music, an instrument of the wind-kind, resembling our flute, or flageloet. See FLUTE.

The principal wind-instruments of the antients, were the tibia and fistula. But how they were constituted, wherein they differed, or how they were played on, does not appear.

**FISTULA, in surgery**, a deep, narrow, and callous ulcer, generally arising from abscesses. See the article ABSCESS.

Fistula's differ from sinuses in this, that the former are callous, the latter not. See the article SINUS.

Fistulas attack all parts of the body without exception, particularly the anus, the perineum, and the foramen lacrymale.
times for a time are shut up; and then at certain intervals break out again.

Unless these fistulas are attended with great molestation, such as an exorbidant evacuation of humours, with a fever, or the like, they are in a great measure to be left to nature to be cured, as serving in manner of a drain, for the discharge of superfluous, peccant humours, in caeco-
chymical and cachectical bodies: these should rather be kept open; but simple fistulas, that are recent, may be cured without danger. When a fistula in the anus is so conditioned, that an operation may be performed without danger of injuring the sphincter muscle, so, as to render it incapable of retaining the excre-
ments, there are two ways of doing it, viz. either by a ligature, or incision.

By ligature it is to be done thus. Let the surgeon take a thread of silk, or some horse-hair, and thread it into the eye of a leaden, or tin probe, with which let him introduce the end of the thread into the fistula, and with the fore-finger of the other hand, being anointed with oil of roses, and thrust up into the anus, let him lay hold of the end of the probe, and draw forth the thread, and then tie the two ends together, as tight as the patient can well bear it; and thus by tying it afresh every day, somewhat stiffer, it will cut quite through, and the fistula will be laid open; and after that the callus must be destroyed, and the ulcer healed, 

A more expeditious way is by making an incision with an instrument, after this manner. A hollow leaden probe is to be thrust into the fistula, till it penetrates into the intestinum reftum; and then the instrument being passed into the anus, with the guidance of a finger, the fistula is to be cut according to the di-
rection of the conductor, yet taking care not to hurt the haemorrhoid veins, to oc-
casion an haemorrhage. When the incision is made, a dosis is to be put in armed
with the white of an egg, and astringent powders: the callus is to be destroy-
ed with a powder made of burnt alum, precipitate mercury, &c.

Fistula in the perineum, is usually the conquence of lithotomy, or making a puncture in the perineum and bladder; or they may proceed from abcesse in the perineum, near the urethra; or from a fistulosity of the prostate gland; or from a wound, or ulcer, which can by no means be healed up, but the lips, be-

coming callous, form a fistula, through which the urine is sometimes preter-
naturally discharged.

The treatment of these fistulas is various, according to the habit and particular dis-
position of the parts affected. The ge-

neral treatment is as follows. Let the callous lips of the fistula be cut off, and
the parts brought together by a thickening platter, after they have been dressed by
some vulnerary balsam; over the platter should be laid a narrow compress, on
each side of the wound, and the whole retained by a strict bandage; which done, the patient's knees are to be tied together, and strict orders given him, to lie still in bed, that the lips of the wound may more easily unite with each other.

For the first few days after the operation, the patient should be allowed very little
drink, that he may not be often excited to make water, and the dressings should not be removed till the second or third day after the operation, or till the pa-
tient can contain his urine. For some time afterwards the patient must observe a strict regimen.

Fistula lachrymalis, a disease which attacks the great caruncle in the inward corner of the eye. See the article Eye.

The first degree of this disease stops up the natural passage of the tears, and
forces them to run down the cheek; the second is when pus is mixed with the tears, which proceeds sometimes from an opening in the skin, between the nose and the great corner of the eye; the last is when the pus has not only corroded the neighbouring parts; which are soft, but has affected the bone which lies un-
derneath. This last sort of fistula sometimes turns cancerous, and Riverius ad-
vises not to meddle with it at all.

Whatever may be the cause of this dis-
order, whether the small-pox, or French
disease, it always stops up the nasal conduit.

If the abcesis is not open, a time must be chosen when it is fullest of pus. For this reason, the eye of the patient must be closed, and small long pieces of platter must be put one upon another, across the eye-lids, from the puncta lachry-
malia to the great angle of the eye. The superior branches of the canal being thus compre
ted, that nothing can pass that way, it will be amasled in the face, and a place proper for an incision should then be pointed out. If the abcesis is already open the orifice and the probe
will thew where it is to be dilated, which
must be done by the bistoury, both above
and below, from the superior part of the
fack to the edge of the orbit. The fack
being opened, it must be filled with dry
lint, which may be taken away next
day, and a pledit dip in a mild diges-
tive applied, which must be repeated once
or twice a day, according to the quantity
of suppuration: when the suppuration
begins to diminish at every dressing, a
small probe must be introduced into the
nasal canal, to dilate it a little, and to
leave a passage for the tears and the pus.
This method must be continued till the
 suppuration is almost ended; then it may
be dressed superficially, with dry lint, or
with a desiccative, which will complete
the cure: after which it will be proper
to wear a compressing bandage a few
weeks longer to prevent its return.
When the bone lies open, and it is ne-
cessary to penetrate into it, you must
direct the instrument towards the nose,
and not towards the nasal canal, for
fear of entering the sinus maxillaris.

FISTULAR, or FISTULOUS; appella-
tions given by surgeons to wounds and
ulcers, which degenerate into fistulas.
See the article FISTULA.

FISTULAR, among botanists, is applied
to leaves and flowers that are tubular, or
resemble a hollow pipe.

FIT, in medicine, denotes much the same
with paroxysm. See PAROXYSM.

FITs of easy reflection and transmission,
in optics. See the articles REFLECTION
and TRANSMISSION.

FITs of the mother; the same with hysteri-
ac affection.

FITCHE, or FITCHOW, in zoology, an
animal more usually called putorius,
and the pole-cat. See PUTORIUS.

FITCHEE, in heraldry, a term applied
to a crofs, when the lower end of it
is sharpened into a point, as in plate
XCVIII. fig. 3.

Croffes are sometimes fitted by only a
point going out from the broad foot
thereof, and sometimes they go tapering
away from the center to the point, in
which case it is said to be fisheé on the
fourth part. The reason of this crofs's
being so painted, Mackenzey supposes to
be, that as the primitive Christians were
wont to carry croffes with them where-
soever they went for devotion, when they
settled themselves in their journey,
at any place, they might fix these por-
table croffes in the ground.

FITCHES; in husbandry, a sort of pulse,
more generally known by the name of
chick pea; or cicer. See CICER.

Fitches are cultivated either for feeding
cattle, or improving the land. They
make a wholesome and nourishing food,
whether given in the straw, or threshed
out. When sown only to improve the
soil, they are plowed in jult as they be-
gin to blossom, by which means a tough
 Flint clay foil is much enriched.

FITZ, makes part of the surname of some
of the natural sons of the kings of
England, as Fitz-roy; which is purely
French, and signifies the king's son.

FIVE CHURCHES, a bishop's See of Lower
Hungary, 76 miles south of Buda.

FIVES, or VIVES, in farriery. See the
article VIVES.

FIUME, or ST. VEIT; a port-town of
Istria, subject to the house of Austria:
east long. 15°, and north lat. 45° 45'.

FIXATION, in chemistry, the rendering
any volatile substance fixed, so as not to
fly off upon being exposed to a great
heat; hence,

FIXED BODIES are those which bear a
considerable degree of heat without
everoparating, or losing any of their
weight.

Gold is the most fixed of all metals. A
quantity of very pure gold, after be-
ing placed in the eye of a glafs fur-
fance for two months, was found not to
have lost any sensible part of its
weight.

However, gold itself, exposed on a piece
of charcoal to the focus of a burning-
glafs, is found to diminish; and, in pro-
portion to this diminution, there arise
an infinite number of little glarry drops
of a greenish colour, which swell and
enlarge as the gold disappears. But
this, say some, is no demonstration that
the gold is vitrified: it is rather the ahes
of the coal; because, if the gold be
everoparated on a body which yields
no ahes, you have no glafs. Be this
as it will, the experiment shews that gold
may be evaporated; and since gold
is not fixed, we may safely conclude,
that there is no body absolutely so. See
the articles GOLD and BURNING-GLASS.

FIXED MERCURY; MERCURY.

FIXED NITRE; NITRE.

FIXED SALTS; SALTS.

FIXED SIGNS; SIGN.

FIXED STARS; STAR.

FLACCIDITY, among physicians, a dis-
order of the iodides; cured by astringent
and
FLA [1251]

and cardiac medicines, joined with exercise and good air.

FLAG, a general name for colours, standards, antents, banners, ensigns, &c. which are frequently confounded with each other. See COLOUR, &c. The fashion of pointed, or triangular flags, as now used, Rod. Toletan affures, came from the mahometan Arabs, or Saracens, upon their seizing of Spain, before which time all the ensigns of war wereretched, or extended on crosps pieces of wood, like the banners of a church. The pirates of Algiers, and throughout the coasts of Barbary, bear an hexagonal flag.

FLAG is more particularly used at Sea; for the colours, antents, standards, &c. borne on the top of the masts of vessels, to notify the peron who commands the ship, of what nation it is, and whether it be equipped for war or trade, see plate XCIX.

The admiral in chief carries his flag on the main-top; the vice-admiral on the fore-top; and the rear-admiral on the mizzen-top.

When a council of war is to be held at sea, if it be on board the admiral, they hang a flag in the main-throds; if in the vice-admiral, in the fore-throds; and if in the rear-admiral, in the mizzen throds.

Besides the national flag, merchant-ships frequently bear lesser flags on the mizen-mast, with the arms of the city where the master ordinarily resides; and on the fore-mast, with the arms of the place where the peron who freights them lives.

FLAG, in french Fanion, a small banner of distinction stuck in the baggage-wagons of the army, to distinguish the baggage of one brigade, or battalion, from that of another, that they may be marched by the waggon-master-general according to the rank of their brigades, where they are to keep during the march, to avoid confusion.

To lower, or strike the FLAG, is to pull it down upon the cap, or to take it in, out of the respect, or submission, due from all ships or fleets inferior to those any way justify their superiors. To lower or strike the flag in an engagement is a sign of yielding.

The way of leading a ship in triumph is to tie the flags to the shrouds, or the gallery, in the hund part of the ship, and let them hang down towards the water, and to tow the vessels by the stern.

Livy relates, that this was the way the Romans used those of Carthage.

To heave out the FLAG, is to put out, or put abroad, the flag.

To hang out the white FLAG, is to ask quarter; or if it flies when a vessel is arrived on a coast, that it has no hostile intention, but comes to trade, or the like. The red flag is a sign of defiance, and battle.

FLAG-OFFICERS, those who command the several squadrons of a fleet, such as the admirals, vice-admirals, and rear-admirals.

The flag-officers in our pay, are the admiral, vice-admiral, and rear-admiral, of the white, red, and blue. See the article ADMIRAL.

FLAG-SHIP, a ship commanded by a general, or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under the command thereof.

FLAG-STAVES, are flaves set on the heads of the top-gallant-masts, serving to let fly, or unfurl, the flag.

FLAGS, in falconry, are the feathers in a hawk's wing, near the principal ones.

FLAG is also used for sedge, a kind of rush; and for the upper part of turf, pared off to burn.

FLAG-FLOWER, in botany, a plant called by botanists Iris. See Iris.

FLAG-WORM, that found in flaggy or seedy places. See the article WORM.

Corn-FLAG, in botany, the same with gladiolus. See the article GLADIOLUS.

Sweet-scented FLAG, a name sometimes given to the acorus or galangal. See the article GALANGAL.

FLAGELLANTES, whippers, in church-history, certain enthusiasts in the thirteenth century, who maintained, that there was no remission of sins without flagellation, or whipping. Accordingly, they walked in procession, preceded by priests carrying the crosps, and publicly lashed themselves, till the blood dropped from their naked backs.

FLAGELLARIA, in botany, a genus of the hexandria monogynia class of plants, without any flower-petals; the perianth is divided into five segments; and the fruit is a roundish berry, containing a single seed.

FLAGOLET, or FLAGOLET, a little flute, used chiefly by shepherds, and country people. It is made of box, or other hard wood, and sometimes of ivory, and has six holes besides that at the bottom,
FLAMBOURGH-HEAD, in geography, a cape or promontory of Yorkshire, five miles east of Burlington: exit long. 10°; north lat. 54° 15'.

The village of Flamborough has its name, as some think, from the word flame, because of a watch-tower here, with lights for the use of sailors.

FLAME, *flamma*, in physiology, the small parts of an inflammable or considerably unctuous body, that are set on fire, or briskly agitated and thrown off, with a certain vibrative motion at the surface of that body into the open air: or, in Sir Isaac Newton's words, the flame of a body is only the smoke thereof heated red hot; and the smoke is only the volatile part of the body separated by the fire. See FIRE and SMOKE.

Flame cannot exist without oil: whence it is that ashes, sand, glass, stones and earth, do not flame upon ignition, but rather damp and extinguish flame. As oil is then the only inflammable substance in nature, we may be directed to the means of preventing conflagrations, by using such materials in buildings as contain little or no oil. And this direction might be likewise extended to the making incombustible paper, for valuable books and manuscripts, &c.

All flame catches and exists only on the surface of inflammable bodies: whence we are led to invent methods of caging or otherwise defending the wood-works of ships and buildings, from accidents by fire.

All inflammable bodies, as sulphur, oil, wax, wood, &c. by flaming, vailes and vanishes into burning smoke; which smoke, if the flame be hastily put out, is very thick and visible, and sometimes smells strongly; but in the flame, loses its smell by burning; and according to the nature of the flame, the flame is of this or that colour: thus the flame of sulphur is blue: that of camphor, white: that of tallow, yellow, &c. When gun-powder takes fire, it goes off in a flaming smoke. Thence proceeds the difference of the colours of bodies, as viewed by day-light, candle-light, fire-light, sulphurous-light, &c.

As the prelude of the fire is greatest about the upper parts, and least towards the circumference of the bafe, whence the air finding least resistance from that part, drives the flame upwards; and as the fire is denser, and consequently stronger, about the middle, it thence follows, that the flame will rise higher from the middle of the fire than from its sides, where the quantity of fire is considerably lessened; and hence we see the reason of the pyramidal figure of flame.

VITAL FLAME, a fine, warm, igneous substance, suppos'd, by some, to reside in the hearts of animals, as necessary to life; or rather as that which constitutes life itself.

To preserve this flame, they judge the air taken in by respiration, to be as necessary as it is to the conservation of ordinary flame. Others, however, not least to be depended on, find no more in the notion of a vital flame, than the natural warmth of the body, which is always as the velocity of the circulating blood, and is the effect of that circulation.

FLAMEN, in roman antiquity, the name of an order of priests, instituted by Romulus or Numa; authors not being agreed on this head.

They were originally only three, *viz.* the flamen dialis, flamen martialis, and flamen
FLAMINGO, in ornithology, a bird otherwise called phoenicopterus. See the article PHOENICOPTERUS.

FLAMMA, or FLAMMULA JOVIS, in botany, a species of clematis, or virgin's bower. See the article CLEMATIS.

FLAMMULA, in antiquity, a kind of flag, so called from its pointed figure. It was painted of different colours, to distinguish the several battalions and companies from each other.

FLANCH, FLANQUE, or FLASQUE, in heraldry, an ordinary always borne double; being the segment of a circular superficies.

FLANDERS, a province of the Netherlands, bounded by the German sea and the United provinces, on the north; by the province of Brabant, on the east; by Hainault and Artois, on the south; and by another part of Artois and the German sea, on the west; being about sixty miles long, and fifty broad, and divided between the Austrians, the French, and the Dutch.

Flammingo. They were chosen by the people, and infall'd by the sovereign pontiff. Afterwards, their number was increased to fifteen; the three first of whom were senators, and called flamines majores; the other twelve, taken from among the people, being denominated flamines minores.

The flamen dialis, or priest of Jupiter, was a considerable person at Rome; the flamen martialis, or priest of Mars, was the second in dignity; and the flamen quirinalis, was the next to him.

The greater flamen wore the robe edged with purple, like that of the great magistrates, had an ivory-chair, and sat in the senate. They wore a little band of thread (filamen) about their head; from whence, according to Varro, they had their name.

There were likewise flaminices, or priestsesses, who were the wives of the flamines diales. These wore a flame-coloured habit, on which was painted the image of a thunder-bolt; and above their head-dress, they wore green oak boughs. They are often mentioned in inscriptions.

Oblique FLANK, or second FLANK, that part which joins the face to the curtin. See the article BAStION.

Engineers differ very much about raising the flank, some making it perpendicular to the face, some to the curtin, and others to the line of defence; some again make it an angle of 98° with the curtin, whereas Vauban makes it the chord of a segment, whose center is the angle of the shoulder of the next bastion. Its use is to defend the curtin, and the flank and face of the opposite bastion; to defend the passageway of the moat, balance the fallant angles of the counter-fcarp and glacis, from whence the besiegers ruin the flanks with their artillery, in order to take away the defence of the opposite bastion.

Retired FLANK, or low FLANK, or covered FLANK, one of the platforms of the caisemate. See the article CAZEMATE.

These retired flanks are great defence to the opposite bastion, and to the passageway of the moat, because the besiegers cannot fee nor easily dismount their guns. The curtin is esteemed the strongest part of a fortification, because flanked at both ends; and the face is accounted the weakest, as having only one defence from the opposite flank.

FLASK, flanquet, in heraldry, is used by the French to express our parti per saltier. See PARTI and SALTIER.

FLASK, in the manege, the side of a horse between the ribs and haunches. A well flanked horse, is one that has wide and well made ribs, and a good body.

FLANKS of an army, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

FLANK of a bastion, in fortification, that part which joins the face to the curtin. See the article BAStION.

Engineers differ very much about raising the flank, some making it perpendicular to the face, some to the curtin, and others to the line of defence; some again make it an angle of 98° with the curtin, whereas Vauban makes it the chord of a segment, whose center is the angle of the shoulder of the next bastion. Its use is to defend the curtin, and the flank and face of the opposite bastion; to defend the passageway of the moat, balance the fallant angles of the counter-fcarp and glacis, from whence the besiegers ruin the flanks with their artillery, in order to take away the defence of the opposite bastion.

FLANKED, flanqué, in heraldry, is used by the French to express our parti per saltier. See PARTI and SALTIER.

FLASK, a horn, or the like, made for carrying of powder, having a measure for the charge of the piece for the top.

FLAT, in the sea-language. To flat in the fore-fail, is to haul it in by the sheet,
as near the ship's side as possible; which
is done, when a ship will not fall off from
the wind.

FLATs, in music, a kind of additional
notes, which, together with sharps, serve
to remedy the defects of musical instru-
ments, wherein temperament is required.
See TEMPERAMENT and SHARP.
The natural scale of music being limited
to fixed sounds, and adjusted to an in-
strument, the instrument will be found
defective in many points; and, particu-
larly, in that we can only proceed from
any note by one particular order of de-
grees; that for this reason, we cannot
find any interval required, from any note
upwards or downwards; and that a long
may be so contrived, as that if it be be-
gun by any particular note or letter, all
the intervals, or other notes, shall be justly
found on the instrument, or in the fixed
series; yet were the long begun with any
other note, we could not so proceed. See
the articles SCALE and INTERVAL.
To remove or supply this defect, musici-
ans have recourse to a scale proceeding
by twelve degrees, that is thirteen notes
to an octave, including the extremes;
which makes the instrument so perfect,
that there is but little reason to complain.
This, therefore, is the present system or
scale for instruments that have their
sounds fixed, viz. between the extremes
of every tone of the natural scale, is put
a found or note, which divides it into
two unequal parts, called semi-tones:

Thus the whole may be called the semi-
tonic scale, containing twelve semi-tones
between thirteen notes, in the compass
of an octave.
Now to preserve the diatonic series dif-
tinctly, these inferted notes either take the
name of the natural note next below,
with the character ♯, called a sharp; or
the name of the natural note next above it,
with the character♭, called a flat. Thus
D♯ or D flat, signifies a semi-tone be-
low D natural; and it is indifferent, in
the main, whether the inferted note be
accounted as a flat or sharp.
This semi-tonic series, or scale, is very
exactly represented by the keys of the
organ, &c. the lowermost range of keys
being the natural or diatonic notes; and
those behind, the artificial ones, or the
flats and sharps.

FLATTING, in gilding, is the giving the
work a light touch, in the places not bur-
nished, with a pencil dipt in size, in which

a little vermilion is sometimes mixt.
This serves to preserve and prevent its
flawing, when handled. See GILDING.

FLATULENCY, in medicine, a disorder of
the bowels arising from a weak stom-
ach, and crude flatulent aliment, as
pease, beans, lentils, colcowers, hard fat
flesh, and the like; which degenerate in-
to wind, creating great anxiety if not
evacuated, and difficulty of breathing.
Another cause of flatulencies are congreg-
tions of blood in the branches of the vena
porta; whence proceed anxieties of the
praecordia, difficult breathing, colic pains,
heart-burn, head-achs, vertigo, and
watchfulness.
If the flatulence arises from crudities in
the stomach, evacuations are first of all
necessary; after which may be given bitters,
aromatics, carminatives, and strengthen-
ers, with a spare diet and exercise. If it
proceeds from congestions of blood, as
is the case of hypochondriacs, a vein
must be opened; and if the body is colitive,
an emollient oyster or a gentle laxative
will be proper. If these fail, chalybeate
medicines are to be called in, as tincture
of vitriol of iron, asp-video finely pow-
dered, from fix to ten grains, or oil of
 cinnamon with sugar or bitters, spaw-
waters, and comforting exercise.

FLATULENT TUMOURS, in surgery. See
the article PNEUMATOCELE.

FLAUTINO, in music, the same with flag-
gelet. See the article FLAGEOLET.

FLAW, in the sea-language, signifies a
sudden gust of wind.

FLAX, linen, in botany. See LINUM.

Flax is an excellent commodity, and the
cultivation of it a good piece of hu-
bandry. It will thrive in any found land,
but that which has lain long fallow is
best; which being well plowed, and laid
flat and even, the seeds must be fown in
a warm season, about the middle or end
of March, or at farthest the beginning of
April; and if a wet season happen,
weeding will be necessary. The best feed
is that brought from the east country,
which, tho' dear, yet easily repays the
charge: this will last two or three crops,
when it is advisable to renew the feeds
again. Of the best feed, two bushels may
serve for an acre; but more must be al-
lowed of home-feed, because it grows
finaller. When grown up, it ought not
to be gathered before it be fully ripe; for
if pulled before the blossom falls, it
beckles away almost to nothing; and,

tho' in appearance very fine, yet it has

no
no substance, and the yarn spun of it is weak and ouzy: it not only waftes in the washing, but the linnen made of it grows extremely thin in the bleaching. The pluckers should be nimble, tie it up in handfuls, let them up till perfectly dry, and then house them. Flax pulsed in the bloom, proves whiter and stronger than if left standing till the feed is ripe; but then the feed will be lost. An acre of good flax, is accounted worth from seven to twelve pounds, or more.

Dressing of Flax. When flax has been watered, and twice swung, as directed under the articles Watering and Swingling, it is then to be heckled in a much finer heckle than that used for hemp. Hold the strike of flax stiff in your hand, and break it very well upon the coarse heckle, saving the hurs to make harden cloth of. This done, the strike is to be passed through a finer heckle, and the hurs coming from thence faved for middling cloth, and the tear itself for the belt linnen.

But to dress flax for the finest use of all, after being handled as before, and laying three strikes together, put them in a plat of three rows, as hard and close together as you can; joining one to the end of another, till you have platted as much as you think convenient: then begin another plat, and add as many several ones, as you think will make a roll; afterwards, wresting them hard together, make up the roll; which done, put as many as you judge convenient into a hemp-trough, and beat them soundly, rather more than less than you do hemp. Next open and unplat them, dividing each strike very carefully from each other; and so strike it through the finest heckle of all, whereof there are three sorts. Great care must be taken to do this gently and lightly, left what is heckled from thence should run to knots; for if preferred felt like cotton, it will make very good linnen, each pound running at least two yards and an half. The tear itself, or finest flax, will make a strong and very fine holland, running at least five yards in the pound. See Spinning.

In Scotland, they have a lint-mill, which greatly facilitates the dressing of flax; which if done by the hand, will cost 3d. the flone; whereas it may be dressed at the mill for 2s. the flone, which is one fourth faved.

Laws regarding Flax and Hemp. Any person may get up the trade of breaking, heckling, and dressing of flax or hemp; also of spinning, weaving, making, whitening, &c. cloth made of hemp or flax only; and that in all places, corporate or incorporate, privileged or not. Foreigners using the foregoing trades for three years, shall, upon taking the oaths to the government, enjoy all the privileges of natural subjects. Rough undressed flax, imported from abroad, pays no duty; but that which is dressed or wrought, pays every hundred weight 4l. 10s. 5d. whereof, upon exporting it, is drawn back 4l. 3s. 3d. However, it is to be observed, that all manner of flax, wrought or unwrought, may be imported from Ireland free of all duty, provided it be done in British or Irish bottoms.

Purging-Flax, linum catharticum. See the article LINUM.

Toad-Flax, linaria. See LINARIA.

FLEA, pulex, in zoology, a genus of insects without wings, or a roundish, compressed figure: the legs are three pair, and formed for leaping; the eyes are two, and simple: the mouth is bent downwards: the colour is a deep purple, approaching to black.

The flea is an insect which infests birds, as well as quadrupeds, and lays eggs, called nits: these produce a kind of nymphs, or white worms; which after some time are transformed, in the manner of caterpillars, into perfect fleas.

Flea-Bane, in botany, a name given to the plant called by authors Conyza. It got the name of flea-bane, from its supposed virtue of killing fleas. See CONYZA.

African Flea-Bane, a plant called by botanists Parthenium. See PARTHENIUM.

Saxet Flea-Bane, the same with tife erigeron of botanists.

Flea-Bitten, that colour of a horse, which is white or grey, spotted all over with dark reddish spots. See HORSE.

Flea-Wort, the English name of the pliy-\_lum of botanists.

FLEAM, in surgery and farriery, an instrument for letting a man or horse blood.

A cale of fleams, as it is called by farriers, comprehends six sorts of instruments: two hooked ones, called drawer; and used for cleaning wounds; a pen-knife; a sharp-pointed lancet, for making incisions; and two fleams, one sharp and the other broad-pointed. These last are somewhat like the point of a lancet, fixed in a flat handle, only no longer than is just necessary to open the vein.

Many of the German surgeons let blood with 7 X 2
with a fleece, represented in plate XCVIII. fig 4. They hold the part B in their hand; and, applying the point A to the vein, strike the part C with one of the fingers of the other hand. Others use a neater instrument, or spring-fleam, represented ibid. n° 2. This being drawn up, they apply the point A to the vein, and then let it go by pressing upon B. However, as the position and size of the veins are different in different persons, the lancet is found to be the most convenient instrument for this purpose. See the article LANCET.

Fleams imported, besides the duty on

steel, pay each 38½ d. and draw back on

exportation 33½ d. See STEEL.

FLECHE, a town of France, under the meridian of London, twenty miles northeast of Angers.

FLEECE, the covering of wool, shorn off the bodies of sheep. See WOOL.

Order of the golden FLEECE, an order of knighthood instituted by Philip II. duke of Burgundy. These knights at first were twenty-four, besides the duke himself, who reserved the nomination of fix more: but Charles V. encreased them to fifty. He gave the guardianship of this order to his son Philip king of Spain, since which the Spanish monarchs are chief of the order. The knights had three different mantles ordained them at the grand solemnity, the collar and fleece.

FLEET, commonly implies a company of ships of war, belonging to any prince or state: but sometimes it denotes any number of trading ships, employed in a particular branch of commerce.

In sailing, a fleet of men of war is usually divided into three squadrons; the admiral's, the vice admiral's, and the rear admiral's squadron, all which, being distinguished by their flags and pendants, are to put themselves, and, as near as may be, to keep themselves in their customary places, vis. The admiral, with his squadron, to sail in the van, that so he may lead the way to all the rest in the day-time, by the flight of his flag in the main-top-mast-head; and in the night-time, by his lights or lanterns. The vice admiral and his squadron, is to sail in the center, or middle of the fleet. The rear admiral, and the ships of his squadron, to bring up the rear. But sometimes other divisions are made, and those composed of the lighter ships and the belt sailors, are placed as wings to the van, center, and rear. See the articles SQUADRON, ADMIRAL, FLAG, &c.

For the disposition of a fleet in time of a sea-engagement or battle. See the article BATTLE.

Merchant-fleets generally take their denomination from the place they are bound to, as the Turky fleet, East-India fleet, &c. These, in time of peace, go in fleets for their mutual aid and assistance; in time of war, besides this security, they likewise procure convoys of men of war, either to escort them to the places whether they are bound, or only a part of the way, to a certain place or latitude, beyond which they are judged out of danger of privateers, &c. See CONVOY.

FLEET is also a noted prison in London, where percons are committed for contempt of the king and his laws, particularly of his courts of justice: or for debt, where any person will not, or is unable to pay his creditors.

There are large rules and a warden belonging to the fleet prison, which had its name from the float or fleet of the river or ditch, on the side whereof it stands.

FLEG and PHLEGmatic. See the articles PHLEG and PHLEGmatic.

FLEMISH, or the FLEMISH TONGUE, is that which we otherwise call low Dutch, to distinguish it from the German, whereas of it is a corruption, and a kind of dialect. See GERMAN.

It differs from the Walloon, which is a corruption of the French language. The Flemish is used through all the provinces of the Netherlands.

FLEMISH BRICKS, a nest, strong, yellow kind of bricks, brought from Flanders, and commonly used in paving yards, stables, &c. being preferable for such purposes to the common bricks. See the article BRICK.

FLENSBURGH, a port-town subject to Denmark, sixteen miles north of the city of Slefwick.

FLESH, caro, in anatomy, a similar, fibrous part of an animal body, soft and bloody, being that whereof most of the other parts are composed, and whereby they are connected together; or more properly, it is such parts of the body where the blood-veins are so small, as only to retain blood enough to preserve their colour red.

The ancient anatomists reckoned five different kinds of flesh: 1. Muscular, fibrous
brous, or filicular flesh: such as is the substance of the heart and other muscles. 2. The parenchymous flesh, as that of the lungs, liver, and spleen: but since the use of glauees, it is plainly discovered that there is no flesh thing as a parenchyma, properly speaking, but that all the visera, as well as other parts of the body, are vacuolar, and nothing but plexus, or net-work, of small vessels and canals.

3. Viscerous, such as the flesh of the stomach and guts. 4. Glandulous, as that of the tonsils, the pancreas, the breasts, &c. 5. Spurious, so they called the flesh of the lips, gums, the glans of the penis, the neck, &c. because it is of a constitution different from all the rest.

The moderns admit only one kind of flesh, viz. the mucular. Sometimes, however, they apply that term to the glands, which they call, by way of distinction, glandulous flesh.

The flesh of young animals abound with a soft and nourishing juice, but that of the older, is more nourishing. The juices of old animals are spirituous, gelatinous, and agreeable to the taste, but the flesh is hard and difficult of digestion. The flesh of wild animals are more light and digestible than that of tame.

Dr. Hales proposes to salt the freshes put on shipboard, by injecting hydrotactically a strong brine into the blood-vessels of animals, immediately after they are killed.

Flesh, among botanists, is all the substance of any fruit that is between the outer rind and the stone; or that part of any root that is fit to be eaten.

Flesh-colour. See Carnation.

Flesus, the Flounder, in ichthyology. See the article Flounder.

Fleur de Lis, in heraldry, the same with Floriz. See the article Floriz.

Fleury, a town of Burgundy, in France, thirty miles north of Chalons.

Flexible, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

Every flexible body, say the schoolmen, is porous, and that in such a manner, as that the pores or chambers may become longer or shorter; and if any corporeal substance fills these pores, it must be conceived to subtile as to be easily expelled by compulsion, or at least capable of being driven from one chamber to another, according as the body is bent in this or that direction.

Flexion, in anatomy, is applied to the motion by which the arm or any other member of the body is bent. It is also applied to the muscles, nerves, &c.

Flexion or Flexure of curvets. See the article Flexure.

Flexor, in anatomy, a name applied to several muscles, which are so called from their office, which is to bend the part to which they belong, in opposition to the extensors, which open or stretch them, as, 1. Flexors of the head, which are the malsideus, the rectus major anticus, and the rectus minor anticus. 2. Flexors of the neck, viz. the scalenus and longus.

3. Flexors of the back and loins, the quadratus lumborum, the ploas parvus, the intertransversales lumborum. 4. Flexors of the cubitus, the brachiazus exterius, and brachiazus internus. 5. Flexors of the carpus, the radizus internus, the ulnaris internus, and the palmaris.

6. Flexors of the first, second, and third phalanx of the fingers, viz. the four lumbricales, the sublimis or perforatus, and the perforans or profundus. 7. Flexors of the thigh, called also elevators, the ploas magnus, the siliacus, and the pectinatus, called also lividus. 8. Flexors of the tibia, the gracilis, the semmembranous, the seminervosus, the biceps, and the poplitaus. 9. Flexors of the tarsus or foot, the tibialis anticus, and the peronaeus anticus. 10. Flexors of the phalanges of the toes, the lumbricales, the perforatus, the perforans, and the flexor longus of the great toe, whose origin is in the posterior part of the fibula, and its termination in the lower part of the long phalanx, together with the flexor brevis, the origin of which is from the middle os cuneiforme, and its termination at the two seftamoide bones of the great toe, which are joined by ligaments to its first phalanx. See Mastoideus, Rectus, Scaleneus, Brachieus, &c. &c.

Flexure of curvets, in the higher geometry, is used to signify that a curve is both concave and convex, with respect to a given right-line Ap, or a fixed point P (plate XCVIII. fig. 5, n° r.). Thus the curve CMD having the part CM concave towards AP or P, and the part MD convex to the same, is said to have a flexure: and the point M which limits the concavity and convexity, is called the point of inflection or contrary flexure. See the article Inflection.
This is to be understood when the point, supposed to describe the curve, coming to M, continues its course towards the same side; but if it turn backwards, as in $n^0 2, 3, 4$; the curve may either have a continued curvature, as in $n^0 4$, or have a cuspis point of reflection or of retrogradation, as in $n^0 2, 3$. As to the method of finding the points of contrary flexure, see L'Hospital's Anal. inf. Petit. sect. 4. See also Inflection.

FLIE, or FLY, in zoology, &c. See the article FLY.

FLIE, in geography, an island at the entrance of the Zuyder-see.

FLIGHT, in general, denotes the act of flying. See the article FLYING.

FLIGHT in heraldry. See the article VOL.

FLIGHT of a flair-case. See STAIR-CASE.

FLINGING, in the manege, the same with Flix-Weed, a genus of plants called by authors erysimum. See Erysimum.

FLINT, $f$lex, in natural history, a semi-pellucid stone, composed of crystal debaied with earth, of one uniform substance, and free from veins; but of different degrees of colour, according to the quantity of earth it contains, and naturally surrounded with a whitish crust.

Flint is a stone of an extremely fine, compact, and firm texture, and very various, both in size and figure. It is of all the degrees of grey, from nearly quite black, to almost quite white. It breaks with a fine, even, glossy surface; and is moderately transparent, very hard, and capable of a fine polish. It readily strikes fire with steel, and makes and not the least effervescence with aquafortis, and burns to a whitenss. Its uses in gla$ making, &c. are too well known to need a particular recital.

It is not uncommon to find on our shores fine, pellucid, flinty bodies, streaked or veined with white, black, brown, &c. These are the agates of this country, and answer in every particular, but fineness, to the gem. See the article AGAT.

The manner of preparing flints for the nicer operations in the glass-trade, is this: after freeing them from the white crusts with which they are commonly surrounded, calcine them in a strong fire; then powdering them in an iron mortar, sift the powder through a very fine sieve: pour upon this powder some weak aquafortis, to dissolve any particles of iron it may have got from the mortar; then, after standing some time, wash it well with hot water, and dry it for use.

Oil of Flints, a name given to the liquor obtained from a mixture of four ounces of calcined and powdered flints, with twelve ounces of salt of tartar; this being melted together in a strong fire, runs into glass; which is to be powdered and set in a cellar, where it runs into an oil per deliquium.

Flint-Castle, an old town and castle, which gives names to Flintshire, in Wales, is situated on the river Dee, ten miles east of St. Asaph, and sends one member to parliament: west long. $53^\circ 12'$, north lat. $51^\circ 20'$.

FLIP, a drink common among sailors, made up of malt-liquor, brandy, and sugar, mixed together.

FLIX, a town and castle of Catalonia, in Spain, twenty miles north of Tortosa.

FLIX-weed, a genus of plants called by authors erysimum. See Erysimum.

FLOAT of a fibing-line, the cork or quill that floats or swims above water. See the article FISHING.

The quills of muscovy ducks are the best floats for flow waters, but for strong streams, cork-floats are the best; for which purpose take a good sound cork, without flaws or holes, and bore it through melted together in a stream, cork-floats are the best.

FLOAT also signifies a certain quantity of timber bound together with rafters, a-thwart, and put into a river to be conveyed down the stream; and even, sometimes, to carry burdens down a river with the stream.

FLOATBOARDS, those boards fixed to water-wheels of under-shot mills, serving to receive the impulse of the stream, whereby the wheel is carried round. See the article WHEEL and MILL.

It is no advantage to have too great a number of float-boards, because, when they are all struck by the water in the belt manner that it can be brought to come against them, the sum of all the impulses will be but equal to the impulse made against one float-board at right angles, by all the water coming out of the penflock through the opening, so as to take place on the float-board. The best rule in this cafe is to have just so many, that each of them may come out of the water as soon as possible, after it has received and acted with its full impulse. As to the length of the float-board, it may be
be regulated according to the breadth of the stream. See the article MILL.

FLOATAGES, all things floating on the top of the sea or any water, a word much used in the commissions of water-bailiffs.

FLOATINGS, in husbandry, the drowning or watering of meadows.

FLOATING of cheese, among housewives, separating the whey from the curd. See the article CHEESE.

FLOATING-BRIDGE. See BRIDGE.

FLOATING-ISLANDS. See ISLAND.

FLOOD, a deluge or inundation of waters. See the article DELUGE.

FLOOD, among seamen, is when the tide begins to come up, or the water begins to rise, then they call it young flood; after which it is quarter flood, half flood, and high flood. See the article TIDE.

FLOOD-MARK, the mark which the sea makes on the shore, at flowing water, and the highest tide: it also called high water mark.

FLOOR, or FLUKE, of an anchor. See the article ANCHOR.

LOOKING, among miners, a term used to express a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its course, by the crossing of a vein of earth or stone, or some different metallic suffurance; in which case the load is moved to one side, and this transient part of the land is called a flooking.

FLOOR, in architecture, the under side of a room, or that part we walk on. Floors are of several sorts, some of earth, some of brick, some of stone, and some of wood.

Earthen floors are commonly made of loam, and sometimes, when they are designed to make malt on, of lime and brook-fand, and gun-duft, or anvil-duft, from the forge. The manner of making these floors for plain country habitations, is as follows. Take two thirds of lime, and one of coal-ahes well sifted, with a small quantity of loamy clay; mix the whole together, and temper it well with water, making it up into a heap: let it lie a week or ten days: then temper it well over again. After which heap it up for three or four days, and repeat the tempering very high, till it become smooth, yielding, tough and gleowy. Then the ground being levelled, lay your floor therewith, about two and a half or three inches thick, making it smooth with a trowel: the hotter the season is the better; and when it is thoroughly dried, it will make the best floor for houses, especially for malt-houses.

If any would choose to have their floors look better, let them take lime made of rag-stones, well tempered with whites of eggs, covering the floor about a quarter or half an inch thick with it, before the under flooring be too dry. If this is well done, and thoroughly dried, it will look, when rubbed with a little oil, as transparent as metal or glais.

Floors are of several sorts, some of earth, some of stone, some of brick, some of stone, and some of wood. Concerning boarded floors, it is to be observed, that the carpenters never floor rooms with boards, till the carcase of the house is set up, and also is enclosed with walls, left the weather should wrong the flooring; yet they generally rough-plane the boards for flooring, before they begin any thing else about the building, that they may let them by to season; which is done by laying them flat upon three or four balks, each board about the breadth of a board a funder, the whole length of the balks: then, by laying another lay of boards athwart the last, and so on till they have laid them all in this manner, by which means they lie hollow for the air to play between them.

The best way of placing the principal timbers in a floor, is not to lay them over doors or windows, nor too near chimneys: the boards should all lie one way, which is generally the way that you have the best visto.

Floor of a ship, is so much of her bottom as the refts upon, when the refts on the ground. See the article SHIP.

Such ships as have long, and withal broad floors, lie on the ground with most security; and those that are narrow in the floor, cannot be grounded without danger either of being overet, or at least of hurting their sides.

FLORAL, in general, something belonging to a flower. See FLOWER.

Thus floral leaves are those found only near flowers.

FLORAL GAMES, in Roman antiquity, annual games instituted in honour of the goddess Flora, which began to be celebrated on the fourth of the calends of May, or April 28, and were continued to the calends, or first of May.

The floralia, or floral games, were celebrated
FLORENCIANS, floriniani, in church-hitory, a sect of heretics, of the 12th century, so denominated from their leader Florinus, who made God the author of evil.

They are a species of the gnostics, but deny the judgment and resurrection, and hold that our Saviour was not born of a virgin. They were also called borborites. See the article BORBORITES.

FLORIST, florifla, according to Linnaeus, is an author, or botanist, who writes a treatise called Flora, comprehending only the plants and trees to be found growing naturally in any place. However, in the more common acceptance of the word, florifla signifies a person well skilled in flowers, their kinds and cultivation. See the article FLOWER.

FLORUS, in ornithology, a bird otherwise called whinchat. See WHINCHAT.

FLORY, FLOWRY, or FLEURY, in heraldry, a cross that has the flowers at the end circumflex and turning down, inasmuch as the latter stretches out more like that which is called patee. See the article POTENCE and PATEE.

The cross flory is represented in plate XCVIII. fig. 2.

FLO, FLOWER, in botany. See the article FLOWER.

FLO, in chemistry, the most subtle part of bodies separated from the more gross parts by sublimation, in a dry form. 1. Flores benzoini, flowers of benjamin, are prepared in the following manner: put powdered benjamin into an earthen pot, placed in sand, and with a small heat the flowers will rise, and may be caught by a paper-cone placed over the pot. See the article BENZOIN. 2. Flores sulphuris, flowers of sulphur: let sulphur be reduced to a powder, and be placed in a fit vessel; and any part of the flowers which may have concreted are to be reduced to powder by a wooden mill, or in a marble mortar with a wooden pestle. They are used in diseases of the breath, and likewise in cutaneous distempers, both internally and externally. 3. Flores sulphuris
Phuris lots, flowers of sulphur washed: pour water on the flowers, to the height of three or four fingers above them, and boil them for a time; then pour off this water, and with fresh cold water wash the remains of this away; then dry the flowers for use.

4. Flores martiales, martial flowers: take of washed colocynth of green vitriol, or of iron filings, one pound; of sal ammoniac, two pounds: mix and sublime them in a retort; and mixing again the bottom with the flowers, renew the sublimation till the flowers acquire a beautiful yellow colour: to the residue may be added half a pound of fresh sal ammoniac, and the sublimation repeated; and the same process may be continued, as long as the flowers rise duly coloured. They are reckoned very attenuating and aperient, and therefore are prescribed in many obstructions, and in affhmas.

5. Flores bifumathi, flowers of bismuth, are used as a focus, being mixed with pomatum or roe-water, &c.

FLOSCULOUS, among botanists, an appellation given to compound flowers, made up of a number of lesser ones, all inclosed in the same common cup. The plants with flocculous flowers make one of Tournefort’s classes, called by Linneus Syn盖nesia. See the articles Botany and Syn盖nesia.

FLOTA, or FLOTTA, FLEET, a name which the Spaniards give particularly to the ships that are annually sent from Cadiz to the port of Vera Crux, to fetch thence the merchandise gathered in Mexico for Spain. This fleet consists of the captains, admiral, and patach or pinnae, which goes on the king’s account; and about sixteen ships, from four hundred to a thousand tons, belonging to particular persons. They set out from Cadiz about the month of August, and make it about eighteen or twenty months before they return.

FLOTILLA, a name given to a number of ships which get before the rest in their return, and give information of the departure and cargo of the flota and galions. See the preceding article.

FLOTSON, or FLOTSOM, goods that by shipwreck are lost, and floating upon the sea; which, with jetson and lagin, are generally given to the lord admiral: but this is the case only where the owners of such goods are not known. And here it is to be observed, that jetson signifies any thing that is cast out of a ship when in danger, and afterwards is beat on the shore by the water; notwithstanding which the ship perishes. Laguna is where heavy goods are thrown overboard, before the wreck of the ship, and sink to the bottom of the sea.

FLOUNDER, the English name of a well-known fish, called by ichthyologists the pleuronectes with the eyes on the right side, the lateral or side lines rough, and small spines at the fins. See the article Pleuronectes.

The flounder is a well tasted fish, known in some parts of the kingdom by the names fluke and bul.

FLOUR, the meal of wheat-corn, finely ground and sifted. See Meal.

The grain itself is not only subject to be eaten by insects in that state, but when ground into flour it gives birth to another race of destroyers, who eat it unmercifully, and increase so fast in it, that it is not long before they wholly destroy the subsistence. The finest flour is most liable to breed these, especially when stale, or ill prepared. In this case, if it be examined in a good light, it will be perceived to be in a continual motion; and on a Nice inspection, there will be found in it a great number of little animals, of the colour of the flour, and very nimble. If a little of this flour be laid on the plate of the double microscope, the insects are very distinctly seen in great numbers, very brisk and lively, continually crawling over one another’s backs, and playing a thousand antic tricks together, whether for diversion, or in search of food, is not easily determined. These animals are of an oblong and slender form; their heads are furnished with a kind of trunk, or hollow tube, by means of which they take in their food, and their body is composed of several rings. They do not mischief among the magazines of flour laid up for armies, and other public uses: when they have once taken possession of a parcel of this valuable commodity, it is impossible to drive them out; and they increase so fast, that the only method of preventing the total loss of the parcel, is to make it up into bread as soon as can be done. The way to prevent their breeding in the flour, is to preserve it from damp: nothing gets more injury by being put up in damp, than floure; and yet nothing is more frequently put up so. It should be always carefully and thoroughly dried, before it is put up; and the barrels also dried into which it is to be put.

7
Flour, in geography, a city of the Lyonnais, in France, forty-five miles south of Clermont.

Flower, flores, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification. See the article Fructification.

The parts of a flower are the ovary or pistil, the corolla or flower-petals, the stamens or chives, the empalement or calyx, the perianthium, pericarpium, and fruit. See the articles Pistil, Corolla, Stamen, &c.

According to the number of petals, or flower-leaves, flowers are called monopetalous or one-leaved, dipetalous or two-leaved, tripetalous or three leaved, &c. Flowers are again distinguished into male, female, and hermaphrodite: the male flowers are those containing stamens, without any pistil or fruit, commonly called staminous flowers. The female flowers are such as contain the pistil, which is succeeded with fruit; these are called fruitful or knitting flowers. The hermaphrodites are those which contain the organs of both sexes, viz. stamens and pistils; and these are by far the most numerous.

From the different figures and disposition of the flower-leaves of plants, Mr. Tournefort has established a system of botany; whereas that of Linnaeus is chiefly founded on the number and disposition of the stamens. See Botany.

Flowers were in great request among the antients: they adorned their temples, houses, and even tombs with them; but their principal use seems to have been at entertainments, where the guests were always decked with flowers, and even the room lined with them.

Quintus tells us, that flowers, designed for medicinal use, should be plucked when they are moderately blown, and on a clear day before noon: and that for conserves, roses must be taken in the bud.

For the method of preferring specimens of flowers, see the article Hortus Siccus.

Flower of Bristol, a plant more usually called lychnis. See Lychnis.

Gentle Flower, the name with amaranth. See the article Amaranth.

Eternal Flower, the English name of the xeranthemum. See Xeranthemum.

Everlasting Flower, the English name of the glyphaicum. See Glyphaicum.

Flower-fence, the English name of the poinciana. See Poinciana.

Flower de Luce, the name with the iris. See the article Iris.

Sultan-Flower, the name with the cyamus. See the article Cyamus.

Sun-Flower, the English name of the helianthus. See Helianthus.

Trumpet-Flower, the name with the bigonia. See the article Bigonia.

Wind-Flower, the name with the anemone. See the article Anemone.

Flowers, in chemistry. See the article Flos, fapra.

Flower de Lis, or Flower de Luce, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some female, or spread all over the escutcheon in great numbers.

The arms of France are, three flower de lis or, in a field azure.

Fownd-sheets, in the sea-language. A ship is said to sail with flown sheets, when her sails are not hauled home, or close to the blocks. The sheets are flown, that is, they are let loose, or run as far as they will.

Flox, among dyers, signifies well cleaned wool, used to absorb the colours of cochineal.

Fludder, or Fluder, a large bird of the columbus or diver-kind, nearly allied to the dumne. See columbus and Lumme.

Fluellin, the English name of a plant called by botanists elatine. See the article Elatine.

Fluent, in fluxions, the flowing quantity, or that which is continually either increasing, or decreasing, whether line, surface, solid, &c. See Fluxion. It is easy to find the fluxions, where the fluents are given; but, on the contrary, it is very difficult to find the fluents of given fluxions.

Fluid, in physiology, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impressed. Some philosophers make the following distinction in liquids; those which flow or spread
spread themselves till their surfaces become level or horizontal, they call liquid; in contradistinction to flame, smoke, vapour, &c. which are also fluids, but do not acquire such a surface. Those which are capable of existing in us the idea of moifness, as water, &c. they call humid, distinguishing them thereby from air, quicksilver, and melted metals. But those distinctions are quite unnecessary in a philosophical sense; the surfaces of all fluids being level, or horizontal, when not prevented by the bodies about them; and humidity is only a relative quality; for though quicksilver will not moisten or stick to a man's finger, it will to silver or gold. See FLAME, SMOKE, LIQUID, &c.

The nature of a fluid, as distinguished from that of a solid, or hard body, consists in this, that its particles are so loosely connected together, that they readily move out of their places, when pressed with the least force one way more than another. From whence philosophers conclude, that those particles are exceedingly minute, smooth, and round, it being otherwise impossible they should move with such freedom upon the least inequality of pressure.

Those particles considered separately, are endowed with all the common properties of matter, and are subject to the same laws of motion and gravitation with larger bodies. To enquire, therefore, into the nature of fluids, is to consider what appearances a collection of very small round bodies, subject to these laws, will exhibit under different circumstances.

**Laws and Properties of Fluids.**

1. All fluids are incompressible, except air; or, they cannot, by any force, be compressed into a less space than what they naturally possess, as is proved by the florentine experiment, of filling a globe of gold with water, which, when pressed with great force, causes the water to transmute or issue through the pores of the gold, in form of a dew all over its surface. See Air.

2. All fluids gravitate, or weigh in proportion to their quantity of matter, and that not only in the air, but in propria loco: or, a fluid weighs the same, communicating with a quantity of that fluid, as in vacuo; which all philosophers, till very lately, have denied.

The reason was this; because philosophers found that a bucket of water, in water, weighed nothing; that is, that because there was no relative gravity in water, they very strangely inferred there was no absolute gravity in any part or particle of water, whilst it remained in water, but only became heavy when taken out or separated from the rest. But their mistake is easily evinced by the following experiment: let a bottle, or phial, with stop in it, to make it sink in water when close stopped, be hung at the end of a nice balance, and then immersed into a jar of water: while thus hanging in water, let it be counterpoised very exactly by weights put into the scale at the other end; then, pulling out the cork, the water will rush into the bottle, and destroy the equilibrium, by causing the balance to descend; which will be a plain proof that water has weight in water.

That fluids gravitate, or are heavy, in the same manner with solids, is evident; because the earth's attraction, which is the center of gravity, equally affects the particles of all sorts of matter, and therefore excites the same endeavour, or tendency towards the center of the earth, in the particles of a fluid, as in those of a solid body: and this is what we call absolute gravity. See Gravity.

Now since in fluids of the same kind as water, all the particles are reasonably supposed equal and alike in all circumstances, they will be all equally affected by attraction, and therefore have, among themselves, an equal tendency towards the center of the earth; whence, since they gravitate equally, if they are equally obstructed in their descent (as by the bottoms of the vessels, &c.) they will all retain the same position among themselves, as if they were affected by no power at all; and thus they are said to be relatively at rest, or in a state of quietus among themselves; since no one particle of the same fluid has a greater share of attracting power than another, no one will tend to descend before another; and therefore, among the particles of the same fluid, there is no such thing as we call relative or residual gravity, which is nothing but the excess of gravity, by which one body tends downwards more than another.

3. From the gravity of fluids arise their pressure, which is always proportional thereto; and since we may suppose all the particles of a fluid to have equal bulk and weight, the gravity of the fluid, and consequently the pressure will be always proportional to the altitude or depth thereof: whence the weight and pressure of fluids on the bottoms of vessels, &c. must be equal.

4. The
4. The pressure of fluids upwards is equal to the pressure downwards, at any given depth. To illustrate this and the foregoing proposition, let ABCD (pl. C. fig. 1.) be a vessel of water, whose altitude EF suppose to consist of a column of 10 aqueous particles; then, it is evident, the first or uppermost particle \( x \) can affect the next particle \( 2 \), only by its weight and pressure, which therefore is as \( x \); and since that particle \( 2 \) is immovable, and action and reaction equal and contrary, the said particle \( 2 \) will act upwards upon the particle \( 1 \), with a force which is as \( x \). In the same manner the particle \( 2 \) acts on the particle \( 3 \), by pressure downwards, with two degrees of force, arising from its own weight and from that of the particle above it; and accordingly it is pressed upwards with an equal force by the reaction of the particle \( 1 \). And so of all the rest, wherefore the propositions are manifest.

5. The pressure is upon all particles of the fluid, at the same depth, equal in every part; or the particles of a fluid, at the same depth, press each other, every way and in all directions, equally. For if any particle were pressed more on one part than another, it must give way and yield, till the pressure become every way equal; otherwise an insensible infinite motion of the particles must ensue, which is absurd, and contrary to experience.

6. From the mutual pressure and equal action of the particles, it follows, that the surface of a fluid must be perfectly smooth and even; for should any part stand higher than the rest, by any force, as attraction, &c. it would immediately subside to a level with the other part, by the force of its own gravity, when that force is removed.

7. The figure of the surface of all fluids is spherical or convex; for all the particles equally gravitating towards the center of the earth, will take their places from it at equal distances at the surface, and so form a part of the superficies of a sphere, equal to the bulk of the earth.

Besides the reason of the thing, we know from experiment, that the surface of large waters, as those of the sea or ocean, is convex; for a person standing on the shore, and viewing a ship under sail, directly before him, will lose sight thereof by degrees, the hull or body of the ship first disappearing, then the lower parts of the mast, then the top of the lower masts, and lastly the top of the tallest mast.

This is more fully explained in determining the figure of the earth. See the article EARTH.

8. Since fluids press equally every way, the pressure of each particle against the side of a vessel will be proportional to its altitude, and consequently the pressures of the particles \( 1, 2, 3, 4, \&c. \) of a perpendicular column against the side \( BC \) (ib. fig. 1.) will be a series of numbers in arithmetical progression, whose first term is 0; therefore the sum of all the pressures is equal to the number of pressures multiplied by half the greatest pressure: but the number of pressures is as the number of particles, or altitude of the fluid \( BC \); also the greatest pressure is as the same altitude; wherefore the total pressure against the side of a vessel, is as the square of the altitude of the fluid. See the article PROGRESSION.

This way of considering the quantity of lateral pressure, by the arithmetical series, is universal; whereas the common method refrains it to the property of an equiangular right-angled triangle, and to a vessel of a cubical form, which we shall here give, for the sake of proving it several ways: suppose ABCD (ib. fig. 1.) a vessel of a cubical form, that is, whose side \( BC \) is equal to the length of the bottom \( CD \). If the diagonal \( BD \) be drawn, we shall have the lines \( 1a = Bb, 2b = B2, 3c = B3, 4d = B4, \&c. \) but \( B1, B2, B3, B4, \&c. \) being as the altitudes of the fluid, will represent the lateral pressures in the points \( 1, 2, 3, 4, \&c. \) therefore also the lines \( a1, b2, c3, d4, \&c. \) will represent the same lateral pressures; hence when the distances \( B1, B2, B3, \&c. \) are indefinitely small, the lines \( a1, b2, c3, d4, \&c. \) will be infinitely near each other; and so all those lines drawn in the triangle BCD, will make the area of that triangle: therefore the sum of all the lateral pressure against the side BC, will be as the area of that triangle. But the area of the triangle \( BCD \) is as the square of the side \( BC \); consequently the sum of all the lateral pressures is as the square of the altitude of the fluid \( BC \).

9. Hence, if the vessel \( AC \) (ib. fig. 1.) be of a cubical form, the pressure against a side \( BC \), is half that upon the bottom \( CD \), and consequently the total pressure against the sides and bottom is equal to three times the weight of the fluid on the bottom of such a vessel.

10. The weight, pressure, or effect of a fluid, upon the bottom \( DE \) (ib. fig. 2.) of
of any vessel A C D E F, is proportional to the altitude A E only, and not to the quantity of the fluid in the vessel. For every column of particles G H, which presses downwards on the side of the vessel E F, has its force destroyed by the equal re-action of the subjacent particle H in the side, and so cannot at all affect the bottom of the vessel. Again, the pressure of any column of particles L M upwards, against the side of any vessel C D, is equally re-acted by the particle of the vessel over it, and so its force or pressure on the bottom must be the same as that of another column of particles A B of equal altitude with the fluid: whence the proposition is evident.

21. Hence a very small quantity of fluid APRS (ib. 22.) may be made to counter-balance, or be equivalent to the weight or force of any given quantity T K G V, how great soever.

22. When any body is immersed in a fluid, it loses just so much of its weight as is equal to the weight of an equal bulk of the fluid; but the weight lost by the body is gained by the fluid, which will be so much heavier than before.

This is the fundamental principle of every hydrostatical process, particularly of the whole doctrine of specific gravities, which therefore cannot be made too plain and easy to be understood.

To this end, let A B C D, (fig. 3.) be a vessel filled with water, to the height E F; and let I be a cylindric body, heavier than water, to be immersed therein, as at L. By this immersion of the body I, a quantity of the fluid a b c d, equal in bulk to the body, will be displaced by the superior force, or greater gravity of the solid; and this quantity of fluid must ascend, as being confined towards the bottom and sides; and so rise the surface of the liquor from E F to G H, and then will the quantity E F G H be equal to the bulk of the immersed solid a b c d. But as the folklore comes to enter the fluid, each particle of the fluid, by its vis inertio, will resist the solid, or endeavour to oppose its descent with all its power; and so the whole body of the fluid, that is removed or displaced by the solid, will resist it by the united force of all the particles: but this force is equal to the gravity of the fluid removed, as is evident from hence, that the fluid so removed is obliged to ascend or move in a direction quite contrary to gravity, wherefore the solid in its descent will be resisted by a force equal to the gravity of an equal bulk of the fluid.

And since the force which resists the descent of solid is proportioned to their bulk only, it follows, that equal bodies immersed in fluids, lose equal parts of their weights; and therefore, a lighter body looses more of its absolute weight than a heavier one of the same bulk; and consequently if two bodies of unequal bulk are in equilibrio in the air, that equilibrium will be destroyed on their being immersed in the fluid, because that which has the largest bulk will lose most weight in the fluid.

Again, it is plain, the weight of the fluid is augmented in the same proportion as that of the immersed solid is diminished; for the force or action of the fluid, on the bottom of the vessel C D, is before immersion to that afterwards, as the altitudes C F to C H; or to the bulks of the fluid E F C D and G H C D. And since those bulks act only by their gravity, it is plain the action of the fluid is increased only by the additional gravity of the quantity G H F E, which is equal to that which the solid loses by immersion.

See the article Gravity.

23. If any body, E (fig. 4.) could be found without weight, it would, if placed on the surface A B, float thereon, without any part immersed; for being devoid of gravity, it could have no force to displace any particles of the fluid, and sink therein.

4. If an heavy body, F, (n° 4.) lighter than an equal bulk of the fluid, be placed on its surface, it will sink, or descend therein, till it has removed or displaced so much of the fluid whose weight is equal to that of the body. For then the pressure upwards and downwards on the surface of the body is equal, and consequently the body will be there quiescent, or in equilibrio with the fluid. Hence the whole solid is to the immersed part as the specific gravity of the fluid is to that of the solid. See the article Hydrostatical Ballance.

This case is not strictly true, but in vacuo; for in the air such a body may be considered as sustained by two mediums, viz. air and water, in one of which, it will sink, or descend; and in the other, rise.

25. If a solid, as G, (n° 4.) equal in weight to an equal bulk of the fluid, be immersed therein, it will take any situation indifferently in any part of the fluid,
FLU. [1266] FLU

fluid, as at G, H, I, without any tendency to ascend or descend therein; for being totally immersed, it must remove a parcel of the fluid of equal bulk and weight, and consequently the pressure upwards is equal to the tendency downwards, on the lower surface, every where; and therefore it can have no power to sink. Also the pressure downwards must be equal to the pressure upwards, on the upper surface whence it can have no tendency to rise or swim: it will therefore remain at rest in any position G, H, I, wherever it is in the fluid.

16: Lastly, if a body K, or L, (fig. 4.) heavier than an equal bulk of the fluid, be immersed therein, it will descend by the excess of its gravity above that of the fluid; for when immersed, it will be resisted by the force of an equal bulk of the fluid, which therefore will destroy so much of the gravity of the solid; and consequently the residue, or excess of gravity in the solid, is that alone by which it must descend.

The relative gravity of solids, by which they sink or swim, is usually illustrated by the descent and ascent of glass images, and bubbles included in a jar of water, covered over with a bladder, so as to include a small quantity of air between the bladder and water: the images, &c. have small holes in the bottom of their feet thro' which some water is put into their bodies, and that in such quantities as will render them but very little specifically lighter than water; but some more so than others, that they may not begin to move altogether. See the representation in (fig. 5.) The images being thus put to float in water, and the bladder tied down, if the hand be laid on the bladder, and gently compresses the air beneath, the air, by its spring, will act upon the water, and cause it to compress the air in the bodies of the images, by which means more water will be driven into their bodies; and when so much is got in as will make them specifically heavier than the water, then they will begin to descend one after another; and by varying the degree of pressure, you may keep them suspend in any part of the fluid as you please.

From what has been premised of the nature of fluids, it will be easy to understand, that the lightest body, P, (plate ibid. fig. 4.) may be depressed in the heaviest fluid by any contrivance to keep the fluid fluid from pressing on the under surface of the light body, by which means only light bodies are made to swim. Thus cork, or wood, will abide at the bottom of a vessel filled with quicksilver.

Again: on the other hand, the heaviest body M may be made to swim in the lightest fluid, by keeping the said fluid from preffing on its upper surface, by means of the tube N O. For when by this means it is immered so deep as to keep off an equal weight of the fluid, the pressure then of the fluid acting upon its under surface upwards, will be equal to the weight of the solid tending downwards; and therefore, if the solid be sunk ever so little deeper, it must swim by the superior force or pressure of the fluid upwards.

Thus, for instance, if the body M be five times heavier than water of an equal bulk, and if by means of the tube N O, placed on its upper surface, the water be kept from pressing thereon, that it beimmered to seven times its thickness below the surface of the water, 'tis plain the pressure on the under surface will be as seven, but downwards only as five; and therefore, since there is the excess of two degrees of pressure upwards, 'tis plain the body cannot descend; but may very properly be said to swim on the water. Hence also the reason of trying the different gravity, density, or density of divers fluids, or spirituous liquors, by the hydrometer, or water-poise. See the article HYDROMETER.

Motion of Fluids. The motion of fluids, viz. their descent or rise below or above the common surface or level of the source or fountain, is caused either, 1. by the natural gravity or preffure of the fluid contained in the resevoir, or fountain; or, 2. by the preffure or weight of the air on the surface of the fluid in the reservoir, when it is at the same time either taken off or diminished on some part in aqueducts, or pipes of conduit. 3. By the spring, or elastic power of compressed or condensed air, as in the common water engine. 4. By the force of pistons, as in all kinds of forcing pumps, &c. 5. By the power of attraction, as in the case of tides, &c.

1. The most natural motion of fluids is that arising from the force of their own gravity, by which those parts which stand highest press upon others below them, till by that means they rise to the same horizontal level. Thus water in a foun-
tain ABCD (fig. 6.) by its preffure, raises that in the aqueduct FGH to the same height IKLM in every direction or position of the duct GH, or GN; unless the orifice of the said duct be below that level, in which case the water will continually flow from the same. The reason hereof is evident from the principles already laid down, viz. that the preffure of fluids was in proportion to the altitude only, and not according to the quantity thereof, and therefore the effect or rife of the fluid in the duct must be equal thereto.

Hence we have conduits often supplied with water from springs, which lie above them; and cocks to supply the inhabitants of a town with water by pipes from a reservoir, in a situation above the highest part of the town: hence also the descent of water in rivers, streams, and canals from springs and sources above the common surface of the earth; and the breaking out of springs at the bottoms and on the side of hills; from cisterns and reservoirs in the internal parts above them, which receive their water from rain, dew, condensed vapour, melted snow, &c. distilling, or percolated through the pores or crevices and chafins of the upper part of the earth. See the articles FOUNTAIN, SYPHON, CONDUIT, TANTALUS'S CUP, JET D'EAU, RESERVOIRS, CANAL, SPRING, CISTERN, &c.

2. The second cause of the rife or motion of fluids is the preffure of the air on the surface of that in the fountain or reservoir: thus if a syphon or crane be immersed with the shorter leg in water, and the air sucked out of the instrument, the fluid will ascend into the vacuous space by the preffure of the air on the water, and fill the whole cavity of the tube; and because there is a greater column of water in the longer leg, it will preponderate and descend through it, and will keep flowing out till the vessel is exhausted to the orifice of the shorter leg. The effect of the common pump is from the same principle. See the article PUMP.

3. The third cause of the rife and motion of fluids is by the spring or elastic power of condensed air, upon which principle water engines are contrived. See the article ENGINE.

4. The fourth cause is the force or preffure of pistons, upon which principle a variety of water engines are constructed, as may be seen under the articles already referred to.

5. The last cause of the motion of fluids which we mentioned, was that of attraction. We have elsewhere shown how by this means any fluid will ascend above the common surface in capillary tubes, &c. See the article CAPILLARY.

But the most notable and obvious motion of fluids arising from attraction, is that of the tides; the waters of the immense ocean forgetful, as it were, of their natural quietus, move and roll in swelling tides obsequious to the sovereign power of the moon, and weaker influence of the sun. See the article TIDES.

Momenta and velocities of Fluids. The momenta of fluids, as well as of solids, is compounded of the quantity of matter and velocity; but in spouting fluids, the quantity of the fluid issuing thro' the same hole, in the same time, is always as the celerity of its motion, as is easy to conceive. Whence the moments of spouting fluids are proportional to the squares of the velocities, or quantities of matter issuing out in a given time. But since the moments are the effect of preffure, it is evident the velocity or quantity of spouting fluids is ever proportional to the square root of the preffure, or altitude of the fluid. From hence it appears, that the velocity of a fluid spouting at any depth below the surface is equal to the velocity a heavy body would acquire by falling from the same height; because the velocity, as was observed, is always as the square root of the space defended through. If therefore on the altitude of the fluid AK (fig. 7,) as a diameter, we describe the semicircle A FK, and from any point therein, as I, we draw the perpendicular IH, that shall be proportional to the distance to which the fluid will spout from an adjutage at H: for the velocity will be, as the square root of AH; and the time, as the square root of HK; whence the product of these two will express both the space passed over by the projected body, and also the line HI. Hence it follows, that a fluid will spout from a hole or adjutage D, in the center of the semicircle, or middle part of the altitude AK, to the greatest horizontal distance KM possible; because the perpendicular FD is the greatest that can be drawn to the diameter AK. Also it is evident, that from two holes B and H, equally distant 'above and below the middle altitude D, the jets of water will be
FLU [1268]

FLUORES, or WHITES, in medicine, an efflux of a whitish, lymphatic, serous, or aqueous humour, from the matrix. It is sometimes white, sometimes pale, yellow, green, or blackish. Sometimes it is sharp and corrosive, sometimes foul and fetid; the face is discoloured, there is a pain in the spine of the back, the appetite is lost, and the eyes and feet swell. Some women have a periodical flux of the whites, instead of the menses. There are remarkable distinctions in this disorder, as the lacteous, the semi-lacteous, and lymphatic: it may be so acrid or caustic, as to excoriare the vulva. Besides the symptoms already mentioned, it is attended with a swelling of the uterus; turbid urine; a loathing for some things, and longing for others; a fever; dropsies of different parts, of which, or a consumption, the patient dies. It may be confounded with an ulcer of the uterus, or a gonorrhœa mallebris. See GONORRHOEA.

The flux albus sometimes is discharged from the uterine vessels, and sometimes from the glands of the vagina. In the first case it stops when the menstrua begin to flow; in the latter it continues with them; and pregnant women are not exempted from it. At first, the parts of the membrane adipose of the loins, kidneys, and the uterine appendages, are wasted by it; but at length the flux becomes acrimonious. When the flux is lacteous, it may be cured in fifteen days; the patient must feed sparingly, use frequent exercise, and sleep little. If this is not complied with, she must bleed in the arm, once or twice a month, and take purges and emetics; or, at least, frequent clysters. The efficacy of all these must be assisted with diaphoretics, decoctions of the woods, and diuretics.

In the semilacteous flux, an inspiriting and nourishing diet will be best, such as creams, soups, boiled milk, roast meat, jellies, &c. Milk, or milk turned with a decoction of china, is very good. Narcotics are highly useful, especially if the patient is reflexes, or delirious. In the beginning, the dose must be small, but it may be gradually increased. When the vesicule lacteæ are relaxed, the tone must be restored with hot mineral baths, and fomentations; and injections of, and bathing in the same: the fumes may also be conveyed into the vagina with a funnel. Decoctions of the woods are also good;
good; as are diaphoretics, and diuretics of a decoction of roots of eryngo and root-harrows, with powder of millipedes, or glauber's salt.

If the lymphatic flux is attended with a febrile flux, scoriatic, or venereal taint, these disorders must first be removed. If the uterine lymphatics are compressed by febrilities, cancers, ganglions, or the like, regard must be had to the causes. In obstructions of the glands of the uterus, begin with bleeding: then a gentle purge, or an emetic of iod gr. of tartar-emetic, or powdered ipecacuanha: after, if the patient's constitution is cold, attenuating appetents. If the is hot and bilious, with a sensible pain in the uterus, cooling broths and apozems, with the addition of clay fish; after milk, with a decoction of barley; chalybeate whey, with chervil boiled therein; gently purging mineral beate whey, with chervil boiled therein; gentle purge, or an emetic of beetroot.

It is a town of great plain, in the north lat. 51° 30', has a good secure, harbour.

German Flute, is an instrument entirely different from the common-flute. It is not, like that, put into the mouth to be played, but the end is stopped with a tampon, or plug; and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest of which is stopped and opened by the little finger's pressing on a brass, or sometimes, a silver key, like those in hautboys, baiusons, &c. It is found exceeding sweet and agreeable; and serves as a treble in a concerto.

Coarse flutes, on importation, pay the gross, containing twelve dozen, 3s. 10d. and on exportation, draw back 3s. 4d.

Flute, or Fluyt, is also a kind of long vessel, with flat ribs, or floor timbers; round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets, or squadrons of ships, though it is also used for merchandise.

Flutes, or Flutings, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. They are chiefly affected in the Ionic order, where they had their first rise; though, indeed, they are used in all the richer orders, as the Corinthian and Composite; but seldom in the Doric, and scarce ever in the Tuscan.

Each column has twenty-four flutes, and each flute is hollowed in exactly a quadrant of a circle; but the Doric has but twenty. Between the flutes are little spaces that separate them, which Vitruvius calls stiria, and we lift; though, in the Doric, the flutes are frequently made to join to one another, without any intermediate space at all; the lift being sharpened off to a thin edge, which forms a part of each flute. See List.

Vignola determines the depth of the flutes by taking the angle of the equilateral triangle for the center. Vitruvius describes the depth from the middle of the square, whose side is the breadth of the flute, which latter method makes them deep. Some columns have flutes that go winding round the shaft, spirally; but this is rather accounted an abuse. The flutes, or stiria, are commonly filled up with a prominent or swelling ornament; sometimes plain, in form of a stave or reed; and sometimes a little curved, or enriched, in imitation of a rope, or otherwise. See the article Cabled. Sometimes the flutings are made flat, and are called Facettes; but these have never such a good effect as the others. Vitruvius says, that when there are flutings in 7 Z
the column, there ought also to be eggs and anchors in the quarter round of the capital, and even pearls and olives, in a baguette, to be made underneath, instead of annulets. These eggs and olives ought to be in the same number with the flutings, and to be regularly distributed.

FLUVIALIS, in botany, the name by which Vaillant calls the najas of Linneas. See the article Najas.

FLUX, in medicine, an extraordinary issue, or evacuation of some humours of the body.

Sometimes it is taken for all kinds of defluxions; in which sense it is the same with a catarrh, or coryza. See the article Catarrh.

Sometimes it signifies a loofeness, or flux, of the belly, which is of four kinds.

When the food is discharged by stool un-digested, it is called a linteria, or li-enteric flux. When the chyle is discharged, it is called Coelica. When excrementitious humours are discharged, as choler, phlegm, &c., it is called simply a diarrhoa; and when the stools are bloody, it is called a dyentery, or bloody-flux. See the articles Lenteria, Coellic Passion, Diarrhoa, and Dyentery.

Again, there is an hepatic flux: but this is supposed to be no other than the hemorrhoidal flux. See the article Hæmorrhoids.

FLUX of the urine. See Diabetes.

Women are subject to three several kinds of fluxes extraordinary; the first, called the menes, or menstrual flux; the second is after delivery, and is called lochia: these are regular and natural. See the articles Menses and Lochia.

The third, being irregular and preternatural, is termed the fluor albus, or whites. See Fluor-Albus.

FLUX, in hydrography. See Tide.

FLUX, in metallurgy, whatever can cause a body otherwise not at all, or hardly, fusible by fire, to melt.

Fluxes, says Dr. Shaw, seem reducible to two general kinds, viz. the vitreous and the saline. By the vitreous we understand all those which either have of themselves, or readily assume, a glaify form in the fire; among the principal whereof are reckoned the gla of lead, the gla of antimony and borax. By the saline kind of fluxes are understood all those that are composed of salts, whether tartar, nitre, fixed alkalii, or the like. Among the principal of this kind we reckon the black flux, sandiver, kelp, &c. See the articles Sandiver and Kelp.

The method of making the black flux is as follows. Take one part nitre, and two parts common tartar, and reducing each to powder, mix them together; deflagrate the whole in a crucible, by lighting the mixture a-top, which thus turns to a kind of alkaline coal, that is to be pulverized and kept close in a glafs, to prevent its dissolving, as it would do in a moist air.

The vitreous kind of fluxes seem more immediately defined to act upon the flony or vitreificable matter, whereas stubborn ores are frequently mixed, and the saline kind to act more immediately upon the ore itself, for the due exclusion or separation of the metal. The more kindly ores require no flux to make them run thin, or to afford all the metal they contain, and sometimes ores are so kindly as to contain their own fluxes within themselves. Thus, we have met with copper-ores, which being barely ground to powder, and melted without any addition in a common wind-furnace, have yielded as much, or even more, pure metal at the first operation, than could be obtained from them by means of the usual fluxes. Whence we see that artificial fluxes are not always necessary; or that the principal use of them is for the stubborn or less tractable ores; and these are sometimes so exceedingly hard to fuse and reduce to a metallic form, that it requires the utmost power of art to treat them advantageously in the larger way of business, where no considerable expense can usually be allowed for fluxes. And on this account it is, that many mines remain unwrought, as being untractable without great charges. Whence the improvement of the business of fluxes, so as to render them cheap and effectual, might greatly contribute to the improvement of metallurgy. The matter in soft ores, which renders them so fusible, has been found by an experiment upon copper-ore, to be a kind of bituminous substance, capable of melting by a strong heat, into a soft and black kind of glafs.
tartar, borax, sal ammoniac, mercury sublimate, &c. may in the smaller, or for the making of assays.

As for compound fluxes, they are numerous; almost every operator having his favourite flux. And, certainly, some fluxes are better adapted than others to certain ores. But perhaps a few general ones might be fixed upon, which should serve instead of all those hitherto commonly known and used: we will here recommend three, which are powerful, almost general, and not expensive.

1. Take of nitre, prepared by long boiling it in lime-water; of sea salt, melted in the fire; sandivier; and dry wine-lees, each one part; glasses of lead, three parts; and powdered glass, eight parts; mix them all well together. This flux added in an equal weight, will fuse a very stubborn ore.

2. For a still stronger, take equal parts of white tartar, common salt and nitre, prepared as above: calcine them to a white powder; and mix therewith its own weight of glass and lead; and of this flux add two parts to one of the most stubborn ore.

3. For a powerful saline flux. Take of the strongest soap-boiler's lees, four pounds; white tartar, and common salt melted in the fire, each one pound; boil them together with five gallons of human urine, to a dry salt. This flux is particularly proper where sulphur and cobalt abound, and render the ore very refractory.

But the great secret, in making and adapting fluxes, is not only to separate the metal already ripened in the ore, but even to mature and ripen the crude and immature parts of the ore in the fire: something of this kind, we apprehend, may be effected, as having reason to believe, that certain fluxes will obtain a larger yield of metal from certain ores, than other fluxes in common use, th'o' esteemed of the best, and though they are perhaps of the dearest kind. Thus clean iron-filings will often do more than borax. But as the scales and crocus, or rust, of iron, have been commonly used, instead of pure and perfect iron itself, for a flux, few operators appear acquainted with the excellence of perfect iron employed for this purpose. And many advantages are now obtained, by a prudent mixing of one ore with another of the same denomination, and with the

flags, or remnants of metals, in this way of flux.

The melting of gold and silver, and of their calxes, is greatly promoted by glasses of lead, alkaline salts, &c. but when gold and silver, in the fusion itself, are to be purged from other metals and semimetals, it is proper to use nitre only; or if not, nitre always must be mixed with the other salts; for the semimetals and the four least perfect metals are destroyed by nitre.

In this operation, nitre, by its detonation with their sulphurs, is in part alkaliified, and, by the help of a gentle fire, turns their calxes into a vitreous, and much attenuated scorce.

From hence, the reason is plain why gold and silver, when made brittle, are readily restored to their malleability by nitre; for the same metals, and among the metals, lead and tin most of all communicate this fault to gold and silver: but these being changed, as before observed, by nitre, are then rejected by gold and silver in a simple fusion, so that they can no longer mix with these metals, unless they are themselves first again reduced to their metallic state; and there is beside these, no other body that can be mixed with silver and gold, to render them brittle, unless crude charcoal, happening to fall into the vessel wherein these metals are melted, should impregnate them with something arsinehical; there being some arsine contained in coals of this kind, as has been demonstrated by Stahl and Hofmann.

The least perfect metals, and semi-metals, melt more easily by adding salts to them, than of themselves: they always, however, lose a great deal of their substance by this means; and this is more particularly the case in regard to copper and iron. To amend this, it is necessary to add some kind of fat body, which prevents the destruction, and even reduces the metals already destroyed; and this is more necessary when the calxes, prepared either by burning, or by a detonation with nitre, are to be reduced. A caution, very necessary to be observed, is, that all fluxes must be kept and used very dry, for moist salts soon very much; and when the operations are made in close vessels, if the fire is quickly increased, not being able to get rid of the moisture, the vessels will split and break.
FLUXION, in mathematics, denotes the continual and parallel motion of the variable principle, and their alkaline fact, in the plane of the variable, of what matter remains, begin to corrode and consume lines AF and BG; for if, are made, and finally make their way line through them, and conduct, and fixed glasses, made of a due mixture of flints, generated rectangle by its and prevents it from easily corroding the class or base; for let the culvilinear, in that position. When the varies, may be thus, the point A, and the velocity of position.

Thus, let the point R, be passed that line, and the fluxion of the base or absciss A m, as before, then the rectangle R S, will be the fluxion of the generated space A m n. Because, if the length and velocity of the generating line m n, continually varies, the fluxion of the area will still be expounded by a rectangle under that line, and the fluxion of the absciss or base: for let the curvilinear space A m n (ibid. n°. 2.) be generated by the continual and parallel motion of the variable line m n; and let R be the fluxion of the base or absciss A m, as before, then the rectangle R S, will be the fluxion of the generated space A m n. Because, if the length and velocity of the generating line m n, were to continue invariable from the position R S, the rectangle R S would then be uniformly generated with the very velocity where- with it begins to be generated, or with which the space A m n is increased in that position.

Notation of Fluxions. Invariable quantities, or those which neither increase nor decrease, are represented by the first letters of the alphabet, as a, b, c, d, &c. and the variable or flowing quantities by the last letters, as v, w, x, y, z: thus, the diameter of a given circle may be denoted by a; and the line of any arch thereof, considered as variable, by x. The fluxion of a quantity represented by a single letter, is expressed by the same letter with a dot or full point over it; thus, the fluxion of x is represented by x, and that of y by y. And, because these fluxions are themselves often variable quantities, the velocities with which they either increase or decrease, are the fluxions of the former fluxions, which may be called second fluxions, and are denoted by the same letters with two dots over them, as x, y. In the same manner the fluxions of second fluxions are called third fluxions, and denoted by the same letters with three dots over them, as x, y; and so on for fourth, fifth, &c. fluxions, which are expressed by the same letters, with four, five, &c. dots over them, as x, y, &c. If the
FLUXIONS

flowing quantity be a fraction, as \( \frac{xx}{d-y} \)
its first, second, third, &c. fluxions are expressed by one, two, three, &c. dots placed in the break of the line that separates the numerator from the denominator, thus \( \frac{xx}{d-y}, \frac{xx}{d-y}, \frac{xx}{d-y} \), &c. The fluxions of surds are denoted in the same manner, by one, two, or more dots placed in the break of the vinculum of the radical character: thus, if the surd quantity be \( \sqrt{x-y} \), then will its first, second, third, &c. fluxions be \( \sqrt{x-y}, \sqrt{x-y}, \sqrt{x-y}, \sqrt{x-y} \), &c.

The whole doctrine of fluxions consists in solving the two following problems, viz.

1. From the fluent, or variable flowing quantity given, to find the fluxion; which constitutes what is called the direct method of fluxions.
2. From the fluxion given, to find the fluent, or flowing quantity; which makes the inverse method of fluxions.

Direct method of Fluxions. The doctrine of this part of fluxions is comprised in these rules.

1. To find the fluxion of any simple variable quantity, the rule is to place a dot over it: thus, the fluxion of \( x \) is \( \dot{x} \), and of \( y, \dot{y} \). Again, the fluxion of the compound quantity \( x+y \), is \( \dot{x} + \dot{y} \); also the fluxion of \( x-y \), is \( \dot{x} - \dot{y} \).

2. To find the fluxion of any given power of a variable quantity, multiply the fluxion of the root by the exponent of the power, and the product by that power of the same root, whose exponent is less by unity than the given exponent. This rule is expressed more briefly, in algebraical characters, by \( n x^{n-1} \dot{x} = \text{the fluxion of } x^{n} \). Thus, the fluxion of \( x^{3} \) is \( 3x^{2} \dot{x} \); and the fluxion of \( x^{5} \) is \( 5x^{4} \dot{x} \). In the same manner, the fluxion of \( a+y \) is \( \dot{y} \); for the quantity \( a \) being constant, \( \dot{y} \) is the true fluxion of the root \( a+y \). Again, the fluxion of \( a^{2} + z^{2} \) is \( 2z \dot{z} \); for the fluxion of \( a^{2} \) being put \( 2a \dot{a} \), we have \( \dot{z} \); and therefore \( \frac{1}{2} x^{\frac{1}{2}} \dot{x} \), for the fluxion of \( x^{\frac{1}{2}} \) (or \( a^{\frac{1}{2}} + z^{\frac{1}{2}} \)) is \( \frac{1}{2} z^{\frac{1}{2}} \sqrt{a^{2} + z^{2}} \).

3. To find the fluxion of the product of several variable quantities, multiply the fluxion of each, by the product of the rest of the quantities; and the sum of the products, thus arising, will be the fluxion sought. Thus, the fluxion of \( xy \) is \( yx + x \dot{x} \); that of \( xy_{z} \) is \( yxz + yz \dot{z} + zx \dot{x} \); and that of \( yxy_{z} \) is \( yxy_{z} + x_{y} y + y_{z} z \dot{y} + z \dot{z} + zx \dot{x} \). Again, the fluxion of \( a+b+\dot{y}=a+b-\dot{a}-\dot{b}-\dot{y} \), is \( b-x - a \dot{y} - x \dot{y} - y \dot{z} \).

4. To find the fluxion of a fraction, the rule is, from the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator. Thus, the fluxion of \( \frac{x}{y} \) is \( \frac{y\dot{x} - x\dot{y}}{y^{2}} \); that of \( \frac{x}{y + z} \) is \( \frac{y\dot{x} + z\dot{z}}{x^{2}} \); and that of \( \frac{x^{2} + y + z}{x+y+z} \) is \( \frac{y^2 + z}{x+y+z} \); and so of others.

In the examples hitherto given, each is resolved by its own particular rule; but in those that follow, the use of two or more of the above rules is requisite: thus (by rule 2. and 3.) the fluxion of \( x^{2} y^{2} \) is found to be \( 2x^{2} y^{2} + 2y^{2} x \dot{x} \); that of \( x^{3} \), is found (by rule 2. and 4.) to be \( 3x^{2} y \dot{y} \); and that of \( x^{2} y^{2} \), is \( y^{2} (\text{by rule 2. and 3. and 4.}) \) found to be \( 2x^{2} y \dot{y} + 2y^{2} x \dot{x} + x \dot{x} + y \dot{y} - x \dot{x} y^{2} \).

5. When the proposed quantity is affected by a coefficient, or constant multiplier, the fluxion found as above must be multiplied by that coefficient or multiplier; thus, the fluxion of \( 5x^{3} \), is \( 15x^{2} \dot{x} \); for the fluxion of \( x^{3} \) is \( 3x^{2} \dot{x} \), which, multiplied by \( 5 \), gives \( 15x^{2} \dot{x} \). And, in the very same manner, the fluxion of \( ax^{n} \) will be \( nan^{n-1} \dot{x} \).

Having thus explained the manner of determining the first fluxions of variable quantities, it remains to say something of second, third, &c. fluxions. We have already observed, that the second fluxion of a quantity is the fluxion of the first fluxion; and by the third fluxion is meant the fluxion of the second; the fourth, of the third; and so on. The fluxions, therefore, of every order are
only the measures of the velocities by which their respective flowing quantities, viz. the fluxions of the immediately preceding order, are generated. Hence it appears, that a second fluxion always shews the rate of the increase or decrease of the first fluxion; and that the third, fourth, &c. fluxions differ in nothing, except their order and notation, from first fluxions; and therefore are also determinable in the very same manner, by the rules already laid down: thus (by rule 4.) the (first) fluxion of \(x^3\) is \(3x^2\dot{x}\): and if \(\dot{x}\) is suppo'd constant, that is, if the root \(x\) be generated with an equable or uniform velocity, the fluxion of \(3x^2\dot{x}\) (or \(3x^2x^3\)) again taken (by the same rule) will be \(3\dot{x}xx^3x\), or \(6xx^2\) which therefore is the second fluxion of \(x^3\). Again, the third fluxion of \(x^3\), or the fluxion of \(6xx^2\), is found to be \(6\dot{x}^2\); further than which we cannot go in this case, because the last fluxion, \(6\dot{x}^2\), is here a constant quantity.

In the preceding example, the root \(x\) is suppo'd to be generated with an equable velocity: but if the velocity be an increasing or decreasing one, then \(\dot{x}\), expressing the measure thereof, being variable, will also have its fluxion, which is denoted, as said above, by \(\ddot{x}\); and the fluxion of \(\ddot{x}\) by \(\dot{x}\), and so on, with respect to the higher orders.

Here follow some examples, wherein the root \(x\) (or \(y\)) is suppo'd to be generated with a variable velocity. Thus, the fluxion of \(x^3\) being \(3x^2\dot{x}\) (or \(3x^2x^3\)) the fluxion of \(3x^2\dot{x}\), considered as a rectangle, will (by rule 3.) be found to be \(6xx\dot{x}x+3x^2x\ddot{x}=6\dot{x}^2+3x^2\ddot{x}\); which is the second fluxion of \(x^3\). Moreover, from the fluxion last found, we shall in like manner get \(6x\dot{x}xx+6\dot{x}xx\dot{x}+6x\dot{x}\ddot{x}+3x^2\dddot{x}\) (or \(6\dot{x}^3+18x\ddot{x}x+3x^2\dddot{x}\)) for the third fluxion of \(x^3\). Thus also, if \(y=x^n-1\dot{x}\), then will \(y'=nx^{n-2}\ddot{x}+\dot{x}n\dddot{x}x^{n-1}\); and if \(z=x^y\), then will \(z'=y\dot{z}\ddot{z}\dddot{z}x^y\); and so of others.

The reader is here defied, once for all, to take particular notice, that the fluxions of all kinds and orders whatever, are contemporaneous, or such as may be generated together, with their respective velocities, in one and the same time.

Inverted method of Fluxions, or the manner of determining the fluxions of given fluxions.
In assigning the fluents of given fluxions, it ought to be considered, whether the flowing quantity, found as above, requires the addition or subtraction of some constant quantity, to render it complete; thus, for instance, the fluent of \( n x^{n-1} \cdot x \) may be either represented by \( x^n \) or by \( x^n \pm a \); for \( a \) being a constant quantity, the fluxion of \( x^n \pm a \), as well as of \( x^n \), is \( n x^{n-1} \cdot x \). Hence it appears, that the variable part of a fluent only can be assigned by the common method, the constant part being only affinable from the particular nature of the problem. Now to do this, the best way is to consider how much the variable part of the fluent, first found, differs from the truth, when the quantity which the whole fluent ought to express, is equal to nothing; then that difference, added to, or subtracted from, the said variable part, as occasion requires, will give the fluent truly corrected. To make this plainer by an example or two, let \( j = a + x \) \( \frac{3}{4} x \). Here we first find \( y = \frac{a + x^4}{4} \); but when \( y = 0 \), then \( a + x^4 \) becomes \( a^4 \) since \( x \), by hypothesis, is then = 0; therefore \( \frac{a + x^4}{4} \) always exceeds \( y \) by \( \frac{a^4}{4} \); and so the fluent, properly corrected, will be \( y = \frac{a + x^4}{4} - \frac{3 a^2 x^2}{2} + \frac{a x^3}{4} \). Again, let \( y = a^m + x^m \frac{a^m + x^m}{m} \); here we first have \( y = \frac{a^m + x^m}{m \cdot x + 1} \); and making \( y = 0 \), the latter part of the equation becomes \( \frac{a^m + x^m}{m \cdot x + 1} = \frac{a^m + x^m}{m \cdot x + 1} \); whence the equation or fluent, properly corrected, is \( y = \frac{a^m + x^m}{m \cdot x + 1} \). 

Hitherto \( x \) and \( y \) are both supposed equal to nothing, at the same time; which will not always be the case: thus, for instance, though the sine and tangent of an arc are both equal to nothing, when the arc itself is 0; yet the secant is then equal to the radius. It will therefore be proper to add some examples, wherein the value of \( y \) is equal to nothing, when that of \( x \) is equal to any given quantity \( a \). Thus, let the equation \( y = x^3 + x \), be proposed; whereof the fluent first found is \( y = \frac{x^3}{3} \); but when \( y = 0 \), then \( \frac{x^3}{3} = a \cdot \frac{3}{3} \), by the hypothesis; therefore the fluent, corrected, is \( y = \frac{x^3}{3} - a \cdot \frac{3}{3} \). Again, suppose \( y = x^3 - x \); then \( \frac{x^3}{3} - \frac{-x}{3} \); which, corrected, becomes \( y = \frac{n^3 + x^3}{n + 1} \). And lastly, if \( y = (c^2 + b x^2) \frac{3}{2} x x \); then, first, \( \frac{(c^2 + b x^2) \frac{3}{2} x x}{3 b} \); the fluent corrected is \( y = \frac{(c^2 + b x^2) \frac{3}{2} x x}{3 b} \).

3. To find the fluents of such fluxionary expressions as involve two or more variable quantities, substitute, instead of such fluxion, its respective flowing quantity; and, adding all the terms together, divide the sum by the number of terms, and the quotient will be the fluent. Thus, the fluent of \( \frac{3}{2} x x \) \( x y + y x = \frac{2}{2} x y = x y \); and the fluent of \( \frac{3}{2} x x + x y + y x = \frac{3}{3} x y z = x y z \).

But it seldom happens that these kinds of fluxions, which involve two variable quantities in one term, and yet admit of known and perfect fluents, are to be met with in practice. Having thus shewn the manner of finding such fluents as can be truly exhibited in algebraic terms, it remains now to lay something with regard to those other forms of expressions involving one variable quantity only; which yet are so affected by compound divisors and radical quantities, that their fluents cannot be accurately determined by any method whatsoever. The only method with regard to these, of which there are innumerable kinds, is to find their fluents by approximation, which,
which, by the method of infinite series, may be done to any degree of exactness. See the article \textit{Series}.

Thus, if it were proposed to find the fluent of \( \frac{ax}{a-x} \), it becomes necessary to throw the fluxion into an infinite series, by dividing \( ax \) by \( a-x \): thus, 
\[
\frac{ax}{a-x} = x + \frac{x^2}{a} + \frac{x^3}{a^2} + \frac{x^4}{a^3} + \frac{x^5}{a^4} + \text{c.c.}
\]

Now the fluent of each term of this series, may be found by the foregoing rules to be 
\[
x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3} + \frac{x^5}{5a^4} + \text{c.c.}
\]

Again, to approximate the fluent of 
\[
\frac{a^2-x^2}{a^2-x} \text{ to } x^n, \text{ we first find the value of }
\]
\[
\frac{a^2-x^2}{a^2-x} = \frac{x}{c} + \frac{a}{2ac} \times x^2 + \frac{3a}{8ac^2} - \frac{1}{8ac^2} \times x^4 + \frac{5a}{16ac^3} - \frac{3}{16ac^3} \times x^6 + \text{c.c.}
\]

the fluent taken by the dividing the content of the cylinder whose diameter is \( \frac{3}{4} \) of its circumfering cylinder: for the area of the circle \( FH \) being expressed by \( \frac{1}{4} ab \), the content of the cylinder whose diameter is \( FH \), and altitude \( AB \), will be \( \frac{b^2}{4} ab \), of which \( \frac{1}{4} ab^2 \) is evidently a two third parts.

For the other uses of fluxions, see the articles \textit{Maximis \& minimis}, \textit{Quadrature}, \textit{Tangents}, \textit{Solids, \&c.}

\textbf{FLUXION, or rather DEFLUXION, in medicine.} See the article \textit{DEFLUXION}.

\textbf{FLY,} in zoology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent; by this they are distinguished from beetles, butterflies, and grasshoppers. See the articles \textit{BEETLE, BUTTERFLY, \&c.}

Flies are subdivided into those which have four, and those which have two wings. Of those with four wings, there are several genera or kinds, as the ant, apis, tennentro, ichneumon, \&c. See the articles \textit{ANT, APIS, \&c.}

Of those with two wings, there are likewise several kinds, as the gad-fly, waff-fly, gnat, tipula, \&c. See the article \textit{GAD FLY, \&c.}

Those who desire a more particular account of the anatomy, generation, structure, and manifold subdivisions of flies, may consult Reaumur's \textit{History of Insects}, tom. 4.
FLY, in mechanics, a cross with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which the force of the power, whatever it be, is not only preferred, but equally distributed in all parts of the revolution of the machine.

The fly may be applied to several sorts of engines, whether moved by men, horses, wind, or water, or any other animate or inanimate power; and is of great use in those parts of an engine which have a quick circular motion, and where the power or the resistance acts unequally in the different parts of a revolution.

This has made some people imagine, that the fly adds a new power; but tho' it may be truly said to facilitate the motion, by making it more uniform, yet upon the whole it causes a loss of power, and not an increase: for as the fly has no motion of its own, it certainly requires a confinute force to keep it in motion; not to mention the friction of the pivots of the axis, and the resistance of the air.

The reason, therefore, why the fly becomes useful in many engines, is not that it adds a new force to them; but because, in cases where the power acts unequally, it serves as a moderator to make the motion of revolution almost everywhere equal; for as the fly has accumulated in itself a great degree of power, which it equally and gradually exerts, and as equally and gradually receives, it makes the motion in all parts of the revolution pretty nearly equal and uniform. The consequence of this is, that the engine becomes more easy and convenient to be acted and moved by the impelling force; and this is the only benefit obtained by the fly.

The best form for a fly, is that of a heavy wheel or circle, of a fit size, as this will not only meet with less resistance from the air, but being continuous, and the weight every where equally distributed through the perimeter of the wheel, the motion will be more easy, uniform, and regular. In this form, the fly is most aptly applied to the perpendicular drill, which it likewise serves to keep upright by its centrifugal force: also to a windlass or common winch, where the motion is quick; for in pulling upwards from the lower part, a person can exercise more power than in thrusting forward in the upper quarter; where, of course, part of his force would be lost, were it not accumulated and conserved in the equable motion of the fly. Hence, by this means, a man may work all day in drawing up a weight of 40 lb., whereas 30 lb. would create him more labour in a day without the fly.

In order to calculate the force of the fly joined to the screw for stamping the image upon coins, let us suppose the two arms of the fly to be each fifteen inches long, measuring from the center of the weight to the axis of motion, the weights to be fifty pounds each, and the diameter of the axis pressing upon the dye, to be one inch. If every stroke be made in half a second, and the weights describe an half circumference, which in this case will be four feet, the velocity will at the instant of the stroke be at the rate of eight feet in a second, so that the momentum of it will be 800; but the arms of the fly being as levers, each fifteen inches long, whilst the semi-axis is only half an inch, we must increase this force thirty times, which will give 24,000; an immense force, equal to 100 lb. falling 120 feet, or near two seconds in time; or to a body of 750 lb. falling 16 \( \frac{2}{3} \) feet, or one second in time. Some of the engines for coining crown-pieces have the arms of the fly five times as long, and the weights twice as heavy; so that the effect is ten times greater. See COINING.

FLY, in the sea-language, that part of the mariner's compass, on which the several winds or points are drawn. See the article COMPASS.

Let fly the sheet, is a word of command to let loose the sheet, in case of a gulf of wind, lest the ship should overlie, or spend her top-fails and masts; which is prevented by letting the sheet go by main, that it may hold no wind.

FLY, among spot-timers. When a hawk missing her quarry, betakes herself to the next check, as crows, &c. they say the flies on head. When a hawk flies at great birds, as cranes, geese, &c. they say the flies gros. A horse is said to fly the heels, when he obeys the spur.

FLY-BOAT, a large vessel with a double prow, carrying from seven to eight hundred weight or goods.

FLYERS, in architecture, such stairs as go straight, and do not wind round; nor have the steps made tapering, but the fore and back part of each stair, and the ends, respectively parallel to one another; so that if one flight do not carry you to your intended height, there is a broad half...
FLYING, the progressive motion of a bird, or other winged animal, in the liquid air. The parts of birds chiefly concerned in flying, are the wings, by which they are sustained or wafted along. The tail, Mefjeurs Wilkugby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air; and to obviate the vacancies of the body and wings; for, as to turning to this or that side, it is performed by the wings, and inclinations of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and prefers the same situation whatever way forever the bird turns. In effect, as a vessel is turned about on its center of gravity to the right, by a brisk application of the oars to the left, so a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons, changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclinations of their head and neck, which altering the course of gravity, the bird will proceed in a new direction.

The manner of FLYING is thus: the bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists thoseuccussions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the wait or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces come to be in equilibrium, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes, makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicularly line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

Artificial FLYING, that attempted by men, by the assistance of mechanics. The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break his fall. Frier Bacon, who lived near five hundred years ago, not only affirms the art of flying possible, but affures us, that he himself knew how to make an engine wherein a man sitting might be able to convey himself through the air, like a bird; and further adds, that there was then one who had tried it with success: but this method, which consisted of a couple of large, thin, hollow copper globes, exhausted of the air, and sustaining a person who sat thereon, Dr. Hook shews to be impracticable. The philosophers of King Charles the second's reign, were mightily busied about this art. The famous bishop Wilkins was so confident of success in it, that he says, he does not question but, in future ages, it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

FLYING-ARMY, a small body under a lieutenant or major general, sent to harass the country, intercept convoys, prevent the enemy's incursions, cover its own garrisons, and keep the enemy in continual alarm.

FLYING-BRIDGE. See the article BRIDGE.

FLYING-CAMP. See the article CAMP.

FLYING-FISH, a name given by the English writers
writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of water a long time. See Exocoetus, Milvus, Mugil-alatus, &c.

FLYING-PINION, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part. See the article CLOCK.

FOAL, or COLT, the young of the horse kind. The word colt among the dealers, is understood of the male kind. Foals are usually foaled about the beginning of summer, and it is the custom to let them run till Michaelmas with the mare, at which time they are to be weaned. Some, however, are of opinion, that a foal is rendered much fooner fit for service by being allowed to fuckle the whole winter, and beaned about Candlemas or Shrove tide. When firft weaned, they must be kept in a convenient house, with a low rack and manger for hay and oats; the hay must be very sweet and fine, especially at fift, and a little wheaf bran should be mixed with their oats, in order to keep their bodies open, and make them eat and drink freely. When foals are kept up in the winter, they are not continually to be immured in the stable; but in the middle of the day, when the fun shines warm, they fhould always be allowed to play about for an hour or two, and when the winter is spent, they fhould be turned into fome dry ground where the green is nice and short, and where there is good water, that they may drink at pleasure. The winter after this, they may be kept in the stable without any further care than that which is taken of other horses; but after the firft year, the mare foals and horfe foals are not to be kept together.

There is no difficulty to know the shape a foal is like to be of; for the fame shape he carries at a month, he will carry at fix years old, if he be not abused in after keeping. As for his height, it is obferved that a large thin bone, long from the knee to the pattern, fhews a tall horfe; for which another way is to fee what fpace he has between his knee and his withers, which being doubled, it will be his height when he is a full aged horfe. There are also means of knowing their goodnes ; for if they are of lively spirits, free from frights, wanton of disposition, and very active in leaping and running, and thriving for maffety, they prove generally good metted horfes. It is a good mark alfo if their hoofs be strong, deep, tough, smooth, upright standing, and hollow. For the manner of breaking them, see the article HORSE.

FOCAGE, the fame with fire-bote. See the article FIRE-BOTE.

FOCHEN, a town of China, capital of the province of Fokien; east long. 118°, north lat. 26° 20'.

FOCUS, in geometry and conic fections, is applied to certain points in the parabola, ellipfis, and hyperbola, where the rays reflected from all parts of these curves concur and meet.

FOCIS of an ellipfis, are two points in the longeft axis, on which as centers the figure is decribed. See ELLIPFIS. If from the foci two right lines are drawn, meeting one another in the periphery of the ellipfis, their fun will be always equal to the longeft axis; and therefore when an ellipfis and its two axis are given, and the foci are required, you need only take half the longeft axis in your compaffes, and fetting one foot in the end of the shorter, the other foot will cut the longer in the focus required.

FOCUS of an hyperbola, is that point in the axis, through which the latus reftum paffes ; from whence if any two right lines are drawn meeting in either of the oppofite hyperbolas, their difference will be equal to the principal axis. See the article HYPERBOLA.

FOCUS of a parabola, a point in the axis within the figure, diftant from the vertex one fourth part of the latus reftum. See the article PARABOLA.

FOCUS, in optics, is the point wherein rays are collected, after they have undergone reflection or refraction. See the articles MIRROUR and LENS.

Principal Foci of a lens, are the two foci $F_1$ and $F_2$, (plate CI. fig. 1. n° 1.) of rays coming parallel to the axis of the lens, and $EF$ or $F_2$ is called its focial distance, and by authors its focial length.

It appears from the laws of optics, as well as from experiments, that the focial distance of a plano-convex, or of a plano-concave glafs, is equal to a diameter of its convex or concave surfaces; that is, of the whole sphere it belongs to: Secondly, that the focial distance of a double convex or a double concave glafs of equal convexities or concavities, is equal to a semi-diameter of either of its surfaces: and confequently that the focial distance of a glafs of unequal convexities or unequal.
equal concavities, will have an intermediate length between a diameter and a semi-diameter of that surface which is most convex or most concave.

Virtual Focus, a term used by Mr. Molyneux for that point from which refracted rays begin to diverge. It is also called point of dispersion or divergency. It is remarkable, 1. That in concave glasses, when a ray falls from air parallel to the axis, the virtual focus is distant from the glass the diameter of the concavity. 2. In plano-concave glasses, when the rays fall parallel to the axis, the virtual focus is distant from the glass the diameter of the concavity. 3. In plano-concave glasses, as 507 to 193, is the radius of the concavity to the distance of the virtual focus. 4. In double concaves of glasses, the axis, produced, is the diameter of the pencil, and with this focal distance of the lens, describe an arch FG, cutting any incident ray QA in G; join EG, and drawing Aq parallel to it, the point q, where it cuts the axis of the pencil, will be the focus of the emergent rays. For supposing other rays, besides GA, to flow from or towards G, they will emerge parallel to their axis GE produced.

The Focus of rays falling almost perpendicularly upon a given spherical surface being given, to find their focus after refractions. Let O1 (ibid. p. 2.) be the given surface, whose center is S; and in any radius OS produced, let Q be the given focus of the incident rays as Q1; it is required to find the focus q of the refracted rays. Call OS, OQ, Oq respectively S, Q, q; and let the given ratio of the sines of refraction be m to n, and let m be bigger than n. Then joining SI, since very small angles are very nearly proportional to their sines, we have the angle OSI: to the angle $S_1Q: : Q: = S$, and the angle $S_1Q: : m: : n$. And by compounding these proportions we have the angle OSI: to the angle $S_1q: : mQ: : nS$, and disjointly we have the angle OSI: to the angle $S_q$, that is $q: : mQ+ns$. Whence, putting $\theta = m-n$, we have this theorem, $q = \frac{mQ}{\frac{\theta}{S}Q+nS}$. This is the value of $q$ in the given case, where the lines OQ, OS, Oq lie all on the same side of the surface O1; and thence the theorem for $q$ may be easily adapted to any other given case, by confiding OQ as being always affirmative, and by changing the sign of $S$ when OS and OQ lie on contrary sides of their origin O; and by changing the sign of $\theta$, when the sine of incidence is less than the sine of refraction; and, lastly, by placing Oq the contrary way to OQ, when the value of $q$ comes out negative by the theorem so changed.

Theorem for reflected rays. Substitute $-m$ in the preceding theorem for $n$, and consequently $\frac{1}{m}$ for $\theta$, and we have $q = \frac{1}{4SQ} = \frac{1}{4S}$; which theorem gives the focus of rays reflected from the spherical surface O1. For the calculation continues the same, whether the rays go forwards or backwards in the line lq; and to change the angle of refraction $S_1q$ (ibid. p. 3.)
Having the Focus of rays falling almost perpendicularly upon a given lens, to find their focus after refractions. Let O I E O (ibid. n° 5.) be the given lens, whose vertex's are O and o; R the center of the first surface O I; r the center of the second o R; P the given focus of incident rays in the axis o O or R; and p the focus of the emergent rays required. Let m be their focus after the first refraction at the surface O I, and m to n the ratio of the fines as above, and call O o, o r, O R, O P, o P, respectively o, r, R, P, p. Then for Q 1, S, m, n, o in the foregoing theorem, write P r, m R, m, n, o; and we have O o = \frac{m P R}{o P + n R}; to which adding O o, or o, we have o o = \frac{m P R + o P + n R o}{o P + n R}.

Again, for Q 2, S, m, n, o in the foregoing theorem, write o, r, n, m, - o; and we have p = \frac{- m P R}{o o + m R}; in which by substituting the value of o o, we have p = \frac{m P R + m R o}{o P + n R o}.

This theorem for a minifcus lens, having its concave surface exposed to P, is easily adapted to a lens of any given form, by conceiving one or both its semi-diameters O R, o R, to decrease or increase, or to become infinite and then negative, till the minifcus acquires the form of the given lens; and by changing the sign of R or r, when the semi-diameters lie on opposite sides of their surfaces O o, to the focus P; and, lastly, by placing p on the opposite side of o to P, when its value in the theorem so changed comes out negative. Thus by writing \infty (which denotes infinite) for R, this theorem is easily adapted to a plano-convex lens, having its first surface plane; and by writing - r for r, it is adapted to a double concave; and by writing \infty for R, and - r for r, it is adapted to a plano-concave whose first surface is plane; and, lastly, it is adapted to a sphere whose semi-diameter is R and diameter O o, by writing - R for R, and R for r, and \infty for o; and by substituting given numbers for the ratio of refraction, the bigger for m, and the smaller for o, it is adapted to lens's of any given substances.

Before the discovery of the law of refraction, according to the given ratio of the fines of incidence and refraction of any given magnitudes, opticians could only consider the refractions of such rays as fell almost perpendicularly upon the refracting surfaces, where the angles of incidence and refraction being but small, were known by experience to be nearly in a given ratio to each other, and these rays they found would all belong to one focus pretty nearly. But Dr. Barrow observing that the several small portions of a large pencil of rays flowing from a given focus, would diverge after refraction or reflection from several different foci, according as they fell with different obliquities upon the several parts of a spherical surface, and being of opinion that the eye receiving a certain small portion of these rays, would judge the object to appear in the place from which they diverged, and consequently to appear in different places according as the eye received a different portion, took occasion from thence to determine these places geometrically by means of the law of refraction, then newly discovered; and consequently to handle the subject of dioptics and catoptrics, in a more extensive manner than any writer had then done. The foci of rays obliquely refracted and reflected, have also been touched upon by Sir Isaac Newton in his optical lectures, in order to determine the diameters and breadths of the rainbows, and to make way for his admirable theorems concerning the separations of heterogeneal rays. The reader, therefore, devious of being fully instructed in the determinations of the foci of rays falling with any degrees of obliquity upon any number of reflecting and refracting surfaces of any sort, may consult the above-mentioned writers, as also Dr. Smith's optics, book 2. ch. 9. and the remarks on that chapter, where the chief discoveries of Sir Isaac and Dr. Barrow.
Barrow are not only comprehended, but made much more general, by shewing that the relation of the focus's of incident and emergent rays, to the focus's of parallel rays coming contrary ways is always the same, after any number of oblique refractions or reflections, as when a pencil of rays is but once refracted or reflected at the vertex of a sphenic surface.

FODDER, any kind of meat for horses, or other cattle. In some places, hay and straw, mingled together, is peculiarly denominated fodder.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

FODDER, in mining, a measure containing twenty-two hundred and an half weight, though in London but twenty hundred weight.

FODINA, in anatomy, the labyrinth of the ear. See the article Ear.

FOECES and FOECULA. See the articles FECES and FECULA.

FOECIALES, or FECIALES, in roman antiquity. See the article FECIALES.

FOECUNDITY, or FECUNDITY, the same with fertility. See FERTILITY.

FOENICULUM, fennel, in botany, agrees in characters with anethum or dill. See the articles DILL and FENNEL.

FOENUGREEK, or SENNUN GRACUM, in botany, is called by Linnaeus trigonella. See the article TRIGONELLA.

The figure of foenugreek-seed is singular, being irregularly rhomboidal, confiderably thick, with a line or depression running obliquely from one of the opposite angles to the other. It is of a pale-yellowish colour, and of an extremely tough and firm texture. It is of a strong and agreeable smell, and of a faint nausous taste. We have it from Germany.

Foenuugreek is used externally on many occasions by way of cataplasms or fomentations; being emollient and diuretiv in a great degree, and found to give great relief in pains, bruises, &c. It is sometimes also an ingredient in emollient clysters, where anodynes and carminatives are required, without too much pungency. It is also an ingredient in the ointment of marsh-mallows, and some other shop-compositions; but is never given internally.

FOETOR, in medicine, flinking or foetid effluvia, arising from the body, or any part thereof.

FOETOR NARIUM, a foetid stench of the nostrils, arising from a deep ulcer within the nose, the cause of which, according to Galen, is a sharp humour falling from the brain upon the mamillary processes. See the article ULCE.

This is one of the causes for which marriage might, in former times, be annulled.

FOETOR ORIS, a term used by medical writers to express that had smell in the mouth, usuall, tho' often improperly, called a flinking breath.

This is a malady arising in different cases from very different cauæs, as from the scurvy, and particularly from that species of it which affects the mouth, and is therefore called stomocace; from the french pox; from an ulceration, whether simple or fistulous, in the lungs, which is the cafe in consumptions; from ulcers in the mouth; from a caries or rottenness of the teeth, or from any other impurity of them; from crudities in the stomach, arising from a bad digestion; and particularly from a weakness about the left orifice of the stomach, from which part of the foetid vapour will often arise in very great abundance.

According to the different causes of this disorder, it requires a very different method of cure; in cases where it depends on the scurvy, pox, or other diseases, then those diseases are to be attacked by the proper medicines. See SCURVY, POX, &c.

When it arises from a carious tooth, there is no other cure for it but drawing the tooth. When the impurities of the teeth occasion it, the cleaning them proves a cure.

FOETUS, in physiology, denotes the child while it is contained in the mother's womb, but particularly after it is formed, till which time it is more properly called embryo. See the article GENERATION.

Formation of a FOETUS. The formation of the bones in a foetus, is very gradual and regularly performed. In the first two months, there is nothing of a bony nature in the whole. After this, the hardnefs of the parts, where the principal bones are to be situated, becomes, by degrees, perceptible. Dr. Keilringer describes the progress of the ossification from skeletons, which he had prepared from foetuses of two months, and thence up to nine. In the first two months, or to the end of that time, there appears not any thing bony. After this, in the third and fourth
fourth months, the several parts, one after another, acquire their bony nature. In the first stages, every thing is membranous, where the bones are to be: these, by degrees, transmigrate into cartilages, and from these, by the same sort of change continued, the bones themselves are by degrees formed. All this is done by nature, by such slow, though such certain progressions, that the nicest eye can never see it doing, though it easily sees it when done.

Foetuses increase proportionably less, the longer they continue in the womb. Maurice pretends, that the increase of a foetus is sixty-four times its own weight in triple the time. Thus, he says, that, at the birth, a child weighs twelve pounds, of sixteen ounces each; at the three months, it weighs three ounces; at one month, ½ of a drachm; and at ten days, less than half a grain.

Anatomy of a Foetus. In the examination of the foetus intire, we first observe the membranes surrounding it in the uterus, as in an egg, the exterior of these is the chorion; the interior, or second membrane, is the amnios; and a third, tho' its existence is disputed in human subjects, is the allantois. See the articles Chorion, Amnios, and Allantois.

After the membranes including the foetus, we are next to examine the placenta, the number of which, in human subjects, answers to that of the foetuses. See the article Placenta.

After the placenta, we are to observe the umbilical vessels of the foetus, which, after the birth, degenerates into ligaments. See Umbilical and Artery.

Another part belonging to the umbilical vessels observable in the human foetus, is the funiculus umbilicalis, or navel-string. See the article Navel-string.

The more essential differences between the human foetus and an adult, considering the foetus not only as yet enclosed within the womb, but as newly come from it, are as follows.

In the abdomen, the umbilical vein and arteries of the navel, and the canalis vevolus in the liver, are in the foetus open and pervious; in adults, they are contracted and solid. The liver is very large, the stomach is filled with a glutinous fluid, and the larger intestines, and often the ilium also, with the faces called meconium. The renes iccenturiati, are larger in the foetus than in adults. The kidneys themselves are not smooth and even on the surface, as in adults, but unequal, and in some measure resemble those of a calf. The urinary bladder is of a longer shape, and extends almost to the navel. The hymen in a female foetus, is very plain and obvious. In the thorax, besides a peculiar fluid, found as well in this cavity as in the abdomen, the gland thymus is larger than it is in adults. The lungs, as they have never yet been inflated by breathing, are collapsed, and of a blackish colour; and if thrown into water they sink in it, contrary to what is the case in those in adults.

In the heart, the foramen ovale between the left and right auricle, and the canalis arteriosus, between the pulmonary artery and the aorta, are open, to serve for a peculiar circulation in the foetus, which has not yet breathed; and there is in the inferior trunk of the vena cava, near the heart, a remarkable valve, called by Chelfelden in his anatomy, valvula nobilis. See the article Valve.

In the head, besides its great size in proportion to the body, we are to observe, that the osa crania are in several places distant from one another, especially at the fontanella; and that the futures are wanting. The brain also is softer than in adults. The teeth are also imperfect, and not rooted in the gums; they lie hid or buried under the gums, to appear at a more advanced period. The meatus auditorius is not yet perfect in them; and in the foetus, whilst it is in the womb, is entirely closed up by a peculiar membrane, which is continuous with the epidermis, and which naturally disappears after delivery. The bones of the whole body, excepting only a very few, are either soft or yet absolutely imperfect: some of them are merely cartilaginous, and the articulations are not at that time perfected.

Situation of the Foetus in the womb. This, in the first months, and even in the middle ones, is perfectly uncertain; but in the latter months, it is more regular; in these it is usually in a posture like that of sitting, and its head and neck are bent downwards; its knees are raised upwards to its cheeks; and its heels drawn up to its buttocks. Its hands are usually hanging down, and embrace the feet. A little time before the delivery, it usually changes its position, in such a manner, that its head falls towards the mouth of the womb, and its buttocks and feet are turned upwards. Frequently, however, it
it varies during the whole time of the pregnancy from the common rule, and at the very infant of the delivery, its head does not present itself, but is turned to one side, or to some other part of the womb.

For the exclusion of the foetus from the uterus, see the article Delivery.

**Nutrition of the Foetus.** How the nutrition of the foetus is performed, is disputed among the learned. Heister is of opinion, that the nutrition of the foetus, during the first months, while the organs of conception are not yet formed, is probably effected by means of the navel-strings alone. But in the more advanced state of the foetus, in the latter months, that great anatomist supposes, that it is also nourished by the mouth, by means of a soft and somewhat glutinous fluid that surrounds it, and which is probably secreted from the amnios. In support of this opinion he observes, 1. That a fluid similar to that of the amnios, is found in the mouth, the oesophagus, and the stomach, not only of the human foetus, but in that of quadrupeds. 2. That this fluid is also found in the small guts of the foetus, but altered and digested. 3. That there are also found in the larger intestines real faeces, called meconium; sometimes the whole ilium is full of these.

4. That in the first months, there is a great quantity of this fluid surrounding the foetus; but in the latter months, there is but very little of it, and the consumption of it is not easily accounted for any other way, than by it being swallowed by the foetus. 5. That the liquid itself is so extremely proper for the nutrition of the foetus, that a more fit one could not have been formed or defined. 6. That it seems to be continually pressed into the mouth, oesophagus, and stomach of the foetus, by the perpetual retency of the uterus itself; and by the preffure of the muscles of the abdomen, and of the ambient air.

Mr. Gibbon, in the Medical Essays of Edinburgh, has lately adopted this opinion as the most probable. Hippocrates, among the antients, was of opinion, that the foetus was nourished both by the mouth and by the umbilical vessels. He maintains, that the child, in the womb, with its lips compressed together, attracts nourishment; for which he assigns this reason, that, unless the child had sucked in utero, it neither could deposit excre-
their red blood? Dr. Monro answers, that fetuses in viviparous animals, have their red blood from the same fource, which chickens in the egg have theirs, which can be no other than the action of their heart, and of the vessels in their body and viscundines.

While fetuses continue in the womb, their muscles commonly act by their natural contraction, or the fetus is said to be in a state of sleeping: but sometimes, when its ease or preservation requires a change of situation, it seems to perform some voluntary motions which are called stirrings. The human fetus is generally supposed to be animated about the end of the sixth, or beginning of the seventh week after conception; though it is seldom felt to breathe three or four times, than it began to stir, till towards the middle of the time of gestation.

Respiration seems to be the great act by which the change is made in animals, from the state of fetus, to that of motion, sensation, and the other qualities of animal life in their larger degree. Mr. Davenant observed this in the fetus of a common snake: he broke the egg of one of these animals, at a time when it was just ready for hatching, and the young snake fell out, rolled in a spiral, at first quite still and motionless; but it had no sooner breathed three or four times, than it began to perform all the motions of animal life, in the most nimble and active manner. See the article Respiration.

Hippocrates and some learned modern physicians suppose, that a fetus respire in the womb; but it seems very difficult to conceive how air should traverse the body of the mother, and the teguments of the child; and since nature hath in new-born infants contrived peculiar temporary vessels, that the blood may circulate through other passages than it does in the same individuals, when they come to have the use of their lungs, it is improbable that the fetus in the womb should properly respire.

The symptoms of the human fetus being dead in the womb, the reasons which may occasion it, the accidents which attend it, and the methods of preventing it, and remedying the consequences thereof, as also the various ways of expelling it, may be seen under the articles Abortion, Conception, Delivery, &c.

For the circulation of the blood, as performed in the fetus, see Circulation. Fog, or Mist, a meteor consisting of gros vapours, floating near the surface of the earth.

Mists, according to lord Bacon, are imperfect condensations of the air, consisting of a large proportion of the air, and a small one of the aqueous vapour; and these happen in the winter, about the change of the weather, from frost to thaw, or from thaw to frost: but in the summer and the spring, from the expansion of the dew.

If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous heat, do, at their first entrance into the atmosphere, meet with cold enough to condense them to a considerable degree, their specific gravity is, by that means, encreased; and so they will be stopped from ascending, and return back, either in form of dew, or drizzling rain; or remain suspended some time in the form of a fog. Vapours may be seen on the high grounds as well as the low, but more especially about marshy places: they are easily diffipated by the wind, as also by the heat of the sun: they continue longest in the lowest grounds, because these places contain most moisture, and are least exposed to the action of the wind.

Hence we may easily conceive, that fogs are only low clouds, or clouds in the lowest region of the air; as clouds are no other than fogs, raised on high. See Cloud. When fogs flink, then the vapours are mixt with sulphurous exhalations, which smell fo. Objects viewed through fogs, appear larger and more remote than through the common air. Mr. Boyle observes, that upon the coast of Coromandel, and the most maritime parts of the East-Indies, there are, notwithstanding the heat of the climate, annual fogs so thick, as to occasion those of other nations who reside there, and even the more tender part of the natives, to keep their houses close shut up.

Fogage, in the forest law, is rank grass not eaten up in summer.

Fogares, a town of Transilvania, thirty miles north-east of Hermannstadt.

Fogo, one of the Cape-Verd islands, subject to Portugal.

FOIL, among glass-grinders, a sheet of tin, with quicksilver or the like, laid on the backside of a looking-glass, to make it reflect. See the articles Foliating and Looking-Glass.

FOIL, among jewelers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give...
FOLIAGE, as possible, and filtered through a presentation of such flowers, leaves, branches, rings, and scarce visible. Thus, if there are two forts; the leaf may be managed by one man only, but the greatest must be carried by two, and used thus: let the net be fixed on both sides to two strong, straight, and light poles about twelve feet long, each man holding one of them; let there be one behind them, at the distance of two yards, to carry lights: the nets must be carried between the wind and the birds, which all naturally roost on their perches with their breasts against the wind; by reason of this, he that heats the bushes on the other side of the hedge, will drive them out that way towards the light.

FOLDAGE, the liberty of penning sheep by night. See the article FALDAGE.

FOLDING OF SHEEP. In some places they let their fold with several partitions, and put the wedders, ewes, and lambs separate by themselves. It is not good to fold them in rainy weather; and, as it is the opinion of some husbandmen that urine of sheep helps, heats, and comforts the land as much or rather more than their dung does, they caufe all the sheep in the fold to be raised before they let them go out, and go about the fides of the fold with a dog; for commonly when sheep see a dog come nigh them, they will dung and flale.

FOLIA, among botanists, particularly signify the leaves of plants; thofe of flowers being expreffed by the word petal. See the article PETAL.

FOLIACEUM EXPANSUM, in anatomy, a term applied to the extreme part of the fallopinian tube, next the ovary, which is expanded like the mouth of a trumpet, and surrounded with a fort of fringe. See the article FALLOPIAN TUBE.

FOLIAGE, a clufter or assemblage of flowers, leaves, branches, &c. FOLIAGE is particularly used for the representations of such flowers, leaves, branches, rings, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

FOLIATE, in the higher geometry, a name given by Mr. de Moivre to a curve of the second order, expreffed by the equation $x^2+y^2=axy$; being a species of defcriptive hyperbolas with one asymptote, and confiting of two infinite legs crossing one another, and forming a fort of leaf.

FOLIATING OF LOOKING-GLAFFES, the spreading the plates over, after they are polished, with quicksilver, &c. in order to reflect the image. It is performed thus: a thin blotting paper is spread on the table, and sprinkled with fine chalk; and then a fine lamina or leaf of tin, called foil, is laid over the paper; upon this mercury is poured, which is to be distributed equally over the leaf with a hare's foot, or cotton: over this is laid a clean paper, and over that the glafs-plate, which is pressed down with the right-hand, and the paper drawn gently out with the left: this being done, the plate is covered with a thicker paper, and loaden with a greater weight.
weight, that the superfluous mercury may be driven out, and the tin adhere more cloely to the glafs. When it is dried, the weight is removed, and the looking-glas is complete. Some add an ounce of marcasite, melted by the fire; and, left the mercury should evaporate in smoke, pour it into cold water; and when cooled, squeeze through a cloth, or through leather. Some add a quarter of an ounce of tin and lead to the marcasite, that the glafs may dry the sooner.

**FOLIATING of globe looking-glasses** is done as follows: take five ounces of quicksilver, and one ounce of bismuth; of lead and tin, half an ounce each. First put the lead and tin into fusion, then put in the bismuth, and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quicksilver into it: after this, take the glafs-globe, which must be very clean, and the inside free from dust; make a paper-funnel, which put into the hole of the globe, as near to the glafs as you can, so that the amalgam, when you pour it in, may not splash, and cause the glafs to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where. If you find the amalgam begin to be curdly and fixed, then hold it over a gentle fire, and it will easily flow again. And if you find the amalgam too thin, add a little more lead, tin, and bismuth to it. The finer and clearer your globe is, the better will the looking-glasses be.

Dr. Shaw observes, that this operation has considerable advantages, as being performable in the cold, and that it is not attended with the danger of poisonous fumes from arsenic, or other unwholfsome matters, usually employed for this purpose: besides, how far it is applicable to the more commodious foltating of the common looking-glasses, and other speculums, he thinks, may deserve to be considered.

**FOLIATION**, a term used by some botanists to denote the corolla, or flower-leaves. See **FLOWER** and **COROLLA**.

**FOLIGNO, or FULIGNO.** See **FULIGNO**.

**FOLIO**. See **FULIGNO**. FOLIO, in merchants books, denotes a page, or rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See **BOOK**.

**FOLIO**, among printers and book-sellers, the largest form of books, when each sheet is so printed, that it may be bound up in two leaves only.

This form is only used in large works; and even, in these, the quart or octavo forms are much more handy.

**FOLIUM LEAF, among botanists.** See the article **LEAF**.

**FOLIUM INDICUM, INDIAN LEAF, in the materia medica, is an oblong, smooth, and pointed leaf, of a grateful smell. They agree in virtues with ipikenard, and are to be chosen fresh and greenish. They are the produce of a species of cinnamon. See the article **CINNAMON**.

**FOLIUM BRANCHIARUM, among ichthyologists, the leaf of the gills, See **GILLS**.

**FOLKLAND, in antient law-writers, the fame with copyhold.** See **COPYHOLD**.

**FOLKMOTE, or FOLCMOTE, according to Kennet, was the common-council of all the inhabitants of a city, town, or borough: though Spelman will have the folkmote to have been a sort of annual parliament or convention of the bishops, thanes, aldermen, and freemen on every May-day. Dr. Brady, on the contrary, tells us, that it was an inferior court, held before the king's reeve, or his steward, every month, to do folk right**.

**FOLKSTONE, a market-town of Kent, six miles west of Dover.**

**FOLLICLE, folliculus, among botanists, denotes a kind of feed-veifel, like the conceptaculum. See **CONCEPTACULUM**.

**FOLLICULUS FELLIS, the gall-bladder.** See the article **GALL-BLADDER**.

**FOMAHANT, in astrarogy, a star of the first magnitude, in the constellation aequi-rus. See the article **AQUARIUS**.

**FOMENTATION, in medicine, the bathing any part of the body with a convenient liquor; which is usually a decoction of herbs, water, wine, or milk; and the applying of bags stuffed with herbs and other ingredients, which is commonly called dry fomentation. Fomentations differ in little else from embrocations, but that they are mostly made with aqueous menstruums, are more extensive in their manner of application, and are afflicted by actual heat, and hot woollen cloths; add to this, that fomentations, when general, or applied to every part of the body, are called baths. See the article **BATH** and **EMBROCATION**. According to some, a fomentation is only a liquid epithem, applied hot. See the article **EPITHEM**.

Fomentations are to be looked on as partial bathings, applied only to a diseased part.

FOLIUM, LEAF, among botanists. See the article **LEAF**.
part, on which they have much the same effect as bathing has on the whole body. See the article Bathing.

Fontceau, in the manage, the same with chaperon. See Chaperon.

Fontainebleau, a city and bishop's see of Naples, in the province of Lavoro, about thirty-five miles north-west of Capua; east long. 14° 26', and north lat. 41° 35'.

Font, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants, or other persons. Its name is called probably because baptism was usually performed among the primitive Christians at springs or fountains. In process of time the font came to be used, being placed at the lower end of the church, to intimate, perhaps, that baptism is the rite of admission into the Christian church.

By the canons of the church of England, every church is to have a font made of stone, or of any other substance, which typified baptism in the wilderness, flowed from a rock; or rather, because Christ is in scripture called the corner-stone, and the rock.

Font, or Fount, among printers. See the article Fount.

Fontaine, a town of Hainault, fifteen miles east of Mons.

Fontainebleau, a village of the isle of France, about thirty miles south-east of Paris; remarkable for an elegant royal palace.

Fontanella, in anatomy, the quadrangular aperture, between the os frontis and os lacrimalis, in infants just born, which is also called fons pulsatilis.

Fontanella, in surgery, the fame with fenticulus. See Fenticulus.

Fontarabia, a port-town of Spain, in the province of Biscay, twenty miles west of Bayonne; west lon. 10° 35'; and north lat. 43° 20'.

Fontenay-le-Vicomte, a town of Orleanois, in France, about forty-six miles west of Poisiers.

Fontenoy, a town of Hainault, situated three miles south-east of Tournay.

Fontevraud, or Order of Fontevraud, a religious order instituted about the latter end of the 11th century. By the rules of this order the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

Fenticulus, or Fontanella, in surgery, an issue, feben, or small ulcer made in various parts of the body, in order to eliminate the latent corruption out of it. See Issue, Seton, &c.

Fontinalia, in roman antiquity, a religious feast celebrated on October 13, in honour of the nymphs of wells and fountains. The ceremony consisted in throwing nosegays into the fountains, and putting crowns of flowers upon the wells. Scaliger, however, in his conjectures upon Varro, takes this not to have been a feast in honour of fountains in general, but of the fountain which had a temple at Rome, near the Porta Capena, called from thence Porta Fontinalis.

Fontinalis, in botany, a genus of the cryptogamia class of mosses; the male flower is almost sessile in the alæ of the leaves; the anthera is roundish, with an open mouth, and covered with calyptrae.

Food implies whatever aliment is taken into the body, to nourish it. See Diet, Drink, Aliment, &c.

As the health of the human body evidently depends upon the quantity and quality of the blood and juices, it is plain that all those aliments which preserve and maintain a just temperament and a due quantity of these are beneficial to health; and that such as have a contrary tendency are to be reckoned unwholesome. As to the nature of food with respect to mankind in general, some is of a good juice, and some of a bad juice; the first generates pure blood; the other bile, or an abstrabulous humour. Moreover, some sorts of food are easy of conception, others difficult; some loosen the belly, others bind it; and every sort is to be endured with some peculiarity virtue or property, the reasons of which are founded in nature.

As the blood, the nutritive juice, and in general all the parts of the body are made up of three elements, viz. of one which is sulphurous, oily, and inflammable; of one of an earthy, subtle, alkaline nature; and of one of an aqueous nature: so the several kinds and virtues of food may be most commodiously reduced to these three classes; and aliments of these three several qualities, duly mixed with one another, afford a proper nourishment for the human body.

The flesh of animals, especially when roasted, affords the body its principal supply of the sulphurous part; but it is to be observed, that wild animals are preferable in this respect to the tame and domestic kind, because their oils and fats are...
are exalted by habitual exercise. Among the aliments which furnish the blood with its humid parts, of animals, fish; and of vegetables, pot-herbs, the milder roots, and some summer-fruits are reckoned the principal. To the third class, which supplies the blood with its fixed parts, belong all kinds of grains, as the lentils, principal. To the third class, &c. several sorts of blood, are fit for nourishment; salts; that is quite opposite to the nourishment, all salts, and all foods, too highly salted, use of salt.

Drained ous liquors, but rather separate from and blood, is unfit for nourishment, because blood must: and the office of nutrition, that the kinds of food, which on account should likewise be easily divisible of the stomach: hence it is plain, that all those kinds of food, which on account of the closenes and compactness of their texture, are with difficulty divided, are for that very reason less conducive to health. Again, as it is necessary to the performance of the office of nutrition, that the small mouths of the internal rough coat of the intestines absorb the chyle, and convey it to the blood, none of those foods which either obstruct or too much corrogate its mouths, can be used, without in some measure injuring health. And as the effete mafs of foods, drained and exhausted by the separation of the chyle from it, ought by the expansive and contractive motion of the intestines, to be thrown off from them; it must of course follow, that all those foods are prejudicial to health, which either pass through the intestines with difficulty, stop their motions, or weaken their tone and impair their strength by suppreffing excretion, so necessary to health. This characteristic of unwholesomeness belongs to all astringent, moulty, glutinous, viscid, aultere foods, to all unripe summer-fruits, and in general to all such aliments as are easily reducible to a firm coagulum, which, by adhering immovable to the coats of the intestines, and incruting the orifices of their small absorbent vessels, occasion copious flatulencies and epistaxis. The unwholesomeness of foods is also to be estimated from their impairing the fermentative and digestive powers of the stomach, since by that meant crudities are generated. Upon the whole, however, it must be observed, that for different intentions, different kinds of foods are required, in which age, constitution, climate, season of the year, and numberless other considerations are to be included; and that abstinence and exercise must conduct with every kind of food, for the preservation of health; and that where exercise is wanting, as in studious persons, the defect must be supplied with abstinence.

The quantity of food also must vary according to age, sex, constitution, and nature of the food itself. Some physicians say, that in winter, where the perspiration of an unexercised person is only equal to the urine, the food for twenty-four hours ought not to exceed four pounds, or four pounds and a half. In summer, the food may be six pounds and an half, which may be carried off without the help of exercise, when the air is hot and dry. Dr. Bryan Robinson thinks, that if the quantity of food be such as to make the perspiration and urine of a natural day nearly equal, and the morning-weight of the body always nearly the same, that quantity is the truly healthful quantity of food for grown persons who use but little exercise. The same author thinks, that the quantity of food necessary to keep a grown body in health, will be better and more easily digested, when it is divided as to make the meals equal, than when they are very unequal: that good and constant health consists in a just quantity of food, and a just proportion of the meat to the drink: and that to be freed from chronic disorders contracted by intermission, the quantity of food ought to be lessened, and the proportion of the meat to the drink increased more or less, according to the greatest of the disorders.

FOOL, according to Mr. Locke, is a person who makes false conclusions from right principles; whereas a madman, on the contrary, draws right conclusions from wrong.
FOOT, in botany, a name given to the orchis. See ORCHIS.

FOOT, in anatomy. The greater foot denotes the extent from the juncture of the hip to the toe-ends, and is divided into the thigh, the leg, and the foot, properly so called. See THIGH and LEG. The lesser foot, or that properly so called, is divided into four parts, viz. the tarfus, the metatarfus, the toes, and the osseous bones. See the articles TARSUS, METATARSUS, TOE, and SESAMOID BONES.

In examining the foot, we are to consider its length, which is greater in man than in any other animal, in order to serve for his treading the firmer. It is also to be remarked, that the under part, or sole, called planta, is contrived hollow in man, and wonderfully formed for digging and scratching up the earth, in order to make way for their head.

FOOT, in poetry, is a foot so denominated in respect of its situation in the verse: thus, the first, third, and fifth foot of the verse are uneven. This denomination of feet chiefly obtains in iambic verse. See IAMBIC.

FOOT is also a long measure, consisting of 12 inches. See the article INCH.

Geometricians divide the foot into 10 digits, and the digit into 10 lines. See the articles DIGIT and LINE.

FOOT square, is the same measure, both in breadth and length, containing 144 square or superficial inches.

Cubic, or Solid FOOT, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

The foot is of different lengths in different countries. The Paris royal foot exceeds the English by nine lines; the ancient Roman foot of the Capitol, consisted of 4 palms, equal to 11 inches English; Rhineland or Leyden foot, by which the northern nations go, is to the Roman foot as 950 to 1000. The proportions of the principal feet of several nations, compared with the English, are as follows.

The English foot being divided into 1000 parts, or into 12 inches, the other feet will be as follows:

- London-foot: 1000 parts = 943 feet, 12 inches, 3 lines
- Amsterdam: 946 feet, 11 inches, 2 lines
- Antwerp: 946 feet, 11 inches, 2 lines
- Bologna: 1204 feet, 1 inch, 2 lines
- Bremen: 964 feet, 11 inches, 3 lines
- Cologne: 954 feet, 11 inches, 4 lines
- Copenhagen: 965 feet, 11 inches, 6 lines
- Danzick
FOOT of a horse, in the manege, the extremity of the leg, from the corneet to the lower part of the hoof. The four feet of a horse are distinguished by four different names: the far fore-foot denotes the right foot before; and the near fore-foot, the stirrup-foot, and the bridle-hand-foot, are used to signify the left foot before; of the two hinder feet, the right is called the far hind-foot, and the left hind-foot is called the near foot behind.

It is a great imperfection in a horse to have feet too large and fat, as also to have them too little: the former sort of horses are, for the most part, heavy, and apt to stumble; on the other hand, too small feet are to be suspected, because they are often painful, and subject to cloven quarters and other imperfections.

Foot-derebe, in the manege. A horse's foot gets this appellation, when it is worn too thin and weak, that, unless the nails are driven very short, he runs the risque of being pinched in shoeing. The English horses are very subject to this disorder.

Foot-bank, or Foot-step, in fortification, the same with banquette. See the article Banquette.

Foot of the forest, pes forestis, in our ancient customs, contained 18 inches, or 1 ½ of the common foot. See Forest.

Foot-guards. See Guards.

Foot-geld, or Faut-geld, in our old customs, an amercement laid upon those who live within the bounds of a forest, for not lawing or cutting out the ball of their dog's feet. To be free of a foot-geld, was a privilege to keep dogs unfawed, within the bounds of a forest.

Foot-hooks, or Futtocks. See the article Futtocks.

Foot-husks, among botanists, short heads out of which flowers grow.

Foot-level, among artificers, an instrument that serves as a foot-rule, a square, and a level. See the articles Level, Rule, and Square.

Foot-pace, or Half-pace, among carpenters, a pair of stairs, whereon, after four or six steps, you arrive at a broad place, where you may take two or three paces before you ascend another step. The design of which is to ease the legs in ascending the rest of the steps. See the article Stair-case.

Foot-soldiers. See Infantry.

Fore-foot, in the sea-language, the foremost part of the keel, which first takes the ground.

Forage, all kind of provision for cattle, especially for horses in time of war. See the article Forrage.

Foramen, in anatomy, a name given to several apertures, or perforations in divers parts of the body; as, 1. The foramen ovale. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranae tympani. See the articles Skull, Jaw, Lachrymale, Ear, &c.

Foramen ovale, an oval aperture or passage through the heart of a foetus which closes up after birth. It arises above the coronal vein, near the right auricle, and passes directly into the left auricle of the heart, serving for the circulation of the blood in the foetus, till such time as the infant breathes and the lungs are open; it being generally reckoned one of the temporary parts of the foetus, wherein it differs from an adult, aloft almost all anatomists, Mr. Cheffelden excepted, affure us, that the foramen ovale has sometimes been found open in adults. See Foetus and Circulation.

The foramen ovale therefore, and the canal of communication in the foetus are in reality no other than a sort of subsidiary parts to the lungs formed only for a certain time, and to become useless and disappear when the act of respiration...
FORCALQUIER, a town of Provence, in France, thirty miles north of Aix.

FORCE, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform, or not direct.

Mechanical forces may be reduced to two sorts, one of a body at rest, the other of a body in motion.

The force of a body at rest is that which we conceive to be in a body lying still on a table, or hanging by a rope, or supported by a spring, and is called by the names of presfure, \(\text{vis mortua}, \&c\). The measure of this force being the weight which the table is to retain through the diaisle of the auricles, but never from the left auricle to the right. See Phil. Trans. n° 427.

The force of a body in motion, called \(\text{moving force, vis motrix, and vis vivâ},\) to distinguish it from the \(\text{vis mortua},\) is allowed to be a power residing in that body so long as it continues its motion, by means of which it is able to remove obstacles lying in its way, to surmount any resistance, as tension, gravity, friction, &c. and which in whole, or in part, continues to accompany it so long as the body moves. Philosophers are fully agreed about the measure of the first of these forces, \(\text{viz. } \text{vis mortua},\) notwithstanding the diversity of appellations by which it is called; but about the measure of the last sort of force, or \(\text{vis vivâ},\) they are divided into two parties.

The newtonians and cartesianians maintain, that the moving force of bodies is in the compound ratio of their weights and velocities; and Leibnitz with his followers, pretend it to be in the compound ratio of the weights and the squares of the velocities. Those who hold the first opinion, lay down for a principle that when two bodies meet one another in contrary directions, if their moving forces be equal, neither body will prevail over each other; and if their moving forces be unequal, the stronger will always prevail over the weaker. But the followers of Leibnitz deny the truth of this principle, and lay down others, which, as they pretend, are more clear and satisfactory; such as, that it always requires a determinate degree of force to bend a given spring to a given degree, whether this be performed in a longer or shorter time, or vice versa, and that a given spring bent to a given degree always communicates the same force to a body by unbending itself, whether the time it takes to unbend itself be longer, or shorter. But these propositions are alike denied by the Newtonians.

Now if the principle of the former be admitted as true, \(\text{viz.}\) that those bodies have equal forces, which meeting each other in contrary directions do not prevail over each other, it cannot be disputed that bodies which have equal quantities of motion have also equal forces; and consequently that the moving forces of bodies are in a compound ratio of their maffes and velocities. On the other hand, if the principles of the Leibnitzians be admitted, it is no less indisputable that the forces of moving bodies will be in a compound ratio of their maffes and the squares of their velocities. Thus let \(M\) and \(m\) denote the maffes of two bodies, \(V\) and \(v\) their velocities; then if any spring bent to a certain degree give the body \(M\) a certain velocity \(V\), the same spring bent to the same degree will never give another body \(m\) a velocity \(v\), so that \(MV\) shall be equal to \(mV\); but will always communicate such a velocity to \(m\), that \(MV\) shall be equal to \(mV\). And this is admitted by the Newtonians, tho' the conclusion that the forces of the bodies \(M\) and \(m\) are equal, is denied.

To put an end therefore to this controversy, other principles must be found; and accordingly many subtle reasonings have been formed by several authors, concerning the nature of action, cause, effect, time, space, &c. by which we believe more readers have been confounded than enlightened; so that after all, the controversy still subsists, though carried on near fifty years, during which time a great many pieces have been published on both sides of the question, and a great many experiments have been made, or proposed to be made, in order to decide it; because tho' both parties agree in the event of the experiments, whether actually made or only proposed, yet as the writers on each side have
have found a way of deducing from those experiments a conclusion suitable to their own opinion, the disagreement still continues as wide as ever, and must remain so, while the newtonians, on the one hand, assume that equal pressures in equal times produce equal moving forces; and that the leibnitzians, on the contrary, maintain that equal pressures acting a body through equal spaces, produce equal forces. Hence, supposing equal pressures to act on equal bodies, either to produce motion in them, or to stop what motion they have, the question will be whether the force generated or destroyed be proportional to the time the pressure acts, or the space thro' which it acts. For example, let two equal bodies, with velocities as 1 and 2, ascend against the action of uniform gravity according to Galileo's hypothesis, it is certain that the body whose velocity is 2 will resist the force of gravity twice the time that the body whose velocity is 1 can do; and it is no less certain, that the body whose velocity is 2 will ascend to four times the height that the other can.

So that if we measure the forces of these bodies by the pressure and time requisite to destroy their motion, these forces will be as the velocities of the moving bodies; but if we measure the forces by the pressure and space through which it extends, requisite to destroy these forces, we shall find them proportional to the squares of the velocities of the moving bodies. This holds in uniform pressures, but if the pressure be not uniform as in the action of springs, which press more or less as they are more or less bent, we must then have recourse to the fluxions of the space and time. Thus if \( p \) stands for the pressure, \( t \) for the time, and \( s \) for the space, the fluxion, or infinitesimal element of the velocity, will, according to both parties, be expressed by \( p \cdot t \). According to the newtonians, this is also the fluxion or element of the force; but according to the followers of Leibnitz, the element of the force is proportional to \( p \cdot t \). This being the case, we shall only remark that we have not met with any conclusive argument on either side, nor do we believe it possible to demonstrate the one or the other of these affections till some body shall be metaphysician enough to analyse the notions of force, action, time, and space, farther than has hitherto been done.

Some leibnitzians do not assume it as a first principle, that action or force is proportional to the pressure and space; but they say, that a pressure being given, its action will be proportional to the velocity of the point moved by that pressure. Hence they infer, that the whole action of a pressure is as its intensity, as the velocity of the point to which it is applied, and as the time the pressure acts. And space being as the time and velocity, they conclude the action of a pressure to be as that pressure, and the space thro' which it acts. Thus 'Gravefande, lib. 2. cap. 2. sect. 728, says, if a point runs thro' a determinate space \( A B \), and presses with a certain given force or intensity of pressure, it will perform the same action whether it move fast or slow, and therefore the time of the action in this case ought not to be regarded. But the New­tonians do not submit to this reasoning, and insist, that we cannot abandon the old doctrine concerning the measures of the forces of bodies in motion, without exchanging plain principles that have been generally received concerning the actions of bodies, upon the most simple and uncontested experiments, for notions that seem at best but very obscure. Let \( A \) and \( B \) (plate CI. fig. 2. no 1.) be two equal bodies that are separated from each other by springs interposed between them (or in any equivalent manner) in a space \( EFGH \), which in the mean time proceeds uniformly in the direction \( BA \), in which the springs act, with a velocity as 1, and suppose that the springs imprint on the equal bodies \( A \) and \( B \) equal velocities in opposite directions that are each as 1. Then the absolute velocity of \( A \) (which was as 1) will be now as 2; and, according to the new doctrine of the leibnitzians, its force as 4. Whereas the absolute velocity and the force of \( B \) (which was as 1) will be now destroyed; so that the action of the springs adds to \( A \) a force as 3, and subducts from the equal body \( B \), a force as 1 only; and yet it seems manifest that the actions of the springs on these equal bodies ought to be equal. In general, if \( m \) represent the velocity of the space \( EFGH \) in the direction \( BA \), \( n \) the velocity added to that of \( A \) and subducted from that of \( B \) by the action of the springs, then the absolute velocities of \( A \) and \( B \) will be represented by \( m + n \) and \( m - n \) respectively.
For the force added to A by the springs will be \(2mn + nn\), and the force taken from B will be \(2mn - nn\) which differ by \(2nn\). Further, it is allowed that the actions of bodies upon one another are the same in a space that proceeds with an uniform motion, as if the space was at rest. But if the space EFGH was at rest, the forces communicated by the springs to A and B had been equal, and the force of each had been represented by \(nn\). These arguments, says Mr. Maclaurin, are simple and obvious, and seem on that account to be the more proper, in treating this question. Th'o' there are certain effects (continues the same author) produced by the forces of bodies that are in the duplicate ratio of their velocities, we are not thence to conclude that the forces themselves are in that ratio, no more than we are to conclude that a force which would carry a body upwards of 500 miles in a minute is infinite, because it may be demonstrated, if we abstract from the refistance of the air, that a body projected with this velocity would rife for ever, and never return to the earth. And as re-action is only equal to action when both are estimated in opposite directions upon the same right line, so we are never to estimate the force which one body lofes or acquires by that which is produced or destroyed in another body in a different direction.

Mr. Euler observes, with respect to this dispute concerning the measure of vivid force, that we cannot absolutely ascribe any force to a body in motion, whether we suppose this force proportional to the velocity, or to the square of the velocity; for the force exerted by a body striking another at rest is different from that which it exerts in striking the same body in motion; so that this force cannot be ascribed to any body considered in itself, but only relatively to the other bodies it meets with. There is no force in a body absolutely considered but its inertia, which is always the same, whether the body be at rest or in motion. But if this body be forced by others to change its state, its inertia then exerts itself as a force properly so called, which is not absolutely determinable, because it depends on the changes that happen in the state of the body. Suppose, for instance, a body. A forced to move in an incurvated tube or along the curv'd surface E a F, the body in this case will press the surface wherever it touches it in a direction a a normal to the curv'd surface; and with a certain force commonly determined in mechanics, by the mass of the body, its velocity, and by the radius of curvature O a. Now the body exerts a pressure or \(vis mortua\), yet it would be absurd to ascribe a certain and determine force of pressure to this body confidered in itself, since this pressure may vary very much according to the difference of the curvatures of E a F. In like manner, it seems unreasonable to place a certain absolute force of percussion in bodies, since it principally depends on the external circumstances accompanying the shock. A second observation which has been made by several great men is, that the effect of a shock of two or more bodies is not produced in an instant, but requires a certain interval of time. If this be so, the homogeneity between the \(vis mortua\) and \(mortua\) vanishes; since a pressure may always be aligned, which in the same time, however little, shall produce the same effect. If then the \(vis mortua\) be homogeneous to the \(vis mortua\), and since we have a perfect measure and knowledge of the latter, we need require no other measure of the former than that which is derived from the \(vis mortua\) equivalent to them.

Mr. Euler has also given some calculations with respect to the force of percussion resulting from the pressures which elastic and non-elastic bodies exert on each other while the collision lasts, determining these pressures for every instant of the shocks; and where the bodies are very hard, he finds the force of percussion to be in a compound ratio of the velocity, and of the subduplicate ratio of the masses of the striking body; so that in this case neither the Leibnitzer, nor the Cartesian proportions take place. But as we cannot pretend to give a full account of this controversy, we must refer the curious to Mr. Euler's dissertations in the Memoirs of the Academy of Berlin, and to some of the principal authors on each side of the question, such as Sir Isaac Newton, Mr. Maclaurin, Dr. Jurin, Dr. Pemberton, Mr. Robins, Mout. de Maupertuis, &c. in favour of the old opinion; Mefl. Leibnitz, Bernoulli, Herman, Poleni, Wolfius, S Graveendane, &c. in support of the new; and shall only observe in this place, that the experiments of Desculiers, Poleni, &c.
which there is a force I, which moves up and down in it. The barrel communicates with two pipes, the one called a fucking-pipe B C, which goes down into the well, and the other called a forcing-pipe F G, which goes upwards. There are two valves, the one D, at any place of the pipe B C, and the other E, in the pipe F G; both which let the water go up, and hinder it from coming down. Then when the force is moved upwards, as it rarefies the air in the pipe B C, (for the valve E hinders the outward air which presses upon it from going thro') the water rises in it, till after several strokes it comes to the force: then at every time the force goes down, the water that is pressed downwards being hindered from going thro' the valve D, opens the valve E, and goes up the pipe F G. When the force goes up again, then the water in the pipe F G shuts by its preflure the valve E, and consequently the water in the well rises up the pipe B E, and the fame happens at every motion of the force. It is to be observed in the forcing pump, that the nearer the force comes to the well, the better it is, for the fame reason as in the fucking pump. See the article PUMP.

There are several ways of making forces: the most common of all consists of a brass-cylinder, a very little less in diameter than the bore of the barrel, (ibid. n° 2.) at the top B and at the bottom D, and turned lefs still at the middle C C in order to let in a leathern collar E E (ibid. n° 3.) which makes it just equal to the bore of the barrel, so as to fit it quite when it is put into it. The second sort of forces consists of three brass-cylinders A, B, C, (ibid. n° 4, 5, 6) which can be screwed together. The middle one B ought to be almost equal in diameter to the bore of the pipe, so as to slide in it without any friction. The upper A and the lower C must be a little less and equal to one another. There are two leathers, D and E, (ibid. n° 7, 8.) which must be put between them when they are unscrewed. Then it is evident, that if the cylinders be screwed together, and the leathers apply themselves folding upwards round the upper part A, and downwards round the lower C, they will become just equal to the bore of the barrel, and consequently they will hinder any air from getting thro' the sides of the force when it moves up and down in the barrel. The use of the

The forcing-pump consists of a barrel ABC (plate Cl. fig. 4. n° 1.) in
the middle brass cylinder \( B \) is to hinder the leathers from turning themselves back by the motion.

But the best way of making forcers is to have a plunger, or solid brass-cylinder \( A \) (ibid. n° 9.) equal in length to the barrel, and a little less in diameter than the bore, so that it can move freely in it without any friction: there must be two hollow short brass rings \( C \), \( D \) (ibid. n° 10, 11.) at the top of the barrel \( F \), (ibid. n° 12.) which can be screwed together. The upper one \( C \) must be equal in bore to it, and the lower \( D \) a little les. There are two leathers as in \( n° 7, 8 \.) both having in the middle a less hole than the bore of the pipe.

The one must be applied between the barrel and the ring \( D \), and the other between the same \( D \) and the upper one \( C \), and the whole must be screwed together. Then if the solid cylinder \( A \) (n° 9.) be put into it and moved up and down, it is evident that the fore-mentioned leathers which are applied the one to the barrel, the other to the inside of the hollow cylinder \( C \) will hinder any air from getting between them and the solid cylinder \( A \). The advantage of this kind of forcers is, that they have no other friction but at the top of the barrel, and that the inside of the barrel need not be smooth as in other kinds of pumps, but only the outside of the forcer \( A \) must be turned true and polished, which can be done a great deal easier. The lower part of the forcer \( A \) must be turned a little conical, that it may be brought into the barrel, without any resistance of the upper leather of the above-mentioned collar or jack-head. See the article Piston.

FORCHAIN, a town of Franconia, in Germany, sixteen miles south of Bamberg.

FORCIBLE, in law, something done illegally. See the article Force.

A FORCIBLE entry, is a violent and actual entry into houles, or lands; and a for- cible detainer, is where one by violence with-holds the possession of lands, \&c. so that the person who has a right of entry is barred, or hindered, therefrom.

At common law, any person that had a right to enter into lands, \&c. might retain possession of it by force. But this liberty being abused, to the breach of the peace, it was therefore found ne- cessary that the same should be restrained. To "'at this day, he who is wrongfully

dispoffessed of goods may by force retake them. By statute, no persons shall make an entry on any lands or tenements, except where it is given by law, and in a peaceable manner, even though they have title of entry, on pain of imprisonment; and where a forcible entry is committed, justices of peace are authorized to view the place, and enquire of the force by a jury, summoned by the sheriff of the county: and they may cause the tenements, \&c. to be restored, and imprison the offenders till they pay a fine. Likewise a writ of forcible entry lies, where a person seized of freehold, is by force put out thereof. See Entry.

FORCIBLE MARRIAGE, of women having estates in lands, \&c. is felony by law, and the takers, procurers, abettors, and receivers of the woman so taken away against her will, and knowing the same, are likewise deemed principal felons; but as to the procurers and abettors, they must be such before the fact committed, to be excluded benefit of clergy.

FORCING, among gardeners, signifies the making trees produce ripe fruit before their usual time. This is done by planting them in a hot bed against a south- wall, and likewise defending them from the injures of the weather by glass frame. They should always be grown trees, as young ones are apt to be destroyd by this management. See Hot-bed.

The glaffes must be taken off at proper seæons, to admit the benefit of fresh air, and especially of gentle flowers.

FORCING OF WINE. See Wine.

FORCING-PUMP. See Forcer, supra.

FORE-CASTLE OF A SHIP, that part where the foremost stands. 'Tis divided from the rest by a bulk-head. See the article Ship.

FORE-CLOSED, in law, signifies the being shut out, and excluded, or barred, the equity of redemption on mortgages, \&c.

FORE-FOOT, in the sea-language, signifies one ship's lying, or failing, crofs another's way: as if two ships being under sail, and in ken one of another, one of them lying in her course with her stem so much a weather the other, that holding on their several ways, neither of them altering their courses, the windward ship will run a-head of the other: then it is said, such a ship lies with the other's forefoot.

FOREIGN, some thing extraneous, or that comes from abroad.
Foreign, in our law, is used in various significations. Thus, Foreign Attachment, is an attachment of the goods of foreigners, found within a city, or liberty, for the satisfaction of some citizen, to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person. See Attachment.

Foreign Opposer, or Opposer, an officer in the exchequer, that apposes, or makes a charge on all sheriffs, &c. of their green wax: that is to say, fines, issues, amerciatments, recognizances, &c.

Foreign Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction. All foreign pleas that are triable by the country on any indictment for murder, or felony, shall be tried, without delay, before the juries, where the party is arraigned, and by the jurors of the same county, though the matters of such pleas are alluded to be in any other county or counties: but this does not extend to treason, nor to appeals; a foreign issue wherein must be tried, as formerly, by a jury of that county where the fact is laid. If a foreign plea is pleaded in a civil action, the court generally makes the defendant put it in upon oath that the same is true, or will cause judgment to be entered for want of a plea.

Foreign Service, that service by which a mean lord holds of another without the compaà of his own fee; or it is that which the tenant performs either to his own lord, or the lord paramount, out of the fee.

Foreign Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural born subjects. Foreigner, the natural-born subject of some foreign prince.

Foreigners, tho' made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy-council, or members of parliament, &c.

This is by the acts of the settlement of the crown. Such persons as are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

Forejudger, in law, signifies a judgment, whereby one is deprived or put by a thing in question. To be forejudged the court, is where an officer, or attorney, of any court, is expelled the same, for male-practice; or for not appearing to an action on a bill filed against him, &c. Where an attorney of the common-pleas is fined, the plaintiff's attorney delivers the bill to another party in Holland.

Foreign Matter, any thing which is done, and, therefore, triable in another country.

Foreign Opposer, or Opposer, an officer in the exchequer, that apposes, or makes a charge on all sheriffs, &c. of their green wax: that is to say, fines, issues, amerciatments, recognizances, &c.

Foreign Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction. All foreign pleas that are triable by the country on any indictment for murder, or felony, shall be tried, without delay, before the juries, where the party is arraigned, and by the jurors of the same county, though the matters of such pleas are alluded to be in any other county or counties: but this does not extend to treason, nor to appeals; a foreign issue wherein must be tried, as formerly, by a jury of that county where the fact is laid. If a foreign plea is pleaded in a civil action, the court generally makes the defendant put it in upon oath that the same is true, or will cause judgment to be entered for want of a plea.

Foreign Service, that service by which a mean lord holds of another without the compaà of his own fee; or it is that which the tenant performs either to his own lord, or the lord paramount, out of the fee.

Foreign Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural born subjects. Foreigner, the natural-born subject of some foreign prince.

Foreigners, tho' made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy-council, or members of parliament, &c.

This is by the acts of the settlement of the crown. Such persons as are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

Forejudger, in law, signifies a judgment, whereby one is deprived or put by a thing in question. To be forejudged the court, is where an officer, or attorney, of any court, is expelled the same, for male-practice; or for not appearing to an action on a bill filed against him, &c. Where an attorney of the common-pleas is fined, the plaintiff's attorney delivers the bill to another party in Holland.

Foreign Matter, any thing which is done, and, therefore, triable in another country.

Foreign Opposer, or Opposer, an officer in the exchequer, that apposes, or makes a charge on all sheriffs, &c. of their green wax: that is to say, fines, issues, amerciatments, recognizances, &c.

Foreign Plea, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction. All foreign pleas that are triable by the country on any indictment for murder, or felony, shall be tried, without delay, before the juries, where the party is arraigned, and by the jurors of the same county, though the matters of such pleas are alluded to be in any other county or counties: but this does not extend to treason, nor to appeals; a foreign issue wherein must be tried, as formerly, by a jury of that county where the fact is laid. If a foreign plea is pleaded in a civil action, the court generally makes the defendant put it in upon oath that the same is true, or will cause judgment to be entered for want of a plea.

Foreign Service, that service by which a mean lord holds of another without the compaà of his own fee; or it is that which the tenant performs either to his own lord, or the lord paramount, out of the fee.

Foreign Seamen, serving two years on board British ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural born subjects. Foreigner, the natural-born subject of some foreign prince.

Foreigners, tho' made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy-council, or members of parliament, &c.

This is by the acts of the settlement of the crown. Such persons as are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

Forejudger, in law, signifies a judgment, whereby one is deprived or put by a thing in question. To be forejudged the court, is where an officer, or attorney, of any court, is expelled the same, for male-practice; or for not appearing to an action on a bill filed against him, &c. Where an attorney of the common-pleas is fined, the plaintiff's attorney delivers the bill to another party in Holland.
FOREMAST OF A SHIP, a large, round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-sail and fore-top-sail yards. Its length is usually \( \frac{3}{4} \) of the main mast. And the fore-top gallant-mast is \( \frac{1}{4} \) of the length of the fore-top-mast. See MAST.

FOREMAST-MEN, are those on board a ship that take in the top-sails, furl the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

FORE-RAKE, in the sea language. See the article RAKE.

FORE-REACH, in the sea-language, a ship is said to fore-reach upon another, when both failing together, one fails better, or out-goeth the other.

FORESCHOKE, in our old authors, signifies the same with forfaken, and is particularly used in one of our statutes for lands or tenements forfeited by the lord for want of services performed by his tenant, and quietly held by such lord above a year and a day, without any due course of law taken by the tenant for recovery thereof; here he does in presumption of law dilatate or forfike all the rights he has thereto, for which reason those lands shall be called foreschoke.

FORE-SKIN, in anatomy, the same with prepuce. See the article PREPUCE.

FOREST, silva, in general, a great wood, or a large extent of ground covered with trees.

FOREST, in law, is defined, by Manwood, a certain territory of woody grounds, and fruitful pastures, privileged for wild beasts and fowls of forest, chase and warren, to rest and abide under the protection of the king, for his princely delight, bounded with unremovable marks, and meres, either known by matter of record or prescription; replenished with wild beasts of venery, or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, with the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of that antiquity in England, that, excepting the new forest in Hampshire, erected by William the Conqueror, and Hampton-Court, erected by Henry VIII. it is said, that there is no record or history which makes any certain mention of their erection, tho' they are mentioned by several writers, and in divers of our laws and statutes.

There are sixty-nine forests in England, thirteen chaces, and 800 parks. The four principal forests are New-Forest, Sherwood-Forest, Dean-Forest, and Windso-Forest.

The manner of erecting a forest is thus, viz. Certain commissioners are appointed under the great seal, who view the ground intended for a forest, and fence it round: this commission being returned into chancery, the king cauleth it to be proclaimed throughout the county where the land lieth, that it is a forest, and prohibits all persons from hunting there, without his leave. Tho' the king may erect a forest on his own ground and waste, he may not do it on the ground of other persons without their consent; and agreements with them for that purpose, ought to be confirmed by parliament.

A forest, strictly taken, cannot be in the hands of any but the king, for no person but the king has power to grant a commission to be justice in eyre of the forest; yet, if he grants a forest to a subject, and that on request made in the Chancery, that subject and his heirs shall have justices of the forest, in which case the subject has a forest in law.

A second property of a forest is the courts thereof, as the justice feat, the swainmote, and the court of attachment. See the article ATTACHMENT, &c.

A third property is the officers belonging to it, as the justices, warden, verifier, forester, agisfor, regardee, keeper, bailiff, beadle, &c. See the articles AGISOR, BAILIFF, FORESTER, &c.

By the laws of the forest, the receivers of trefpayers in hunting, or killing of the deer, if they know them to be the king's property, are principal trefpayers. Likewise, if a trefpay be committed in a forest, and the trefpayer dies, after his death, it may be punished in the lifetime of the heir, contrary to common law. Our Norman kings punished such as killed dear in any of their forests with great severity; also in various manners; as by hanging, loss of limbs, gelding, and putting out eyes. By magna charta de foresell, it is ordained, that no person shall lose life or member for killing the king's deer in forests, but shall be fined; and if the offender has nothing to pay the fine, he shall be imprisoned a year and a day, and then be delivered, if he can give security, not to offend for the future, &c. 9 Hen. III. c. 1.
FOREST-TREES. Many are averse to pruning of forest-trees; but tho' it is to be done with care, yet it is by no means to be wholly omitted. It is observable in most forests, that, where one tree thrives well, there are twenty that grow faultily, all owing to their want of pruning, or lopping in a proper manner: for this, when wisely executed, is not only a renewal of their age, but of their growth too; the want of it being the occasion of trees running out with suckers, and over-loading themselves with wasteful boughs, which draw all the sap from the upper part of the tree, and make it knotty, mossy, and unthrifty. If a tree grows crooked, at the crooked place cut it off, flopping upwards, and nurse up one of the principal shoots to be a leading shoot, except it is of such a fort as is subject to die when headed: crooked trees may be made straight by shredding up the side-branches, till you come above the crook where they are young. If any boughs are cropt by goats, or other cattle, cut them off close to the body, for cattle leave a drive where they bite, which not only infects the branches, but sometimes endangers the whole tree. See the articles LOPPING, PRUNING, and TREE.

Advis of a Forest. See ASSISE.

Charter of a Forest. See the article CHARTER.

Drift of the Forest. See DRIFT.

Foot of the Forest. See the article FOOT.

Keeper of the Forest. See KEEPER.

Perambulation of the Forest. See the article PERAMBULATION.

Reposition of the Forest. See the article REPOSITION.

Waste of the Forest. See WASTE.

FOREST-TOWNS, in geography, certain towns of Swabia, in Germany, lying along the Rhine, and the confines of Switzerland, and subject to the house of Austria. Their names are Rhinsfeld, Seekingen, Laufenburg, and Waldshut.

FORE-STAFF, or CROSS-STAFF, an instrument used at sea for taking the altitude of the sun, moon, or stars. It is called fore-staff, because the observer, in using it, turns his face towards the object: whereas, in using Davis's quadrant, the back of the observer is towards the object; and hence its denomination of back-staff. See the article BACK-STAFF.

The fore-staff is a square graduated staff ABB, (plate CII. fig. 1. n°. 1.) about three feet long, and half an inch thick. Each side is graduated like a line of tangents, and has a peculiar cross piece or vane, which slides thereon. The first cross piece, FF, belongs to that side where the divisions begin at 0°, and end with 10°; and hence called the ten-cross. The second, EE, is called the thirty-cross, as belonging to that side where the degrees begin at 10° and end at 30°. The third, DD, is called the sixty-cross, as belonging to that side of the instrument where the divisions begin at 30° and end at 60°. The fourth cross-piece, CC, is called the ninety-cross, as belonging to that side where the divisions begin at 60° and end at 90°.

For the manner of graduating the staff AB like a line of tangents. See the article TANGENT.

To observe the sun's altitude by this instrument. First consider, as near as you can guess, whether the altitude be under 10°; in which case, the shortest or ten-cross is to be used. If the altitude be guessed to be above 10°, but under 30°, the thirty-cross is to be used; if under 60°, the sixty-cross; and if above 60°, the ninety-cross. Having fitted on the proper cross, place the flat end of the staff A (ibid. n°. 2.) to the outside of the eye, and look for the object at the upper end of the cross D; and for the horizon, at the lower end C; moving the cross backward and forward on the staff, till you see the center of the sun, or other object, by the upper end D, and the horizon by the lower end C. Then the degrees and minutes cut by the inner edge of the cross, on the proper side of the staff for that cross, make the altitude of the sun or star at the time of observation. In order to enable the eye to bear the splendor of the sun, a coloured glass is used at the top of the cross. If the meridian altitude be required, continue your observation
servation as long as the altitude of the object increases, still moving the cross nearer to the eye.

By fitting a horizontal vane on the eye-end of the staff $A$, (ibid. n° 2.) and a fight-vane on the lower end of the proper cross at $C$, the sun's altitude may be found with the observer's back turned towards the luminary: for looking through the sight-vane at $C$, let the cross-piece be moved up or down, till the shadow made by its upper end fall on the flat in the horizontal vane; the horizon being seen at the same time through the vanes at $C$ and $A$; then will the degrees cut on the proper side of the staff, be the sun's altitude required.

**FORESTAGE**, in our old law-writers, a duty paid to have been formerly by foresters to the king. See FORESTER.

**FORESTALLER**, a person who is guilty of foresfalling. See the next article.

**FORESTALLING**, in law, buying or bargaining for any corn, cattle, victuals, or merchandize in the way as they come to fairs or bargaining for any corn, cattle, victuals, or more two. See the article FORE-STEALLING.

**FOREST**, in our old law-writers, a buying or selling of any goods, or the value; for the conviction or discovery of an offended, or the offender shall be imprisoned during the time required.

**FORESTAGE**.

The punishment for this offence, upon conviction at the quarter sessions, by two or more witnesses, is, for the first time, two months imprisonment and the loss of the goods, or the value; for the second offence, the offender shall be imprisoned six months, and lose double the value of the goods; for the third offence, he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattels, and stand on the pillory: but the statute does not extend to malcontents buying barley, or to badgers licensed.

**FORESTER**, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest all hours, watch over the vert and venison; also to make attachments and true prentiments of all trespassers committed within the forest.

If a man comes into a forest in the night, a forester cannot lawfully beat him before he makes some resistance; but in case such a person retires the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. do kill a person that opposes them, it is murder in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

**FORE-TOP-MAST**, and **FORE-TOP-GALLANT-MAST**. See FORE-MAST.

**FORFAR**, the capital of the county of Angus, in Scotland: west long. $2^\circ 32'$, and north lat $56^\circ 25'$. It is a parliament-town, clased with Perth, Dundee, Cowper, and St. Andrew, which all together send one member.

**FORFEITURE**, properly signifies the effect of transgressing some penal law, and extends to lands or goods. Forfeiture differs from confiscation, in that the former is more general, whilst confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods conficatted, are said to be such as no body claims.

**Full Forfeiture**, *plena forfication*, called also *plena ruina*, is the forfeiture of life and member, and all that a person has: this obtains in criminal cases, as where a person is attained of treason, felony, &c. There is also a forfeiture in civil cases, as where a person hath an estate for life or years, he may forfeit it by alienation and claiming, or granting a larger estate than is vested in him. All the lands or tenements of an offender, whether held in fee or tail, are forfeited on his committing high treason; and the king shall be deemed in possession thereof without any office found, saving the rights of others. For petit treason, murder, robbery, burglary, and all felonies punished with death, the offenders forfeit their lands in fee, goods and chattels. In manslaughter, goods and chattels are forfeited; so in chance-medly, and so defending, though here an offender has his pardon of course. In the case of petit larceny, goods are also forfeited. See the article TREASON, &c.

**Forfeiture of marriage**, a writ which formerly lay against a person that held lands by knights' service, who, being under age and unmarried, refused her whom the lord offered him, without disparagement, and married another.

**FORFX**, among surgeons, the fame with forceps. See the article FORCEPS.

Some also call an instrument for drawing teeth by the name of forfex.

**FORFICULA**, the ear-wig, in zoology, a troublesome insect, which takes its English name from its introducing itself into peoples ears, where it caueth a great deal of
of pain; and its Latin name, *foricula*, from its forked tail, which is a sort of forceps, capable of pinching. The exterior wings are very short or dimidiated, and wholly cover the inner ones. The antennae are long and slender, consisting of thirteen or fourteen articulations.

According to Lemeriy, the dried powder of these insects, is good in cases of deafness; and the oil drawn from them, in convulsive cases.

*Foricula marina*, the *sea-ear-wig*, an insect found about the sea-shores, and so called from its resemblance to the common ear-wig.

*Forefield*, among miners, the farthest place of a meer of ground. See Meer.

*Forge*, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red hot, in order to soften and render them more malleable and manageable on the anvil. See Furnace.

The forge used by the several operators in iron, is very simple: we shall instance in that of the black-smiths, to which all the rest are reducible, the construction of which is as follows. The hearth or fire-place of the forge, marked A. (See plate of smithery, fig. 1.) is to be built up from your floor with brick, about two feet and an half, or sometimes more, according to the purpose you design to forge for: if your forge be intended for heavy work, your hearth must lie lower than it need be for light work: the forge may be of what breadth is thought convenient. It may be built with hollow arches underneath, to set several things out of the way: the back of it is built upright to the top of the ceiling, and enclosed over the fire-place with a hovel, which ends in a chimney, to carry away the smoke, as at B. In the back of the forge, against the fire-place, is fixed a thick iron-plate, and a taper pipe in it, about five inches long, which pipe comes through the back of the forge at C. Into this taper pipe is placed the nose or pipe of the bellows: the office of this tewel is to preferve the pipe of the bellows and the back of the forge about the fire-place, from burning. Right before the back is placed, at about two feet distance, the trough, which reaches commonly the whole breadth of the forge, and is as broad as is thought necessary, as at D. The bellows is placed behind the back of the forge, having one of its boards so fixed, that it can neither move upwards nor downwards. At the ear of the upper board is fastened a rope or chain at E, which reaches up to the rocker, and is fastened there to the further end of the handle, at F. This handle is fastened across a rock-raft, which moves between two cheeks upon the center pins, in two sockets, at G; so that by drawing down this handle, the moving board of the bellows rises; and by a considerable weight set on the top of its upper board, sinks down again, and by this agitation performs the office of a pair of bellows. See Bellows and Smithery.

Forge is also used for a large furnace, wherein iron-ore, taken out of the mine, is melted down; or it is more properly applied to another kind of furnace, where in the iron-ore, melted down and separated in a former furnace, and then cast into fows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

Of these there are two kinds: the first is called the finery, where the pigs are worked into great iron, and prepared for the second, which is called the chafery, where it is further wrought into bars fit for use. See the articles Forging, Finery, and Chafery.

Forge, in law, one guilty of forgery. See the next article.

Forgery, in a legal sense, is where a person fraudulently makes and publishes false writings to another's prejudice: or, it signifies the writ that lies against him who offends that way.

Forgery is either at common law, or by statute; and is an offence punishable by indictment, information, &c. and not only where a person makes a false deed, but where any fraudulent alteration is made of a true one, in a material point thereof. Likewise a writing may be said to be forged, where one being directly to draw up a will for another, does insert some legacies therein falsely of his own head; though, in such cases, there is no forgery of the hand or seal of the party: but a person cannot regularly be guilty of this crime by an act of omission, unless it alters the limitation of an estate to another, in which case he may be forgery.

By a statute of Geo. II. c. 25, the forging or counterfeiting any deed, will, bond, bill, note, &c. with intent to defraud any person, &c. publishing such false deed,
deed, bond, &c. knowingly, is declared to be felony; and the offender shall suffer death. The king may pardon the corporal punishment of forgery which tends to public example, tho' the plaintiff cannot release it: yet in an extraordinary case, a forgery has been compounded, and the defendant discharged on paying a small fine.

FORGING, in smithery, the heating or hammering iron on the anvil, after having first made it red hot in the forge, in order to extend it into various forms, and fashion it into works. See FORGE.

There are two ways of forging and hammering iron; one is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewife, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron-chains fastened to the ceiling of the forge. See MILL.

This latter way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for, requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it, when it will not batter under the hammer; and if it be too hot, it will red-fear, that is, break or crack under the hammer.

The several degrees of heats the smiths give their irons, are, first, a blood-red heat; secondly, a white flame-heat; and, thirdly, a sparkling or welding heat. See the article HEAT.

FORGING MILLS. See the article MILL.

FORFESAMILIRI, in law, is where a son accepts of his father's part of lands, &c. in the lifetime of the father, and sells contented with it, so that he cannot claim any more; upon which account he is termed forofamiliaris.

FORKED HEAD, among sportmen, those deer's heads, &c. have their croches doubled.

FORK-TAIL, given in some parts of the kingdom, the salmon, in the fourth year of its growth.

FORLANA, in music, a kind of dance, nearly allied to the saltarella. See the article SALTARELLA.

FORLII, a town of Romania, in the pope's territories, fifteen miles south-west of Ravenna.

FORLORN, or FORELORN. See the article FORELORN.

FORM, forma, in physics, the essential or distinguishing modification of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence; being that which constitutes it such a particular body, and distinguishes it from every other body. The origin of forms, though esteemed the noblest, hath yet been found one of the most perplexed inquiries in philosophy, especially as managed by the schools. The sum of the controversy is whether the form of natural things be, in generation, educed out of the power of the matter; or whether these forms are true substantial entities, distinct from the other substantial principle of natural bodies, that is matter.

The reasons which move me to embrace the negative, says Mr. Boyle, are principally these. First, I see no necessity for admitting any such substantial forms in natural things; matter and its accidents being sufficient to explain as much of the phenomena of nature as we are likely to understand. In the next place, I see no use of this puzzling doctrine of substantial forms in natural philosophy: nor can I imagine how a particular phenomenon should be explained by a principle whose nature is unknown: and, lastly, I cannot conceive how forms could be generated, as the peripatetics would have it.

On the other hand, the schoolmen tell us, that the power of matter, with regard to forms, is partly educative, as the agent can make the form out of it; and partly receptive, whereby it can receive the form so made: but since the schoolmen will not allow that the form of a generated body was actually pre-existent in its matter, or any where else, it is hard to conceive how a substance can be educed out of another substance totally distinct in nature from it, without being before such education actually existent in it. And as for the receptive power of the matter, that fits it to receive or lodge a form, when united with it, how can it intelligibly be made to appear to contribute to the production of a new substance of a
quite different nature from that matter, though it harbours it, when produced. In short, the form of a natural body, as is illustrated and confirmed by Sir Isaac Newton’s doctrine of motion, (see Newton’s Optic. p. 372, 37.) is but an essential modification, and, as it were, the stamp of its matter; or such a convention of the magnitude, shape, motion or rest, situation and contexture of the small parts that compose it, as is necessary to constitute and denominate it a particular body; and all those accidents being producible in matter by local motion, we may well say that the first and universal, though not immediate cause of forms, is no other than God, who put matter into motion, established its laws among bodies, and also guided it, in several cafes, at the beginning of things; and that among second causes, the grand efficient of forms is local motion, which by various dividing, sequenceing, transposing, and connecting the parts of matter, produces in them those accidents and qualities upon account whereof the portion of matter they diversify belongs to a determinate species of natural bodies: yet this is not so to be understood as if motion were only an efficient cause in the generation of bodies, for it is also frequently one of the chief accidents, as in water, fire, &c. that concur to make up the form. See the articles Motion and Fire.

Some modern writers, as particularly Sennertus, teach us, that besides the specific form in plants and animals, there reside, and especially in some determinate parts of them, certain other forms proper to those parts, but so subjected to the predominant form, as to deserve the title of subordinate; being, during the reign of the specific form, subjacent to it: though, when the specific form comes to be abolished, these subordinate forms may set up for themselves, and in reference to those parts of matter they belong to, exercise the functions of specific forms; as in a dog or a horse, besides the sensitive soul, which is the specific form of the whole creature, the flesh, blood, and bones have their distinct forms appertaining to them, though they are ruled and employed by the soul, but as the matter which the animates and informs; and when by death the sensitive soul or specific form is deposited or abolished, the body is not presently resolved into its several elements, but those subordinate forms still preserve the flesh, as in the state of the flesh; and the bones, as in the state of the bones; the one for a little, and the other for a much longer time. This doctrine is urged from the specific virtues observable in gathered plants, as the purgative faculty of rhubarb, fenna, and other cathartic vegetables. But, says Mr. Boyle, it were not difficult to propose experiments, which would determine this matter otherwise, were it important enough to deserve it. However, as this doctrine of subordinate forms affords such countenance to that of substantial ones, that author has been at the pains to prove, that subordinate forms are explicable upon other principles. See Shaw’s Boyle, vol. 1. p. 224.

Form of syllogisms, or syllogistic Form, among logicians, a just disposition both of the terms, in respect of predicate and subject, and of the propositions, in respect of quantity and quality: by which is only meant a disposition wherein the conclusion follows duly and legitimately from the two premises; there being no form, where there is no conclusion. See the article Syllogism.

Form, in theology, is said to be one of the essential parts of the sacraments; being that which gives them their sacramental nature and efficacy, and confuting in certain words, which the priest pronounces in administering them.

Form is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

Form, in law, the rules established and requisite to be observed in legal proceedings.

Form, in carpentry, is used to denote the long feet or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars to sit on. At schools, the word form is frequently applied to what is otherwise termed a class. See the article Class.

Form also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness. See the article Figure.

Form is also used, among mechanics, for a sort of mould, whereon any thing is fashioned or wrought: as the hatter’s form, the paper-makers form, &c. See the article Hatter, &c.

Printer’s Form, an assemblage of letters, words and lines, ranged in order, and
FORMERS, in gunnery, round pieces of wood, fitted to the diameter of the bore of a gun, chiefly used for making cartridges.

On these formers, the paper, parchment, or cotton, which is to make the cartridge, are rolled before it be fewed.

FORMICĂ,
FORMICA, the Ant, in zoology. See the article ANT.

FORMICA, in medicine, a callous fort of wart, more ufually called myrmecia. See the article MYRMECIA.

FORMICA-LEO, the ANT-LION, or ANT-EATER, in zoology, an insect lo called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resemblying the libelle, or dragon-fly.

The address of this insect in catching the ants, is admirable; it makes a hole of a conical or funnel-shape, in the loofe sand; and is sure to catch all the ants that come within the verge of this hole, by throwing up sand on them, whereby they are forcibly carried into the power of the enemy at the bottom of the hole.

FORMICATION, a term used among builders for arching or vaulting.

FORMING OF A SIEGE, in the military art. See the article SIEGE.

FORMING, in grammar. See the article FORMATION.

FORMOSA, an island in the Pacific ocean, between 119° and 122° of east longitude, and between 22° and 25° north latitude, about 100 miles east of Canton in China. It is subject to the Chinese.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in church history and theology, signifies a profession of faith. See the article FORM.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence. Paracelus calls red and clear urine, formula urina.

FORMULARY, a writing containing the form of an oath, declaration, attestation, &c. to be made on certain occasions.

FORNACALIA, or FORNICALIA, in roman antiquity, a festival instituted by Numa in honour of Fornax, the goddes of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNICATION, the act of incontinency between single persons; for when either of the parties is married, such act is adultery. See the article ADULTERY. The spiritual court now has the sole cognizance of this offence, which antiently was cognizable in other courts, as the court-leet, &c. in which the king had a fine affixed on the offenders.

FORNICATION is sometimes also used as a general term, including all kinds of offences against chastity.

FORNIX, in anatomy, a part of the brain placed under the septum lucidum, and, like it, composed of a medullary substance. Its anterior part rises with a double base, but the two parts soon unite: the hinder part is likewise bifid, and thence called crura fornicens, and by some, pedes hippocampi. See the article BRAIN.

FORPRIZE, in law, signifies an exception or refervation, and is frequently used in leaves and conveyances, wherein any exception is inferred; as such a thing excepted and forprized.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

Dry forrage is the hay, oats, &c. delivered out of the magazines, to an army in garrison, or when they take the field, before the green forrage is sufficiently grown up to supply the troops.

It is the business of the quarter master-general to appoint the method of forrage, and post proper guards for the security of the forragers. He ought also, in encamping an army, to take care that it be in a country abounding with forrage.

Ratio of Forrage. See RATION.

FORRES, a parliament-town of Scotland, in the county of Murray, about thirteen miles west of Elgin; west long. 3° 20', and north lat. 57° 40'. It is clasped with Inverness, Fortrose, and Nairn. See the article BOROUGH.

FORSES, a name used in some parts of the kingdom for a cataract, or water-fall. See the article CATARACT.

FORSTALLING, in law. See the article FORESTALLING.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon.

A fort differs from a citadel, as this last is built to command some town. See the article CITADEL.
Royal Fort, one whose line of defence is at least twenty-six fathoms long.

To fortify a square fort, having inscribed the square in a circle. 1. Divide each of its sides A B, B D, &c. (plate CII. fig. 4.) into two equal parts, in the point F. 2. From the center E, draw an indefinite line EF. 3. From the center draw also the lines E A, E B, E D, E C, to the angles of the square. 4. Divide the side A B into eight equal parts. 5. Let one of these parts be laid off from F to G, and from G draw the lines of defence A G, B G. 6. Divide another side of the square into seven equal parts. 7. Lay off two of these parts from A to K, and from B to L, which will be the faces of the bastions. 8. Take the distance K L in your compasses, and lay it off the lines of defence from K to H, and from L to I; and drawing H I, it will be the curtin; and the lines K I, L H, will be the flanks. See another method of fortifying a square, ibid. n° 3. Also two different methods of fortifying a triangle, ibid. n° 4 and 5.

Star-Fort, a redoubt formed by a number of re-entering and slanting angles, the sides of which flank each other. See plate CII. fig. 2. n° 2.

To describe a star-fort. 1. Draw an hexagon A B C d e f. 2. Divide one of its sides B C into four equal parts. 3. Upon the middle of this side, raise the perpendicular D A, equal to ⅛ of the side B C, from D to A. 4. From the point A, draw the faces A C, A B. Let the same operations be performed with respect to the other sides of the hexagon, and you will have the star-fort required.

Fortamenté, in music, the same with forte. See the article Forte.

Forta-ventura, one of the Canary-islands, subject to Spain: well long. 14°, and north lat. 27°.

Forte, or Fortamente, in music, directs to play strong and loud; and forte forte, or piu forte, signifies a degree louder and stronger than forte alone.

Fortification, the art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a small number of men within, may be able to defend themselves for a considerable time against the assaults of a numerous army without; so that the enemy, in attacking them, must of necessity suffer great loss.

Fortification is either ancient or modern, regular or irregular. Ancient fortification, at first, consisted of walls or defences made of trunks, and other branches of trees, mixed with earth, to secure them against the attacks of the enemy. This was afterwards altered to stone-walls, on which were raised breast-works, behind which they made use of their dart and arrows in security. Modern fortification, is that which is flanked and defended by bastions and out-works, the ramparts of which are so solid, that they cannot be beat down but by the continual fire of several batteries of cannon. Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equident, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like. See Bastion, &c.

The principal maxims of fortification are these: 1. That every part of the works be seen and defended by other parts, so that the enemy can lodge nowhere without being exposed to the fire of the place. 2. A fortress should command all places round it; and therefore all the out-works ought to be lower than the body of the place. 3. The works farthest from the center, ought always to be open to those more near. 4. No line of defence should exceed a point blank musket-shot, which is about an hundred and twenty or an hundred and twenty-five fathoms. 5. The more acute the angle at the center is, the stronger will be the place. 6. In great places, dry trenches are preferable to those filled with water, because fallies, retreats, and succours are frequently necessary; but, in small fortresses, water-trenches that cannot be drained, are best, as standing in need of no fallies, &c.

Different authors recommend different methods of fortification; but the principal are those of Pagan, Blondel, Vauban, and Scheiter.

Fortification, according to the method of count Pagan, supposes the side A B (plate CII. fig. 3.) of the external polygon, in larger fortifications, 160 perches; in the smaller, 80; and in those of middle
Fig. 1. Fore-staff.

Fig. 2. Forts No. 2.

Fig. 3. Fortification, according to Count Pavan.
For [1307] For

die size, 90; with the corresponding faces, 30, 25, and 27½; the perpendicular, CD, being in all of them 15.
Here too the flanks GF, HE, are perpendicular to the lines of defence, AE and BF; these flanks are also covered with an orillon and threefold. LMN is the boundary of the moat, parallel to the faces AG, BH. The curtain is defended by a double ravelin, OQP being the external one, and aeb the internal; the faces of the bastions being likewise defended by counter-guards gfs, ed.
This method, though received with great applause, is not without its defects. It is not only very expensive, but its threefold flanks are too close, so as to be too much exposed to bombs; the largeness of the orillons is prejudicial to the length of the flanks, and the outer rampart is too thick.

Mr. Blondel’s method of fortification has a great affinity with that of Count Pagan, only that the lines and angles are otherwise determined. Thus by subtracting a right angle from that of the polygon, and adding 15 to a third part of the remainder, you find the quantity of the diminished angle ABE. In the greater fortifications, the side AB (plate CIII. fig. 1.) of the outer polygon is 100 perches, in the lesser only 85; and AB being divided into ten equal parts, seven of them give the lines of defence AF, BE. The faces of the bastions AG, BH, are equal to half those of the tenaille AD, BD. In these faces is a kind of flanking batteries QR, to defend the faces of the ravelin edc. The flanks HF, GE, are threefold, as in Count Pagan’s method; and in the middle of the moat is a deep trench ab. The other out-works are as represented in plate CIII. fig. 1.

Fortification, according to Vauban’s method, supposes the outer polygon to be 100 perches in larger places, 80 in smaller ones, and 90 in those of a middle size. The faces are made ⅔ of the same, the perpendicular ⅕ in a square, ⅗ in a pentagon, ⅙ in other polygons. He also makes the complement of the face to the line of defence, equal to the distance of the epaule; uses re-entering crooked flanks, and places a low tenaille before the curtain. See plate CIII. fig. 2, n°7.

This method of fortification is much tried up by many, both as it increases the strength without much expense, and agrees very well with the maxims above laid down. Its greatest fault lies in this, that the faces lie altogether exposed to the enemy.

Vauban’s new method places large bastions before small ones; the curtain being covered with a low tenaille and a double ravelin, ibid. n°2.

Fortification, according to Scheiter’s method, supposes the external side AB, (plate CIII. fig. 3.) in large fortifications, 100 perches; in lesser ones, 80; and in those of middle size, 90. The flanks NO, PQ, are perpendicular to the lines of defence AQ, BO; which in greater fortifications are 70, in lesser 60, and in those of middle size, 65 perches; these detach the bastions from the curtain, and form a kind of inner recce behind the curtain. The angle of the bastion in a square, is 64°; in a pentagon, 72°; in a hexagon, 78°; in a heptagon, 83°; and in works of more sides, this angle is found by adding 2° for every side above the heptagon.

As to the out-works, they are much the same as in the preceding methods, only that the covert-way is double; as is the ravel, which covers the curtain.

To lay down the plan of a regular fortification. 1. Measure exactly the circuit of the place to be fortified, at about twelve paces distance from the houfes; and dividing the whole circuit by 180 geometrical places at least, or 180 at most, the quotient will give the number of the bastions, in such a manner that their lines of defence shall not exceed the carriage of a musket-shot. 2. Inscribe in a circle a polygon with as many sides as the place is to have bastions; and from the center A (plate CIV. fig. 1.) through the angle B of the polygon, draw lines at pleasure, which lines are called principals. Afterwards take Ba = ⅓ of the side of the polygon, and BF = ⅔; then drawing the lines of defence Fga, Fge, from each point a raise perpendiculars; which meeting the lines of defence in the points gs, will form the bastions ag Fga, ag F, &c. 3. Having thus described the outward circuit of the rampart, draw lines e, e, e, parallel to the faces of the bastions Fg, Fg, Fg; these will determine the outward circuit of the moat, which ought to be rounded before the angles of the bastions F, F. 4. To finish the plan, draw within the place lines parallel to those which form the outward
Outward circuit of the rampart, at the distance of \( \frac{1}{2} \) of the flank for the parapet; at the distance of \( \frac{2}{3} \) the demi-gorge \( BA \), for the rampart; and at the distance of five feet from the parapet, for the banket. In the same manner, on the outside of the moat, must be drawn lines parallel to its outward circuit, at the distance of \( \frac{1}{3} \) of the flank for the covered way; and at the distance of \( \frac{2}{3} \) of the flank for the glacis.

To lay down the profile of these works. Let \( AR(\text{plate CIV. fig. 2.}) \) represent the level of the place; take \( AB, 5 \) paces, for the place of arms; the perpendicular \( OC, 16 \) feet, for the talus or slope; the thickness of the lower part of the rampart, \( BR, 12 \) paces; the upper part, \( CD, 6 \frac{1}{2} \) paces; the banket, \( dD, 6 \) feet; the thickness of the lower part of the parapet \( DV, 3 \frac{1}{2} \) paces; the upper, at \( E, 2 \frac{1}{2} \) paces; its inward height, \( ED, 6 \) feet; and its outward height, 5 feet; the talus of the rampart to the moat, \( GR, 7 \) feet; the width of the channel, \( T, 15 \) feet; the talus of the counter-carp, \( aK, 10 \) feet; and the banket of the covered way, at \( L, 5 \) feet. Then follows the pali-fade at \( N \), and the glacis or esplanade, \( M \).

In plate CIV. fig. 3. is represented a hexagon fortified with all the kinds of out-works, together with the manner of carrying on the trenches of approach. Here is also delineated a pentagonal citadel, with its out-works. The names of the different works and parts of this fortification, are these; \( d, a, c, e, \&c. \) represent the declivity or slope, usually called glacis; \( b, b, b, \&c. \) the covert way; \( c, c, c, \&c. \) the counter-carp; \( d, a \) single tenaille; \( e, a \) double tenaille; \( f, f \) a horn-work; \( g, g, g, \&c. \) places of arms; \( h, h, b, \&c. \) the moat or ditch; \( k, k, k, \&c. \) ravellins; \( k, k, k, \&c. \) half moons; \( l, l, \) a crown-work; \( m, m \) a bonnet or priest's cap; \( n, n, \) a counter-guard; \( o, o, o, \&c. \) bastions; \( p, p, p, \&c. \) bastions with circular flanks; \( q, q, \) the curtin; \( r, r, r, \&c. \) the ramparts; and \( s, s, s, \&c. \) bridges over the moat. With respect to the approaches, \( 1, 1, 1, \&c. \) represent the trenches; \( 2, 2, 2, \&c. \) the lines of communication; \( 3, 3, \) batteries; \( 4, 4, 4, \&c. \) forts for the defence of the trenches; \( 5, \) the descent into the covered way; and \( 6, a \) mine.

Irregular Fortifications, are those raised about irregular polygons; in which the engineer ought to follow, as much as possible, the proportions laid down for the regular ones. If bastions are found too high to sweep the circumjacent campaign, a second bastion must be added to the first, or even a third, if necessary; still taking care that their faces be well defended. If, on the contrary, a bastion is too low, a cavalier must be raised on it. It will sometimes also happen, that the faces of bastions would become excessive long, if they were to be extended till they meet; in which case, they are usually closed with a re-entering angle, (ibid. fig. 4.) When one side of the polygon is long enough to admit of a bastion in its middle, it is remedied by raising one; but if it will not admit of this, it may be remedied by forming a salient angle in the middle; or by advancing the neighbouring bastions nearer to each other, so that both may be entirely formed upon that side. When a long extended side of a place cannot admit of bastions, as being cut off by a river, or stands upon a deep ascent, it may be fortified with redents or re-entering angles, not unlike the teeth of a saw. See plate CIV. fig. 5. But the defect of these redents is, that both the sides of the tenaille or front of a place, may be ruined from one battery; so that the besiegers may then make an assault without fear of being enfiladed.

Marine Fortifications. Though these have nothing peculiar in them, yet it may not be improper to give some directions with relation to batteries. 1. In raising batteries to hinder a descent, care should be taken to dispose them in such places where the descent is most easy; and the guns should be so levelled, as to pour the surface of the water, that they may fire effectually upon the boats as they approach. 2. It is likewise convenient to have batteries to play upon places where there is good anchorage; and these should be somewhat more elevated than the former. 3. It is also necessary to erect batteries at the entrance of roads; and these ought to be so made, as to discover ships at a distance. 4. It is very necessary that these batteries should be defended by some works, against attacks; and, if possible, should be under the fire of the place; or, at least, they ought not to be too far advanced.
See the articles Rampart, Bastion, &c. and the preceding article.

Fortin, Fortlet, or field-Fort, a scone or little fort, whose flanked angles are generally distant one from another 120 fathoms. See the article Fort. The extent and figure of forts are different, according to the situation or nature of the ground; some of them having whole baftions, and others demi-baftions. They are made use of only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

Fortiori, or a motto Fortiori. See the article Mulso.

Fortis aqua. See the article Aqua.

Fortissimo, in mufic, sometimes denoted by F F F, or fff, signifies to sing or play very loud or strong.

Fort-lewis, a fortress of Allace, in Germany, situated on the western shore of the Rhine, subject to France: east long. 8°, and north lat. 48° 46'.

Fortuna, in our antient law-books, is the name with what we call treasure-trove. See the article Treasure-trove.

Fortuna equesris, in roman antiquity, a statue of the goddess Fortune, mounted on horseback in the middle of the city.

Fortunate-islands, in antient geography, certain islands concerning the situation of which authors are not agreed, famous for the golden apples of the Hesperides. See the article Hesperides. The common opinion is, that they are the same with the Canary-islands. See the article Canary.

Fortune, fortuna, a goddess worshiped with great devotion by the antient Greeks and Romans, who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure.

The Greeks had a great number of temples dedicated to Fortune, under the name of τυχη. The poet Pindar makes her one of the parce, or deities, and the daughter of Jupiter. Ancus Martius, king of the Romans, was the first who built a temple at Rome to this deity, under the name of fortuna virilis, on account that courage, no less than good fortune, is requisite to obtain a victory. Servius Tullus built a temple to fortune, under the name of primogenia. The Romans gave several other appellations to fortune, such as fortuna libera, redux, publica, &c. There was a statue of Fortune at Athens, holding between her arms Plutos the god of riches. Pausanias says, that her most antient form was that which Bupalus made in Greece, in shape of a woman with a round ball on her head, and a cornucopia under her arm. Macrobius says, that she was first set forth with wings on her shoulders, having by her side the rudder of a ship; and that she was placed upon a wheel, and held in her right hand a golden ball, and in her left a whip. In Egypt she was painted like a woman, turning a great glass wheel, on whose top were represented a great number of men playing, others climbing up, and others, having attained the summit of the wheel, precipitating themselves, and falling down again. Modern painters represent Fortune by a naked woman, standing on a globe, with a bandage on her eyes. Horace's description of this goddess, and her great power, may be seen in ode xxxv. lib. 1. Juvenal, in Satire x. v. 365, calls Fortune the deity of fools.

Forty-shilling land, a certain quantity of arable land; that of old extent, containing eight ox-gang, or an hundred and four acres.

Forum, in roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

There were six of these forums, viz. the Romanum, Julianum, Augustum, Palladium, Trojanum, and Salutii forum. The first and most eminent of these was the Forum Romanum, called absolutely the Forum. In this was an apartment called the rostra, where the lawyers pleaded, and the orators harangued the people, &c. Here was also the co(nitum, or hall of justice, with the sanctuary of Saturn, the temple of Cæsars, &c. All the compass of the forum was arched with porticos, some passages being only left for places of entrance.

Forum was also used for a place of traffic, answering to our market-place: of these there were vast numbers, as the forum pircarium, oligarium, &c. These were generally called fora venaliter, in contradistinction to the former, which were called fora civilia.

Forum, is also used, among cauils, &c. for jurisdiction, thus they say, In fora legis, &c.

Foss, or Fossa, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

**F O S**

*Foss* is particularly used for the cavity, or indenture, in the back part of the neck.

*Fossa magna*, the interior cavity, or rima magna, of the pudendum muliebre. Bartholin calls it fossa navicularis. This cavity appears, upon opening the labia; it has the carunculae myrtiformes in the middle of it. See the article *Carunculae Myrtiformes*.

*Foss*, in fortification, a hollow place, commonly full of water, lying between the swarp and counter-carp, below the rampart; and turning round a fortified place or a pott, that is to be defended. See the article *Moat*.

*Fossa*, in our ancient customs, was used to signify a ditch full of water, wherein women, convicted of felony, were drowned. See the article *Furca*.

*Fossa-way*, one of the four principal highways of England, that antiently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side thereof.

*Fossano*, a town of Piedmont, nineteen miles south-east of Turin.

*Fossarii*, in antiquity, a sort of officers in the eastern church, whose busines it was to interr the dead.

St. Jerom affures us, that the rank of the fossarii held the first place among the clerks; but he is to be understood of those clerks only who had the direction and intendance of the interment of the devout. Some authors intimate, that the fossarii were instituted in the time of the apostles.

*Fossatorum operatione*, signifies the foss-work; or the service of labouring performed by inhabitants, and adjoining tenants, for the repair and maintenance of the ditches round a city or town. The contribution towards this work was termed *Fossagium*.

*Fossigny*, a country in the dutchy of Savoy. See the article *Savoy*.

*Fossil*, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, falls, earths, and other minerals; or extraneous, reposed in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See the articles *Metal, Stone, &c.*

Native fossils, according to Dr. Hill, are substances found either buried in the earth, or lying on its surface, of a plain simple structure, and having no signs of containing veins or circulating juices. They are subdivided, by the same au-

**F O T**

1. Into fossils naturally and essentially simple. Of these, some are neither inflammable, nor soluble in water, as simple earths, talcs, fibrians, gypsum, selenite, crytal, and fpar; others, the unimflammable, are soluble in water, as all the simple salts; and others, on the contrary, are inflammable, but not soluble in water, as sulphur, auripigmentum, zarnich, amber, amber-grease, gages, alpahlum, ampeliotes, lithanthrax, naphthha, and piaffalpaha. 2. The second general subdivision of fossils comprehends all such as are naturally compound, but unmetallic. Of these, some are neither inflammable, nor soluble in water; as compound earths, stones, lapis, fiderochita, ferup, semi-pellucid gems, lithidia, conifalae, and pellucid gems; others are soluble in water, but not inflammable, as all the metallic salts; and, lastly, some are inflammable, but not soluble in water, as the marcasites, pyrites, and phlogonia. 3. The third, and last, general division of fossils comprehends all the metallic ones; which are bodies naturally hard, remarkably heavy, and fusible in fire. Of these, some are perfectly metallic, as being malleable when pure; such are gold, lead, silver, copper, iron, and tin: others are imperfectly metallic, as not being malleable even in their purest state, such as antimony, bismuth, cobalt, zinc, and quicksilver, or mercury. Of all which substances the reader will find a particular description under their respective heads, *Earth, Talc, Fibrians, Gypsum, &c.*

Extraneous fossils are bodies of the vegetable or animal kingdoms accidentally buried in the earth. Of the vegetable kingdom, there are principally three kinds, trees or parts of them, herbaceous plants, and corals; and of the animal kingdom there are four kinds, sea-fisshes, the teeth or bony palates, and bones of fishes, complete fishes, and the bones of land animals. See the articles *Tree, Wood, Plant, Shell, &c.*

As to the reason why these extraneous fossils come to be lodged in the bowels of the earth, the common opinion is, that this great change was effected by the universal deluge. See *Deluge*.

*Fossombrone*, a city and bishop's see of Italy, ten miles south-east of Urbino.

*Fother*, of *Fodder*, in mining. See the article *Fodder*.

*Fotus*, a fermentation. See the article *Fomentation*.
FOVEA CORDIS, in anatomy, the pit of the heart, or rather of the stomach.

FOUGADE, or FOUGASSE, in the art of war, a little mine, about eight or ten feet wide, and ten or twelve deep, dug under some work or post, which is in danger of falling into the enemies hands; and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a fauciffé.

FOUGIERES, a town of Brittany, in France, thirty-five miles south east of St. Malo.

FOUL, or FOULE, in the sea-language, is used when a ship has been long untrimmed, so that the graps-weeds, or barnacles grow to her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run, or be over-hawled.

FOUL imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul are of the nature of those in which both parties must bear a part. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury: but in cafes where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

FOUL WATER. A ship is said to make foul-water, when being under sail, she comes into such shoal-water, that tho’ her keel do not touch the ground, yet it comes so near it, that the motion of the water under her, raises the mud from the bottom.

FOUL is also a distemper in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell. See SWELLED LEGS.

FOULNESS, in surgery, a term applied to wounds, where the flesh is putrid, fungous, black or livid. Wounds must be well cleaned before any attempts are made to heal them. For which intention the antients used honey, but the moderns apply a digestive ointment made of turpentine dissolved in the yolk of an egg, and afterwards mixed with honey of rofses; but where this is not found strong enough for the purpose, they substitute the Egyptian ointment, mixed either with spirit of wine, or with the common digestive. To these digestive ointments, a small quantity of aloes or myrrh may be added, and where more strength is required, a small quantity of red precipitate. The use of lime-water as a detergent is also known to be very beneficial, especially if there be added to every pint of it, twenty or thirty grains of sublimate, which from its known efficacy is called by the surgeons phagedenic-water. Applications of this kind are to be continued till the wound is entirely clean, and then it is to be healed with the common digestives. See the article WOUND.

FOUMART, a name used in some parts of the kingdom for the mustela, or weasel. See the article MUSTELA.

FOUNDATION, in architecture, is that part of a building which is underground. See BUILDING.

Foundation, called by Daviler, Fondation, is the coffre or bed dug below the level of the ground to raise a building upon, in which sense the foundation either goes to the whole area of the building, as when there are to be vaults, cellars, &c. or it is drawn in trenches, as when only walls are to be raised. The foundation, Fondement, according to the same author, is properly so much of the masonry as reaches as high as the surface of the ground, and ought always to be proportioned to the load or weight of the building that it is to bear. Sometimes the foundation is massive, and continued under the whole building, as in the antique arches and aqueducts, and some amphitheatres; but it is more usually in spaces or intervals, either to avoid expense, or because the vacuities are at too great a distance, in which latter case they make use of inflated pillars bound together by arches.

 Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging, unless there be cellars under-ground, in which case he would have it somewhat lower, and as to thickness, double the width of a wall is no bad rule. Palladio also lays down several rules to know if the earth be firm enough for the foundation, by observations from the digging of wells, and the like; but the best way to discover the nature of the soil is to try it with an iron-crow, or else with a boring, such as is used by well-diggers.

Foundations are either natural or arti-
FOU [1312] FOU

ficial  Natural as when we build upon a rock, or very solid earth, in which case we need not seek for any further strengthening; for these, without digging, or other artificial helps, are of themselves fit to uphold the greatest buildings. But if the ground be sandy, or marly, or have lately been dug, recourse must be had to art. If the ground be sandy or marly, you must dig till you find sound ground, and the belt that which requires most labour in cutting, and when wet, does not dissolve into dirt. If the earth to be built upon is very soft, as in moonlight grounds, lay good pieces of oak whose length must be about the breadth of the trench, or two feet longer than the breadth of the wall, across the foundation, about two feet thinner, and being well rammed down, lay long planks upon them, pinning or spiking down each plank to the pieces of oak on which it lies. But if the ground be very bad, let piles of oak of a diameter about one twelfth part of their length be drove down to reach the ground, and placed as close as one can stand by another; then spike down long planks upon them. And it must not be forgot to place the piles not only under the outer walls, but also under the inner walls that divide the building; for if these should sink, it would make the outer wall crack, and so ruin the whole building. If the ground be faulty here and there, let arches be turned over the faulty places, which will discharge them of the weight. As to the rules necessary to be observed in the substruction or artificial part of the foundation, they are these, 1. That the bottom of the trench be made exactly level. 2. That the lowest ledge or row be all of stone (the broader the better) laid close together. 3. That the breadth of the ground-work be at least double that of the wall to be raised on it. However, the breadth may be regulated according to the goodness of the ground, and the weight of the intended edifice. 4. That the foundation be made to diminish as it rises, taking care, however, that it do so equally on both sides. 5. That you ought never to build on the ruins of an old foundation, unless well affured of its depth and strength to bear the superstructure. 6. And lastly, the stones in a foundation should be laid as they naturally lay in the quarry, a precept generally observed by all good architects, because they find the stones are subject to cleave that way of the grain that lay horizontally in the quarry. In some places, buildings near the water are founded on packs of wool laid like matrasses, which being well pressed and greasy, will never give way, nor rot in the water.

Foundation of Bridges, is laid after different manners. The first is by enclosing all round the space of ground you would build upon, by dams made with piles set deep in the ground in double rows, well strengthened and bound together with crofs pieces and cords, and filling the vacant spaces between them with chalk or other earthy matter. This being done, the water must be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be necessary, upon which the walls of the foundation must be laid. But this method is only practicable in building on such rivers, where the water is neither very rapid, nor very deep. The second is done by laying the foundation on grating-work, rafts of stout oak well bound together, and made fast at the surface of the water with cables or machines, and building upon them large quarters of stone, cramped together, and joined with good mortar, or cement, and afterwards letting them descend softly by these cables and machines perpendicularly to the bottom of the water. This was the method practised in laying the foundation of Westminster-Bridge, the grating being made of the bottom of a frame called by the French Caiffon, the sides of which were so contrived, that they might be taken off, after a pier was finished. The third is by drawing off all, or the greatest part of the water of the river into some other place; and this was done at London-Bridge, if we could believe Stow, who alleges, that during the time of building, the river was turned from Battersea to Rotherhithe: but this is not warranted. See further on this subject in Belidor's Architec. Hydraulique. Livre iv. ch. 11, and 12.

FOUNDAION denotes also a donation or legacy either in money or lands, for the maintenance and support of some community, hospital, school, lecture, &c.

FOUNDATION is also used figuratively for the establishment of a city, empire, or the like.

FOUNDAY, in metallurgy, a term used by the workers at the iron-mines in many counties of England, for the space of six
FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. The founder of a church may preferve to himself the right of patronage, or presentation to the living.

FOUNDER, also implies, an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See the article FOUNDERY.

FOUNDER, in glass-making, a term appropriated to the green glass, and is the person there, who in the same office in the white-glass making is called conictator. See the article CONCIATOR.

FOUNDER, in the sea-language, a ship is said to founder, when by an extraordinary leak; or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer; but lie like a log; and not being able to swim long, will at last sink.

FOUNDERING, in the manage, a disorder in horses, whereof there are two kinds, viz. in the feet and in the chest.

Foundering in the feet, is an universal rheumatism, or defluxion of humours upon the sinews of a horse's feet, which causes so great a stiffness in the hoofs, that the horse has no sense nor feeling of them.

This disorder arises from hard riding; from great heats and colds; and is sometimes occasioned by watering a horse when he is very hot, by which means, as the farriers term it, his greafe is melted within him; also by wearing too flat a shoe, or travelling upon hard ground.

The general methods of curing this disorder are, first to pare all the horse's foles so thin, that you may fee the quick; then bleed him well at every toe; flop the vein with tallow and rosin; and having tacked hollow shoes on his feet, stop them with bran, tar, and tallow, as boiling hot as may be; and this renew once in two days for a week together; after which, let him have good exercise, &c. or, after he is pared thin, and let blood at his toes, flop his feet with cow's dung, kitchen-fee, tar, and foot, boiled together, and poured boiling-hot into them.

Foundering in the chest, may proceed from crudities in the stomach, or other infirmities, obstructing the passageways of the lungs; and may be discovered by the horse's not being able to bow his joints; and being once laid, he cannot rise again; his legs swell, &c.

As a particular remedy for chest-foundering, take five or six pennyworth of oil of peter, and mingle it with an equal quantity of ale, or beer; then rub this mixture with your hand on the part affected; and cause a red hot fire-shovel to be held before it during the application.

FOUNDERY, or FOUNDRY, the art of casting all sorts of metals into different forms. It likewise signifies the work-house, or melting-furnace, wherein these operations are performed.

FOUNDER of small works, or casting in sand. The sand used for casting small works, is, at first, of a pretty soft, yellowish, and clammy nature; but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared. This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass-cylinder, as the chief canal for the metal to run through, when melted, into the models, or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loofening them all round, that the sand may not give way. Then they proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes that
that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.
The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and throwing mill-dust over them, dries them in a kind of oven for that purpose.
Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of a press.
While the moulds are thus preparing, the metal is fused in a crucible of a size proportionate to the quantity of metal intended to be cast.
Some of these small work founder's furnaces are like a smith's forge; others stand a few feet underground for the more easily and safely taking out a weighty pot of metal; which is done by means of a circular tongs that grasps round the top of the crucible. When the metal is melted, the workman pours it through the chief canal of each mould, which conveys it to every distinct pattern. See the articles Flux and Forge.
When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is worked over again for other castings.

**FOUNDERY of Statues.** The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone, or brick; or when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.
The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron-grade, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair, and horse-dung; or of platter of Paris mixed with brick-dust. The use of the core is to support the wax, the shell, and leffen the weight of the metal. The iron-bars, and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron-bars of the core, that contribute to the fineness of the projecting part, within the brass figure.
The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core; though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick-dust, whereby the inner core is proportioned as the sculptor carries on the wax.
When the wax, which is the intended thickness of the metal is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder, when the hot metal came to encompass it.
The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impreffion of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according to different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water, to the confidence of a colour fit for painting; accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whiles. For the second impreffion, they add horse-dung, and natural earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand. The shell, thus finished, is secured by several iron-girts, bound round it, at about half a foot distance from each other,
FOU [1315] FOU

other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate. If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways: in the first a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone, or brick. At the bottom is made a hole of the same materials with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and lining furnace. For the matter of a statue, which is kept very close, that, upon opening the furnace, the brafs, which gushes out with violence, may not enter any of them, till the bason be full enough of matter to run into them all at once. Upon which occasion, they pull out the plugs, which are long iron-rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the reft being the sculptor's or carver's business, who taking the figure out of the mould, and earth, wherewith it is encompafled, faws off the jets with which it appears covered over, and repairs it with chiftels, gravers, punch-choons, &c.

F O U N D E R Y OF B E L L S. The metal, it is to be obferved, is different for bells, from what it is for statues; there being no tin in the statue-metal: but there is a fifth, and sometimes more, in the bell-metal. See the article BELL.

The dimensions of the core, and the wax, for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness necessary for the several tones required. See the article DIAPASON.

It is on the wax that the several mouldings and other ornaments are formed to be represented in relievo, on the outside of the bell.

The business of bell-foundery is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould; and, 3. The melting of the metal.

The proportions of our bells differ much from those of the Chinese: in ours the modern proportions are to make the diameter fifteen times the thickness of the brim, and twelve times the height.

There are two kinds of preparations, viz. the simple and the relative: the former are those proportions only that are between the several parts of a bell, to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The
The particulars necessary for making the mould of a bell, are, 1. The earth: the most cohesive is the best: it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon trefillus. Upon this, they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consists of two different legs, joined by a third piece. And last of all, the founders shelve, on which are the engravings of the letters, cartouches, coats of arms, &c.

They first dig a hole, of a sufficient depth to contain the mould of the bell, together with the cafl, or cannon, under-ground; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole; or between one mould and another, when several bells are to be cast. At the center of the hole is a flake erected, that is strongly fastened in the ground. This supports an iron-peg, on which the pivot of the second branch of the compasses turns. The flake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell’s diameter. This they call a mill-stone. The parts of the mould are the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core.

This work is covered with a layer of cement, made of earth and horse-dung, on which they move the compasses of construction, to make it of an even smoothness every where. The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth, that has been separately baked. The first fire consumes the flake, and the fire is left in the core half, or, sometimes, a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place, to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried, before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. being smeared with a pencil dipped in a vessel of wax in a chaffing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the ref, fifted very fine; whilst it is tempering in water, it is mixed with cow’s hair, to make it cohere. The whole being a thin cullis, is gently pored on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but something thicker: when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow’s hair a quantity of hemp, spread upon the layers, and afterwards
FOU [1317] FOU

afterwards smoothed by the board of the compasses. The thicknes of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravafation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings, the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron-peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron-keys. There are models made of the rings, with mafles of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united may make the hollows of the fix rings: the fame they do for the hollow of the bridge; and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and folded with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist, to fix on the place, which is itrewed, at several times, upon the cover of the core; and they beat it gently with a pelle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outsides of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacancy of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up, and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the fame interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mas of baked cement. After which they put on this mas of the cap, the rings, and the vent, over the shell, and folder it with thin cement, which is dried gradually by covering it with burning coals.

Then they fill up the pit with earth, beating it strongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious aff-hole. The furnace which contains the metal, is vaulted, whose bottom is made of earth, rammed down; the side is built with brick. It has four apertures; the first, through which the flame reverberates; the second is closed with a flopper that is opened for the metal to run; the others are to separate the dross, or fcorie, of the metal by wooden rakes: through these last apertures paffes the thick smoke. The ground of the furnace is built flopping, for the metal to run down. Foundery of great guns and mortar-pieces.

The method of casting these pieces is little different from that of bells: they are run maffy, without any core, being determined by the hollow of the shell; and they are afterwards boded with a feel trepan, that is worked either by horses, or a water-mill.

For the metal, parts, proportions, &c. of these pieces. See CANNON.
Letter Foundery, or Casting of printing letters. The first thing requisite is to prepare good steel-punches, on the face of which is drawn the exact shape of the letter with pen and ink, if the letter be large, or with a smooth blunted point of a needle, if small; and then, with proper gravers, the cutter digs deep between the strokes, letting the marks stand on the punch; the work of hollowing being generally regulated by the depth of the counter-punch: then he files the outside, till it is fit for the matrice. They have a mould to justify the matrices by, which consists of an upper and under part, both which are alike, except the stool and spring behind, and a small roundish wire in the upper part, for making the nick in the flank of the letter. These two parts are exactly fitted into each other; being a male and female gage, to slide backwards and forwards. See the article Gage.

Then they justify the mould, by casting about twenty samples of letters, which are set in a compoling-flick, with the nick towards the right hand; and comparing these every way with the pattern-letters, set up in the same manner, they find the exact measure of the body to be cast.

Next they prepare the matrix, which is of brass or copper, an inch and a half long, and of a proportionable thickness to the size of the letter it is to contain. In this metal is sunk the face of the letter, by striking the letter-punch the depth of an n. After this, the sides and face of the matrice are justified, and cleared, with files, of all bunched that have been made byinking the punch.

Then it is brought to the furnace, which is built upright of brick with four square sides, and a stone at top, in which is a hole for the pan to stand in. They have several of these furnaces. See the article Furnace.

Printing-letters are made of lead, hardened with iron or stub-nails. To make the iron run, they mingle an equal weight of antimony, beaten small in an iron mortar, and stub-nails together. They charge a proper number of earthen pots, that bear the fire, with the two ingredients, as full as they can hold, and melt it in an open furnace, built for that purpose. See the article Flux.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compost is ladled into an iron-pot, wherein is melted lead, that is fixed on a furnace close to the former, 2 lb. of melted iron to 2½ lb. of lead; this they incorporate according to art.

The cafter taking the pan off the fcone, and having kindled a good fire, he lets the pan in again, and metal in it to melt. If it be a small-bodied letter, or a thin letter with great bodies, that he intends to cast, his metal must be very hot, and sometimes red hot, to make the letter come. Then taking a ladle, of which he has several sorts, that will hold as much as will make the letter and break, he lays it at the hole where the flame burfts out; then he ties a thin leather, cut with its narrow end against the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice-check; and places the foot of the matrice on the stool of the mould, and the broad end of the leather on the wood of the upper half of the mould, but not tight up, lest it hinder the foot of the matrice from sinking close down upon the stool, in a train of work. Afterwards laying a little rosin on the upper part of the mould, and having his cafting-ladle hot, he, with the bolling side, melts the rosin and presses the broad end of the leather hard down on the wood and so fastens it thereto. Now he comes to casting, when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the lower part of the ball of his thumb and his three hinder fingers; then he lays the upper half of the mould upon the under half, so as the male gages may fall into the female; and, at the same time, the foot of the matrice presses itself upon the stool, and clasping his left hand thumb strongly over the upper half, he nimbly catches hold of the bow or spring, with his right hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the backside of the matrice, pressing it forwards as well towards the mould, as downwards, by the shoulder of the notch, close upon the stool, while at the same time with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of his thumb, and thrusts, by the ball of his thumb, the upper part towards his fingers, that both the register of the mould
mould may press against both sides of the matrice, and his thumb and fingers press both sides of the mould close together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three strokes outwards upon the surface of the melted metal, to clear it of the scum; then he takes up the ladle full, and having the mould in the left hand, turns his left side a little from the furnace, and brings the great of his ladle to the mouth of the mould; and turns the upper part of his right hand towards him, to pour the metal into it, while, at the same instant, he puts the mould in his left hand forwards, to receive the metal with a strong shake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the shank. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he tosses the letter, break and all, out upon a sheet of waffe paper, laid on a bench, a little beyond his left hand; and then is ready to cast another letter, as before, and likewise the whole number in that matrix.

Then boys, commonly employed for this purpose, separate the breaks from the shanks, and rub them on a stone, and afterwards a man cuts them all of an even height, which finishes the fount for the use of the printer. See the next article.

A workman will ordinarily cast 3000 of these letters in a day. The perfection of letters thus cast, consists in their being all severally square and straight on every side; and all generally of the same height, and evenly lined, without flopping one way or other: neither too big in the foot, nor the head; well grooved, so as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and scraped, with a sensible notch, &c. See the article PRINTING.

FOUNT, or FONT, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and forted. Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When a printer orders a fount of five hundred, he means that the fount, consisting of letters, points, spaces, quadrates, &c. shall weigh 500 lb. When he demands a fount of ten sheets, it is understood, that with that fount he shall be able to compose ten sheets, or twenty forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons 120 lb. for a sheet, including the quadrates, &c. or 60 lb. for a form, which is only half a sheet; not that the sheet always weighs 120 lb. or the form 60 lb. On the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the caie. As therefore every sheet does not comprehend the same number of letters, nor the same sort of letters, we must observe, that as in every language some sounds recur more frequently than others, some letters will be in much more use, and oftener repeated than others, and consequently their cells or caies should be better flored than those of the letters which do not recur fo frequently: thus, a fount does not contain an equal number of a and b, or of b and c, &c. the letter-founders have therefore a lift or tariff, or, as the French call it, a police, by which they regulate the proportions between the different sorts of characters that compose a fount; and it is evident that this tariff will vary in different languages, but will remain the same for all sorts of characters employed in the same language.

FOUNTAIN, font, in philosophy, a spring or source of water rising out of the earth. Among the antients, fountains were held sacred, and even worshiped as a kind of divinities. For the phenomena, theory, and origin of fountains or springs, see the article SPRING.

FOUNTAIN, or Artificial Fountain, in hydraulics, called also a jet d'eau, is a contrivance by which water is violently spouted upwards.

The theory of fountains, in regard to the action of the several parts of a fluid upon each other, depends on the following principles. It has been shewn, under the article FLUID, that water coming from a revoir, as ABCD (pl. CV. n° 1.) through the pipe EFGH, will rise from the lowest part, G, to the same altitude H, in the part GH, as is upon a level with the surface of the water AB, in the revoir: and also, that it thus rose from the point G, by a force of pressure proportional to the altitude of the water in the revoir, which is equal to the altitude GH. Now it is very evident that
the tube GH itself, can contribute nothing towards the waters rising in it; on the contrary it rather impedes the ascent, by the friction it occasions to the particles which move against the internal surface thereof. Therefore, if the part GH be taken away, the water would rise to the same height H, excepting so far as it is obstructed by other concurring incidents; for in all fountains the height GI is somewhat less than GH, the height of the tube, for the following reasons: 1. The air's resistance is an obftruftion to the jet, and diminishes its height; and since we know that the resistance of fluids is proportional to the squares of the velocity, and the deficiency of the height HI is proportional to the resistance; therefore a jet that plays with a double velocity, will have that deficiency four times as great; and with three times the velocity, nine times as great, and so on.

2. The second impediment is the friction against the sides of the hole, and the adjutage at G; and since this is in proportion to the quantity of surface in the hole, it will be greater in a small hole than in a great one, in respect to the body of the spouting water; because the jet will increase in magnitude with the square of the diameter of the hole, whereas the resistance will increase only with the diameter simply: or, a hole of twice the diameter emits four times the water, and gives but twice the resistance: this makes a small jet rise to less height than a large one from the same fountain. 3. A third impediment arises from hence, that since all the particles set out from G, with an equal velocity, and this velocity is continually diminishing, it follows, that the velocity of the interior parts is greater than the velocity of the parts above them, and therefore must, in some degree strike against them: by which impulse, since fluids move every way, the particles will be urged side-ways, and the column of the jet become wider, and consequently shorter than it would otherwise be. 4. The fourth cause why jets do not rise to the height of the refervoirs, is because the water upon the top of the jet does not immediately run off, but spreading into a head, lies with its weight upon the ascending water below, and hinders it from rising so high as it would otherwise do: this will appear by inclining the jet a little, that the upper water may not bear upon the rising stream; for the jet will then play higher, but be less beautiful.

If the hole of the adjutage G be less than a quarter of an inch in diameter, the force of the attraction of cohesion will extend itself through the body of the jet at the hole, and greatly obstruct its ascent: whence all jets of larger fountains, such as are in gentlemen's gardens, ought to exceed a quarter of an inch in diameter, and that in proportion to the height of the refervoir.

And one thing more is necessary to be known, that the jet may play the highest possible, viz. that the part of the conduct pipe at the adjutage, does not turn up at right angles, but with a gentle easy curve; that is, not as at G, but as at L, where the jet plays to a greater height at K: the upright part at G directly refists the water coming from F, whereas the curve at L causes the impulse of the water against it to be oblique; and therefore a less part of its momentum will be destroyed, and consequently the greater remaining force will throw the jet the higher.

A Table of the height to which jets will rise, in feet and decimal parts, from refervoirs of an height of five feet to an hundred and fifty feet.

From
From what has been said upon the second cause assigned for the obtrusion the jet meets with in rising to the height of the reservoir, which is the friction against the sides of the hole and the adjunctage, it appears, ceteris paribus, that the hole in the adjunctage ought to be made in a thin plate of brass, and not through the bore of a tube of any length, because of the quantity of surface in such an adjunctage-piece which must greatly retard the jet, and diminish the height.

If the conduit-pipe EFG be not of a proper size to supply water as fast as it can be expended at the adjunctage G, the jet will likewise be checked, and it will not rise to the full height. To ascertain the proportion of the conduit-pipe to the bore of the adjunctage, is shewn by the following table, made by Mr. Mariotte, Dr. Defaguliers, and others, who, by various experiments, found that if the reservoir be 5 feet high, a conduit-pipe \( \frac{1}{4} \) inch diameter will admit a hole in the adjunctage from \( \frac{1}{2} \) of an inch to \( \frac{3}{4} \) of an inch; and so on, as in the following table.

<table>
<thead>
<tr>
<th>Height of the reservoir, Feet.</th>
<th>Diameter of the adjunctages, Inch.</th>
<th>Diameter of the pipes of conduit, Inch.</th>
</tr>
</thead>
