To this end, let *ABCD*, (*fig. 3.*) be a vessel filled with water, to the height *EF* ; and let *I* be a cylindric body, heavier than water, to be immersed therein, as at *L*. By this immersion of the body *I*, a quantity of the fluid *abcd*, equal in bulk to the body, will be displaced by the superior force, or greater gravity of the solid ; and this quantity of fluid must ascend, as being confined towards the bottom and sides ; and so rise the surface of the liquor from *EF* to *GH*, and then will the quantity *EFGH* be equal to the bulk of the immersed solid *abcd*. But as the solid comes to enter the fluid, each particle of the fluid, by its vis inertiz, will resist the solid, or endeavour to oppose its descent with all its power ; and so the whole body of the fluid, that is removed or displaced by the solid, will resist it by the united force of all the particles : but this force is equal to the gravity of the fluid removed, as is evident from hence, that the fluid so removed is obliged to ascend or move in a direction quite contrary to gravity, wherefore the solid in its descent will be

resisted by a force equal to the gravity of an equal bulk of the fluid.

And, since the force which resists the descent of solids is proportioned to their bulk only, it follows, that equal bodies immersed in fluids, lose equal parts of their weights ; and therefore, a lighter body loses more of its absolute weight than a heavier one of the same bulk ; and consequently if two bodies of unequal bulk are in equilibrio in the air, that equilibrium will be destroyed on their being immersed in the fluid, because that which has the largest bulk will lose most weight in the fluid.

Again, it is plain, the weight of the fluid is augmented in the same proportion as that of the immersed solid is diminished ; for the force or action of the fluid, on the bottom of the vessel *CD*, is before immersion to that afterwards, as the altitudes *CF* to *CH* ; or to the bulks of the fluid *EFCD* and *GHCD*. And since those bulks act only by their gravity, 'tis plain the action of the fluid is increased only by the additional gravity of the quantity *GHFE*, which is equal to that which the solid loses by immersion. See the article *GRAVITY*.

13. If any body, *E* (*fig. 4.*) could be found without weight, it would, if placed on the surface *AB*, float thereon, without any part immersed ; for being devoid of gravity, it could have no force to displace any particles of the fluid, and sink therein.

14. If an heavy body, *F*, (*n<sup>o</sup> 4.*) lighter than an equal bulk of the fluid, be placed on its surface, it will sink, or descend therein, till it has removed or displaced so much of the fluid whose weight is equal to that of the body. For then the pressure upwards and downwards on the surface of the body is equal, and consequently the body will be there quiescent, or in equilibrio with the fluid. Hence the whole solid is to the immersed part as the specific gravity of the fluid is to that of the solid. See the article *HYDROSTATIC BALANCE*.

This case is not strictly true, but in vacuo ; for in the air such a body may be considered as sustained by two mediums, *viz.* air and water, in one of which, it will sink, or descend ; and in the other, rise.

15. If a solid, as *G*, (*n<sup>o</sup> 4.*) equal in weight to an equal bulk of the fluid, be immersed therein, it will take any situation indifferently in any part of the fluid,

fluid, as at G, H, I, without any tendency to ascend or descend therein; for being totally immersed, it must remove a parcel of the fluid of equal bulk and weight, and consequently the pressure upwards is equal to the tendency downwards, on the lower surface, every where; and therefore it can have no power to sink. Also the pressure downwards must be equal to the pressure upwards, on the upper surface whence it can have no tendency to rise or swim: it will therefore remain at rest in any position G, H, I, wheresoever in the fluid.

16. Lastly, if a body K, or L, (fig. 4.) heavier than an equal bulk of the fluid, be immersed therein, it will descend by the excess of its gravity above that of the fluid; for when immersed, it will be resisted by the force of an equal bulk of the fluid, which therefore will destroy so much of the gravity of the solid; and consequently the residue, or excess of gravity in the solid, is that alone by which it must descend.

The relative gravity of solids, by which they sink or swim, is usually illustrated by the descent and ascent of glass images, and bubbles included in a jar of water, covered over with a bladder, so as to include a small quantity of air between the bladder and water: the images, &c. have small holes in the bottom of their feet thro' which some water is put into their bodies, and that in such quantities as will render them but very little specifically lighter than water; but some more so than others, that they may not begin to move altogether. See the representation in (fig. 5.) The images being thus put to float in water, and the bladder tied down, if the hand be laid on the bladder, and gently compresses the air beneath, the air, by its spring, will act upon the water, and cause it to compress the air in the bodies of the images, by which means more water will be driven into their bodies; and when so much is got in as will make them specifically heavier than the water, then they will begin to descend one after another; and by varying the degree of pressure, you may keep them suspended in any part of the fluid as you please.

From what has been premised of the nature of fluids, it will be easy to understand, that the lightest body, P, (plate *ibid.* fig. 4.) may be depressed in the heaviest fluid by any contrivance to keep the said fluid from pressing on the under

surface of the light body, by which means only light bodies are made to swim. Thus cork, or wood, will abide at the bottom of a vessel filled with quicksilver.

Again: on the other hand, the heaviest body M may be made to swim in the lightest fluid, by keeping the said fluid from pressing on its upper surface, by means of the tube NO. For when by this means it is immersed so deep as to keep off an equal weight of the fluid, the pressure then of the fluid acting upon its under surface upwards, will be equal to the weight of the solid tending downwards; and therefore, if the solid be sunk ever so little deeper, it must swim by the superior force or pressure of the fluid upwards.

Thus, for instance, if the body M be five times heavier than water of an equal bulk, and if by means of the tube NO, placed on its upper surface, the water be kept from pressing thereon, that it be immersed to seven times its thickness below the surface of the water, 'tis plain the pressure on the under surface will be as seven, but downwards only as five; and therefore, since there is the excess of two degrees of pressure upwards, 'tis plain the body cannot descend; but may very properly be said to swim on the water. Hence also the reason of trying the different gravity, density, or strength of divers fluids, or spirituous liquors, by the hydrometer, or water-poise. See the article *HYDROMETER*.

*Motion of FLUIDS.* The motion of fluids, viz. their descent or rise below or above the common surface or level of the source or fountain, is caused either, 1. by the natural gravity or pressure of the fluid contained in the reservoir, or fountain; or, 2. by the pressure or weight of the air on the surface of the fluid in the reservoir, when it is at the same time either taken off or diminished on some part in aqueducts, or pipes of conduit. 3. By the spring, or elastic power of compressed or condensed air, as in the common water engine. 4. By the force of pistons, as in all kinds of forcing pumps, &c. 5. By the power of attraction, as in the case of tides, &c.

1. The most natural motion of fluids is that arising from the force of their own gravity, by which those parts which stand highest press upon others below them, till by that means they rise to the same horizontal level. Thus water in a fountain

tain ABCD (fig. 6.) by its pressure, raises that in the aqueduct FGH to the same height IKLM in every direction or position of the duct GH, or GN; unless the orifice of the said duct be below that level, in which case the water will continually flow from the same. The reason hereof is evident from the principles already laid down, *viz.* that the pressure of fluids was in proportion to the altitude only, and not according to the quantity thereof, and therefore the effect or rise of the fluid in the duct must be equal thereto.

Hence we have conduits often supplied with water from springs, which lie above them; and cocks to supply the inhabitants of a town with water by pipes from a reservoir, in a situation above the highest part of the town: hence also the descent of water in rivers, streams, and canals from springs and sources above the common surface of the earth; and the breaking out of springs at the bottoms and on the side of hills; from cisterns and reservoirs in the internal parts above them, which receive their water from rain, dew, condensed vapour, melted snow, &c. distilling, or percolated through the pores or crevices and chasms of the upper part of the earth. See the articles FOUNTAIN, SYPHON, CONDUIT, TANTALUS'S CUP, JET D'EAU, RESERVOIRS, CANAL, SPRING, CISTERN, &c.

2. The second cause of the rise or motion of fluids is the pressure of the air on the surface of that in the fountain or reservoir: thus if a syphon or crane be immersed with the shorter leg in water, and the air sucked out of the instrument, the fluid will ascend into the vacuous space by the pressure of the air on the water, and fill the whole cavity of the tube; and because there is a greater column of water in the longest leg, it will preponderate and descend thro' it, and will keep flowing out till the vessel is exhausted to the orifice of the shorter leg. The effect of the common pump is from the same principle. See the article PUMP.

3. The third cause of the rise and motion of fluids is by the spring or elastic power of condensed air, upon which principle water engines are contrived. See the article ENGINE.

4. The fourth cause is the force or pressure of pistons, upon which principle a variety of water engines are constructed,

as may be seen under the articles already referred to.

5. The last cause of the motion of fluids which we mentioned was that of attraction. We have elsewhere shewn how by this means any fluid will ascend above the common surface in capillary tubes, &c. See the article CAPILLARY.

But the most notable and obvious motion of fluids arising from attraction, is that of the tides; the waters of the immense ocean forgetful, as it were, of their natural quietus, move and roll in swelling tides obsequious to the sovereign power of the moon, and weaker influence of the sun. See the article TIDES.

*Momenta and velocities of FLUIDS.* The momenta of fluids, as well as of solids, is compounded of the quantity of matter and velocity; but in spouting fluids, the quantity of the fluid issuing thro' the same hole, in the same time, is always as the celerity of its motion, as is easy to conceive. Whence the momenta of spouting fluids, are proportional to the squares of the velocities, or quantities of matter issuing out in a given time. But since the momenta are the effect of pressure, it is evident the velocity or quantity of spouting fluids is ever proportional to the square root of the pressure, or altitude of the fluid. From hence it appears, that the velocity of a fluid spouting at any depth below the surface is equal to the velocity a heavy body would acquire by falling from the same height; because the velocity, as was observed, is always as the square root of the space descended through. If therefore on the altitude of the fluid AK, (fig. 7.) as a diameter, we describe the semicircle AFK, and from any point therein, as I, we draw the perpendicular IH, that shall be proportional to the distance to which the fluid will spout from an adjutage at H: for the velocity will be, as the square root of AH; and the time, as the square root of HK; whence the product of these two will express both the space passed over by the projected body, and also the line HI. Hence it follows, that a fluid will spout from a hole or adjutage D, in the center of the semicircle, or middle part of the altitude AK, to the greatest horizontal distance KM possible; because the perpendicular FD is the greatest that can be drawn to the diameter AK. Also it is evident, that from two holes B and H, equally distant above and below the middle altitude D, the jets of water will

be made to the same horizontal distance  $KN$ ; because the perpendiculars to these two points, *viz.*  $CB$  and  $IH$ , are equal. Moreover, the horizontal distance  $KM$ , to which the water spouts from  $D$  the center, is equal to the diameter or altitude  $AK$ , or twice  $DF$ . For since the velocity of the jet at  $Q$  is equal to that acquired by falling through the height  $AD$ , or  $DK$ , it will, as being uniform, carry the fluid in an horizontal direction over twice the space  $DK$  or  $DF$  in the same time. And therefore, since the distances of jets from  $D$  and  $B$  are as  $DF$  to  $BC$ , and the distance of the jet from  $D$  is equal to twice  $DF$ , the distance of the jet from  $B$  will be also equal to twice  $BC$ , or  $KN = 2 BC$ . From what has been said, it is easy to observe, that the motion of a spouting fluid is every way similar to that of a projected solid. The path of the fluid is a parabola, because it is impelled by two forces, one horizontal, the other of gravity in the perpendicular, in the same manner as in the projected solid. See **PROJECTILE**.

The impetus of the jets  $B$ ,  $D$ ,  $H$ ,  $E$ , is as the height of the reservoir  $AB$ ,  $AD$ ,  $AH$ ,  $AE$ ; the greatest horizontal random  $KM$ , is that from the jet  $D$ , directed to the middle point  $F$  of the semi-circle; and any two jets equally distant as  $B$ ,  $H$ , go to the same distance  $KN$  on the horizon. If the adjutage be horizontal, the jet will be a semiparabola; if oblique, it will be a whole parabola. See the article **PARABOLA**.

**FLUKE**, in ichthyology. See **FLOUNDER**.

**FLUKE of an anchor**. See **ANCHOR**.

**FLUMMERY**, a wholesome sort of jelly made of oat-meal.

The manner of preparing it is as follows. Put three large handfuls of finely ground oat-meal to steep, for twenty-four hours, in two quarts of fair water: then pour off the clear water, and put two quarts of fresh water to it: strain it through a fine hair sieve, putting in two spoonfuls of orange flower-water, and a spoonful of sugar: boil it till it is as thick as a hasty pudding, stirring it continually while it is boiling, that it may be very smooth.

**FLUOR**, in physics, a fluid, or more properly, the state of a body that was before hard or solid, but is now reduced by fusion, or fire, into a state of fluidity.

**FLUOR**, in mineralogy, implies a sort of mineral concretion, frequently found amongst ores and stones, in mines and quarries.

**FLUOR ALBUS**, or **WHITES**, in medicines an efflux of a whitish, lymphatic, serous, or aqueous humour, from the matrix. It is sometimes white, sometimes pale, yellow, green, or blackish. Sometimes it is sharp and corrosive, sometimes foul and fetid; the face is discoloured, there is a pain in the spine of the back, the appetite is lost, and the eyes and feet swell. Some women have a periodical flux of the whites, instead of the menses. There are remarkable distinctions in this disorder, as the lacteous, the semi-lacteous, and lymphatic: it may be so acrid or caustic, as to excoriate the vulva. Besides the symptoms already mentioned, it is attended with a swelling of the uterus; turbid urine; a loathing of some things, and longing for others; a slow fever; dropsies of different parts, of which, or a consumption, the patient dies. It may be confounded with an ulcer of the uterus, or a gonorrhœa muliebris. See **GONORRHOEA**.

The fluor albus sometimes is discharged from the uterine vessels, and sometimes from the glands of the vagina. In the first case it stops when the menses begin to flow; in the latter it continues with them; and pregnant women are not exempted from it. At first, the parts of the membranæ adiposæ of the loins, kidneys, and the uterine appendages, are wasted by it: but at length the flux becomes acrimonious. When the flux is lacteous, it may be cured in fifteen days; the patient must feed sparingly, use frequent exercise, and sleep little. If this is not complied with, she must bleed in the arm, once or twice a month, and take purges and emetics; or, at least, frequent clysters. The efficacy of all these must be assisted with diaphoretics, decoctions of the woods, and diuretics.

In the semilacteous flux, an inspissating and nourishing diet will be best, such as creams, soups, boiled milk, roast meat, jellies, &c. Milk, or milk turned with a decoction of china, is very good. Narcotics are highly useful, especially if the patient is restless, or delirious. In the beginning, the dose must be small, but it may be gradually increased. When the vesiculæ lacteæ are relaxed, the tone must be restored with hot mineral baths, and fomentations; and injections of, and bathing in the same: the fumes may also be conveyed into the vagina with a funnel. Decoctions of the woods are also good;

good; as are diaphoretics, and diuretics a decoction of roots of eryngo and rest-harrow, with powder of millepedes, or glauher's salt.

If the lymphatic flux is attended with a scrophulous, scorbutic, or venereal taint, these disorders must first be removed. If the uterine lymphatics are compressed by scirrhoties, cancers, ganglions, or the like, regard must be had to the causes.

In obstructions of the glands of the uterus, begin with bleeding: then a gentle purge, or an emetic of iij gr. of tartar-emetic, or ipecacuanha: afterwards, if the patient's constitution is cold, attenuating aperients. If she is hot and bilious, with a sensible pain in the uterus, cooling broths and apozems, with the addition of cray-fish; asses milk, with a decoction of barley; chalybeate whey, with chervil boiled therein; gently purging mineral waters; baths and half baths are convenient in the summer.

**FLUSH-DECK**, in a ship. See **DECK**.

**FLUSHER**, in ornithology, a bird otherwise called the *lanius minor*, or lesser butcher-bird. See the article **LANIUS**.

**FLUSHING**, or **VLISSGEN**, a port town of Zealand, in Holland, five miles south of Middleburg: east long.  $3^{\circ} 25'$ , north lat.  $51^{\circ} 30'$ .

It is a town of great foreign trade, and has a good secure harbour.

**FLUTE**, *fistula*, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side. The antient fistulæ, or flutes, were made of reeds, afterwards of wood, and last of metal: but how they were blown, whether as our flutes, or as hautboys, does not appear.

'Tis plain some had holes, which, at first, were but few, but afterwards increased to a great number, and some had none; some had single pipes, and some a combination of many, particularly Pan's syringa, which consisted of seven reeds joined together sideways.

*German* **FLUTE**, is an instrument intirely different from the common-flute. It is not, like that, put into the mouth to be played, but the end is stoppt with a tampion, or plug; and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the

end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest of which is stoppt and opened by the little finger's pressing on a brass, or sometimes, a silver key, like those in hautboys, bassoons, &c. It is found exceeding sweet and agreeable; and serves as a treble in a concert.

Coarse flutes, on importation, pay the gros, containing twelve dozen, 3s. 10<sup>2</sup>/<sub>10</sub>d. and on exportation draw back 3s. 4<sup>2</sup>/<sub>10</sub>d.

**FLUTE**, or **FLUYT**, is also a kind of long vessel, with flat ribs, or floor timbers; round behind, and swelled in the middle; serving chiefly for the carrying of provisions in fleets, or squadrons of ships, though it is also used for merchandize.

**FLUTES**, or **FLUTINGS**, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. They are chiefly affected in the ionic order, where they had their first rise; though, indeed, they are used in all the richer orders, as the corinthian and composite; but seldom in the doric, and scarce ever in the tuscan.

Each column has twenty-four flutes, and each flute is hollowed in exactly a quadrant of a circle: but the doric has but twenty. Between the flutes are little spaces that separate them, which Vitruvius calls *stria*, and we list: though, in the doric, the flutes are frequently made to join to one another, without any intermediate space at all; the list being sharpened off to a thin edge, which forms a part of each flute. See **LIST**.

Vignola determines the depth of the flutes by taking the angle of the equilateral triangle for the center. Vitruvius describes the depth from the middle of the square, whose side is the breadth of the flute, which latter method makes them deep. Some columns have flutes that go winding round the shaft, spirally; but this is rather accounted an abuse. The flutes, or *striae*, are commonly filled up with a prominent or swelling ornament; sometimes plain, in form of a staff or reed; and sometimes a little curved, or enriched, in imitation of a rope, or otherwise. See the article **CABLED**.

Sometimes the flutings are made flat, and are called *Facettes*: but these have never such a good effect as the others. Vitruvius says, that when there are flutings in

the column, there ought also to be eggs and anchors in the quarter round of the capital, and even pearls and olives, in a baguette, to be made underneath, instead of annulets. These eggs and olives ought to be in the same number with the flutings, and to be regularly distributed.

**FLUVIALIS**, in botany, the name by which Vaillant calls the najas of Linnaeus. See the article **NAJAS**.

**FLUX**, in medicine, an extraordinary issue, or evacuation of some humours of the body.

Sometimes it is taken for all kinds of defluxions; in which sense it is the same with a catarrh, or coryza: See the article **CATARRH**.

Sometimes it signifies a looseness, or flux, of the belly, which is of four kinds. When the food is discharged by stool undigested, it is called a lientery, or lienteric flux. When the chyle is discharged, it is called coeliaca. When excrementitious humours are discharged, as cholera, phlegm, &c. it is called simply a diarrhoea; and when the stools are bloody, it is called a dysentery, or bloody-flux. See the articles **LIENTERY**, **COELIAC PASSION**, **DIARRHOEA**, and **DYSENTERY**.

Again, there is an hepatic flux: but this is supposed to be no other than the hæmorrhoidal flux. See the article **HÆMORRHOIDS**.

**FLUX** of the urine. See **DIABETES**.

Women are subject to three several kinds of fluxes extraordinary; the first, called the menses, or menstrual flux; the second is after delivery, and is called lochia: these are regular and natural. See the articles **MENSES** and **LOCHIA**.

The third, being irregular and preternatural, is termed the fluor albus, or whites. See **FLUOR-ALBUS**.

**FLUX**, in hydrography. See **TIDE**.

**FLUX**, in metallurgy, whatever can cause a body otherwise not at all, or hardly, fusible by fire, to melt.

Fluxes, says Dr. Shaw, seem reducible to two general kinds, viz. the vitreous and the saline. By the vitreous we understand all those which either have of themselves, or readily assume, a glassy form in the fire; among the principal whereof are reckoned the glass of lead, the glass of antimony and borax. By the saline kind of fluxes are understood all those that are composed of salts, whether tartar, nitre, fixed alkali, or the like. Among the principal of this kind we reckon the

black flux, sandiver, kelp, &c. See the articles **SANDIVER** and **KELP**.

The method of making the black flux is as follows. Take one part nitre, and two parts common tartar, and reducing each to powder, mix them together: deflagrate the whole in a crucible, by lighting the mixture a-top, which thus turns to a kind of alkaline coal, that is to be pulverized and kept close in a glass, to prevent its dissolving, as it would do in a moist air.

The vitreous kind of fluxes seem more immediately destined to act upon the stony or vitrescible matter, wherewith stubborn ores are frequently mixed, and the saline kind to act more immediately upon the ore itself, for the due exclusion or separation of the metal. The more kindly ores require no flux to make them run thin, or to afford all the metal they contain, and sometimes ores are so kindly as to contain their own fluxes within themselves. Thus, we have met with copper-ores, which being barely ground to powder, and melted without any addition in a common wind-furnace, have yielded as much, or even more, pure metal at the first operation, than could be obtained from them by means of the usual fluxes. Whence we see that artificial fluxes are not always necessary; or that the principal use of them is for the stubborn or less tractable ores; and these are sometimes so exceedingly hard to fuse and reduce to a metalline form, that it requires the utmost power of art to treat them advantageously in the larger way of business, where no considerable expence can usually be allowed for fluxes. And on this account it is, that many mines remain unwrought, as being untractable without great charges. Whence the improvement of the business of fluxes, so as to render them cheap and effectual, might greatly contribute to the improvement of metallurgy. The matter in soft ores, which renders them so fusible, has been found by an experiment upon copper-ore, to be a kind of bituminous substance, capable of melting by a strong heat, into a soft and black kind of glass.

Some of the most powerful and cheap simple fluxes hitherto known, are dried wine-lees, dried cow-dung and horse-dung, dried river-mud, fuller's earth, iron-silings, common salt, glass, kelp, or pot-ashes, sandiver, &c. which may be used in the larger work; as nitre, tartar,

tartar, borax, sal ammoniac, mercury sublimate, &c. may in the smaller, or for the making of assays.

As for compound fluxes, they are numerous; almost every operator having his favourite flux. And, certainly, some fluxes are better adapted than others to certain ores. But perhaps a few general ones might be fixed upon, which should serve instead of all those hitherto commonly known and used: we will here recommend three, which are powerful, almost general, and not expensive.

1. Take of nitre, prepared by long boiling it in lime-water; of sea salt, melted in the fire; sandiver; and dry wine-lees, each one part; glass of lead, three parts; and powdered glass, eight parts; mix them all well together. This flux added in an equal weight, will fuse a very stubborn ore.

2. For a still stronger, take equal parts of white tartar, common salt and nitre, prepared as above: calcine them to a white powder; and mix therewith its own weight of glass and lead; and of this flux add two parts to one of the most stubborn ore.

3. For a powerful saline flux. Take of the strongest soapboiler's lees, four pounds; white tartar, and common salt melted in the fire, each one pound: boil them together with five gallons of human urine, to a dry salt. This flux is particularly proper where sulphur and cobalt abound, and render the ore very refractory.

But the great secret, in making and adapting fluxes, is not only to separate the metal already ripened in the ore, but even to mature and ripen the crude and immature part of the ore in the fire: something of this kind, we apprehend, may be effected, as having reason to believe, that certain fluxes will obtain a larger yield of metal from certain ores, than other fluxes in common use, tho' esteemed of the best, and though they are perhaps of the dearest kind. Thus clean iron-slings will often do more than borax. But as the scales and crocus, or rust, of iron, have been commonly used, instead of pure and perfect iron itself, for a flux, few operators appear acquainted with the excellence of perfect iron employed for this purpose. And many advantages are now obtained, by a prudent mixing of one ore with another of the same denomination, and with the

flags, or recrements of metals, in this way of flux.

The melting of gold and silver, and of their calxes, is greatly promoted by glass of lead, alkaline salts, &c. but when gold and silver, in the fusion itself, are to be purged from other metals and semimetals, it is proper to use nitre only; or if not so, nitre always must be mixed with the other salts; for the semimetals and the four less perfect metals are destroyed by nitre.

In this operation, nitre, by its detonation with their sulphurs, is in part alkalisied, and, by the help of a gentle fire, turns their calxes into a vitreous, and much attenuated scoriæ.

From hence, the reason is plain why gold and silver, when made brittle, are readily restored to their malleability by nitre; for the same metals, and among the metals, lead and tin most of all communicate this fault to gold and silver: but these being changed, as before observed, by nitre, are then rejected by gold and silver in a simple fusion, so that they can no longer mix with these metals, unless they are themselves first again reduced to their metallic state; and there is beside these, no other body that can be mixed with silver and gold, to render them brittle, unless crude charcoal, happening to fall into the vessel wherein these metals are melted, should impregnate them with something arsenical; there being some arsenic contained in coals of this kind, as has been demonstrated by Stahl and Hoffman.

The less perfect metals, and semi-metals, melt more easily by adding salts to them, than of themselves: they always, however, lose a great deal of their substance by this means; and this is more particularly the case in regard to copper and iron. To amend this, it is necessary to add some kind of fat body, which prevents the destruction, and even reduces the metals already destroyed; and this is more necessary when the calxes, prepared either by burning, or by a detonation with nitre, are to be reduced. A caution, very necessary to be observed, is, that all fluxes must be kept and used very dry, for moist salts foam very much; and when the operations are made in close vessels, if the fire is quickly increased, not being able to get rid of the moisture, the vessels will split and break.

Fluxes being greatly attenuated, though confined in close vessels, part with their oily principle, and their alkaline salt remaining, begin to corrode and consume the vessels, of what matter soever they are made, and finally make their way through them, and get out. The first of these accidents is prevented by adding coal-dust, which will never part with its oil without the help of a free air; and the others by an admixture of common glass, made of a due mixture of flints, and fixed alkali; for this is sufficiently fusible, and melts with the fluxes; and by its viscosity in some sort coagulates and holds the salt of the flux together, and prevents it from easily corroding the vessels.

**FLUXION**, in mathematics, denotes the velocity by which the fluents or flowing quantities increase or decrease; and may be considered as positive or negative, according as it relates to an increment or decrement.

The doctrine of fluxions, first invented by sir Isaac Newton, is of great use in the investigation of curves, and in the discovery of the quadratures of curvilinear spaces, and their rectifications. In this method, magnitudes are conceived to be generated by motion, and the velocity of the generating motion is the fluxion of the magnitude. Thus, the velocity of the point that describes a line, is its fluxion, and measures its increase or decrease.

When the motion of this point is uniform, its fluxion or velocity is constant, and may be measured by the space described in a given time. But when the motion varies, the fluxion or velocity at any given point is measured by the space that would be described in a given time, if the motion was to be continued uniformly from that term.

Thus, let the point  $m$  be conceived to move

from A, and generate the variable right line  $Am$ , by a motion any how regulated; and let its velocity, when it arrives at any proposed position or point R, be such as would, was it to continue uniform from that point, be sufficient to describe the line  $Rr$ , in the given time allotted for the fluxion, then will  $Rr$  be the fluxion of the variable line  $Am$ , in the term or point R. See **MOTION** and **VELOCITY**. The fluxion of a plane surface is conceived in like manner, by supposing a

given right line  $mn$  (plate XCVIII. fig. 6. n<sup>o</sup> 1.) to move parallel to itself, in the plane of the parallel and immoveable lines  $AF$  and  $BG$ : for if, as above,  $Rr$  be taken to express the fluxion of the line  $Am$ , and the rectangle  $Rr \cdot s$  be completed; then that rectangle, being the space which would be uniformly described by the generating line  $mn$ , in the time that  $Am$  would be uniformly increased by  $mr$ , is therefore the fluxion of the generated rectangle  $Bm$ , in that position. If the length of the generating line  $mn$ , continually varies, the fluxion of the area will still be expounded by a rectangle under that line, and the fluxion of the absciss or base: for let the curvilinear space  $Anm$  (*ibid.* n<sup>o</sup> 2.) be generated by the continual and parallel motion of the variable line  $mn$ ; and let  $Rr$  be the fluxion of the base or absciss  $Am$ , as before, then the rectangle  $Rr \cdot s$ , will be the fluxion of the generated space  $Amm$ . Because, if the length and velocity of the generating line  $mn$ , were to continue invariable from the position  $RS$ , the rectangle  $Rr \cdot s$  would then be uniformly generated with the very velocity where-with it begins to be generated, or with which the space  $Amm$  is increased in that position.

**Notation of FLUXIONS.** Invariable quantities, or those which neither increase nor decrease, are represented by the first letters of the alphabet, as  $a, b, c, d$ , &c. and the variable or flowing quantities by the last letters, as  $v, w, x, y, z$ : thus, the diameter of a given circle may be denoted by  $a$ ; and the sine of any arch thereof, considered as variable, by  $x$ . The fluxion of a quantity represented by a single letter, is expressed by the same letter with a dot or full point over it: thus, the fluxion of  $x$  is represented by  $\dot{x}$ , and that of  $y$  by  $\dot{y}$ . And, because these fluxions are themselves often variable quantities, the velocities with which they either increase or decrease, are the fluxions of the former fluxions, which may be called second fluxions, and are denoted by the same letters with two dots over them, as  $\ddot{x}, \ddot{y}$ . In the same manner the fluxions of second fluxions are called third fluxions, and denoted by the same letters with three dots over them, as  $\dddot{x}, \dddot{y}$ ; and so on for fourth, fifth, &c. fluxions, which are expressed by the same letters, with four, five, &c. dots over them, as  $\ddot{\ddot{x}}, \ddot{\ddot{y}}$ ; and  $\ddot{\ddot{\ddot{x}}}, \ddot{\ddot{\ddot{y}}}$ , &c. If the

flowing

flowing quantity be a fraction, as  $\frac{xx}{d-y}$ , its first, second, third, &c. fluxions are expressed by one, two, three, &c. dots placed in the break of the line that separates the numerator from the denominator, thus  $\frac{\dot{x}x}{d-y}$ ,  $\frac{\ddot{x}x}{d-y}$ ,  $\frac{\ddot{\ddot{x}}x}{d-y}$ , &c.

The fluxions of surds are denoted in the same manner, by one, two, or more dots placed in the break of the vinculum of the radical character: thus, if the surd quantity be  $\sqrt{x-y}$ , then will its first, second, third, &c. fluxions be  $\sqrt{\dot{x}-\dot{y}}$ ,  $\sqrt{\ddot{x}-\ddot{y}}$ ,  $\sqrt{\ddot{\ddot{x}}-\ddot{\ddot{y}}}$ , &c.

The whole doctrine of fluxions consists in solving the two following problems, viz.

1. From the fluent, or variable flowing quantity given, to find the fluxion; which constitutes what is called the direct method of fluxions. 2. From the fluxion given, to find the fluent, or flowing quantity; which makes the inverse method of fluxions.

*Direct method of FLUXIONS.* The doctrine of this part of fluxions is comprized in these rules.

1. To find the fluxion of any simple variable quantity, the rule is to place a dot over it: thus, the fluxion of  $x$  is  $\dot{x}$ , and of  $y$ ,  $\dot{y}$ . Again, the fluxion of the compound quantity  $x+y$ , is  $\dot{x}+\dot{y}$ ; also the fluxion of  $x-y$ , is  $\dot{x}-\dot{y}$ .

2. To find the fluxion of any given power of a variable quantity, multiply the fluxion of the root by the exponent of the power, and the product by that power of the same root, whose exponent is less by unity than the given exponent. This rule is expressed more briefly, in algebraical characters, by  $nx^{n-1}\dot{x}$  = the fluxion of  $x^n$ . Thus, the fluxion of  $x^3$  is  $\dot{x} \times 3 \times x^2 = 3x^2\dot{x}$ ; and the fluxion of  $x^5$  is  $\dot{x} \times 5 \times x^4 = 5x^4\dot{x}$ . In the same manner the fluxion of  $(a+y)^7$  is  $7\dot{y} \times (a+y)^6$ ; for the quantity  $a$  being constant,  $\dot{a}$  is the true fluxion of the root  $a+y$ . Again, the fluxion of  $(a^2+z^2)^{\frac{3}{2}}$  will be  $\frac{3}{2} \times 2z\dot{z} \times (a^2+z^2)^{\frac{1}{2}}$ : for here,  $x$  being put  $=a^2+z^2$ , we have  $\dot{x} = 2z\dot{z}$ ; and therefore  $\frac{3}{2} x^{\frac{1}{2}}\dot{x}$ , for the fluxion of  $x^{\frac{3}{2}}$  (or  $(a^2+z^2)^{\frac{3}{2}}$ ) is  $= 3z\dot{z}\sqrt{a^2+z^2}$ .

3. To find the fluxion of the product of several variable quantities, multiply the

fluxion of each, by the product of the rest of the quantities; and the sum of the products, thus arising, will be the fluxion sought. Thus, the fluxion of  $xy$  is  $\dot{x}y+y\dot{x}$ ; that of  $xyz$ , is  $\dot{x}yz+\dot{y}xz+\dot{z}xy$ ; and that of  $vwyz$  is  $\dot{v}xyz+\dot{w}vz+\dot{y}vwz+\dot{z}vwy$ . Again, the fluxion of  $a+x \times b-y$  is  $ab+bx-\dot{a}y-\dot{y}x$ .

4. To find the fluxion of a fraction, the rule is, from the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator. Thus the fluxion of  $\frac{x}{y}$ , is  $\frac{y\dot{x}-x\dot{y}}{y^2}$ ;

that of  $\frac{x}{x+y}$ , is  $\frac{\dot{x} \times x+y-\dot{x}+\dot{y} \times x}{(x+y)^2} = \frac{y\dot{x}-x\dot{y}}{(x+y)^2}$ ; and that of  $\frac{x+y+z}{x+y}$ , or  $1+\frac{z}{x+y}$ , is  $\frac{\dot{z} \times x+y-\dot{x}+\dot{y} \times z}{(x+y)^2}$ ; and

so of others.

In the examples hitherto given, each is resolved by its own particular rule; but in those that follow, the use of two or more of the above rules is requisite: thus (by rule 2. and 3.) the fluxion of  $x^2y^2$  is found to be  $2x^2y\dot{y}+2y^2x\dot{x}$ ; that of  $\frac{x^2}{y^2}$ , is found (by rule 2. and 4.) to be

$$\frac{2y^2x\dot{x}-2x^2y\dot{y}}{y^4}; \text{ and that of } \frac{x^2y^2}{z}, \text{ is}$$

$$\frac{(2x^2y\dot{y}+2y^2x\dot{x}) \times z - x^2y^2\dot{z}}{z^2}.$$

5. When the proposed quantity is affected by a coefficient, or constant multiplier, the fluxion found as above must be multiplied by that coefficient or multiplier: thus, the fluxion of  $5x^3$ , is  $15x^2\dot{x}$ ; for the fluxion of  $x^3$  is  $3x^2\dot{x}$ , which, multiplied by 5, gives  $15x^2\dot{x}$ . And, in the very same manner, the fluxion of  $ax^n$  will be  $nax^{n-1}\dot{x}$ .

Having thus explained the manner of determining the first fluxions of variable quantities, it remains to say something of second, third, &c. fluxions. We have already observed, that the second fluxion of a quantity is the fluxion of the first fluxion; and by the third fluxion is meant the fluxion of the second; the fourth, of the third; and so on. The fluxions, therefore, of every order are

only

only the measures of the velocities by which their respective flowing quantities, viz. the fluxions of the immediately preceding order, are generated. Hence it appears, that a second fluxion always shews the rate of the increase or decrease of the first fluxion; and that the third, fourth, &c. fluxions differ in nothing, except their order and notation, from first fluxions; and therefore are also determinable in the very same manner, by the rules already laid down: thus (by rule 4.) the (first) fluxion of  $x^3$  is  $3x^2\dot{x}$ : and if  $\dot{x}$  is supposed constant, that is, if the root  $x$  be generated with an equable or uniform velocity, the fluxion of  $3x^2\dot{x}$  (or  $3\dot{x}\times x^2$ ) again taken (by the same rule) will be  $3\dot{x}\times 2x\dot{x}$ , or  $6x\dot{x}^2$ ; which therefore is the second fluxion of  $x^3$ . Again, the third fluxion of  $x^3$ , or the fluxion of  $6x\dot{x}^2$ , is found to be  $6\dot{x}^3$ ; further than which we cannot go in this case, because the last fluxion,  $6\dot{x}^3$ , is here a constant quantity.

In the preceding example, the root  $x$  is supposed to be generated with an equable velocity: but if the velocity be an increasing or decreasing one, then  $\dot{x}$ , expressing the measure thereof, being variable, will also have its fluxion, which is denoted, as said above, by  $\ddot{x}$ ; and the fluxion of  $\dot{x}$  by  $\ddot{x}$ , and so on, with respect to the higher orders.

Here follow some examples, wherein the root  $x$  (or  $y$ ) is supposed to be generated with a variable velocity. Thus, the fluxion of  $x^3$  being  $3x^2\dot{x}$  (or  $3x^2\times\dot{x}$ ) the fluxion of  $3x^2\dot{x}$ , considered as a rectangle, will (by rule 3.) be found to be  $6x\dot{x}\times\dot{x}+3x^2\times\ddot{x}=6x\dot{x}^2+3x^2\ddot{x}$ ; which is the second fluxion of  $x^3$ . Moreover, from the fluxion last found, we shall in like manner get  $6\dot{x}\times\dot{x}^2+6x\dot{x}\times 2\dot{x}\ddot{x}+6x\dot{x}\times\ddot{x}+3x^2\times\ddot{\ddot{x}}$  (or  $6\dot{x}^3+18x\dot{x}\ddot{x}+3x^2\ddot{\ddot{x}}$ ) for the third fluxion of  $x^3$ . Thus also, if  $y=nx^{n-1}\dot{x}$ , then will  $\dot{y}=n(n-1)\times x^{n-2}\dot{x}^2+n\ddot{x}x^{n-1}$ ; and if  $\ddot{z}=\dot{x}\dot{y}$ , then will  $2\ddot{z}=\dot{x}\ddot{y}+\dot{y}\ddot{x}$ : and so of others.

The reader is here desired, once for all, to take particular notice, that the fluxions of all kinds and orders whatever, are contemporaneous, or such as may be generated together, with their respective velocities, in one and the same time.

*Inverse method of FLUXIONS*, or the manner of determining the fluents of given fluxions.

If what is already delivered, concerning the direct method, be duly considered, there will be no great difficulty in conceiving the reasons of the inverse method: though the difficulties that occur in this last part, upon another account, are indeed vastly great. It is an easy matter, or not impossible at most, to find the fluxion of any flowing quantity whatever; but, in the inverse method, the case is quite otherwise; for, as there is no method for deducing the fluent from the fluxion *a priori*, by a direct investigation; so it is impossible to lay down rules for any other forms of fluxions, than those particular ones that we know, from the direct method, belong to such kinds of flowing quantities: thus, for example, the fluent of  $2x\dot{x}$  is known to be  $x^2$ ; because, by the direct method, the fluxion of  $x^2$  is found to be  $2x\dot{x}$ : but the fluent of  $y\dot{x}$  is unknown, since no expression has been discovered that produces  $y\dot{x}$  for its fluxion. Be this as it will, the following rules are those used by the best mathematicians, for finding the fluents of given fluxions.

1. To find the fluent of any simple fluxion, you need only write the letters without the dots over them: thus, the fluent of  $\dot{x}$  is  $x$ , and that of  $a\dot{x}+b\dot{y}$ , is  $ax+by$ .

2. To assign the fluent of any power of a variable quantity, multiplied by the fluxion of the root; first divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased: for dividing the fluxion  $nx^{n-1}\dot{x}$  by  $\dot{x}$ , it becomes

$nx^{n-1}$ ; and adding 1 to the exponent  $(n-1)$  we have  $nx^n$ ; which, divided by

$n$ , gives  $x^n$ , the true fluent of  $nx^{n-1}\dot{x}$ . Hence, by the same rule, the fluent of  $3x^2\dot{x}$  will be  $=x^3$ ; that of  $2x^3\dot{x}=x^4$ ; that of  $y^{\frac{1}{2}}\dot{y}=\frac{2}{3}y^{\frac{3}{2}}$ ; that of

$ay^{\frac{5}{3}}\dot{y}=\frac{3ay^{\frac{8}{3}}}{8}$ ; and that of  $y^{\frac{m}{n}}\dot{y}=y^{\frac{m}{n}+1}$

$y^{\frac{m}{n}+1}=\frac{ny^{\frac{m}{n}+1}}{\frac{m}{n}+1}$ ; that of  $\frac{a\dot{x}}{x^n}$ , or

$a\dot{x}x^{-n}=\frac{ax^{1-n}}{1-n}$ ; that of  $\frac{a+z}{a+z}^3\times\dot{z}=\frac{(a+z)^4}{4}$ ; and that of  $\frac{a^m+z^m}{a^m+z^m}^n\times\dot{z}$

$$x^{m-1} \dot{x} = \frac{a^m + x^m}{m \times n + 1} \dot{x} + 1$$

In assigning the fluents of given fluxions, it ought to be considered, whether the flowing quantity, found as above, requires the addition or subtraction of some constant quantity, to render it complete: thus, for instance, the fluent of  $n x^{n-1} \dot{x}$  may be either represented by  $x^n$  or by  $x^n \pm a$ ; for  $a$  being a constant quantity, the fluxion of  $x^n \pm a$ , as well as of  $x^n$ , is  $n x^{n-1} \dot{x}$ .

Hence it appears, that the variable part of a fluent only can be assigned by the common method, the constant part being only assignable from the particular nature of the problem. Now to do this, the best way is to consider how much the variable part of the fluent, first found, differs from the truth, when the quantity which the whole fluent ought to express, is equal to nothing; then that difference, added to, or subtracted from, the said variable part, as occasion requires, will give the fluent truly corrected. To make this plainer by an example or two, let  $y = a + x^4$ . Here we first find

$$y = \frac{a + x^4}{4}; \text{ but when } y = 0, \text{ then}$$

$$\frac{a + x^4}{4} \text{ becomes } = \frac{a^4}{4}; \text{ since } x, \text{ by hy-}$$

pothesis, is then = 0: therefore  $\frac{a + x^4}{4}$

always exceeds  $y$  by  $\frac{a^4}{4}$ ; and so the flu-

$$\text{ent, properly corrected, will be } y = \frac{a + x^4 - a^4}{4} = a^3 x + \frac{3 a^2 x^2}{2} + a x^3 +$$

$$\frac{x^4}{4}. \text{ Again, let } y = a^m + x^m \dot{x} \times x^{m-1} \dot{x};$$

$$\text{here we first have } y = \frac{a^m + x^m}{m \times n + 1};$$

and making  $y = 0$ , the latter part of the

$$\text{equation becomes } \frac{a^m}{m \times n + 1} = \frac{a^{m+n+m}}{m \times n + 1};$$

whence the equation or fluent, properly

$$\text{corrected, is } y = \frac{a^m + x^m}{m \times n + 1} - \frac{a^{m+n+m}}{m \times n + 1}.$$

Hitherto  $x$  and  $y$  are both supposed equal to nothing, at the same time; which will

not always be the case: thus, for instance, though the sine and tangent of an arch are both equal to nothing, when the arch itself is so; yet the secant is then equal to the radius. It will therefore be proper to add some examples, wherein the value of  $y$  is equal to nothing, when that of  $x$  is equal to any given quantity  $a$ . Thus, let the equation  $y = x^2 \dot{x}$ , be proposed; whereof the fluent first found is  $y = \frac{x^3}{3}$ ; but when  $y$

$$= 0, \text{ then } \frac{x^3}{3} = \frac{a^3}{3}, \text{ by the hypothesis;}$$

$$\text{therefore the fluent, corrected, is } y = \frac{x^3 - a^3}{3}. \text{ Again, suppose } y = x^n \dot{x};$$

$$\text{then will } y = \frac{x^{n+1}}{n+1}; \text{ which, corrected,}$$

$$\text{becomes } y = \frac{a^{n+1} - x^{n+1}}{n+1}. \text{ And last-}$$

$$\text{ly, if } y = \frac{c^3 + b x^2}{3 b} \dot{x} \times x \dot{x}; \text{ then, first,}$$

$$y = \frac{c^3 + b x^2}{3 b}; \text{ therefore the fluent cor-}$$

$$\text{rected is } y = \frac{c^3 + b x^2}{3 b} - \frac{c^3 + b a^2}{3 b}.$$

3. To find the fluents of such fluxionary expressions as involve two or more variable quantities, substitute, instead of such fluxion, its respective flowing quantity; and, adding all the terms together, divide the sum by the number of terms, and the quotient will be the fluent. Thus,

$$\text{the fluent of } \dot{x}y + y\dot{x} = \frac{xy + xy}{2} = \frac{2xy}{2} =$$

$$xy; \text{ and the fluent of } \dot{x}yz + y\dot{x}z + \dot{y}zx = \frac{xyz + xyz + xyz}{3} = \frac{3xyz}{3} = xyz.$$

But it seldom happens that these kinds of fluxions, which involve two variable quantities in one term, and yet admit of known and perfect fluents, are to be met with in practice.

Having thus shewn the manner of finding such fluents as can be truly exhibited in algebraic terms, it remains now to say something with regard to those other forms of expressions involving one variable quantity only; which yet are so affected by compound divisors and radical quantities, that their fluents cannot be accurately determined by any method whatsoever. The only method with regard to these, of which there are innumerable kinds, is to find their fluents by approximation, which,

which, by the method of infinite series, may be done to any degree of exactness. See the article *SERIES*.

Thus, if it were proposed to find the fluent of  $\frac{ax}{a-x}$ , it becomes necessary to throw

the fluxion into an infinite series, by dividing  $ax$  by  $a-x$ : thus,  $ax \div a-x = x + \frac{x^2}{a} + \frac{x^3}{a^2} + \frac{x^4}{a^3} + \frac{x^5}{a^4} + \dots$ , &c.

Now the fluent of each term of this series, may be found by the foregoing rules to be  $x + \frac{x^2}{2a} + \frac{x^3}{3a^2} + \frac{x^4}{4a^3} + \frac{x^5}{5a^4} + \dots$ , &c.

Again, to approximate the fluent of  $\frac{a^2-x^2}{c^2-x^2} \times x^n$ , we first find the value of  $\frac{a^2-x^2}{c^2-x^2}$  expressed in a series to be

$\frac{a}{c} + \frac{a}{2c^3} - \frac{1}{2ac} \times x^2 + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times x^4 + \frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times x^6 + \dots$ , &c. which value being multiplied by  $x^n$ , and the fluent taken by the

rules above laid down, we get  $\frac{ax^{n+1}}{n+1 \times c} +$

$\frac{a}{2c^3} \times \frac{x^{n+3}}{n+3} + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times \frac{x^{n+5}}{n+5} + \frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times \frac{x^{n+7}}{n+7} + \dots$ , &c.

In order to shew the usefulness of fluxions, we shall give an example or two. Thus, suppose it were required to divide the given right line *AB* into two such parts,

*AC*, *CB*, that their products or rectangles, may be the greatest possible. Let *AB* = *a*, and let the part *AC*, considered as variable (by the motion of *C* towards *B*) be denoted by *x*. Then *BC* being = *a* - *x*, we have *AC* × *BC* = *ax* - *xx*, whose fluxion  $ax - 2xx$  being put = 0, we get  $ax = 2xx$ ; and, consequently,  $x = \frac{1}{2}a$ . Hence it appears that *AC* (or *x*) must be exactly one half of *AB*.

Again, suppose it were required to find the solid contents of a spheroid, *AFBH* (plate *XCVIII.* fig. 6. n<sup>o</sup> 3.) Let the axis *AB*, about which the solid is generated, be = *a*, the radius = *p* = 1, and the other axis *FH* of the generating ellipsis = *b*; then, from the property of the ellipsis, we have  $a^2 : b^2 :: AD \times BD$  ( $x \times a - x$ ) :  $DE^2$  ( $y^2$ ). Hence  $y^2 = \frac{b^2}{a^2} \times ax - xx$ ; and the fluxion of the

solid  $\dot{s} (= py^2 \dot{x}) = \frac{pb^2}{a^2} \times ax\dot{x} - x^2\dot{x}$ ;

and the solidity  $s = \frac{pb^2}{a^2} \times \frac{1}{2} axx - \frac{1}{3} x^3$

= the segment *AIE*; which, when *AD* (*x*) = *AB* (*a*), becomes  $\left( \frac{pb^2}{a^2} \times \frac{1}{2} a^3 - \frac{1}{3} a^3 \right)$

$\frac{1}{8} pab^2$  = the content of the whole spheroid. Where, if *b* (*FH*) be taken = *a* (*AB*), we shall also get  $\frac{1}{8} pa^3$  for the true content of the sphere, whose diameter is *a*. Hence a sphere or spheroid is  $\frac{2}{3}$  of its circumscribing cylinder: for the area of the circle *FH* being expressed by  $\frac{pb^2}{4}$ , the content of the cylinder whose

diameter is *FH*, and altitude *AB*, will be  $\frac{pb^2a}{4}$ ; of which  $\frac{1}{8} pab^2$  is evidently two third parts.

For the other uses of fluxions, see the articles *MAXIMIS & minimis*, *QUADRATURE*, *TANGENTS*, *SOLIDS*, &c.

*FLUXION*, or rather *DEFLUXION*, in medicine. See the article *DEFLUXION*.

*FLY*, in zoology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent; by this they are distinguished from beetles, butterflies, and grasshoppers. See the articles *BETTER*, *BUTTERFLY*, &c.

Flies are subdivided into those which have four, and those which have two wings.

Of those with four wings, there are several genera or kinds, as the ant, apis, tenthredo, ichneumon, &c. See the articles *ANT*, *APIS*, &c.

Of those with two wings, there are likewise several kinds, as the gad-fly, wasp-fly, gnat, tipula, &c. See the article *GAD FLY*, &c.

Those who desire a more particular account of the anatomy, generation, structure, and manifold subdivisions of flies, may consult *Reaumur's History of Insects*, tom. 4.

FLY,

**FLY**, in mechanics, a cross with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which the force of the power, whatever it be, is not only preserved, but equally distributed in all parts of the revolution of the machine.

The fly may be applied to several sorts of engines, whether moved by men, horses, wind, or water, or any other animate or inanimate power; and is of great use in those parts of an engine which have a quick circular motion, and where the power or the resistance act unequally in the different parts of a revolution. This has made some people imagine, that the fly adds a new power; but tho' it may be truly said to facilitate the motion, by making it more uniform, yet upon the whole it causes a loss of power, and not an increase: for as the fly has no motion of its own, it certainly requires a constant force to keep it in motion; not to mention the friction of the pivots of the axis, and the resistance of the air. The reason, therefore, why the fly becomes useful in many engines, is not that it adds a new force to them; but because, in cases where the power acts unequally, it serves as a moderator to make the motion of revolution almost every where equal: for as the fly has accumulated in itself a great degree of power, which it equally and gradually exerts, and as equally and gradually receives, it makes the motion in all parts of the revolution pretty nearly equal and uniform. The consequence of this is, that the engine becomes more easy and convenient to be acted and moved by the impelling force; and this is the only benefit obtained by the fly.

The best form for a fly, is that of a heavy wheel or circle, of a fit size, as this will not only meet with less resistance from the air, but being continuous, and the weight every where equally distributed through the perimeter of the wheel, the motion will be more easy, uniform, and regular. In this form, the fly is most aptly applied to the perpendicular drill, which it likewise serves to keep upright by its centrifugal force: also to a windlass or common winch, where the motion is quick; for in pulling upwards from the lower part, a person can exercise more power than in thrusting forward in the upper quarter; where, of course, part of his force would be lost, were it not ac-

cumulated and conserved in the equable motion of the fly. Hence, by this means, a man may work all day in drawing up a weight of 40 lb. whereas 30 lb. would create him more labour in a day without the fly.

In order to calculate the force of the fly joined to the screw for stamping the image upon coins, let us suppose the two arms of the fly to be each fifteen inches long, measuring from the center of the weight to the axis of motion, the weights to be fifty pounds each, and the diameter of the axis pressing upon the dye, to be one inch. If every stroke be made in half a second, and the weights describe an half circumference, which in this case will be four feet, the velocity will at the instant of the stroke be at the rate of eight feet in a second, so that the momentum of it will be 800; but the arms of the fly being as levers, each fifteen inches long, whilst the semi-axis is only half an inch, we must increase this force thirty times, which will give 24,000; an immense force, equal to 100 lb. falling 120 feet, or near two seconds in time; or to a body of 750 lb. falling 16  $\frac{1}{2}$  feet, or one second in time. Some of the engines for coining crown-pieces have the arms of the fly five times as long, and the weights twice as heavy; so that the effect is ten times greater. See COINING.

**FLY**, in the sea-language, that part of the mariner's compass, on which the several winds or points are drawn. See the article COMPASS.

*Let fly the sheet*, is a word of command to let loose the sheet, in case of a gust of wind, lest the ship should overset, or spend her top-sails and masts; which is prevented by letting the sheet go a-main, that it may hold no wind.

**FLY**, among sportsmen. When a hawk missing her quarry, betakes herself to the next check, as crows, &c. they say she *flies on head*. When a hawk flies at great birds, as cranes, geese, &c. they say she *flies gross*. A horse is said to fly the heels, when he obeys the spurs.

**FLY-BOAT**, a large vessel with a double prow, carrying from seven to eight hundred weight of goods.

**FLYERS**, in architecture, such stairs as go straight, and do not wind round; nor have the steps made tapering, but the fore and back part of each stair, and the ends, respectively parallel to one another; so that if one flight do not carry you to your intended height, there is a broad

half-space, from whence you begin to fly again, with steps every where of the same length and breadth, as before.

**FLYING**, the progressive motion of a bird, or other winged animal, in the liquid air. The parts of birds chiefly concerned in flying, are the wings, by which they are sustained or wafted along. The tail, Messieurs Willughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air; and to obviate the vacillations of the body and wings: for, as to turning to this or that side, it is performed by the wings, and inclinations of the body, and but very little by the help of the tail. The flying of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards: nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and preserves the same situation what way soever the bird turns.

In effect, as a vessel is turned about on its center of gravity to the right, by a brisk application of the oars to the left, so a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons, changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclinations of their head and neck, which altering the course of gravity, the bird will proceed in a new direction.

*The manner of FLYING* is thus: the bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings, with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those succussions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently

the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces come to be in equilibrio, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes, makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

*Artificial FLYING*, that attempted by men, by the assistance of mechanics.

The art of flying has been attempted by several persons in all ages. The Leucadians, out of superstition, are reported to have had a custom of precipitating a man from a high cliff into the sea, first fixing feathers, variously expanded, round his body, in order to break his fall. Frier Bacon, who lived near five hundred years ago, not only affirms the art of flying possible, but assures us, that he himself knew how to make an engine wherein a man sitting might be able to convey himself through the air, like a bird; and further adds, that there was then one who had tried it with success: but this method, which consisted of a couple of large, thin, hollow copper globes, exhausted of the air, and sustaining a person who sat thereon, Dr. Hook shews to be impracticable. The philosophers of king Charles the second's reign, were mightily busied about this art. The famous bishop Wilkins was so confident of success in it, that he says, he does not question but, in future ages, it will be as usual to hear a man call for his wings, when he is going a journey, as it is now to call for his boots.

**FLYING-ARMY**, a small body under a lieutenant or major general, sent to harass the country, intercept convoys, prevent the enemy's incursions, cover its own garrisons, and keep the enemy in continual alarm.

**FLYING-BRIDGE**. See the article **BRIDGE**.

**FLYING-CAMP**. See the article **CAMP**.

**FLYING-FISH**, a name given by the english writers

writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of water a long time. See EXOCOETUS, MILVUS, MUGIL-ALATUS, &c.

**FLYING-PINION**, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part. See the article CLOCK.

**FOAL**, or **COLT**, the young of the horse kind. The word colt among the dealers, is understood of the male kind.

Foals are usually foaled about the beginning of summer, and it is the custom to let them run till Michaelmas with the mare, at which time they are to be weaned. Some, however, are of opinion, that a foal is rendered much sooner fit for service by being allowed to suck the whole winter, and weaned about Candlemas or Shrovetide. When first weaned, they must be kept in a convenient house, with a low rack and manger for hay and oats; the hay must be very sweet and fine, especially at first, and a little wheat bran should be mixed with their oats, in order to keep their bodies open, and make them eat and drink freely.

When foals are kept up in the winter, they are not continually to be immured in the stable; but in the middle of the day, when the sun shines warm, they should always be allowed to play about for an hour or two, and when the winter is spent, they should be turned into some dry ground where the grass is sweet and short, and where there is good water, that they may drink at pleasure. The winter after this, they may be kept in the stable without any further care than that which is taken of other horses; but after the first year, the mare foals and horse foals are not to be kept together.

There is no difficulty to know the shape a foal is like to be of; for the same shape he carries at a month, he will carry at six years old, if he be not abused in after keeping. As for his height, it is observed that a large thin bone, long from the knee to the pastern, shews a tall horse; for which another way is to see what space he has between his knee and his withers, which being doubled, it will be his height when he is a full aged horse. There are also means of knowing their goodness; for if they are of stirring spirits, free from frights, wanton of disposition, and very active in leaping and running, and striving for mastery, they

prove generally good mettled horses. It is a good mark also if their hoofs be strong, deep, tough, smooth, upright standing, and hollow. For the manner of breaking them, see the article HORSE.

**FOCAGE**, the same with fire-bote. See the article FIRE-BOTE.

**FOCHEN**, a town of China, capital of the province of Fokien: east long.  $118^{\circ}$ , north lat.  $26^{\circ} 26'$ .

**FOCUS**, in geometry and conic sections, is applied to certain points in the parabola, ellipsis, and hyperbola, where the rays reflected from all parts of these curves concur and meet.

**FOCI of an ellipsis**, are two points in the longest axis, on which as centers the figure is described. See ELLIPSIS.

If from the foci two right lines are drawn, meeting one another in the periphery of the ellipsis, their sum will be always equal to the longest axis; and therefore when an ellipsis and its two axes are given, and the foci are required, you need only take half the longest axis in your compasses, and setting one foot in the end of the shorter, the other foot will cut the longer in the focus required.

**Focus of an hyperbola**, is that point in the axis, through which the latus rectum passes; from whence if any two right lines are drawn meeting in either of the opposite hyperbolas, their difference will be equal to the principal axis. See the article HYPERBOLA.

**Focus of a parabola**, a point in the axis within the figure, distant from the vertex one fourth part of the latus rectum. See the article PARABOLA.

**FOCUS**, in optics, is the point wherein rays are collected, after they have undergone reflection or refraction. See the articles MIRROR and LENS.

**Principal FOCI of a lens**, are the two foci  $F, f$ , (plate CI. fig. 1. n<sup>o</sup> 1.) of rays coming parallel to the axis of the lens, and  $EF$  or  $Ef$  is called its focal distance, and by authors its focal length.

It appears from the laws of optics, as well as from experiments, that the focal distance of a plano-convex, or of a plano-concave glass, is equal to a diameter of its convex or concave surfaces; that is, of the whole sphere it belongs to: secondly, that the focal distance of a double convex or a double concave glass of equal convexities or concavities, is equal to a semi-diameter of either of its surfaces: and consequently that the focal distance of a glass of unequal convexities or un-

equal concavities, will have an intermediate length between a diameter and a semi-diameter of that surface which is most convex or most concave.

*Virtual Focus*, a term used by Mr. Molyneux for that point from which refracted rays begin to diverge. It is also called point of dispersion or divergency.

It is remarkable, 1. That in concave glasses, when a ray falls from air parallel to the axis, the virtual focus by its first refraction, is at the distance of a diameter and a half of the concavity. 2. In plano-concave glasses, when the rays fall parallel to the axis, the virtual focus is distant from the glass the diameter of the concavity. 3. In plano-concave glasses, as 107 to 193, so is the radius of the concavity to the distance of the virtual focus. 4. In double concaves of the same sphere, parallel rays have their virtual focus at the distance of the radius of the concavity. 5. But whether the concavities be equal or unequal, the virtual focus or point of divergency of the parallel rays is determined by this rule. As the sum of the radii of both concavities is to the radius of either concavity, :: so is the double radius of the other concavity : to the distance of the virtual focus. 6. In concave glasses, if the point to which the incident ray converges be distant from the glass farther than the virtual focus of parallel rays, the rule for finding the virtual focus of this ray is this. As the difference of the distance

between this point from the glass, and the distance of the virtual focus from the glass : is to the distance of the virtual focus :: so is the distance of this point of convergence from the glass : to the distance of the virtual focus of this converging ray. 7. In concave glasses, if the point to which the incident ray converges be nigher to the glass than the virtual focus of parallel rays, the rule to find where it crosses the axis is this. As the excess of the virtual focus more than this point of convergence : is to the virtual focus :: so is the distance of this point of convergence from the glass : to the distance of the point where this ray crosses the axis.

*The Focus of incident rays upon a lens being given, to find the Focus of the emergent rays.* Let  $Q$  (*ibid.* n<sup>o</sup> 2.) be the focus of incident rays given, and  $q$  the focus of emergent rays required; draw  $QE$  the axis of the pencil, and with the center  $E$  and semidiameter  $EF$ , equal to the focal distance of the lens, describe an

arch  $FG$ , cutting any incident ray  $QA$  in  $G$ ; join  $EG$ , and drawing  $Aq$  parallel to it, the point  $q$ , where it cuts the axis of the pencil, will be the focus of the emergent rays. For supposing other rays, besides  $GA$ , to flow from or towards  $G$ , they will emerge parallel to their axis  $GE$  produced.

*The Focus of rays falling almost perpendicularly upon a given spherical surface being given, to find their focus after refractions.* Let  $OI$  (*ibid.* n<sup>o</sup> 3.) be the given surface, whose center is  $S$ ; and in any radius  $OS$  produced, let  $Q$  be the given focus of the incident rays as  $QI$ , it is required to find the focus  $q$  of the refracted rays. Call  $OS$ ,  $OQ$ ,  $Oq$  respectively  $S$ ,  $Q$ ,  $q$ ; and let the given ratio of the sines of refraction be  $m$  to  $n$ , and let  $m$  be bigger than  $n$ . Then joining  $SI$ , since very small angles are very nearly proportionable to their sines, we have the angle  $OSI$  : to the angle  $SIQ$  ::  $Q$  :  $Q - S$ , and the angle  $SIQ$  : to the angle  $SIq$  ::  $m$  :  $n$ . And by compounding these proportions we have the angle  $OSI$  : to the angle  $SIq$  ::  $mQ$  :  $nQ - nS$ , and disjointly we have the angle  $OSI$  : to the angle  $SqI$ , that is  $q$  :  $S$  ::  $mQ$  :  $m - nQ + nS$ . Whence, putting  $\theta = m - n$ , we have this theorem,  $q =$

$$\frac{mQS}{\theta Q + nS} = \frac{\frac{m}{\theta}SQ}{Q + \frac{n}{\theta}S}. \text{ This is the value}$$

of  $q$  in the given case, where the lines  $OQ$ ,  $OS$ ,  $Oq$  lie all on the same side of the surface  $OI$ ; and thence the theorem for  $q$  may be easily adapted to any other given case, by considering  $OQ$  as being always affirmative, and by changing the sign of  $S$  when  $OS$  and  $OQ$  lie on contrary sides of their origin  $O$ ; and by changing the sign of  $\theta$ , when the sine of incidence is less than the sine of refraction; and, lastly, by placing  $Oq$  the contrary way to  $OQ$ , when the value of  $q$  comes out negative by the theorem so changed.

*Theorem for reflected rays.* Substitute  $-m$  in the preceding theorem for  $n$ , and consequently  $2m$  for  $\theta$ , and we have  $q = \frac{\frac{1}{2}SQ}{Q - \frac{1}{2}S}$ ; which theorem gives the focus of rays reflected from the spherical surface  $OI$ . For the calculation continues the same, whether the rays go forwards or backwards in the line  $Iq$ ; and to change the angle of refraction  $SIq$  (*ibid.* n<sup>o</sup> 3.)

n° 3.) into an angle of reflection, it and its sine  $n$  must be diminished to nothing, and then become negative and equal to  $-m$ , the sine of the angle of incidence *SIQ* (*ibid.* n° 4.)

*Having the Focus of rays falling almost perpendicularly upon a given lens, to find their focus after refractions.* Let *OIEo* (*ibid.* n° 5.) be the given lens, whose vertex's are *O* and *o*; *R* the center of the first surface *OI*; *r* the center of the second *oE*; *P* the given focus of incident rays in the axis *oOrR*; and *p* the focus of the emergent rays required. Let  $\omega$  be their focus after the first refraction at the surface *OI*, and  $m$  to  $n$  the ratio of the sines as above, and call *Oo*, *or*, *OR*, *OP*, *op*, respectively  $a$ ,  $r$ , *R*, *P*,  $p$ . Then for  $Q$ ,  $S$ ,  $m$ ,  $n$ ,  $\theta$  in the foregoing theorem, write *P*, *R*,  $m$ ,  $n$ ,  $\theta$ ; and we have

$$O\omega = \frac{mPR}{\theta P + nR}; \text{ to which adding } Oo,$$

$$\text{or } o, \text{ we have } o\omega \text{ or } \omega = \frac{mPR + \theta Po + nRo}{\theta P + nR}$$

Again, for  $Q$ ,  $S$ ,  $m$ ,  $n$ ,  $\theta$  in the foregoing theorem, write  $\omega$ ,  $r$ ,  $n$ ,  $m$ ,  $-\theta$ ; and

$$\text{we have } p = \frac{nr\omega}{-\theta\omega + nr}; \text{ in which by}$$

$$\text{substituting the value of } \omega, \text{ we have } p = \frac{m\theta P r - m\theta P R + m n R r - \theta\theta P o - n\theta R o}{m n P R r + n\theta P r o + n n R r o}$$

This theorem for a miniscus lens, having its concave surface exposed to *P*, is easily adapted to a lens of any given form, by conceiving one or both its semi-diameters *OR*, *or*, to decrease or increase, or to become infinite and then negative, till the miniscus acquires the form of the given lens; and by changing the sign of *R* or *r*, when the semi-diameters lie on opposite sides of their surfaces *O*, *o*, to the focus *P*; and, lastly, by placing *p* on the opposite side of *o* to *P*, when its value in the theorem so changed comes out negative. Thus by writing  $\infty$  (which denotes infinite) for *R*, this theorem is easily adapted to a plano-convex lens, having its first surface plane; and by writing  $-R$  for *R*, it is adapted to a double convex lens; and by writing  $-R$  for *R*, and  $\infty$  for *r*, it is adapted to a plano-convex lens whose first surface is convex; and by writing  $-R$  for *R*, and  $-r$  for *r*, and  $o+r$  for *R*, it is adapted to a lens of concentric surfaces, whose first surface is convex; and by writing  $R+o$  for *r*, it is adapted to a lens of concentric surfaces whose first surface is concave; and by writing  $\infty$  for *r*, it is adapted to a plano-

concave lens, whose first surface is concave; and by writing  $-r$  for *r*, it is adapted to a double concave; and by writing  $\infty$  for *R*, and  $-r$  for *r*, it is adapted to a plano-concave whose first surface is plane; and, lastly, it is adapted to a sphere whose semi-diameter is *R* and diameter *Oo*, by writing  $-R$  for *R*, and *R* for *r*, and  $2R$  for *o*; and by substituting given numbers for the ratio of refraction, the bigger for  $m$ , and the lesser for  $n$ , it is adapted to lens's of any given substances.

Before the discovery of the law of refraction, according to the given ratio of the sines of incidence and refraction of any given magnitudes, opticians could only consider the refractions of such rays as fell almost perpendicularly upon the refracting surfaces, where the angles of incidence and refraction being but small, were known by experience to be nearly in a given ratio to each other, and these rays they found would all belong to one focus pretty nearly. But Dr. Barrow observing that the several small portions of a large pencil of rays flowing from a given focus, would diverge after refraction or reflection from several different foci, according as they fell with different obliquities upon the several parts of a spherical surface, and being of opinion that the eye receiving a certain small portion of these rays, would judge the object to appear in the place from which they diverged, and consequently to appear in different places according as the eye received a different portion, took occasion from thence to determine these places geometrically by means of the law of refraction, then newly discovered; and consequently to handle the subject of dioptrics and catoptrics, in a more extensive manner than any writer had then done. The foci of rays obliquely refracted and reflected, have also been touched upon by Sir Isaac Newton in his optical lectures, in order to determine the diameters and breadths of the rainbows, and to make way for his admirable theorems concerning the separations of heterogeneous rays. The reader, therefore, desirous of being fully instructed in the determinations of the foci of rays falling with any degrees of obliquity upon any number of reflecting and refracting surfaces of any sort, may consult the above-mentioned writers, as also Dr. Smith's optics, book 2. ch. 9. and the remarks on that chapter, where the chief discoveries of Sir Isaac and Dr.

Barrow are not only comprehended, but made much more general, by shewing that the relation of the focus's of incident and emergent rays, to the focus's of parallel rays coming contrary ways is always the same, after any number of oblique refractions or reflections, as when a pencil of rays is but once refracted or reflected at the vertex of a single surface.

**FODDER**, any kind of meat for horses, or other cattle. In some places, hay and straw, mingled together, is peculiarly denominated fodder.

**FODDER**, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

**FODDER**, in mining, a measure containing twenty-two hundred and an half weight, though in London but twenty hundred weight.

**FODINA**, in anatomy, the labyrinth of the ear. See the article **EAR**.

**FOECES** and **FOECULA**. See the articles **FÆCES** and **FÆCULA**.

**FOECIALES**, or **FECIALES**, in roman antiquity. See the article **FECIALES**.

**FOECUNDITY**, or **FECUNDITY**, the same with fertility. See **FERTILITY**.

**FOENICULUM**, *fennel*, in botany, agrees in characters with anethum or dill. See the articles **DILL** and **FENNEL**.

**FOENUGREEK**, *fenum graecum*, in botany, is called by Linnæus *trigonella*. See the article **TRIGONELLA**.

The figure of foenugreek-feed is singular, being irregularly rhomboidal, considerably thick, with a line or depression running obliquely from one of the opposite angles to the other. It is of a pale-yellowish colour, and of an extremely tough and firm texture. It is of a strong and agreeable smell, and of a faint nauseous taste. We have it from Germany.

Fœnugreek is used externally on many occasions by way of cataplasm or fomentation; being emollient and discutient in a great degree, and found to give great relief in pains, bruises, &c. It is sometimes also an ingredient in emollient clysters, where anodynes and carminatives are required, without too much pungency. It is also an ingredient in the ointment of marsh-mallows, and some other shop-compositions; but is never given internally.

**FOETOR**, in medicine, stinking or foetid effluvia, arising from the body, or any part thereof.

**FOETOR NARIUM**, a foetid stench of the nostrils, arising from a deep ulcer within the nose, the cause of which, according to Galen, is a sharp humour falling from the brain upon the mamillary processes. See the article **ULCER**.

This is one of the causes for which marriage might, in former times, be annulled.

**FOETOR ORIS**, a term used by medical writers to express that bad smell in the mouth, usually, tho' often improperly, called a stinking breath.

This is a malady arising in different cases from very different causes, as from the scurvy, and particularly from that species of it which affects the mouth, and is therefore called stomocace; from the french pox; from an ulceration, whether simple or fistulous, in the lungs, which is the case in consumptions; from ulcers in the mouth; from a caries or rottenness of the teeth, or from any other impurity of them; from crudities in the stomach, arising from a bad digestion; and particularly from a weakness about the left orifice of the stomach, from which part of the foetid vapour will often arise in very great abundance.

According to the different causes of this disorder, it requires a very different method of cure; in cases where it depends on the scurvy, pox, or other diseases, then those diseases are to be attacked by the proper medicines. See **SCURVY**, **POX**, &c.

When it arises from a carious tooth, there is no other cure for it but drawing the tooth. When the impurities of the teeth occasion it, the cleaning them proves a cure.

**FOETUS**, in physiology, denotes the child while it is contained in the mother's womb, but particularly after it is formed, till which time it is more properly called embryo. See the article **GENERATION**.

*Formation of a FOETUS*. The formation of the bones in a foetus, is very gradual and regularly performed. In the first two months, there is nothing of a bony nature in the whole. After this, the hardness of the parts, where the principal bones are to be situated, becomes, by degrees, perceptible. Dr. Keiskring describes the progress of the ossification from skeletons, which he had prepared from foetuses of two months, and thence up to nine. In the first two months, or to the end of that time, there appears not any thing bony. After this, in the third and

fourth

fourth months, the several parts, one after another, acquire their bony nature. In the first stages, every thing is membranous, where the bones are to be: these, by degrees, transigrate into cartilages, and from these, by the same sort of change continued, the bones themselves are by degrees formed. All this is done by nature, by such slow, though such certain progressions, that the nicest eye can never see it doing, though it easily sees it when done.

Fœtuses increase proportionably less, the longer they continue in the womb. Mauriceau pretends, that the increase of a fœtus is sixty-four times its own weight in triple the time. Thus, he says, that, at the birth, a child weighs twelve pounds, of sixteen ounces each; at the three months, it weighs three ounces; at one month,  $\frac{3}{8}$  of a drachm; and at ten days, less than half a grain.

*Anatomy of a Fœtus.* In the examination of the fœtus intire, we first observe the membranes surrounding it in the uterus, as in an egg, the exterior of these is the chorion; the interior, or second membrane, is the amnios; and a third, tho' its existence is disputed in human subjects, is the allantois. See the articles CHORION, AMNIOS, and ALLANTOIS.

After the membranes including the fœtus, we are next to examine the placenta, the number of which, in human subjects, answers to that of the fœtuses. See the article PLACENTA.

After the placenta, we are to observe the umbilical vessels of the fœtus, which, after the birth, degenerates into ligaments. See UMBILICAL and ARTERY.

Another part belonging to the umbilical vessels observable in the human fœtus, is the funiculus umbilicalis, or navel-string. See the article NAVEL-STRING.

The more essential differences between the human fœtus and an adult, considering the fœtus not only as yet enclosed within the womb, but as newly come from it, are as follows.

In the abdomen, the umbilical vein and arteries of the navel, and the canalis vefosus in the liver, are in the fœtus open and pervious; in adults, they are contracted and solid. The liver is very large, the stomach is filled with a glutinous fluid, and the larger intestines, and often the ilium also, with the fœces called meconium. The renes succenturiati, are larger in the fœtus than in adults. The kidneys themselves are not smooth and

even on the surface, as in adults, but unequal, and in some measure resembling those of a calf. The urinary bladder is of a longer shape, and extends almost to the navel. The hymen in a female fœtus, is very plain and obvious. In the thorax, besides a peculiar fluid, found as well in this cavity as in the abdomen, the gland thymus is larger than it is in adults. The lungs, as they have never yet been inflated by breathing, are collapsed, and of a blackish colour; and if thrown into water they sink in it, contrary to what is the case in those in adults. In the heart, the foramen ovale between the left and right auricle, and the canalis arteriosus, between the pulmonary artery and the aorta, are open, to serve for a peculiar circulation in the fœtus, which has not yet breathed; and there is in the inferior trunk of the vena cava, near the heart, a remarkable valve, called by Cheselden in his anatomy, *valvula nobilis*. See the article VALVE.

In the head, besides its great size in proportion to the body, we are to observe, that the ossa cranii are in several places distant from one another, especially at the fontanella; and that the sutures are wanting. The brain also is softer than in adults. The teeth are also imperfect, and not rooted in the gums; they lie hid or buried under the gums, to appear at a more advanced period. The meatus auditorius is not yet perfect in them; and in the fœtus, whilst it is in the womb, is entirely closed up by a peculiar membrane, which is continuous with the epidermis, and which naturally disappears after delivery. The bones of the whole body, excepting only a very few, are either soft or yet absolutely imperfect: some of them are merely cartilaginous, and the articulations are not at that time perfected.

*Situation of the Fœtus in the womb.*

This, in the first months, and even in the middle ones, is perfectly uncertain; but in the latter months, it is more regular; in these it is usually in a posture like that of sitting, and its head and neck are bent downwards; its knees are raised up towards its cheeks; and its heels drawn up to its buttocks. Its hands are usually hanging down, and embrace the feet. A little time before the delivery, it usually changes its position, in such a manner, that its head falls towards the mouth of the womb, and its buttocks and feet are turned upwards. Frequently, however,

it varies during the whole time of the pregnancy from the common rule, and at the very instant of the delivery, its head does not present itself, but is turned to one side, or to some other part of the womb.

For the exclusion of the foetus from the uterus, see the article DELIVERY.

*Nutrition of the FOETUS.* How the nutrition of the foetus is performed, is disputed among the learned. Heister is of opinion, that the nutrition of the foetus, during the first months, while the organs of concoction is not yet formed, is probably effected by means of the navel-string alone. But in the more advanced state of the foetus, in the latter months, that great anatomist supposes, that it is also nourished by the mouth, by means of a soft and somewhat glutinous fluid that surrounds it, and which is probably secreted from the amnios. In support of this opinion he observes, 1. That a fluid similar to that of the amnios, is found in the mouth, the œsophagus, and the stomach, not only of the human foetus, but in that of quadrupeds. 2. That this fluid is also found in the small guts of the foetus, but altered and digested. 3. That there are also found in the larger intestines real fæces, called meconium: sometimes the whole ilium is full of these. 4. That in the first months, there is a great quantity of this fluid surrounding the foetus; but in the latter months, there is but very little of it, and the consumption of it is not easily accounted for any other way, than by its being swallowed by the foetus. 5. That the liquid itself is so extremely proper for the nutrition of the foetus, that a more fit one could not have been formed or desired. 6. That it seems to be continually pressed into the mouth, œsophagus, and stomach of the foetus, by the perpetual renitency of the uterus itself, and by the pressure of the muscles of the abdomen, and of the ambient air.

Mr. Gibson, in the Medical Essays of Edinburgh, has lately adopted this opinion as the most probable. Hippocrates, among the antients, was of opinion, that the foetus was nourished both by the mouth and by the umbilical vessels. He maintains, that the child, in the womb, with its lips compressed together, attracts nourishment; for which he assigns this reason, that, unless the child had sucked in utero, it neither could deposit excre-

ment, nor know how to suck so soon as it was born.

On the other hand, Dr. Monro, of Edinburgh, is of opinion, that the foetus in viviparous animals, is nourished by the navel alone. He has given a curious dissertation on this subject in the Medical Essays, where he observes, 1. That the foetus is capable of receiving its whole nourishment by the umbilical vein alone, whereas no foetus can subsist without the umbilical vessels. 2. That the liquor of the amnios is ill calculated in its natural state for the food of a foetus, and becomes altogether unfit food in morbid cases. 3. That it is highly improbable, that a creature should furnish its subsistence out of its own body, which must be the case, if the foetus feeds on the liquor of the amnios. 4. That it cannot be inferred from any resemblance of the liquor of the stomach and amnios, nor from any other appearances, that the liquor of the amnios is ever sent down into the stomach. 5. That no direct proof can be had of the liquor of the amnios being pressed or swallowed down, but, on the contrary, all circumstances make it probable, that it does not go down. 6. That all the phenomena of a foetus can most reasonably be accounted for, without supposing the liquor of the amnios to be any part of its food: hence he thinks it reasonable to exclude the mouth from the office of conveying the aliment of the foetuses of viviparous animals, and to believe that all their nourishment is conveyed by the vessels. See Medical Essays, vol. II. page 102, *seq.*

Dr. Monro has, in these essays, given several other curious observations relating to the question about the nutrition of foetuses of viviparous animals: he has also considered the nourishment of plants in a foetus-state, and shewn the analogy there is between these and the animal-foetuses. To fix the analogy between animals and plants, he observes that the former may be said to remain in the state of a foetus, so long as the young creature is solely nourished by liquors furnished by the uterus of the parent; and plants are to be considered as foetuses only, while the seed is ripening, and before the earth, water, moisture of the air, &c. have communicated immediately any matter for its increase. Medical Essays, vol. II. page 201. *seq.*

To the question, Whence foetuses have their

their red blood? Dr. Monro answers, that fœtuses in viviparous animals, have their red blood from the same source that chickens in the egg have theirs, which can be no other than the action of their heart, and of the vessels in their body and secundines.

While fœtuses continue in the womb, their muscles commonly act by their natural contraction, or the fœtus is said to be in a state of sleeping: but sometimes, when its ease or preservation requires a change of situation, it seems to perform some voluntary motions which are called stirrings. The human fœtus is generally supposed to be animated about the end of the sixth, or beginning of the seventh week after conception; though it is seldom felt to stir, till towards the middle of the time of gestation.

Respiration seems to be the great act by which the change is made in animals, from the state of fœtus, to that of motion, sensation, and the other qualities of animal life in their larger degree. Mr. Duverney observed this in the fœtus of a common snake: he broke the egg of one of these animals, at a time when it was just ready for hatching, and the young snake fell out, rolled in a spiral, at first quite stiff and motionless; but it had no sooner breathed three or four times, than it began to perform all the motions of animal life, in the most nimble and active manner. See the article **RESPIRATION**.

Hippocrates and some learned modern physicians suppose, that a fœtus respire in the womb; but it seems very difficult to conceive how air should traverse the body of the mother, and the teguments of the child; and since nature hath in new-born infants contrived peculiar temporary vessels, that the blood may circulate through other passages than it does in the same individuals, when they come to have the free use of their lungs, it is improbable that the fœtus in the womb should properly respire.

The symptoms of the human fœtus being dead in the womb, the reasons which may occasion it, the accidents which attend it, and the methods of preventing it, and remedying the consequences thereof, as also the various ways of expelling it, may be seen under the articles **ABORTION**, **CONCEPTION**, **DELIVERY**, &c.

For the circulation of the blood, as performed in the fœtus, see **CIRCULATION**.

**FOG**, or **MIST**, a meteor consisting of

gross vapours, floating near the surface of the earth.

Mists, according to lord Bacon, are imperfect condensations of the air, consisting of a large proportion of the air, and a small one of the aqueous vapour; and these happen in the winter, about the change of the weather, from frost to thaw, or from thaw to frost: but in the summer and the spring, from the expansion of the dew.

If the vapours, which are raised plentifully from the earth and waters, either by the solar or subterraneous heat, do, at their first entrance into the atmosphere, meet with cold enough to condense them to a considerable degree, their specific gravity is, by that means, increased; and so they will be stopped from ascending, and return back, either in form of dew, or drizzling rain; or remain suspended some time in the form of a fog. Vapours may be seen on the high grounds as well as the low, but more especially about marshy places: they are easily dissipated by the wind, as also by the heat of the sun: they continue longest in the lowest grounds, because these places contain most moisture, and are least exposed to the action of the wind.

Hence we may easily conceive, that fogs are only low clouds, or clouds in the lowest region of the air; as clouds are no other than fogs, raised on high. See **CLOUD**.

When fogs stink, then the vapours are mixt with sulphureous exhalations, which smell so. Objects viewed through fogs, appear larger and more remote than through the common air. Mr. Boyle observes, that upon the coast of Coromandel, and the most maritime parts of the East-Indies, there are, notwithstanding the heat of the climate, annual fogs so thick, as to occasion those of other nations who reside there, and even the more tender part of the natives, to keep their houses close shut up.

**FOGAGE**, in the forest law, is rank grass not eaten up in summer.

**FOGARES**, a town of Transilvania, thirty miles north-east of Hermanstadt.

**FOGO**, one of the Cape-Verd-islands, subject to Portugal.

**FOIL**, among glass-grinders, a sheet of tin, with quicksilver or the like, laid on the backside of a looking-glass, to make it reflect. See the articles **FOLIATING** and **LOOKING-GLASS**.

**FOIL**, among jewellers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give

it an agreeable different colour, either deep or pale : thus, if you want a stone to be of a pale colour, put a foil of that colour under it ; or if you would have it deep, lay a dark one under it.

These foils are made either of copper, gold, or gold and silver together : the copper foils are commonly known by the name of nuremberg or german foils ; they are prepared as follows : procure the thinest copper-plates you can get ; beat these plates gently upon a well polished anvil, with a polished hammer, as thin as possible ; and placing them between two iron-plates as thin as writing-paper, heat them in the fire ; then boil the foils, in a pipkin, with equal quantities of tartar and salt, constantly stirring them till by boiling they become white ; after which, taking them out, and drying them, give them another hammering, till they are made fit for your purpose : however, care must be taken not to give the foils too much heat, for fear of melting, nor must they be too long boiled, for fear of attracting too much salt.

The manner of polishing these foils is as follows : take a plate of the best copper, one foot long and about five or six inches wide, polished to the greatest perfection ; bend this to a long convex, fasten it upon a half roll, and fix it to a bench or table ; then take some chalk, washed as clean as possible, and sifted through a fine linnen-cloth, till it be as fine as you can make it ; and having laid some thereof on the roll, and wetted the copper all over, lay your foils upon it, and with a polishing stone and the chalk, polish your foils till they are as bright as a looking glass ; after which they must be dried, and laid up secure from dust.

**FOILING**, among huntsmen, the footing and treading of a deer, that is on the grass and scarce visible.

**FOLCLAND** and **FOLCMOTE**. See the articles **FOLKLAND** and **FOLKMOTE**.

**FOLD-NET**, among sportsmen, a sort of net with which small birds are taken in the night, of which there are two sorts ; the least may be managed by one man only, but the greatest must be carried by two, and used thus : let the net be fixed on both sides to two strong, straight, and light poles about twelve feet long, each man holding one of them ; let there be one behind them, at the distance of two yards, to carry lights : the nets must be carried between the wind and the birds, which all naturally roost on their perches with their

breasts against the wind ; by reason of this, he that beats the bushes on the other side of the hedge, will drive them out that way towards the light.

**FOLDAGE**, the liberty of penning sheep by night. See the article **FALDAGE**.

**FOLDING** of *sheep*. In some places they fet their fold with several partitions, and put the widders, ewes, and lambs separate by themselves. It is not good to fold them in rainy weather : and, as it is the opinion of some husbandmen that urine of sheep heats, helps, and comforts the land as much or rather more than their dung does, they cause all the sheep in the fold to be raised before they let them go out, and go about the sides of the fold with a dog ; for commonly when sheep see a dog come nigh them, they will dung and stale.

**FOLIA**, among botanists, particularly signify the leaves of plants ; those of flowers being expressed by the word petal. See the article **PETAL**.

**FOLIACEUM EXPANSUM**, in anatomy, a term applied to the extreme part of the fallopian tube, nex the ovary, which is expanded like the mouth of a trumpet, and surrounded with a sort of fringe. See the article **FALLOPIAN TUBE**.

**FOLIAGE**, a cluster or assemblage of flowers, leaves, branches, &c.

**FOLIAGE** is particularly used for the representations of such flowers, leaves, branches, rings, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

**FOLIATE**, in the higher geometry, a name given by Mr. de Moivre to a curve of the second order, expressed by the equation  $x^3 + y^3 = axy$  ; being a species of defective hyperbolas with one asymptote, and consisting of two infinite legs crossing one another, and forming a sort of leaf.

**FOLIATING** of *looking-glasses*, the spreading the plates over, after they are polished, with quicksilver, &c. in order to reflect the image. It is performed thus : a thin blotting paper is spread on the table, and sprinkled with fine chalk ; and then a fine lamina or leaf of tin, called foil, is laid over the paper ; upon this mercury is poured, which is to be distributed equally over the leaf with a hare's foot, or cotton : over this is laid a clean paper, and over that the glass-plate, which is pressed down with the right-hand, and the paper drawn gently out with the left : this being done, the plate is covered with a thicker paper, and loaded with a greater weight,

weight, that the superfluous mercury may be driven out, and the tin adhere more closely to the glass. When it is dried, the weight is removed, and the looking-glass is complete.

Some add an ounce of marcasite, melted by the fire; and, lest the mercury should evaporate in smoke, pour it into cold water; and when cooled, squeeze through a cloth, or through leather.

Some add a quarter of an ounce of tin and lead to the marcasite, that the glass may dry the sooner.

**FOLIATING of globe looking-glasses**, is done as follows: take five ounces of quicksilver, and one ounce of bismuth; of lead and tin, half an ounce each: first put the lead and tin into fusion, then put in the bismuth, and when you perceive that in fusion too, let it stand till it is almost cold, and pour the quicksilver into it: after this, take the glass-globe, which must be very clean, and the inside free from dust; make a paper-funnel, which put into the hole of the globe, as near to the glass as you can, so that the amalgam, when you pour it in, may not splash, and cause the glass to be full of spots; pour it in gently, and move it about, so that the amalgam may touch every where. If you find the amalgam begin to be curdly and fixed, then hold it over a gentle fire, and it will easily flow again. And if you find the amalgam too thin, add a little more lead, tin, and bismuth to it. The finer and clearer your globe is, the better will the looking-glass be.

Dr. Shaw observes, that this operation has considerable advantages, as being performable in the cold, and that it is not attended with the danger of poisonous fumes from arsenic, or other unwholesome matters, usually employed for this purpose: besides, how far it is applicable to the more commodious foliating of the common looking-glasses, and other speculums, he thinks, may deserve to be considered.

**FOLIATION**, a term used by some botanists to denote the corolla, or flower-leaves. See **FLOWER** and **COROLLA**.

**FOLIGNO**, or **FULIGNO**. See **FULIGNO**.

**FOLIO**, in merchants books, denotes a page, or rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See **BOOK**.

**FOLIO**, among printers and booksellers, the largest form of books, when each sheet is

so printed, that it may be bound up in two leaves only.

This form is only used in large works; and even, in these, the quarto or octavo forms are much more handy.

**FOLIUM**, **LEAF**, among botanists. See the article **LEAF**.

**FOLIUM INDICUM**, **INDIAN LEAF**, in the materia medica, is an oblong, smooth, and pointed leaf, of a grateful smell. They agree in virtues with spikenard, and are to be chosen fresh and greenish. They are the produce of a species of cinnamon. See the article **CINNAMON**.

**FOLIUM BRANCHIARUM**, among ichthyologists, the leaf of the gills. See **GILLS**.

**FOLKLAND**, in ancient law-writers, the same with copyhold. See **COPYHOLD**.

**FOLKMOTE**, or **FOLCMOTE**, according to Kennet, was the common-council of all the inhabitants of a city, town, or borough: though Spelman will have the folkmore to have been a sort of annual parliament or convention of the bishops, thanes, aldermen, and freemen on every May-day. Dr. Brady, on the contrary, tells us, that it was an inferior court, held before the king's reeve, or his steward, every month, to do folk right.

**FOLKSTONE**, a market-town of Kent, six miles west of Dover.

**FOLLICLE**, *folliculus*, among botanists, denotes a kind of seed-vessel, like the conceptaculum. See **CONCEPTACULUM**.

**FOLLICULUS FELLIS**, the **GALL-BLADDER**. See the article **GALL-BLADDER**.

**FOMAHANT**, in astronomy, a star of the first magnitude, in the constellation aquarius. See the article **AQUARIUS**.

**FOMENTATION**, in medicine, the bathing any part of the body with a convenient liquor; which is usually a decoction of herbs, water, wine, or milk; and the applying of bags stuffed with herbs and other ingredients, which is commonly called dry fomentation.

Fomentations differ in little else from embrocations, but that they are mostly made with aqueous menstrua, are more extensive in their manner of application, and are assisted by actual heat, and hot woollen cloths: add to this, that fomentations, when general, or applied to every part of the body, are called baths. See the article **BATH** and **EMBROCATION**.

According to some, a fomentation is only a liquid epitherm, applied hot. See the article **EPITHERM**.

Fomentations are to be looked on as partial bathings, applied only to a diseased

part, on which they have much the same effect as bathing has on the whole body. See the article BATHING.

FONCEAU, in the manege, the same with chaperon. See CHAPERON.

FONDI, a city and bishop's see of Naples, in the province of Lavoro, about thirty-five miles north-west of Capua: east long.  $14^{\circ} 20'$ , and north lat.  $41^{\circ} 35'$ .

FONT, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants, or other persons. It is so called probably because baptism was usually performed among the primitive christians at springs or fountains. In process of time the font came to be used, being placed at the lower end of the church, to intimate, perhaps, that baptism is the rite of admission into the christian church.

By the canons of the church of England, every church is to have a font made of stone; because, says Durandus, the water which typified baptism in the wilderness, flowed from a rock; or rather, because Christ is in scripture called the corner-stone, and the rock. See BAPTISM.

FONT, or FOUNT, among printers. See the article FOUNT.

FONTAINE, a town of Hainalt, fifteen miles east of Mons.

FONTAINEBLEAU, a village of the isle of France, about thirty miles south-east of Paris; remarkable for an elegant royal palace.

FONTANELLA, in anatomy, the quadrangular aperture, between the os frontis and ossa sincipitis, in infants just born, which is also called fons pufatilis.

FONTANELLA, in surgery, the same with fonticulus. See FONTICULUS.

FONTARABIA, a port-town of Spain, in the province of Biscay, twenty miles west of Bayonne: west lon.  $1^{\circ} 35'$ , and north lat.  $43^{\circ} 20'$ .

FONTENAYLE, a town of Orleans, in France, about forty-six miles west of Poitiers.

FONTENOY, a town of Hainalt, situated three miles south-east of Tournay.

FONTEVRAUD, or Order of FONTEVRAUD, a religious order instituted about the latter end of the XIth century. By the rules of this order the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

FONTICULUS, or FONTANELLA, in surgery, an issue, seton, or small ulcer made

in various parts of the body, in order to to eliminate the latent corruption out of it. See ISSUE, SETON, &c.

FONTALIALIA, in roman antiquity, a religious feast celebrated on October 13, in honour of the nymphs of wells and fountains. The ceremony consisted in throwing nosegays into the fountains, and putting crowns of flowers upon the wells. Scaliger, however, in his conjectures upon Varro, takes this not to have been a feast in honour of fountains in general, but of the fountain which had a temple at Rome, near the Porta Capena, called from thence Porta Fontinalis.

FONTALIS, in botany, a genus of the *cryptogamia* class of mosses; the male flower is almost sessile in the axæ of the leaves; the anthera is roundish, with an open mouth, and covered with calyptræ.

FOOD implies whatever aliments are taken into the body, to nourish it. See DIET, DRINK, ALIMENT, &c.

As the health of the human body evidently depends upon the quantity and quality of the blood and juices, it is plain that all those aliments which preserve and maintain a just temperament and a due quantity of these are beneficial to health; and that such as have a contrary tendency are to be reckoned unwholesome. As to the nature of food with respect to mankind in general, some is of a good juice, and some of a bad juice; the first generates pure blood; the other bile, or an atrabilious humour. Moreover, some sorts of food are easy of concoction, others difficult: some loosen the belly, others bind it: and every sort is said to be endowed with some peculiar virtue or property, the reasons of which are founded in nature.

As the blood, the nutritive juice, and in general all the parts of the body are made up of three elements, *viz.* of one which is sulphureous, oily, and inflammable; of one of an earthy, subtle, alkaline nature; and of one of an aqueous nature: so the several kinds and virtues of food may be most commodiously reduced to these three classes; and aliments of these three several qualities, duly mixed with one another, afford a proper nourishment for the human body.

The flesh of animals, especially when roasted, affords the body its principal supply of the sulphureous part; but it is to be observed, that wild animals are preferable in this respect to the tame and domestic kind, because their oils and salts

are exalted by habitual exercise. Among the aliments which furnish the blood with its humid parts, of animals, fish; and of vegetables, pot-herbs, the milder roots, and some summer-fruits are reckoned the principal. To the third class, which supplies the blood with its fixed and earthy parts, belong all kinds of grains, as the several sorts of bread, rice, peas, beans, lentils, chestnuts, almonds, cacao, cheese, &c. From what has been said, it will appear that all such aliments as are of a mild quality, and resemble the chyle and blood, are fit for nourishment; that all such food as either recedes from, or is quite opposite to the nature of the chyle and blood, is unfit for nourishing the parts; that all food in which there is too much of an acid, is improper for nourishment, because milk and blood will not mix with an acid, which is quite opposite to their natures, and induces a coagulation of the circulating juices; that all salts, and all foods too highly salted, must be unfit for nourishment, because no salt whatever can be mixed with the blood, chyle, and milk; and lastly, that the free use of spirits must be very detrimental both to health and nourishment, because blood and chyle never incorporate with spirituous liquors, but rather separate from them.

Foods proper for preserving health ought not only to contain a laudable juice, but should likewise be easily dissolved by the stomach: hence it is plain, that all those kinds of food, which on account of the closeness and compactness of their texture, are with difficulty dissolved, are for that very reason less conducive to health. Again, as it is necessary to the performance of the office of nutrition, that the small mouths of the internal rough coat of the intestines absorb the chyle, and convey it to the blood, none of those foods which either obstruct or too much corrugate its mouths, can be used, without in some measure injuring health. And as the effects of foods, drained and exhausted by the separation of the chyle from it, ought by the expansive and contractive motion of the intestines, to be thrown off from them; it must of course follow, that all those foods are prejudicial to health, which either pass through the intestines with difficulty, stop their motions, or weaken their tone and impair their strength by suppressing excretion, so necessary to health. This characteristic of unwholesomeness belongs to all astringent, mouldy,

glutinous, viscid, austere foods, to all unripe summer-fruits, and in general to all such aliments as are easily reducible to a firm coagulum, which, by adhering immovably to the coats of the intestines, and incrustating the orifices of their small absorbent vessels, occasion copious flatulencies and spasms. The unwholesomeness of foods is also to be estimated from their impairing the fermentative and solutive powers of the stomach, since by that means crudities are generated. Upon the whole, however, it must be observed, that for different intentions, different kinds of foods are required, in which age, constitution, climate, season of the year, and numberless other considerations are to be included; and that abstinence and exercise must conduce with every kind of food, for the preservation of health; and that where exercise is wanting, as in studious persons, the defect must be supplied with abstinence.

The quantity of food also must vary according to age, season, constitution, and nature of the food itself. Some physicians say, that in winter, where the perspiration of an unexercised person is only equal to the urine, the food for twenty-four hours ought not to exceed four pounds, or four pounds and a half. In summer, the food may be six pounds and an half, which may be carried off without the help of exercise, when the air is hot and dry. Dr. Bryan Robinson thinks, that if the quantity of food be such as to make the perspiration and urine of a natural day always nearly equal, and the morning-weight of the body always nearly the same, that quantity is the truly healthful quantity of food for grown persons who use but little exercise. The same author thinks, that the quantity of food necessary to keep a grown body in health, will be better and more easily digested, when it is so divided as to make the meals equal, than when they are very unequal: that good and constant health consists in a just quantity of food, and a just proportion of the meat to the drink; and that to be freed from chronical disorders contracted by intemperance, the quantity of food ought to be lessened, and the proportion of the meat to the drink increased more or less, according to the greatness of the disorders.

**FOOL**, according to Mr. Locke, is a person who makes false conclusions from right principles; whereas a madman, on the contrary, draws right conclusions from wrong

wrong principles. See REASON and UNDERSTANDING.

FOOL'S STONES, in botany, a name given to the orchis. See ORCHIS.

FOOT, *pes*, a part of the body of most animals whereon they stand, walk, &c. Animals are distinguished, with respect to the number of their feet, into *bipedes*, two-footed; such are men and birds: *quadripedes*, four-footed; such are most land-animals: and *multipedes*, or many-footed, as insects. The reptile-kind, as serpents, &c. have no feet; the crab-kind of fish have got ten feet, but most other fishes have no feet at all: the spider, mites, and polypuses have eight; flies, grasshoppers, and butterflies have six feet. Animals destined to swim, and water-fowl, have their toes webbed together, as the phocæ, goose, duck, &c. The fore-feet of the mole, rabbit, &c. are wonderfully formed for digging and scratching up the earth, in order to make way for their head.

FOOT, in anatomy. The greater foot denotes the extent from the juncture of the hip to the toe-ends, and is divided into the thigh, the leg, and the foot, properly so called. See THIGH and LEG. The lesser foot, or that properly so called, is divided into four parts, *viz.* the tarsus, the metatarsus, the toes, and the ossa sesamoidea. See the articles TARSUS, METATARSUS, TOE, and SESAMOIDE BONES.

In examining the foot, we are to consider its length, which is greater in man than in any other animal, in order to serve for his treading the firmer. It is also to be remarked, that the under part, or sole, called *planta*, is contrived hollow in man, lest the vessels should be pressed on in walking, as we press there with our whole weight, whilst we are in this posture. See the article PLANTA.

FOOT, in the latin and greek poetry, a metre or measure, composed of a certain number of long and short syllables.

These feet are commonly reckoned twenty-eight, of which some are simple, as consisting of two or three syllables, and therefore called disyllabic or trisyllabic feet; others are compound, consisting of four syllables, and are therefore called tetrasyllabic feet.

The disyllabic feet are four in number, *viz.* the pyrrhichius, spondeus, iambus, and trocheus. See PYRRHICHIVS, &c. The trisyllabic feet are eight in number, *viz.* the dactylus, anapæstus, tribra-

chys, molossus, amphibrachys, amphi-macer, bacchius, and antibacchius. See DACTYL, &c.

The tetrasyllabic are in number sixteen, *viz.* the procleusmaticus, dispondeus, coriambus, antispastus, diiambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus secundus, epitritus tertius, epitritus quartus, pæon primus, pæon secundus, pæon tertius, and pæon quartus. See the articles PROCLEUSMATICUS, &c.

There are several other sorts of feet invented by idle grammarians, of five, six, or more syllables, but they are not worth the reciting. The number of feet each sort of verse contains, will be found under that particular verse. See the articles HEXAMETER, &c.

Even and odd FOOT, in poetry, is a foot so denominated in respect of its situation in the verse: thus, the first, third, and fifth foot of the verse are uneven. This denomination of feet chiefly obtains in iambic verse. See IAMBIC.

FOOT is also a long measure, consisting of 12 inches. See the article INCH.

Geometricians divide the foot into 10 digits, and the digit into 10 lines. See the articles DIGIT and LINE.

FOOT square, is the same measure, both in breadth and length, containing 144 square or superficial inches.

Cubic, or Solid FOOT, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

The foot is of different lengths in different countries. The paris royal foot exceeds the english by nine lines; the antient roman foot of the Capitol, consisted of 4 palms, equal to  $11\frac{7}{16}$  inches english; rhineland or leyden foot, by which the northern nations go, is to the roman foot as 950 to 1000. The proportions of the principal feet of several nations, compared with the english, are as follow.

The english foot being divided into 1000 parts, or into 12 inches, the other feet will be as follow:

		1000 parts.	Feet. inch.	lines.
London-foot	—	1000	0 12	0
Amsterdam	—	942	0 11	3
Antwerp	—	946	0 11	2
Bologna	—	1204	1 2	4
Bremen	—	964	0 11	6
Cologne	—	954	0 11	4

**FOOT of a horse**, in the manege, the extremity of the leg, from the coronet to the lower part of the hoof.

The four feet of a horse are distinguished by four different names: the far fore-foot denotes the right foot before; and the near fore-foot, the stirrup-foot, and the bridle-hand-foot, are used to signify the left foot before: of the two hinder feet, the right is called the far hind-foot, and the left hind-foot is called the near foot behind.

It is a great imperfection in a horse to have feet too large and fat, as also to have them too little: the former sort of horses are, for the most part, heavy, and apt to stumble; on the other hand, too small feet are to be suspected, because they are often painful, and subject to cloven quarters and other imperfections.

**FOOT DEROBE**, in the manege. A horse's foot gets this appellation, when it is worn and wasted by going without shoes, so that for want of hoof it is a hard matter to shoe him.

**Fat FOOT**, in the manege. A horse is said to have a fat foot, when the hoof is so thin and weak, that, unless the nails be driven very short, he runs the risque of being pricked in shoeing. The English horses are very subject to this disorder.

**FOOT-BANK**, or **FOOT-STEP**, in fortification, the same with **banquette**. See the article **BANQUETTE**.

**FOOT of the forest**, *pes forestæ*, in our ancient customs, contained 18 inches, or  $1\frac{1}{2}$  of the common foot. See **FOREST**.

**FOOT-GUARDS**. See **GUARDS**.

**FOOT-GELD**, or **FAUT-GELD**, in our old customs, an amercement laid upon those who live within the bounds of a forest, for not lawing or cutting out the ball of their dog's feet. To be free of a foot-geld, was a privilege to keep dogs un-lawed, within the bounds of a forest.

**FOOT-HOOKS**, or **FUTTOCKS**. See the article **FUTTOCKS**.

**FOOT-HUSKS**, among botanists, short heads out of which flowers grow.

**FOOT-LEVEL**, among artificers, an instrument that serves as a foot-rule, a square, and a level. See the articles **LEVEL**, **RULE**, and **SQUARE**.

**FOOT-PACE**, or **HALF-PACE**, among carpenters, a pair of stairs, whereon, after four or six steps, you arrive at a broad place, where you may take two or three paces before you ascend another step. The design of which is to ease the legs in ascending the rest of the steps. See the article **STAIR-CASE**.

**FOOT-SOLDIERS**. See **INFANTRY**.

**Fore-FOOT**, in the sea-language, the foremost part of the keel, which first takes the ground.

**FORAGE**, all kind of provision for cattle, especially for horses in time of war. See the article **FORRAGE**.

**FORAMEN**, in anatomy, a name given to several apertures, or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranæ tympani. See the articles **SKULL**, **JAW**, **LACHRYMALE**, **EAR**, &c.

**FORAMEN OVALE**, an oval aperture or passage through the heart of a foetus which closes up after birth. It arises above the coronal vein, near the right auricle, and passes directly into the left auricle of the heart, serving for the circulation of the blood in the foetus, till such time as the infant breathes and the lungs are open; it being generally reckoned one of the temporary parts of the foetus, wherein it differs from an adult, altho' almost all anatomists, Mr. Cheselden excepted, assure us, that the foramen ovale has sometimes been found open in adults. See **FOETUS** and **CIRCULATION**.

The foramen ovale therefore, and the canal of communication in the foetus are in reality no other than a sort of subsidiary parts to the lungs formed only for a certain time, and to become useless and disappear when the act of respiration

has

has given the turn to the circulation of the blood, which it is to retain through the whole life of the animal. Dr. Trew affirms, that the membrane of the foramen ovale is so placed, as to permit the blood to pass freely from the right auricle to the left, during the diastole of the auricles, but never from the left auricle to the right. See Phil. Trans. n° 457.

**FORCALQUIER**, a town of Provence, in France; thirty miles north of Aix.

**FORCE**, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform, or not direct.

Mechanical forces may be reduced to two sorts, one of a body at rest, the other of a body in motion.

The force of a body at rest is that which we conceive to be in a body lying still on a table, or hanging by a rope, or supported by a spring, and is called by the names of *pressure*, *vis mortua*, &c. The measure of this force being the weight with which the table is pressed; or the spring bent. See **INERTIA**.

The force of a body in motion, called *moving force*, *vis motrix*, and *vis viva*, to distinguish it from the *vis mortua*, is allowed to be a power residing in that body so long as it continues its motion, by means of which it is able to remove obstacles lying in its way, to surmount any resistance, as tension, gravity, friction, &c. and which in whole, or in part, continues to accompany it so long as the body moves. Philosophers are fully agreed about the measure of the first of these forces, *viz.* *vis mortua*, notwithstanding the diversity of appellations by which it is called; but about the measure of the last sort of force, or *vis viva*, they are divided into two parties.

The newtonians and cartesian maintain, that the moving force of bodies is in the compound ratio of their weights and velocities; and Leibnitz with his followers, pretend it to be in the compound ratio of the weights and the squares of the velocities. Those who hold the first opinion, lay down for a principle that when two bodies meet one another in contrary directions, if their moving forces be equal, neither body will prevail over each other: and if their moving forces be unequal, the stronger will always prevail over the

weaker. But the followers of Leibnitz deny the truth of this principle, and lay down others, which, as they pretend, are more clear and satisfactory; such as, that it always requires a determinate degree of force to bend a given spring to a given degree, whether this be performed in a longer or shorter time, or vice versa, and that a given spring bent to a given degree always communicates the same force to a body by unbending itself, whether the time it takes to unbend itself be longer, or shorter. But these propositions are alike denied by the Newtonians.

Now if the principle of the former be admitted as true, *viz.* that those bodies have equal forces, which meeting each other in contrary directions do not prevail over each other, it cannot be disputed that bodies which have equal quantities of motion have also equal forces; and consequently that the moving forces of bodies are in a compound ratio of their masses and velocities. On the other hand, if the principles of the Leibnicians be admitted, it is no less indisputable that the forces of moving bodies will be in a compound ratio of their masses and the squares of their velocities. Thus let  $M$  and  $m$  denote the masses of two bodies,  $V$  and  $v$  their velocities; then if any spring bent to a certain degree give the body  $M$  a certain velocity  $V$ , the same spring bent to the same degree will never give another body  $m$  a velocity  $v$ , so that  $MV$  shall be equal to  $mv$ ; but will always communicate such a velocity to  $m$ , that  $MVV$  shall be equal to  $mvv$ . And this is admitted by the Newtonians, tho' the conclusion that the forces of the bodies  $M$  and  $m$  are equal, is denied. To put an end therefore to this controversy, other principles must be found; and accordingly many subtle reasonings have been formed by several authors, concerning the nature of action, cause, effect, time, space, &c. by which we believe more readers have been confounded than enlightened; so that after all, the controversy still subsists, though carried on near seventy years, during which time a great many pieces have been published on both sides of the question, and a great many experiments have been made, or proposed to be made, in order to decide it; because tho' both parties agree in the event of the experiments, whether actually made or only proposed, yet as the writers on each side have

have found a way of deducing from those experiments a conclusion suitable to their own opinion, the disagreement still continues as wide as ever, and must remain so, while the newtonians, on the one hand, assume that *equal pressures in equal times produce equal moving forces*; and that the leibnitians, on the contrary, maintain that *equal pressures urging a body through equal spaces, produce equal forces*. Hence, supposing equal pressures to act on equal bodies, either to produce motion in them, or to stop what motion they have, the question will be whether the force generated or destroyed be proportional to the time the pressure acts, or the space thro' which it acts. For example, let two equal bodies, with velocities as 1 and 2, ascend against the action of uniform gravity according to Galileo's hypothesis, it is certain that the body whose velocity is 2 will resist the force of gravity twice the time that the body whose velocity is only 1 can do: and it is no less certain, that the body whose velocity is 2 will ascend to four times the height that the other can. So that if we measure the forces of these bodies by the pressure and time requisite to destroy their motion, these forces will be as the velocities of the moving bodies; but if we measure the forces by the pressure and space through which it extends, requisite to destroy these forces, we shall find them proportional to the squares of the velocities of the moving bodies. This holds in uniform pressures, but if the pressure be not uniform as in the action of springs, which press more or less as they are more or less bent, we must then have recourse to the fluxions of the space and time. Thus if  $p$  stand for the pressure,  $t$  for the time, and  $s$  for the space, the fluxion, or infinitesimal element of the velocity, will, according to both parties, be expressed by  $p \dot{t}$ . According to the newtonians, this is also the fluxion or element of the force; but according to the followers of Leibnitz, the element of the force is proportional to  $p \dot{s}$ . This being the case, we shall only remark that we have not met with any conclusive argument on either side, nor do we believe it possible to demonstrate the one or the other of these assertions till some body shall be metaphysician enough to analyse the notions of force, action, time, and space, farther than has hitherto been done.

Some leibnitians do not assume it as a

first principle, that action or force is proportional to the pressure and space; but they say, that a pressure being given, its action will be proportional to the velocity of the point moved by that pressure. Hence they infer, that the whole action of a pressure is as its intensity, as the velocity of the point to which it is applied, and as the time the pressure acts. And space being as the time and velocity, they conclude the action of a pressure to be as that pressure, and the space thro' which it acts. Thus 'S Gravefande, lib. 2. cap. 2. sect. 728, says, if a point runs thro' a determinate space A B, and presses with a certain given force or intensity of

pressure, it will perform the same action whether it move fast or slow, and therefore the time of the action in this case ought not to be regarded. But the Newtonians do not submit to this reasoning, and insist, that we cannot abandon the old doctrine concerning the measures of the forces of bodies in motion, without exchanging plain principles that have been generally received concerning the actions of bodies, upon the most simple and uncontested experiments, for notions that seem at best but very obscure. Let A and B (plate CI. fig. 2. n° 1.) be two equal bodies that are separated from each other by springs interposed between them (or in any equivalent manner) in a space EFGH, which in the mean time proceeds uniformly in the direction BA, in which the springs act, with a velocity as 1, and suppose that the springs imprint on the equal bodies A and B equal velocities in opposite directions that are each as 1. Then the absolute velocity of A (which was as 1) will be now as 2; and, according to the new doctrine of the Leibnitians, its force as 4. Whereas the absolute velocity and the force of B (which was as 1) will be now destroyed; so that the action of the springs adds to A a force as 3, and subducts from the equal body B, a force as 1 only; and yet it seems manifest that the actions of the springs on these equal bodies ought to be equal. In general, if  $m$  represent the velocity of the space EFGH in the direction BA,  $n$  the velocity added to that of A and subducted from that of B by the action of the springs, then the absolute velocities of A and B will be represented by  $m + n$  and  $m - n$  respectively.

tively, the force added to A by the springs will be  $2mn + nn$ , and the force taken from B will be  $2mn - nn$  which differ by  $2nn$ . Further, it is allowed that the actions of bodies upon one another are the same in a space that proceeds with an uniform motion, as if the space was at rest. But if the space EFGH was at rest, the forces communicated by the springs to A and B had been equal, and the force of each had been represented by  $nn$ . These arguments, says Mr. Maclaurin, are simple and obvious, and seem on that account to be the more proper, in treating this question. Tho' there are certain effects (continues the same author) produced by the forces of bodies that are in the duplicate ratio of their velocities, we are not thence to conclude that the forces themselves are in that ratio, no more than we are to conclude that a force which would carry a body upwards of 500 miles in a minute is infinite, because it may be demonstrated, if we abstract from the resistance of the air, that a body projected with this velocity would rise for ever, and never return to the earth. And as reaction is only equal to action when both are estimated in opposite directions upon the same right line, so we are never to estimate the force which one body loses or acquires by that which is produced or destroyed in another body in a different direction.

Mr. Euler observes, with respect to this dispute concerning the measure of vivid force, that we cannot absolutely ascribe any force to a body in motion, whether we suppose this force proportional to the velocity, or to the square of the velocity: for the force exerted by a body striking another at rest is different from that which it exerts in striking the same body in motion; so that this force cannot be ascribed to any body considered in itself, but only relatively to the other bodies it meets with. There is no force in a body absolutely considered but its inertia, which is always the same, whether the body be at rest or in motion. But if this body be forced by others to change its state, its inertia then exerts itself as a force properly so called, which is not absolutely determinable, because it depends on the changes that happen in the state of the body. Suppose, for instance, a body A forced to move in an incurvated tube or along the curve surface E a F, (*ibid.* n° 2.) the body in this case will

press the surface wherever it touches it in a direction *a a* normal to the curve; and with a certain force commonly determined in mechanics, by the mass of the body, its velocity, and by the radius of curvature O a. Now the body exerts a pressure or *vis mortua*, yet it would be absurd to ascribe a certain and determinate force of pressure to this body considered in itself, since this pressure may vary very much according to the difference of the curvature of E a F. In like manner, it seems unreasonable to place a certain absolute force of percussion in bodies, since it principally depends on the external circumstances accompanying the shock. A second observation which has been made by several great men is, that the effect of a shock of two or more bodies is not produced in an instant, but requires a certain interval of time. If this be so, the heterogeneity between the *vires viue* and *mortue* vanishes; since a pressure may always be assigned, which in the same time, however little, shall produce the same effect. If then the *vires viue* be homogeneous to the *vires mortue*, and since we have a perfect measure and knowledge of the latter, we need require no other measure of the former than that which is derived from the *vires mortue* equivalent to them.

Mr. Euler has also given some calculations with respect to the force of percussion resulting from the pressures which elastic and non-elastic bodies exert on each other while the collision lasts, determining these pressures for every instant of the shocks; and where the bodies are very hard, he finds the force of percussion to be in a compound ratio of the velocity, and of the subduplicate ratio of the mass of the striking body; so that in this case neither the Leibnitian, nor the Cartesian proportions take place. But as we cannot pretend to give a full account of this controversy, we must refer the curious to Mr. Euler's dissertations in the Memoirs of the Academy of Berlin, and to some of the principal authors on each side of the question, such as Sir Isaac Newton, Mr. Maclaurin, Dr. Jurin, Dr. Pemberton, Mr. Robins, Monf. de Mailan, &c. in favour of the old opinion; Mess. Leibnitz, Bernoulli, Herman, Poleni, Wolfius, 'S Gravefande, &c. in support of the new; and shall only observe in this place, that the experiments of Desaguliers, Poleni, &c.

tho' they do not decide the controversy, are nevertheless of great use, and that whatever may be said of the metaphysical part, it is certain, that no useful conclusion in mechanics is affected by the disputes concerning the mensuration of the force of bodies in motion, as has been objected to mathematicians by the analyst in Query IX.

*Central FORCE.* See CENTRAL.

*Centrifugal FORCE.* See CENTRIFUGAL.

*Centripetal FORCE.* See CENTRIPETAL.

*FORCE of inactivity.* See INERTIA.

*FORCE of wind.* See WIND.

**FORCE**, in law, signifies any unlawful violence offered to things or persons, and is divided into simple and compound. *Simple force* is what is so committed, that it has no other crime attending it, as when a person by force enters on another's possession without committing any other unlawful act. *Compound force*, is where some other violence is committed with such an act which of itself alone is criminal; as if one enters by force into another's house, and there kills a person, or ravishes a woman. There is likewise a force implied in law, as in every trespass, forcous or disseisin, and an actual force with weapons, number of persons, &c. Any person may lawfully enter a tavern, inn, or victualling-house; so may a landlord his tenant's house to view repairs, &c. But if, in these cases, the person that enters commits any violence or force, the law will intend that he entered for that purpose.

*Fresh FORCE.* See the article FRESH.

**FORCEPS**, in surgery, &c. a pair of scissars for cutting off, or dividing, the fleshy membranous parts of the body, as occasion requires. See SCISSARS.

A surgeon should be well provided with these; some straight, and of different sizes, like common scissars; others crooked, proper to be used in fistulæ, and in many other cases, (see plate CL fig. 3. n° 1.) and others, again, furnished with teeth at one end, used to remove dressings, to extract musket-balls, splinters, thorns, &c. and on many other occasions, (*ibid.* n° 2.)

Forcepses are commonly made of steel, but those of silver are much neater.

**FORCER**, or **FORCING-PUMP**, in mechanics, is a kind of pump in which there is a forcer or piston without a valve.

The forcing-pump consists of a barrel ABC (plate CL fig. 4. n° 1.) in

which there is a forcer I, which moves up and down in it. The barrel communicates with two pipes, the one called a sucking-pipe BC, which goes down into the well, and the other called a forcing-pipe FG, which goes upwards. There are two valves, the one D, at any place of the pipe BC, and the other E, in the pipe FG; both which let the water go up, and hinder it from coming down.

Then when the forcer is moved upwards, as it rarefies the air in the pipe BC, (for the valve E hinders the outward air which presses upon it from going thro') the water rises in it, till after several strokes it comes to the forcer: then at every time the forcer goes down, the water that is pressed downwards being hindered from going thro' the valve D, opens the valve E, and goes up the pipe FG. When the forcer goes up again, then the water in the pipe FG shuts by its pressure the valve E, and consequently the water in the well rises up the pipe BE, and the same happens at every motion of the forcer. It is to be observed in the forcing pump, that the nearer the forcer comes to the well, the better it is, for the same reason as in the sucking pump. See the article PUMP.

There are several ways of making forcers: the most common of all consists of a brass-cylinder, a very little less in diameter than the bore of the barrel, (*ibid.* n° 2.) at the top B and at the bottom D, and turned less still at the middle CC in order to let in a leathern collar EE (*ibid.* n° 3.) which makes it just equal to the bore of the barrel, so as to fit it quite when it is put into it. The second sort of forcers consists of three brass-cylinders A, B, C, (*ibid.* n° 4, 5, 6) which can be screwed together. The middle one B ought to be almost equal in diameter to the bore of the pipe, so as to slide in it without any friction. The upper A and the lower C must be a little less and equal to one another. There are two leathers, D and E, (*ibid.* n° 7, 8.) which must be put between them when they are unscrewed. Then it is evident, that if the cylinders be screwed together, and the leathers apply themselves folding upwards round the upper part A, and downwards round the lower C, they will become just equal to the bore of the barrel, and consequently they will hinder any air from getting thro' the sides of the forcer when it moves up and down in the barrel. The use of

the middle brass cylinder B is to hinder the leathers from turning themselves back by the motion.

But the best way of making forcers is to have a plunger, or solid brass-cylinder A (*ibid.* n° 9.) equal in length to the barrel, and a little less in diameter than the bore, so that it can move freely in it without any friction: there must be two hollow short brass rings C C, D D (*ibid.* n° 10, 11.) at the top of the barrel F, (*ibid.* n° 12.) which can be screwed together. The upper one C C must be equal in bore to it, and the lower D a little less. There are two leathers as in (n° 7, 8.) both having in the middle a less hole than the bore of the pipe.

The one must be applied between the barrel and the ring D, and the other between the same D and the upper one C, and the whole must be screwed together. Then if the solid cylinder A (n° 9.) be put into it and moved up and down, it is evident that the fore-mentioned leathers which are applied the one to the barrel, the other to the inside of the hollow cylinder C will hinder any air from getting between them and the solid cylinder A. The advantage of this kind of forcers is, that they have no other friction but at the top of the barrel, and that the inside of the barrel need not be smooth as in other kinds of pumps, but only the outside of the forcer A must be turned true and polished, which can be done a great deal easier. The lower part of the forcer A must be turned a little conical, that it may be brought into the barrel, without any resistance of the upper leather of the above-mention'd collar or jack-head. See the article PISTON.

**FORCHAIN**, a town of Franconia, in Germany, sixteen miles south of Bamberg.

**FORCIBLE**, in law, something done illegally. See the article FORCE.

A **FORCIBLE entry**, is a violent and actual entry into houses, or lands; and a forcible detainer, is where one by violence with-holds the possession of lands, &c. so that the person who has a right of entry is barred, or hindered, therefrom.

At common law, any person that had a right to enter into lands, &c. might retain possession of it by force. But this liberty being abused, to the breach of the peace, it was therefore found necessary that the same should be restrained. That at this day, he who is wrongfully

dispossessed of goods may by force retake them. By statute, no persons shall make an entry on any lands or tenements, except where it is given by law, and in a peaceable manner, even though they have title of entry, on pain of imprisonment; and where a forcible entry is committed, justices of peace are authorized to view the place, and enquire of the force by a jury, summoned by the sheriff of the county: and they may cause the tenements, &c. to be restored, and imprison the offenders till they pay a fine. Likewise a writ of forcible entry lies, where a person seized of freehold, is by force put out thereof. See ENTRY.

**FORCIBLE MARRIAGE**, of women having estates in lands, &c. is felony by law, and the takers, procurers, abettors, and receivers of the woman so taken away against her will, and knowing the same, are likewise deemed principal felons; but as to the procurers and abettors, they must be such before the fact committed, to be excluded benefit of clergy.

**FORCING**, among gardeners, signifies the making trees produce ripe fruit before their usual time. This is done by planting them in a hot bed against a south-wall, and likewise defending them from the injuries of the weather by glass frame. They should always be grown trees, as young ones are apt to be destroyed by this management. See HOT-BED. The glasses must be taken off at proper seasons, to admit the benefit of fresh air, and especially of gentle showers.

**FORCING OF WINE**. See WINE.

**FORCING-PUMP**. See FORCER, supra.

**FORE-CASTLE OF A SHIP**, that part where the foremast stands. 'Tis divided from the rest by a bulk-head. See the article SHIP.

**FORE-CLOSED**, in law, signifies the being shut out, and excluded, or barred, the equity of redemption on mortgages, &c.

**FORE-FOOT**, in the sea-language, signifies one ship's lying, or sailing, cross another's way: as if two ships being under sail, and in ken one of another, one of them lying in her course with her stem so much a weather the other, that holding on their several ways, neither of them altering their courses, the windward ship will run a-head of the other: then it is said, such a ship lies with the other's forefoot.

**FOREIGN**, some thing extraneous, or that comes from abroad.

Foreign, in our law, is used in various significations. Thus,

**FOREIGN ATTACHMENT**, is an attachment of the goods of foreigners, found within a city, or liberty, for the satisfaction of some citizen, to whom the foreigner is indebted; or it signifies an attachment of a foreigner's money in the hands of another person. See **ATTACHMENT**.

**FOREIGN KINGDOM**, a kingdom under the dominion of a foreign prince.

At the instance of an ambassador, or consul, an offender against the laws here may be sent for hither from a foreign kingdom. And where a stranger of Holland, or any foreign country, buys goods at London, for instance, and there gives a note under his hand for payment, after which he goes away privately into Holland; in that case, the seller may have a certificate from the lord mayor, on the proof of the sale and delivery of such goods, whereupon a process will be executed on the party in Holland.

**FOREIGN MATTER**, any thing which is done, and, therefore, triable in another country.

**FOREIGN OPPOSER, or APPOSER**, an officer in the exchequer, that apposes, or makes a charge on all sheriffs, &c. of their green wax: that is to say, fines, issues, amerciaments, recognizances, &c.

**FOREIGN PLEA**, signifies an objection to the judge of the court, by refusing him as incompetent, because the matter in question is not within his jurisdiction. All foreign pleas that are triable by the country on any indictment for murder, or felony, shall be tried, without delay, before the justices, where the party is arraigned, and by the jurors of the same county, though the matters of such pleas are alleged to be in any other county or counties: but this does not extend to treason, nor to appeals; a foreign issue wherein must be tried, as formerly, by a jury of that county where the fact is laid. If a foreign plea is pleaded in a civil action, the court generally makes the defendant put it in upon oath that the same is true, or will cause judgment to be entered for want of a plea.

**FOREIGN SERVICE**, that service by which a mean lord holds of another without the compass of his own fee; or it is that which the tenant performs either to his own lord, or the lord paramount, out of the fee.

**FOREIGN SEAMEN**, serving two years on

board british ships, whether of war, trade, or privateers, during the time of war, shall be deemed natural-born subjects.

**FOREIGNER**, the natural-born subject of some foreign prince.

Foreigners, tho' made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy-council, or members of parliament, &c. This is by the acts of the settlement of of the crown. Such persons as are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

**FOREJUDGER**, in law, signifies a judgment, whereby one is deprived or put by a thing in question.

To be forejudged the court, is where an officer, or attorney, of any court, is expelled the same, for male-practice; or for not appearing to an action on a bill filed against him, &c. And where an attorney of the common-pleas is sued, the plaintiff's attorney delivers the bill to one of the criers of the court, who calls the attorney defendant, and solemnly proclaims aloud, that if he does not appear thereto, he will be forejudged; likewise a rule is given by the secondary for his appearance, and if the attorney appears not in four days, then the clerk of the warrants strikes such an attorney off the roll of attorneys; after which he becomes liable to be arrested like any other person: but where an attorney is forejudged, he may be restored on clearing himself from his contumacy, and making satisfaction to the plaintiff, &c.

**FORE-KNIGHTS**. See **KNIGHTS**.

**FORELAND**, in the sea-language, the same with a capc. See the article **CAPE**.

**FORELAND**, in fortification, the same with liziere. See the article **LIZIERE**.

**FORELOCKS**, in the sea-language, little flat wedges made with iron, used at the ends of bolts, to keep them from flying out of their holes.

**FORELOIN**, among huntmen, is when a hound, going before the rest of the cry, meets chase, and goes away with it.

**FORELORN-HOPE**, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle, or, at a siege, to storm the counterscarpe, mount the breach, or the like.

They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

**FOREMAST** OF A SHIP, a large, round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-sail and fore-top-sail yards. Its length is usually  $\frac{3}{4}$  of the main mast. And the fore-top gallant-mast is  $\frac{1}{2}$  the length of the fore-top-mast. See **MAST**.

**FOREMAST-MEN**, are those on board a ship that take in the top-sails, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

**FORE-RAKE**, in the sea language. See the article **RAKE**.

**FORE-REACH**, in the sea-language, a ship is said to fore-reach upon another, when both sailing together, one sails better, or out-goeth the other.

**FORESCHOKE**, in our old authors, signifies the same with forsaken, and is particularly used in one of our statutes for lands or tenements seised by the lord for want of services performed by his tenant, and quietly held by such lord above a year and a day, without any due course of law taken by the tenant for recovery thereof; here he does in presumption of law disavow or forsake all the rights he has thereto, for which reason those lands shall be called foreschoke.

**FORE-SKIN**, in anatomy, the same with prepuce. See the article **PREPUCE**.

**FOREST**, *sylva*, in general, a great wood, or a large extent of ground covered with trees.

**FOREST**, in law, is defined, by Manwood, a certain territory of woody grounds, and fruitful pastures, privileged for wild beasts and fowls of forest, chase and warren, to rest and abide under the protection of the king, for his princely delight, bounded with unremoveable marks, and meres, either known by matter of record or prescription; replenished with wild beasts of venery, or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, with the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of that antiquity in England, that, excepting the new forest in Hampshire, erected by William the Conqueror, and Hampton-Court, erected by Henry VIII. it is said, that there is no record or history which makes any certain mention of their erection, tho' they are mentioned by several writers, and in divers of our laws and statutes.

There are sixty-nine forests in England, thirteen chaces, and 300 parks. The four principal forests are New-Forest, Sherwood-Forest, Dean-Forest, and Windsor-Forest.

The manner of erecting a forest is thus, *viz.* Certain commissioners are appointed under the great seal, who view the ground intended for a forest, and fence it round: this commission being returned into chancery, the king causeth it to be proclaimed throughout the county where the land lieth, that it is a forest, and prohibits all persons from hunting there, without his leave. Tho' the king may erect a forest on his own ground and waste, he may not do it on the ground of other persons without their consent; and agreements with them for that purpose, ought to be confirmed by parliament.

A forest, strictly taken, cannot be in the hands of any but the king, for no person but the king has power to grant a commission to be justice in eyre of the forest; yet, if he grants a forest to a subject, and that on request made in the Chancery, that subject and his heirs shall have justices of the forest, in which case the subject has a forest in law.

A second property of a forest is the courts thereof, as the justice seat, the swainmote, and the court of attachment. See the article **ATTACHMENT**, &c.

A third property is the officers belonging to it, as the justices, warden, verderer, forester, agistor, regarder, keeper, bailiff, beadle, &c. See the articles **AGISTOR**, **BAILIFF**, **FORESTER**, &c.

By the laws of the forest, the receivers of trespassers in hunting, or killing of the deer, if they know them to be the king's property, are principal trespassers. Likewise, if a trespass be committed in a forest, and the trespasser dies, after his death, it may be punished in the lifetime of the heir, contrary to common law. Our Norman kings punished such as killed deer in any of their forests with great severity; also in various manners; as by hanging, loss of limbs, gelding, and putting out eyes. By *magna charta de foresta*, it is ordained, that no person shall lose life or member for killing the king's deer in forests, but shall be fined; and if the offender has nothing to pay the fine, he shall be imprisoned a year and a day, and then be delivered, if he can give security, not to offend for the future, &c. 9 Hen. III. c. 1.

Before

Before this statute, it was felony to hunt the king's deer; and by a late act, persons armed and disguised, appearing in any forest, &c. if they hunt, kill, or steal any deer, &c. are guilty of felony. 9 Geo. I. c. 22.

He who has any licence to hunt in a forest or chase, &c. is to take care that he do not exceed his authority: otherwise he shall be deemed a trespasser from the beginning, and be punished for that fact, as if he had no licence. See the article FORESTER.

**FOREST-TREES.** Many are averse to pruning of forest-trees; but tho' it is to be done with care, yet it is by no means to be wholly omitted. It is observable in most forests, that, where one tree thrives well, there are twenty that grow faulty, all owing to their want of pruning, or lopping in a proper manner: for this, when wisely executed, is not only a renewal of their age, but of their growth too; the want of it being the occasion of trees running out with suckers, and over-loading themselves with wasteful boughs, which draw all the sap from the upper part of the tree, and make it knotty, mossy, and unthrifty.

If a tree grows crooked, at the crooked place cut it off, sloping upwards, and nurse up one of the principal shoots to be a leading shoot, except it is of such a sort as is subject to die when headed: crooked trees may be made straight by shredding up the side-branches, till you come above the crook where they are young. If any boughs are crot by goats, or other cattle, cut them off close to the body, for cattle leave a drivel where they bite, which not only infects the branches, but sometimes endangers the whole tree. See the articles LOPPING, PRUNING, and TREE.

*Assise of a FOREST.* See ASSISE.

*Charter of a FOREST.* See the article CHARTER.

*Drift of the FOREST.* See DRIFT.

*Foot of the FOREST.* See the article FOOT.

*Keeper of the FOREST.* See KEEPER.

*Perambulation of the FOREST.* See the article PERAMBULATION.

*Reposition of the FOREST.* See the article REPOSITION.

*Waste of the FOREST.* See WASTE.

**FOREST-TOWNS**, in geography, certain towns of Swabia, in Germany, lying along the Rhine, and the confines of Switzerland, and subject to the house of

Austria. Their names are Rhinefeld, Seckingen, Laufenburg, and Waldshut.

**FORE-STAFF**, or **CROSS-STAFF**, an instrument used at sea for taking the altitude of the sun, moon, or stars. It is called *fore-staff*, because the observer, in using it, turns his face towards the object: whereas, in using Davis's quadrant, the back of the observer is towards the object; and hence its denomination of *back-staff*. See the article BACK-STAFF.

The *fore-staff* is a square graduated staff AB, (plate CII. fig. 1. n<sup>o</sup>. 1.) about three feet long, and half an inch thick. Each side is graduated like a line of tangents, and has a peculiar cross piece or vane, which slides thereon. The first cross piece, FF, belongs to that side where the divisions begin at 3°, and end with 10°; and hence called the *ten-cross*. The second, EE, is called the *thirty-cross*, as belonging to that side where the degrees begin at 10° and end at 30°. The third, DD, is called the *sixty-cross*, as belonging to that side of the instrument where the divisions begin at 20° and end at 60°. The fourth cross-piece, CC, is called the *ninety-cross*, as belonging to that side where the divisions begin at 30° and end at 90°.

For the manner of graduating the staff AB like a line of tangents. See the article TANGENT.

To observe the sun's altitude by this instrument. First consider, as near as you can guess, whether the altitude be under 10°; in which case, the shortest or *ten-cross* is to be used. If the altitude be guessed to be above 10°, but under 30°, the *thirty-cross* is to be used; if under 60°, the *sixty-cross*; and if above 60°, the *ninety-cross*. Having fitted on the proper cross, place the flat end of the staff A (*ibid.* n<sup>o</sup>. 2.) to the outside of the eye, and look for the object at the upper end of the cross D; and for the horizon, at the lower end C; moving the cross backward and forward on the staff, till you see the center of the sun, or other object, by the upper end D, and the horizon by the lower end C. Then the degrees and minutes cut by the inner edge of the cross, on the proper side of the staff for that cross, make the altitude of the sun or star at the time of observation. In order to enable the eye to bear the splendor of the sun, a coloured glass is used at the top of the cross. If the meridian altitude be required, continue your observation

servation as long as the altitude of the object increases, still moving the cross nearer to the eye.

By fitting a horizontal vane on the eye-end of the staff A, (*ibid.* n<sup>o</sup> 2.) and a sight-vane on the lower end of the proper cross at C, the sun's altitude may be found with the observer's back turned towards the luminary: for looking through the sight-vane at C, let the cross-piece be moved up or down, till the shadow made by its upper end fall on the slit in the horizontal vane; the horizon being seen at the same time through the vanes at C and A; then will the degrees cut on the proper side of the staff, be the sun's altitude required.

**FORESTAGE**, in our old law-writers, a duty said to have been formerly paid by foresters to the king. See **FORESTER**.

**FORESTALLER**, a person who is guilty of forestalling. See the next article.

**FORESTALLING**, in law, buying or bargaining for any corn, cattle, victuals, or merchandize in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

The punishment for this offence, upon conviction at the quarter sessions, by two or more witnesses, is, for the first time, two months imprisonment and the loss of the goods, or the value; for the second offence, the offender shall be imprisoned six months, and lose double the value of the goods; for the third offence, he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattles, and stand on the pillory: but the statute does not extend to maltsters buying barley, or to badgers licensed.

**FORESTER**, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest at all hours, watch over the vert and venison; also to make attachments and true preiements of all trespasses committed within the forest. See the article **FOREST**.

If a man comes into a forest in the night, a forester cannot lawfully beat him before he makes some resistance; but in case such a person resists the forester, he may justify a battery. And a forester shall not be questioned for killing a trespasser that, after the peace, cried to him, will not surrender himself, if it be not done on any former malice; though, where trespassers in a forest, &c. do kill a person that opposes them, it is murder

in all, because they were engaged in an unlawful act, and therefore malice is implied to the person killed.

**FORE-TOP-MAST**, and **FORE-TOP-GALLANT-MAST**. See **FORE-MAST**.

**FORFAR**, the capital of the county of Angus, in Scotland: west long. 2° 32', and north lat 56° 25'.

It is a parliament-town, classed with Perth, Dundee, Cowper, and St. Andrews, which all together send one member.

**FORFEITURE**, properly signifies the effect of transgressing some penal law, and extends to lands or goods.

Forfeiture differs from confiscation, in that the former is more general, whilst confiscation is particularly applied to such things as become forfeited to the king's exchequer; and goods confiscated, are said to be such as no body claims.

*Full* **FORFEITURE**, *plena forisfactura*, called also *plena civita*, is the forfeiture of life and member, and all that a person has: this obtains in criminal cases, as where a person is attainted of treason, felony, &c. There is also a forfeiture in civil cases, as where a person hath an estate for life or years, he may forfeit it by alienation and claiming, or granting a larger estate than is veiled in him. All the lands or tenements of an offender, whether held in fee or tail, are forfeited on his committing high treason; and the king shall be deemed in possession thereof without any office found, saving the rights of others. For petit treason, murder, robbery, burglary, and all felonies punished with death, the offenders forfeit their lands in fee, goods and chattels. In manslaughter, goods and chattels are forfeited; so in chance-medly, and se defendendo, though here an offender has his pardon of course. In the case of petit larceny, goods are also forfeited. See the article **TREASON**, &c.

**FORFEITURE of marriage**, a writ which formerly lay against a person that held lands by knights service, who, being under age and unmarried, refused her whom the lord offered him, without disparagement, and married another.

**FORFEX**, among surgeons, the same with forceps. See the article **FORCEPS**.

Some also call an instrument for drawing teeth by the name of *forfex*.

**FORFICULA**, the **EAR-WIG**, in zoology, a troublesome insect, which takes its english name from its introducing itself into peoples ears, where it causes a great deal

of pain; and its latin name, *forficula*, from its forked tail, which is a sort of forceps, capable of pinching. The exterior wings are very short or dimidiated, and wholly cover the inner ones. The antennæ are long and slender, consisting of thirteen or fourteen articulations.

According to Lemery, the dried powder of these insects, is good in cases of deafness; and the oil drawn from them, in convulsive cases.

**FORFICULA MARINA**, the SEA-EAR-WIG, an insect found about the sea-shores, and so called from its resemblance to the common ear-wig.

**FOREFIELD**, among miners, the farthest place of a meer of ground. See **MEER**.

**FORGE**, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red hot, in order to soften and render them more malleable and manageable on the anvil. See **FURNACE**.

The forge used by the several operators in iron, is very simple: we shall instance in that of the black-smiths, to which all the rest are reducible, the construction of which is as follows. The hearth or fire-place of the forge, marked A, (See plate of smithery, fig. 1.) is to be built up from your floor with brick, about two feet and an half, or sometimes more, according to the purpose you design to forge for: if your forge be intended for heavy work, your hearth must lie lower than it need be for light work: the forge may be of what breadth is thought convenient. It may be built with hollow arches underneath, to set several things out of the way: the back of it is built upright to the top of the ceiling, and inclosed over the fire-place with a hovel, which ends in a chimney, to carry away the smoke, as at B. In the back of the forge, against the fire-place, is fixed a thick iron-plate, and a taper pipe in it, about five inches long, which pipe comes through the back of the forge at C. Into this taper pipe is placed the nose or pipe of the bellows: the office of this tewel is to preserve the pipe of the bellows and the back of the forge about the fire-place, from burning. Right before the back is placed, at about two feet distance, the trough, which reaches commonly the whole breadth of the forge, and is as broad as is thought necessary, as at D. The bellows is placed behind the back of the forge, having one of its

boards so fixed, that it can neither move upwards nor downwards. At the ear of the upper board is fastened a rope or chain at E, which reaches up to the rocker, and is fastened there to the further end of the handle, at F. This handle is fastened across a rock-staff, which moves between two cheeks upon the center pins, in two sockets, at G; so that by drawing down this handle, the moving board of the bellows rises; and by a considerable weight set on the top of its upper board, sinks down again, and by this agitation performs the office of a pair of bellows. See **BELLOWS** and **SMITHERY**.

**FORGE** is also used for a large furnace, wherein iron-ore, taken out of the mine, is melted down; or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

Of these there are two kinds: the first is called the finery, where the pigs are worked into gross iron, and prepared for the second, which is called the chafery, where it is further wrought into bars fit for use. See the articles **FORGING**, **FINERY**, and **CHAFERY**.

**FORGER**, in law, one guilty of forgery. See the next article.

**FORGERY**, in a legal sense, is where a person fraudulently makes and publishes false writings to another's prejudice: or, it signifies the writ that lies against him who offends that way.

Forgery is either at common law, or by statute; and is an offence punishable by indictment, information, &c. and not only where a person makes a false deed, but where any fraudulent alteration is made of a true one, in a material point thereof. Likewise a writing may be said to be forged, where one being directed to draw up a will for another, does insert some legacies therein falsely of his own head; though, in such cases, there is no forgery of the hand or seal of the party: but a person cannot regularly be guilty of this crime by an act of omission, unless it alters the limitation of an estate to another, in which case it may be forgery. By a statute of George II. c. 25. the forging or counterfeiting any deed, will, bond, bill, note, &c. with intent to defraud any person, or publishing such false deed,

deed, bond, &c. knowingly, is declared to be felony; and the offender shall suffer death. The king may pardon the corporal punishment of forgery which tends to public example, tho' the plaintiff cannot release it: yet in an extraordinary case, a forgery has been compounded, and the defendant discharged on paying a small fine.

**FORGING**, in smithery, the beating or hammering iron on the anvil, after having first made it red hot in the forge, in order to extend it into various forms, and fashion it into works. See **FORGE**.

There are two ways of forging and hammering iron; one is by the force of the hand, in which there are usually several persons employed, one of them turning the iron and hammering likewise, and the rest only hammering. The other way is by the force of a water-mill, which raises and works several huge hammers beyond the force of man; under the strokes whereof the workmen present large lumps or pieces of iron, which are sustained at one end by the anvils, and at the other by iron-chains fastened to the ceiling of the forge. See **MILL**.

This last way of forging is only used in the largest works, as anchors for ships, &c. which usually weigh several thousand pounds. For the lighter works, a single man serves to hold, heat, and turn with one hand, while he hammers with the other.

Each purpose the work is designed for, requires its proper heat; for if it be too cold, it will not feel the weight of the hammer, as the smiths call it, when it will not batter under the hammer; and if it be too hot, it will red-sear, that is, break or crack under the hammer.

The several degrees of heats the smiths give their irons, are, first, a blood-red heat; secondly, a white flame-heat; and, thirdly, a sparkling or welding heat. See the article **HEAT**.

**FORGING MILLS**. See the article **MILL**.

**FORISFAMILIARI**, in law, is where a son accepts of his father's part of lands, &c. in the lifetime of the father, and rests contented with it, so that he cannot claim any more; upon which account he is termed *forisfamiliatus*.

**FORKED HEAD**, among sportsmen, those deer's heads, which have their crookes doubled.

**FORK-TAIL**, is given in some parts of the kingdom to the salmon, in the fourth year of its growth.

**FORLANA**, in music, a kind of dance, nearly allied to the saltarella. See the article **SALTARELLA**.

**FORLI**, a town of Romania, in the pope's territories, fifteen miles south-west of Ravenna.

**FORLORN**, or **FORELORN**. See the article **FORELORN**.

**FORM**, *forma*, in physics, the essential or distinguishing modification of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence; being that which constitutes it such a particular body, and distinguishes it from every other body. The origin of forms, though esteemed the noblest, hath yet been found one of the most perplexed inquiries in philosophy, especially as managed by the schools. The sum of the controversy is whether the form of natural things be, in generation, educed out of the power of the matter; or whether these forms are true substantial entities, distinct from the other substantial principle of natural bodies, that is matter.

The reasons which move me to embrace the negative, says Mr. Boyle, are principally these. First, I see no necessity for admitting any such substantial forms in natural things; matter and its accidents being sufficient to explain as much of the phenomena of nature as we are likely to understand. In the next place, I see no use of this puzzling doctrine of substantial forms in natural philosophy: nor can I imagine how a particular phenomenon should be explained by a principle whose nature is unknown: and, lastly, I cannot conceive how forms could be generated, as the peripatetics would have it.

On the other hand, the schoolmen tell us, that the power of matter, with regard to forms, is partly eductive, as the agent can make the form out of it; and partly receptive, whereby it can receive the form so made: but since the schoolmen will not allow that the form of a generated body was actually pre-existent in its matter, or any where else, it is hard to conceive how a substance can be educed out of another substance totally distinct in nature from it, without being before such education actually existent in it. And as for the receptive power of the matter, that fits it to receive or lodge a form, when united with it, how can it intelligibly be made to appear to contribute to the production of a new substance of a quite

quite different nature from that matter, though it harbours it, when produced.

In short, the form of a natural body, as is illustrated and confirmed by Sir Isaac Newton's doctrine of motion, (see Newton's Optic. p. 372, 37 .) is but an essential modification, and, as it were, the stamp of its matter; or such a convention of the magnitude, shape, motion or rest, situation and contexture of the small parts that compose it, as is necessary to constitute and denominate it a particular body; and all those accidents being producible in matter by local motion, we may well say that the first and universal, though not immediate cause of forms, is no other than God, who put matter into motion, established its laws among bodies, and also guided it, in several cases, at the beginning of things; and that among second causes, the grand efficient of forms is local motion, which by variously dividing, sequestering, transposing, and connecting the parts of matter, produces in them those accidents and qualities upon account whereof the portion of matter they diversify belongs to a determinate species of natural bodies: yet this is not so to be understood as if motion were only an efficient cause in the generation of bodies, for it is also frequently one of the chief accidents, as in water, fire, &c. that concur to make up the form. See the articles MOTION and FIRE.

Some modern writers, as particularly Sennertus, teach us, that besides the specific form in plants and animals, there reside, and especially in some determinate parts of them, certain other forms proper to those parts, but so subjected to the predominant form, as to deserve the title of subordinate; being, during the reign of the specific form, subservient to it: though, when the specific form comes to be abolished, these subordinate forms may set up for themselves, and in reference to those parts of matter they belong to, exercise the functions of specific forms; as in a dog or a horse, besides the sensitive soul, which is the specific form of the whole creature, the flesh, blood, and bones have their distinct forms appertaining to them, though they are ruled and employed by the soul, but as the matter which she animates and informs; and when by death the sensitive soul or specific form is deposed or abolished, the body is not presently resolved into its several elements, but those sub-

ordinate forms still preserve the flesh, as in the state of the flesh; and the bones, as in the state of the bones; the one for a little, and the other for a much longer time. This doctrine is urged from the specific virtues observable in gathered plants, as the purgative faculty of rhubarb, senna, and other cathartic vegetables. But, says Mr. Boyle, it were not difficult to propose experiments, which would determine this matter otherwise, were it important enough to deserve it. However, as this doctrine of subordinate forms affords such countenance to that of substantial ones, that author has been at the pains to prove, that subordinate forms are explicable upon other principles. See Shaw's Boyle, vol. I. p. 224.

**FORM of Syllogisms**, or **Syllogistic FORM**, among logicians, a just disposition both of the terms, in respect of predicate and subject, and of the propositions, in respect of quantity and quality: by which is only meant a disposition wherein the conclusion follows duly and legitimately from the two premises; there being no form, where there is no conclusion. See the article SYLLOGISM.

**FORM**, in theology, is said to be one of the essential parts of the sacraments; being that which gives them their sacramental nature and efficacy, and consisting in certain words, which the priest pronounces in administering them.

**FORM** is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

**FORM**, in law, the rules established and requisite to be observed in legal proceedings.

**FORM**, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars to sit on. At schools, the word form is frequently applied to what is otherwise termed a class. See the article CLASS.

**FORM** also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness. See the article FIGURE.

**FORM** is also used, among mechanics, for a sort of mould, whereon any thing is fashioned or wrought: as the hatters form, the paper-makers form, &c. See the article HATTER, &c.

**Printer's FORM**, an assemblage of letters, words and lines, ranged in order, and

so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every form is inclosed in an iron-chase, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages, according to the size of the book.

**FORM**, in hunting, the seat of a hare; or the place and time, when and where she squats.

**FORM** of a *series*, in algebra, that affection of an undeterminate series, which arises from the different values of the indices of the unknown quantity. See **SERIES**.

**FORMA PAUPERIS**, in law, is when a person has just cause of suit, but is so poor, that he cannot defray the usual charges of suing at law or in equity; in which case, on making oath that he is not worth 5*l.* in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in *forma pauperis*; that is, without paying any fee to counsellors, attorneys, or clerk: the statute 11 Hen. VII. c. 12, having enacted, that council and attorneys, &c. shall be assigned such poor persons gratis. Where it appears that any pauper has sold or contrasted for the benefit of his suit, whilst it is depending in court, such cause shall be thenceforth totally dismissed; and a person suing in *forma pauperis*, shall not have a new trial granted him, but is to acquiesce in the judgment of the court.

**FORMAL**, something belonging to, or constituting the form of a thing. See the article **FORM**.

**FORMAL CAUSE**. See the article **CAUSE**.

**FORMALLY**, *formaliter*, a term of various import in the schools. 1. Sometimes it denotes a subject, in which the predicate is contained merely on account of its form: thus white implies whiteness. 2. In a synonymous sense with adequately. 3. For really, &c. See the article **FORM**.

**FORMALITY**, in the schools, that quality which constitutes the form of a thing. See the article **FORM**.

**FORMALITY**, in matters of law and polity, certain rules of judiciary proceedings, negotiations, and contracts, which custom or law hath made necessary, and

therefore ought to be strictly observed. See the article **CEREMONY**.

**FORMATION**, in philosophy, an act whereby something is formed or produced. For the formation of the foetus in the womb, see the articles **FOETUS** and **GENERATION**.

**FORMATION** of *stones and pebbles*. See the articles **STONE** and **PEBBLE**.

**FORMATION** of *metals and minerals*. See the articles **METAL** and **MINERAL**.

**FORMATION**, in grammar, signifies the manner of forming one word from another: thus accountantship is formed from accountant, and this last from account.

**FORMATUM PUNCTUM**. See the article **PUNCTUM**.

**FORME'**, or **CROSS FORMY**, in heraldry, a cross narrow in the center, and broad at the extremities, otherwise called *patée*. See the article **PATÉE**.

**FORMED**, or **FIGURED STONES**, among naturalists. See the article **STONE**.

**FORMED**, in heraldry, the same with seated. See the article **SEATED**.

**FORMEDON**, in law, a writ that lies for a person who has a right to lands or tenements, by virtue of any intail, arising from the statute of Westm. 2 Ch. II.

This writ is of three kinds, *viz.* a descender, remainder, and reverter. **Formedon** in descender, lies where a tenant in tail infeoffs a stranger, or is disseised and dies, the heir may bring this writ to recover the land. **Formedon** in remainder, lies where a man gives lands, &c. to a person in tail, and for default of issue of his body, the remainder to another in tail: here if the tenant in tail die without issue, and a stranger abates and enters into the land, he in remainder shall have this writ. **Formedon** in reverter, lies where lands are intailed on certain persons and their issue, with remainder over for want of issue, and on that remainder failing, then to revert to the donor and his heirs: in this case, if the tenant in tail dies without issue, and also he in remainder, the donor and his heirs, to whom the reversion returns, may have this writ for the recovery of the estate, tho' the same be aliened, &c.

**FORMERS**, in gunnery, round pieces of wood, fitted to the diameter of the bore of a gun, chiefly used for making cartridges.

On these formers, the paper, parchment, or cotton, which is to make the cartridge, are rolled before it be sewed.

**FORMICĀ,**

**FORMICA**, the **ANT**, in zoology. See the article **ANT**.

**FORMICA**, in medicine, a callous sort of wart, more usually called myrmecia. See the article **MYRMECIA**.

**FORMICA-LEO**, the **ANT-LION**, or **ANT-EATER**, in zoology, an insect so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resembling the libellæ, or dragon-flies.

The address of this insect in catching the ants, is admirable; it makes a hole of a conical or funnel-shape, in the loose sand; and is sure to catch all the ants that come within the verge of this hole, by throwing up sand on them, whereby they are forcibly carried into the power of the enemy at the bottom of the hole.

**FORMICATION**, a term used among builders for arching or vaulting.

**FORMING** of a *siege*, in the military art. See the article **SIEGE**.

**FORMING**, in grammar. See the article **FORMATION**.

**FORMOSA**, an island in the Pacific ocean, between  $119^{\circ}$  and  $122^{\circ}$  of east longitude, and between  $22^{\circ}$  and  $25^{\circ}$  north latitude, about 100 miles east of Canton in China. It is subject to the Chinese.

**FORMULA**, or **FORMULARY**, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

**FORMULA**, in church history and theology, signifies a profession of faith. See the article **FORM**.

**FORMULA**, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence. Paracelsus calls red and clear urine, formula urinæ.

**FORMULARY**, a writing containing the form of an oath, declaration, attestation, abjuration, &c. to be made on certain occasions.

**FORNACALIA**, or **FORNICALIA**, in roman antiquity, a festival instituted by Numa in honour of Fornax, the goddess of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

**FORNICATION**, the act of incontinency between single persons; for when either of the parties is married, such act is adultery. See the article **ADULTERY**.

The spiritual court now has the sole cognizance of this offence, which antiently was cognizable in other courts, as the

court-leet, &c. in which the king had a fine assessed on the offenders.

**FORNICATION** is sometimes also used as a generical term, including all kinds of offences against chastity.

**FORNIX**, in anatomy, a part of the brain placed under the septum lucidum, and, like it, composed of a medullary substance. Its anterior part rises with a double base, but the two parts soon unite: the hinder part is likewise bifid, and thence called crura fornicis, and by some, pedes hippocampi. See the article **BRAIN**.

**FORPRISE**, in law, signifies an exception or reservation, and is frequently used in leases and conveyances, wherein any exception is inserted; as such a thing excepted and forprised.

**FORRAGE**, in the military art, denotes hay, oats, barley, wheat, grafs, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

Dry forrage is the hay, oats, &c. delivered out of the magazines, to an army in garrison, or when they take the field, before the green forrage is sufficiently grown up to supply the troops.

It is the business of the quarter master-general to appoint the method of forrage, and post proper guards for the security of the forragers. He ought also, in encamping an army, to take care that it be in a country abounding with forrage.

*Ration* of **FORRAGE**. See **RATION**.

**FORRES**, a parliament-town of Scotland, in the county of Murray, about thirteen miles west of Elgin: west long.  $3^{\circ} 20'$ , and north lat.  $57^{\circ} 40'$ .

It is classed with Inverness, Fortrose, and Nairn. See the article **BOROUGH**.

**FORSES**, a name used in some parts of the kingdom for a cataract, or water-fall. See the article **CATARACT**.

**FORSTALLING**, in law. See the article **FORESTALLING**.

**FORT**, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town. See the article **CITADEL**.

**Royal FORT**, one whose line of defence is at least twenty-six fathoms long.

To fortify a square fort, having inscribed the square in a circle. 1. Divide each of its sides AB, BD, &c. (plate CII. fig. 2. n° 1.) into two equal parts, in the point F. 2. From the center E, draw an indefinite line EF. 3. From the center draw also the lines EA, EB, ED, EC, to the angles of the square. 4. Divide the side AB into eight equal parts. 5. Let one of these parts be laid off from F to G, and from G draw the lines of defence AG, BG. 6. Divide another side of the square into seven equal parts. 7. Lay off two of these parts from A to K, and from B to L, which will be the faces of the bastions. 8. Take the distance KL in your compasses, and lay it off the lines of defence from K to H, and from L to I; and drawing HI, it will be the curtain; and the lines KI, LH, will be the flanks. See another method of fortifying a square, *ibid.* n° 3. Also two different methods of fortifying a triangle, *ibid.* n° 4 and 5.

**Star-FORT**, a redoubt formed by a number of re-entering and salient angles, the sides of which flank each other. See plate CII. fig. 2. n° 2.

To describe a star-fort, 1. Draw a hexagon *ABCDEF*. 2. Divide one of its sides BC into four equal parts. 3. Upon the middle of this side, raise the perpendicular DA, equal to  $\frac{1}{4}$  of the side BC, from D to A. 4. From the point A, draw the faces AC, AB. Let the same operations be performed with respect to the other sides of the hexagon, and you will have the star-fort required.

**FORTAMENTE**, in music, the same with forte. See the article FORTE.

**FORTAVENTURA**, one of the Canary-islands, subject to Spain: west long.  $14^{\circ}$ , and north lat.  $27^{\circ}$ .

**FORTE**, or **FORTAMENTE**, in music, directs to play strong and loud; and forte forte, or *piu forte*, signifies a degree louder and stronger than forte alone.

**FORTIFICATION**, the art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a small number of men within, may be able to defend themselves for a considerable time against the assaults of a numerous army without;

so that the enemy, in attacking them, must of necessity suffer great loss.

Fortification is either antient or modern, regular or irregular. Antient fortification, at first, consisted of walls or defences made of trunks, and other branches of trees, mixed with earth, to secure them against the attacks of the enemy. This was afterwards altered to stone-walls, on which were raised breast-works, behind which they made use of their darts and arrows in security. Modern fortification, is that which is flanked and defended by bastions and out-works, the ramparts of which are so solid, that they cannot be beat down but by the continual fire of several batteries of cannon. Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like. See **BASTION**, &c.

The principal maxims of fortification are these: 1. That every part of the works be seen and defended by other parts, so that the enemy can lodge nowhere without being exposed to the fire of the place. 2. A fortress should command all places round it; and therefore all the out-works ought to be lower than the body of the place. 3. The works farthest from the center, ought always to be open to those more near. 4. No line of defence should exceed a point blank musket-shot, which is about an hundred and twenty or an hundred and twenty-five fathoms. 5. The more acute the angle at the center is, the stronger will be the place. 6. In great places, dry trenches are preferable to those filled with water, because sallies, retreats, and succours are frequently necessary; but, in small fortresses, water-trenches that cannot be drained, are best, as standing in need of no sallies, &c.

Different authors recommend different methods of fortification; but the principal are those of Pagan, Blondel, Vauban, and Scheiter.

Fortification, according to the method of count Pagan, supposes the side AB (plate CII. fig. 3.) of the external polygon, in larger fortifications, 100 perches; in the smaller, 80; and in those of middle

*Fig. 1. FORE-STAFF.*

*N<sup>o</sup> 1.*

*N<sup>o</sup> 2.*

*Fig. 3. SCHEITER'S Method of FORTIFICATION.*

*J. Gifford del.*

die size, 90; with the corresponding faces, 30, 25, and  $27\frac{1}{2}$ ; the perpendicular, CD, being in all of them 15. Here too the flanks GF, HE, are perpendicular to the lines of defence, AE and BE: these flanks are also covered with an orillon and threefold. LMN is the boundary of the moat, parallel to the faces AG, BH. The curtain is defended by a double ravelin, OQP being the external one, and acb the internal; the faces of the bastions being likewise defended by counter-guards *gf, ed*. This method, though received with great applause, is not without its defects. It is not only very expensive, but its threefold flanks are too close, so as to be too much exposed to bombs; the largeness of the orillons is prejudicial to the length of the flanks, and the outer rampart is too thick.

Mr. Blondel's method of fortification has a great affinity with that of count Pagan, only that the lines and angles are otherwise determined. Thus by subtracting a right angle from that of the polygon, and adding 15 to a third part of the remainder, you find the quantity of the diminished angle ABE. In the greater fortifications, the side AB (plate CIII. fig. 1.) of the outer polygon is 100 perches, in the lesser only 85; and AB being divided into ten equal parts, seven of them give the lines of defence AF, BE. The faces of the bastions AG, BH, are equal to half those of the tenaille AD, BD. In these faces is a kind of flanking batteries QR, to defend the faces of the ravelin *ecd*. The flanks HF, GE, are threefold, as in count Pagan's method; and in the middle of the moat is a deep trench *adb*. The other out-works are as represented in plate CIII. fig. 1.

Fortification, according to Vauban's method, supposes the outer polygon to be 100 perches in larger places, 80 in smaller ones, and 90 in those of a middle size. The faces are made  $\frac{2}{3}$  of the same, the perpendicular  $\frac{1}{8}$  in a square,  $\frac{1}{7}$  in a pentagon, and  $\frac{1}{6}$  in other polygons. He also makes the complement of the face to the line of defence, equal to the distance of the epaule; uses re-entering crooked flanks, and places a low tenaille before the curtain. See plate CIII. fig. 2. n° 1.

This method of fortification is much tried up by many, both as it increases the

strength without much expence, and agrees very well with the maxims above laid down. Its greatest fault lies in this, that the faces lie altogether exposed to the enemy.

Vauban's new method places large bastions before small ones; the curtain being covered with a low tenaille and a double ravelin, *ibid*. n° 2.

Fortification, according to Scheiter's method, supposes the external side AB, (plate CIII. fig. 3.) in large fortifications, 100 perches; in lesser ones, 80; and in those of middle size, 90. The flanks NO, PQ, are perpendicular to the lines of defence AQ, BO; which in greater fortifications are 70, in lesser 60, and in those of middle size, 65 perches: these detach the bastions from the curtain, and form a kind of inner recess behind the curtain. The angle of the bastion in a square, is  $64^{\circ}$ ; in a pentagon,  $72^{\circ}$ ; in a hexagon,  $78^{\circ}$ ; in a heptagon,  $83^{\circ}$ ; and in works of more sides, this angle is found by adding  $2^{\circ}$  for every side above the heptagon.

As to the out-works, they are much the same as in the preceding methods, only that the covert-way is double; as is the ravel, which covers the curtain.

To lay down the plan of a regular fortification. 1. Measure exactly the circuit of the place to be fortified, at about twelve paces distance from the houses; and dividing the whole circuit by 150 geometrical paces at least, or 180 at most, the quotient will give the number of the bastions, in such a manner that their lines of defence shall not exceed the carriage of a musket-shot. 2. Inscribe in a circle a polygon with as many sides as the place is to have bastions; and from the center A (plate CIV. fig. 1.) through the angle B of the polygon, draw lines at pleasure, which lines are called principals. Afterwards take  $Ba = \frac{1}{3}$  of the side of the polygon, and  $Bf = \frac{1}{5}$ ; then drawing the lines of defence Fga, Fga, from each point *a* raise perpendiculars; which meeting the lines of defence in the points *g, g*, will form the bastions *agFga, agF, &c*. 3. Having thus described the outward circuit of the rampart, draw lines *e, e, e*, parallel to the faces of the bastions Fg, Fg, Fg: these will determine the outward circuit of the moat, which ought to be rounded before the angles of the bastions F, F. 4. To finish the plan, draw within the place lines parallel to those which form the outward

outward circuit of the rampart, at the distance of  $\frac{1}{3}$  of the flank for the parapet; at the distance of  $\frac{1}{2}$  the demigorge *Ba*, for the rampart; and at the distance of five feet from the parapet, for the banquet. In the same manner, on the outside of the moat, must be drawn lines parallel to its outward circuit, at the distance of  $\frac{1}{4}$  of the flank for the covered way; and at the distance of  $\frac{2}{3}$  of the flank for the glacis.

To lay down the profile of these works. Let *ARR* (plate *CIV*. fig. 2.) represent the level of the place; take *AB*, 5 paces, for the place of arms; the perpendicular *OC*, 16 feet, for the talus or slope; the thickness of the lower part of the rampart, *BR*, 12 paces; the upper part, *CD*,  $6\frac{2}{3}$  paces; the banquet, *dD*, 6 feet; the thickness of the lower part of the parapet *DV*,  $3\frac{1}{3}$  paces; the upper, at *E*,  $2\frac{1}{3}$  paces; its inward height, *ED*, 6 feet; and its outward height, 5 feet; the talus of the rampart to the moat, *GR*, 7 feet; the talus of the scarp, *xy*, 2 paces; the depth of the moat, *Rx*, 16 feet; the width of its channel, *T*, 15 feet; the talus of the counterscarp, *aK*, 10 feet; and the banquet of the covered way, at *L*, 5 feet. Then follows the palisade at *N*, and the glacis or esplanade, *M*. In plate *CIV*. fig. 3. is represented a hexagon fortified with all the kinds of out-works, together with the manner of carrying on the trenches of approach. Here is also delineated a pentagonal citadel, with its out-works. The names of the different works and parts of this fortification, are these; *a, a, a*, &c. represent the declivity or slope, usually called glacis; *b, b, b*, &c. the covert way; *c, c, c*, &c. the counterscarp; *d*, a single tenaille; *e*, a double tenaille; *f*, a horn-work; *g, g, g*, &c. places of arms; *h, h, h*, &c. the moat or ditch; *i, i, i*, &c. ravelins; *k, k, k*, &c. half moons; *l*, a crown-work; *m*, a bonnet or priest's cap; *n, n*, a counter-guard; *o, o, o*, &c. bastions; *p, p, p*, bastions with circular flanks; *q, q*, the curtain; *r, r, r*, &c. the ramparts; and *s, s, s*, &c. bridges over the moat. With respect to the approaches, *1, 1, 1*, &c. represent the trenches; *2, 2, 2*, &c. the lines of communication; *3, 3*, batteries; *4, 4, 4*, &c. forts for the defence of the trenches; *5*, the descent into the covered way; and *6*, a mine.

**Irregular FORTIFICATIONS**, are those raised about irregular polygons; in which the en-

gineer ought to follow, as much as possible, the proportions laid down for the regular ones. If bastions are found too high to sweep the circumjacent campaign, a second bastion must be added to the first, or even a third, if necessary; still taking care that their faces be well defended. If, on the contrary, a bastion is too low, a cavalier must be raised on it. It will sometimes also happen, that the faces of bastions would become excessive long, if they were to be extended till they meet; in which case, they are usually closed with a re-entering angle, (*ibid*. fig. 4.) When one side of the polygon is long enough to admit of a bastion in its middle, it is remedied by raising one; but if it will not admit of this, it may be remedied by forming a salient angle in the middle; or by advancing the neighbouring bastions nearer to each other, so that both may be entirely formed upon that side. When a long extended side of a place cannot admit of bastions, as being cut off by a river, or stands upon a deep ascent, it may be fortified with redents or re-entering angles, not unlike the teeth of a saw. See plate *CIV*. fig. 5. But the defect of these redents is, that both the sides of the tenaille or front of a place, may be ruined from one battery; so that the besiegers may then make an assault without fear of being enfiladed.

**Marine FORTIFICATIONS**. Though these have nothing peculiar in them, yet it may not be improper to give some directions with relation to batteries. 1. In raising batteries to hinder a descent, care should be taken to dispose them in such places where the descent is most easy; and the guns should be so levelled, as to scour the surface of the water, that they may fire effectually upon the boats as they approach. 2. It is likewise convenient to have batteries to play upon places where there is good anchorage; and these should be somewhat more elevated than the former. 3. It is also necessary to erect batteries at the entrance of roads; and these ought to be so made, as to discover ships at a distance. 4. It is very necessary that these batteries should be defended by some works, against attacks; and, if possible, should be under the fire of the place; or, at least, they ought not to be too far advanced.

**FORTIFIED**, an appellation given to places defended by ramparts, bastions, ditches, covert-ways, half-moons, ravelins, tenailles, and other out-works.

See

*Fig. 1 Plan of a Regular FORTIFICATION.*

*Fig. 2 Profile of a Regular FORTIFICATION.*

*Fig. 3. A fortified Hexagon & Citadel, with Outworks & APPROACHES.*

*Fig. 4.*

*Fig. 5.*

*J. Gifford sculp.*

See the articles RAMPART, BASTION, &c. and the preceding article.

**FORTIN**, **FORTLET**, or *field-FORT*, a sence or little fort, whose flanked angles are generally distant one from another 120 fathoms. See the article **FORT**.

The extent and figure of fortins are different, according to the situation or nature of the ground; some of them having whole bastions, and others demi-bastions. They are made use of only for a time, either to defend the lines of circumvallation, or to guard some passage or dangerous post.

**FORTIORI**, or *a multo FORTIORI*. See the article **MULTO**.

**FORTIS AQUA**. See the article **AQUA**.

**FORTISSIMO**, in music, sometimes denoted by **FFF**, or *fff*, signifies to sing or play very loud or strong.

**FORT-LEWIS**, a fortress of Alsace, in Germany, situated on the western shore of the Rhine, subject to France: east long. 8°, and north lat. 48° 46'.

**FORTUNA**, in our antient law-books, is the same with what we call treasure-trove. See the article **TREASURE-TROVE**.

**FORTUNA EQUESTRIS**, in roman antiquity, a statue of the goddess Fortune, mounted on horseback in the middle of the city.

**FORTUNATE-ISLANDS**, in antient geography, certain islands concerning the situation of which authors are not agreed, famous for the golden apples of the Hesperides. See the article **HESPERIDES**. The common opinion is, that they are the same with the Canary-islands. See the article **CANARY**.

**FORTUNE**, *fortuna*, a goddess worshiped with great devotion by the antient Greeks and Romans, who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure.

The Greeks had a great number of temples dedicated to Fortune, under the name of *τυχη*. The poet Pindar makes her one of the parçæ, or destinies, and the daughter of Jupiter. Ancus Martius, king of the Romans, was the first who built a temple at Rome to this deity, under the name of *fortuna virilis*, on account that courage, no less than good fortune, is requisite to obtain a victory. Servius Tullus built a temple to fortune, under the name of primogenia. The Romans gave several other appellations to fortune; such as *fortuna libera*, *redux*, *publica*, &c. There was a statue of Fortune at Athens, holding betwixt her arms Plutus the god

of riches. Pausanias says, that her most antient form was that which Bupalus made in Greece, in shape of a woman with a round ball on her head, and a cornucopia under her arm. Macrobius says, that she was first set forth with wings on her shoulders, having by her side the rudder of a ship; and that she was placed upon a wheel, and held in her right hand a golden ball, and in her left a whip. In Ægypt she was painted like a woman, turning a great glass wheel, on whose top were represented a great number of men playing, others climbing up, and others, having attained the summit of the wheel, precipitating themselves, and falling down again. Modern painters represent Fortune by a naked woman, standing on a globe, with a bandage on her eyes. Horace's description of this goddess, and her great power, may be seen in ode xxxv. lib. i. Juvenal, in Satire x. v. 365. calls Fortune the deity of fools.

**FORTY-SHILLING LAND**, a certain quantity of arable land; that of old extent, containing eight ox-gang, or an hundred and four acres.

**FORUM**, in roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

There were six of these forums, *viz.* the Romanum, Julianum, Augustum, Palladium, Trojanum, and Salustii forum. The first and most eminent of these was the Forum Romanum, called absolutely the Forum. In this was an apartment called the rostra, where the lawyers pleaded, and the orators harangued the people, &c. Here was also the comitium, or hall of justice, with the sanctuary of Saturn, the temple of Castor, &c. All the compass of the forum was arched with porticos, some passages being only left for places of entrance.

**FORUM**, was also used for a place of traffic, answering to our market-place: of these there were vast numbers, as the *forum piscarium*, *olitorium*, &c. These were generally called *fora venalia*, in contradistinction to the former, which were called *fora civilia*.

**FORUM**, is also used, among cauists, &c. for jurisdiction, thus they say, *In fora legis*, &c.

**FOSS**, or **FOSSA**, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

**Foss** is particularly used for the cavity, or indenture, in the back part of the neck.

**Fossa magna**, the interior cavity, or rima magna, of the pudendum muliebre. Bartholin calls it fossa navicularis. This cavity appears, upon opening the labia; it has the carunculæ myrtiformes in the middle of it. See the article **CARUNCULÆ MYRTIFORMES**.

**Foss**, in fortification, a hollow place, commonly full of water, lying between the scarp and counterescarp, below the rampart; and turning round a fortified place or a post, that is to be defended. See the article **MOAT**.

**Fossa**, in our antient customs, was used to signify a ditch full of water, wherein women, convicted of felony, were drowned. See the article **FURCA**.

**Foss-way**, one of the four principal highways of England, that antiently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side thereof.

**FOSSANO**, a town of Piedmont, nineteen miles south-east of Turin.

**FOSSARII**, in antiquity, a sort of officers in the eastern church, whose business it was to inter the dead.

St. Jerom assures us, that the rank of the fossarii held the first place among the clerks: but he is to be understood of those clerks only who had the direction and intendance of the interment of the devout. Some authors insinuate, that the fossarii were instituted in the time of the apostles.

**FOSSATORUM operatio**, signifies the foss-work; or the service of labouring performed by inhabitants, and adjoining tenants, for the repair and maintenance of the ditches round a city or town. The contribution towards this work was termed *Fossagium*.

**FOSSIGNY**, a county in the dutchy of Savoy. See the article **SAVOY**.

**FOSSIL**, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, reposit in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c. See the articles **METAL**, **STONE**, &c.

Native fossils, according to Dr. Hill, are substances found either buried in the earth, or lying on its surface, of a plain simple structure, and shewing no signs of containing vessels or circulating juices. These are subdivided, by the same au-

thor, 1. Into fossils naturally and essentially simple. Of these, some are neither inflammable, nor soluble in water, as simple earths, talcs, fibriaræ, gypsum, selenitæ, crystal, and spars; others, tho' uninflammable, are soluble in water, as all the simple salts; and others, on the contrary, are inflammable, but not soluble in water, as sulphur, auripigmentum, zarnich, amber, amber-grease, gagates, asphaltum, ampelites, lithanthrax, naphtha, and pissasphalta. 2. The second general subdivision of fossils comprehends all such as are naturally compound, but unmetallic.

Of these, some are neither inflammable, nor soluble in water, as compound earths, stones, septariæ, siderochita, scrupi, semipellucid gems, lithidia, conissalæ, and pellucid gems; others are soluble in water, but not inflammable, as all the metallic salts; and, lastly, some are inflammable, but not soluble in water, as the marcasites, pyritæ, and phlogonia.

3. The third, and last, general division of fossils comprehends all the metallic ones; which are bodies naturally hard, remarkably heavy, and fusible in fire. Of these, some are perfectly metallic, as being malleable when pure; such are gold, lead, silver, copper, iron, and tin: others are imperfectly metallic, as not being malleable even in their purest state, such are antimony, bismuth, cobalt, zinc, and quicksilver, or mercury. Of all which substances the reader will find a particular description under their respective heads, **EARTH**, **TALC**, **FIBRIARÆ**, **GYPNUM**, &c.

Extraneous fossils are bodies of the vegetable or animal kingdoms accidentally buried in the earth. Of the vegetable kingdom, there are principally three kinds, trees or parts of them, herbaceous plants, and corals; and of the animal kingdom there are four kinds, sea-shells, the teeth or bony palates, and bones of fishes, complete fishes, and the bones of land animals. See the articles **TREE**, **WOOD**, **PLANT**, **SHELL**, &c.

As to the reason why these extraneous fossils come to be lodged in the bowels of the earth, the common opinion is, that this great change was effected by the universal deluge. See **DELUGE**.

**FOSSOMBRONE**, a city and bishop's see of Italy, ten miles south-east of Urbino.

**FOTHER**, or **FODDER**, in mining. See the article **FODDER**.

**FOTUS**, a fomentation. See the article **FOMENTATION**.

**FOVEA CORDIS**, in anatomy, the pit of the heart, or rather of the stomach.

**FOUGADE**, or **FOUGASSE**, in the art of war, a little mine, about eight or ten feet wide, and ten or twelve deep, dug under some work or post, which is in danger of falling into the enemies hands; and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a saucisse.

**FOUGIERES**, a town of Britany, in France, thirty-five miles south east of St. Malo.

**FOUL**, or **FOULE**, in the sea-language, is used when a ship has been long untrimmed, so that the grafs-weeds, or barnacles grow to her sides under water. A rope is also foul when it is either tangled in itself, or hindered by another, so that it cannot run, or be over-hawled.

**FOUL** imports, also, the running of one ship against another. This happens sometimes by the violence of the wind, and sometimes by the carelessness of the people on board, to ships in the same convoy, and to ships in port by means of others coming in. The damages occasioned by running foul, are of the nature of those in which both parties must bear a part. They are usually made half to fall upon the sufferer, and half upon the vessel which did the injury: but in cases where it is evidently the fault of the master of the vessel, he alone is to bear the damage.

**FOUL-WATER**. A ship is said to make foul-water, when being under sail, she comes into such shoal-water, that tho' her keel do not touch the ground, yet it comes so near it, that the motion of the water under her, raises the mud from the bottom.

**FOUL** is also a disease in cattle, proceeding from blood, and a waterish rheum that falls down into the legs, and makes them swell. See *Swelled LEGS*.

**FOULNESS**, in surgery, a term applied to wounds, where the flesh is putrid, fungous, black or livid. Wounds must be well cleansed before any attempts are made to heal them. For which intention the antients used honey, but the moderns apply a digestive ointment made of turpentine dissolved in the yolk of an egg, and afterwards mixed with honey of roses; but where this is not found strong enough for the purpose, they substitute the egyptian ointment, mixed

either with spirit of wine, or with the common digestive. To these digestive ointments, a small quantity of aloes or myrrh may be added, and where more strength is required, a small quantity of red precipitate. The use of lime-water as a detergent is also known to be very beneficial, especially if there be added to every pint of it, twenty or thirty grains of sublimate, which from its known efficacy is called by the surgeons phagedenic-water. Applications of this kind are to be continued till the wound is intirely clean, and then it is to be healed with the common digestives. See the article **WOUND**.

**FOUMART**, a name used in some parts of the kingdom for the mustela, or weasel. See the article **MUSTELA**.

**FOUNDATION**, in architecture, is that part of a building which is underground. See **BUILDING**.

Foundation, called by Daviler, *Fondation*, is the coffer or bed dug below the level of the ground to raise a building upon, in which sense the foundation either goes to the whole area of the building, as when there are to be vaults, cellars, &c. or it is drawn in trenches, as when only walls are to be raised. The foundation, *Fondement*, according to the same author, is properly so much of the masonry as reaches as high as the surface of the ground, and ought always to be proportioned to the load or weight of the building that it is to bear. Sometimes the foundation is massive, and continued under the whole building, as in the antique arches and aqueducts, and some amphitheatres; but it is more usually in spaces or intervals, either to avoid expence, or because the vacuities are at too great a distance, in which latter case they make use of insulated pillars bound together by arches.

Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging, unless there be cellars or under-ground, in which case he would have it somewhat lower, and as to thickness, double the width of a wall is no bad rule. Palladio also lays down several rules to know if the earth be firm enough for the foundation, by observations from the digging of wells, and the like; but the best way to discover the nature of the soil is to try it with an iron-crow, or else with a borer, such as is used by well-diggers.

Foundations are either natural or artificial

ificial Natural as when we build upon a rock, or very solid earth, in which case we need not seek for any further strengthening; for these, without digging, or other artificial helps, are of themselves fit to uphold the greatest buildings. But if the ground be sandy, or marshy, or have lately been dug, recourse must be had to art. If the ground be sandy or marshy, you must dig till you find sound ground, and the best is that which requires most labour in cutting, and when wet, does not dissolve into dirt. If the earth to be built upon is very soft, as in moorish grounds, lay good pieces of oak whose length must be about the breadth of the trench, or two feet longer than the breadth of the wall, across the foundation, about two feet asunder, and being well rammed down, lay long planks upon them, pinning or spiking down each plank to the pieces of oak on which it lies. But if the ground be very bad, let piles of oak of a diameter about one twelfth part of their length be drove down to reach the good ground, and placed as close as one can stand by another; then spike down long planks upon them. And it must not be forgot to place the piles not only under the outer walls, but also under the inner walls that divide the building; for if these should sink, it would make the outer wall crack, and so ruin the whole building. If the ground be faulty here and there, let arches be turned over the faulty places, which will discharge them of the weight. As to the rules necessary to be observed in the substruction or artificial part of the foundation, they are these, 1. That the bottom of the trench be made exactly level. 2. That the lowest ledge or row be all of stone (the broader the better) laid close together. 3. That the breadth of the ground-work be at least double that of the wall to be raised on it. However, the breadth may be regulated according to the goodness of the ground, and the weight of the intended edifice. 4. That the foundation be made to diminish as it rises, taking care, however, that it do so equally on both sides. 5. That you ought never to build on the ruins of an old foundation, unless well assured of its depth and strength to bear the superstructure. 6. And lastly, The stones in a foundation should be laid as they naturally lay in the quarry, a precept generally observed by all good architects, because they find the stones

are subject to cleave that way of the grain that lay horizontally in the quarry. In some places, buildings near the water are founded on sacks of wool laid like matresses, which being well pressed and greasy, will never give way, nor rot in the water.

*Foundation of Bridges*, is laid after different manners. The first is by enclosing all round the space of ground you would build upon, by dams made with piles set deep in the ground in double rows, well strengthened and bound together with cross pieces and cords, and filling the vacant spaces between them with chalk or other earthy matter. This being done, the water must be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be necessary, upon which the walls of the foundation must be laid. But this method is only practicable in building on such rivers, where the water is neither very rapid, nor very deep. The second is done by laying the foundation on grate-work, rafts of stout oak well bound together, and made fast at the surface of the water with cables or machines, and building upon them large quarters of stone, cramped together, and joined with good mortar, or cement, and afterwards letting them descend softly by these cables and machines perpendicularly to the bottom of the water. This was the method practised in laying the foundation of Westminster-Bridge, the grating being made of the bottom of a frame called by the French *Caisson*, the sides of which were so contrived, that they might be taken off, after a pier was finished. The third is by drawing off all, or the greatest part of the water of the river into some other place; and this was done at London-Bridge, if we could believe Stow, who alleges, that during the time of building, the river was turned from Battersea to Rotherhith: but this is not warranted. See further on this subject in Belidor's *Architect. Hydraulique*. Livre iv. ch. 11, and 12.

**FOUNDATION** denotes also a donation or legacy either in money or lands, for the maintenance and support of some community, hospital, school, lecture, &c.

**FOUNDATION** is also used figuratively for the establishment of a city, empire, or the like.

**FOUNDAY**, in metallurgy, a term used by the workers at the iron-mines in many counties of England, for the space of  
fix

six days, in which time they contrive to make a determinate quantity of iron ; so that they count their work by these foundays, or weeks.

**FOUNDER**, in a general sense, the person who lays a foundation, or endows a church, school, religious-house, or other charitable institution. The founder of a church may preserve to himself the right of patronage, or presentation to the living.

**FOUNDER**, also implies, an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See the article **FOUNDRY**,

**FOUNDER**, in glass-making, a term appropriated to the green glass, and is the person there, who in the same office in the white-glass making is called conciator. See the article **CONCIATOR**.

**FOUNDER**, in the sea-language, a ship is said to founder, when by an extraordinary leak ; or by a great sea breaking in upon her, she is so filled with water, that, she cannot be freed of it ; so that she can neither veer nor steer, but lie like a log ; and not being able to swim long, will at last sink.

**FOUNDERING**, in the manege, a disorder in horses, whereof there are two kinds, *viz.* in the feet and in the chest.

Foundering in the feet, is an universal rheumatism, or defluxion of humours upon the sinews of a horse's feet, which causes so great a stiffness in the hoofs, that the horse has no sense nor feeling of them.

This disorder arises from hard riding ; from great heats and colds ; and is sometimes occasioned by watering a horse when he is very hot, by which means, as the farriers term it, his grease is melted within him ; also by wearing too strait a shoe, or travelling upon hard ground.

The general methods of curing this distemper are, first to pare all the horse's soles so thin, that you may see the quick ; then bleed him well at every toe ; stop the vein with tallow and rosin ; and having tacked hollow shoes on his feet, stop them with bran, tar, and tallow, as boiling hot as may be ; and this renew once in two days for a week together, after which, let him have good exercise,

&c. or, after he is pared thin, and let blood at his toes, stop his feet with cow's dung, kitchen-fee, tar, and soot, boiled together, and poured boiling-hot into them.

Foundering in the chest, may proceed from crudities in the stomach, or other infirmities, obstructing the passages of the lungs ; and may be discovered by the horse's not being able to bow his joints ; and being once laid, he cannot rise again ; his legs swell, &c.

As a particular remedy for chest-foundering, take five or six pennyworth of oil of peter, and mingle it with an equal quantity of ale, or beer : then rub this mixture with your hand on the part affected ; and cause a red hot fire-shovel to be held before it during the application.

**FOUNDRY**, or **FOUNDRY**, the art of casting all sorts of metals into different forms. It likewise signifies the work-house, or smelting-hut, wherein these operations are performed.

**FOUNDRY of small-works, or casting in sand.** The sand used for casting small works, is, at first, of a pretty soft, yellowish, and clammy nature : but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife ; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them so to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass-cylinder, as the chief canal for the metal to run through, when melted, into the models, or patterns ; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes that

that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counterpart, and adding the cross canals to the several models in both, and srewing mill-dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing through the chief cylindrical canal, they are screwed or wedged up like a kind of a press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

Some of these small work founder's furnaces are like a smith's forge; others stand a few feet under-ground for the more easily and safely taking out a weighty pot of metal; which is done by means of a circular tongs that grasps round the top of the crucible. When the metal is melted, the workman pours it through the chief canal of each mould, which conveys it to every distinct pattern. See the articles *FLUX* and *FORGE*.

When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is worked over again for other castings.

**FOUNDRY of statues.** The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone, or brick; or when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron-grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair, and horse-dung; or of plaster of Paris mixed

with brick-dust. The use of the core is to support the wax, the shell, and lessen the weight of the metal. The iron-bars, and the core are taken out of the bra's figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron-bars of the core, that contribute to the steadiness of the projecting part, within the bra's figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core; though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick-dust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder, when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water, to the consistence of a colour fit for painting: accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whites. For the second impression, they add horse-dung, and natural earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron-girts, bound round it, at about half a foot distance from each other,

other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate. If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways : in the first a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone, or brick. At the bottom is made a hole of the same materials with a kind of furnace, having its aperture outwards : in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof, a massive made for a melting furnace. For the rest, the method is the same in both. The mould being finished, and inclosed as described, whether under-ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented, till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they take out the bricks and fill up their place with earth, moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen basin, over the

mould, into the bottom of which all the big branches of the jets, or casts, which are to convey the metal into all the parts of the mould, are inserted.

These casts, or jets, are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence, may not enter any of them, till the basin be full enough of matter to run into them all at once. Upon which occasion, they pull out the plugs, which are long iron-rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part ; the rest being the sculptor's or carver's business, who taking the figure out of the mould, and earth, wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chisels, gravers, punches, &c.

**FOUNDRY OF BELLS.** The metal, it is to be observed, is different for bells, from what it is for statues ; there being no tin in the statue-metal : but there is a fifth, and sometimes more, in the bell-metal. See the article **BELL**.

The dimensions of the core, and the wax, for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness necessary for the several tones required. See the article **DIAPASON**.

It is on the wax that the several mouldings and other ornaments are formed to be represented in relievo, on the outside of the bell.

The business of bell-foundry is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould ; and, 3. The melting of the metal.

The proportions of our bells differ much from those of the Chinese : in ours the modern proportions are to make the diameter fifteen times the thickness of the brim, and twelve times the height.

There are two kinds of preparations, viz. the simple and the relative : the former are those proportions only that are between the several parts of a bell, to render it sonorous ; the relative proportions establish a requisite harmony between several bells.

The particulars necessary for making the mould of a bell, are, 1. The earth : the most cohesive is the best : it must be well ground and sifted, to prevent any chinks. 2. Brick-stone ; which must be used for the mine, mould, or core, and for the furnace. 3. Horfe-dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon tressels. Upon this, they carry the earth, grossly diluted, to mix it with horfe-dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consist of two different legs, joined by a third piece. And last of all, the founders shelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole, of a sufficient depth to contain the mould of the bell, together with the case, or cannon, under-ground ; and about six inches lower than the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole ; or between one mould and another, when several bells are to be cast. At the center of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron-peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a mill-stone. The parts of the mould are the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an

opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horfe-dung, on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals, through an opening that is kept shut, during the baking, with a cake of earth, that has been separately baked. The first fire consumes the stake, and the fire is left in the core half, or, sometimes, a whole day : the first layer being thoroughly dry, they cover it with a second, third, and fourth ; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place, to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter, smoothed by the compasses, and thoroughly dried, before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chaffing-dish : this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine ; whilst it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but something thicker : when this second layer becomes of some consistence, they apply the compasses again, and light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards

afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings, the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron-peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron-keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united may make the hollows of the six rings: the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and foldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist, to fix on the place, which is strewed, at several times, upon the cover of the core; and they beat it gently with a peltle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outsidings of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without

breaking. To make room for the metal they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up, and got out of the pit.

When this and the wax are removed, they break the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and folder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal, is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame reverberates; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross, or scoriæ, of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

#### FOUNDRY of great guns and mortar-pieces.

The method of casting these pieces is little different from that of bells: they are run maffy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trepan, that is worked either by horses, or a water-mill.

For the metal, parts, proportions, &c. of these pieces. See CANNON.

*Letter FOUNDRY, or Casting of printing letters.* The first thing requisite is to prepare good steel-punches, on the face of which is drawn the exact shape of the letter with pen and ink, if the letter be large, or with a smooth blunted point of a needle, if small; and then, with proper gravers, the cutter digs deep between the strokes, letting the marks stand on the punch; the work of hollowing being generally regulated by the depth of the counter-punch: then he files the outside, till it is fit for the matrice.

They have a mould to justify the matrices by, which consists of an upper and under part, both which are alike, except the stool and spring behind, and a small roundish wire in the upper part, for making the nick in the flank of the letter. These two parts are exactly fitted into each other, being a male and female gage,\* to slide backwards and forwards. See the article GAGE.

Then they justify the mould, by casting about twenty samples of letters, which are set in a composing-stick, with the nicks towards the right hand; and comparing these every way with the pattern-letters, set up in the same manner, they find the exact measure of the body to be cast.

Next they prepare the matrix, which is of brass or copper, an inch and a half long, and of a proportionable thickness to the size of the letter it is to contain. In this metal is sunk the face of the letter, by striking the letter-punch the depth of an *n*. After this, the sides and face of the matrice are justified, and cleared, with files, of all bunchings that have been made by sinking the punch.

Then it is brought to the furnace, which is built upright of brick with four square sides, and a stone at top, in which is a hole for the pan to stand in. They have several of these furnaces. See the article FURNACE.

Printing-letters are made of lead, hardened with iron or stub-nails. To make the iron run, they mingle an equal weight of antimony, beaten small in an iron mortar, and stub-nails together. They charge a proper number of earthen pots, that bear the fire, with the two ingredients, as full as they can hold, and melt it in an open furnace, built for that purpose. See the article FLUX.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compott is ladled into an iron-pot,

wherein is melted lead, that is fixed on a furnace close to the former, 3 lb of melted iron to 2 1/2 lb of lead; this they incorporate according to art.

The caster taking the pan off the stone, and having kindled a good fire, he sets the pan in again, and metal in it to melt. If it be a small-bodied letter, or a thin letter with great bodies, that he intends to cast, his metal must be very hot, and sometimes red hot, to make the letter come. Then taking a ladle, of which he has several sorts, that will hold as much as will make the letter and break, he lays it at the hole where the flame bursts out; then he ties a thin leather, cut with its narrow end against the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice-cheek; and places the foot of the matrice on the stool of the mould, and the broad end of the leather on the wood of the upper half of the mould, but not tight up, lest it hinder the foot of the matrice from sinking close down upon the stool, in a train of work. Afterwards laying a little rosin on the upper part of the mould, and having his casting-ladle hot, he, with the boiling side, melts the rosin and presses the broad end of the leather hard down on the wood and so fastens it thereto. Now he comes to casting, when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the lower part of the ball of his thumb and his three hinder fingers; then he lays the upper half of the mould upon the under half, so as the male gages may fall into the female; and, at the same time, the foot of the matrice places itself upon the stool, and clasping his left hand thumb strongly over the upper half, he nimbly catches hold of the bow or spring, with his right hand fingers at the top of it, and his thumb under it, and places the point of it against the middle of the notch in the backside of the matrice, pressing it forwards as well towards the mould, as downwards, by the shoulder of the notch, close upon the stool, while at the same time with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of his thumb, and thrusts, by the ball of his thumb, the upper part towards his fingers, that both the registers of the mould

mould may press against both sides of the matrice, and his thumb and fingers press both sides of the mould close together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three strokes outwards upon the surface of the melted metal, to clear it of the scum; then he takes up the ladle full, and having the mould in the left hand, turns his left side a little from the furnace, and brings the geat of his ladle to the mouth of the mould; and turns the upper part of his right hand towards him, to pour the metal into it, while, at the same instant, he puts the mould in his left hand forwards, to receive the metal with a strong shake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the shank. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he tosses the letter, break and all, out upon a sheet of waste paper, laid on a bench, a little beyond his left hand; and then is ready to cast another letter, as before, and likewise the whole number in that matrix.

Then boys, commonly employed for this purpose, separate the breaks from the shanks, and rub them on a stone, and afterwards a man cuts them all of an even height, which finishes the fount for the use of the printer. See the next article.

A workman will ordinarily cast 3000 of these letters in a day. The perfection of letters thus cast, consists in their being all severally square and straight on every side; and all generally of the same height, and evenly lined, without stooping one way or other; neither too big in the foot, nor the head; well grooved, so as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and scraped, with a sensible notch, &c. See the article PRINTING.

**FOUNT**, or **FONT**, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted. Founts are large or small, according to the demand of the printer, who orders them by the hundred weight, or by sheets. When a printer orders a fount of five hundred, he means that the fount, consisting of letters, points, spaces, qua-

drates, &c. shall weigh 500 lb. When he demands a fount of ten sheets, it is understood, that with that fount he shall be able to compose ten sheets, or twenty forms, without being obliged to distribute. The founder takes his measures accordingly; he reckons 120 lb. for a sheet, including the quadrates, &c. or 60 lb. for a form, which is only half a sheet: not that the sheet always weighs 120 lb. or the form 60 lb. on the contrary, it varies according to the size of the form; besides, it is always supposed that there are letters left in the cases. As therefore every sheet does not comprehend the same number of letters, nor the same sort of letters, we must observe, that, as in every language some sounds recur more frequently than others, some letters will be in much more use, and oftener repeated than others, and consequently their cells or cases should be better stored than those of the letters which do not recur so frequently: thus, a fount does not contain an equal number of *a* and *b*, or of *b* and *c*, &c. the letter-founders have therefore a list or tariff, or, as the French call it, a *police*, by which they regulate the proportions between the different sorts of characters that compose a fount; and it is evident that this tariff will vary in different languages, but will remain the same for all sorts of characters employed in the same language.

**FOUNTAIN**, *fons*, in philosophy, a spring or source of water rising out of the earth. Among the antients, fountains were held sacred, and even worshipped as a kind of divinities. For the phenomena, theory, and origin of fountains or springs, see the article SPRING.

**FOUNTAIN**, or *Artificial FOUNTAIN*, in hydraulics, called also a *jet d'eau*, is a contrivance by which water is violently spouted upwards.

The theory of fountains, in regard to the action of the several parts of a fluid upon each other, depends on the following principles. It has been shewn, under the article FLUID, that water coming from a reservoir, as ABCD (pl. CV. n° 1.) through the pipe EFGH, will rise from the lowest part, G, to the same altitude H, in the part GH, as is upon a level with the surface of the water AB, in the reservoir: and also, that it thus rose from the point G, by a force of pressure proportional to the altitude of the water in the reservoir, which is equal to the altitude GH. Now it is very evident that

the tube GH itself can contribute nothing towards the waters rising in it; on the contrary it rather impedes the ascent, by the friction it occasions to the particles which move against the internal surface thereof. Therefore, if the part GH be taken away, the water would rise to the same height H, excepting so far as it is obstructed by other concurring incidents; for in all fountains the height GI is somewhat less than GH, the height of the tube, for the following reasons: 1. The air's resistance is an obstruction to the jet, and diminishes its height; and since we know that the resistance of fluids is proportional to the squares of the velocity, and the deficiency of the height HI is proportional to the resistance; therefore a jet that plays with a double velocity, will have that deficiency four times as great; and with three times the velocity, nine times as great, and so on. 2. The second impediment is the friction against the sides of the hole, and the adjutage at G; and since this is in proportion to the quantity of surface in the hole, it will be greater in a small hole than in a great one, in respect to the body of the spouting water; because the jet will increase in magnitude with the square of the diameter of the hole, whereas the resistance will increase only with the diameter simply: or, a hole of twice the diameter emits four times the water, and gives but twice the resistance: this makes a small jet rise to less height than a large one from the same fountain. 3. A third impediment arises from hence, that since all the particles set out from G, with an equal velocity, and this velocity is continually diminishing, it follows, that the velocity of the inferior parts is greater than the velocity of the parts above them, and therefore must in some degree strike against them: by which impulse, since fluids move every way, the particles will be urged side-ways, and the column of the jet become wider, and consequently shorter than it would otherwise be. 4. The fourth cause why jets do not rise to the height of the reservoirs, is because the water upon the top of the jet does not immediately run off, but spreading into a head, lies with its weight upon the ascending water below, and hinders it from rising so high as it would otherwise do: this will appear by inclining the jet a little, that the upper water may not bear upon the rising stream; for the jet will then play higher, but be less beautiful.

If the hole of the adjutage G be less than a quarter of an inch in diameter, the force of the attraction of cohesion will extend itself through the body of the jet at the hole, and greatly obstruct its ascent: whence all jets of larger fountains, such as are in gentlemen's gardens, ought to exceed a quarter of an inch in diameter, and that in proportion to the height of the reservoir.

And one thing more is necessary to be known, that the jet may play the highest possible, *viz.* that the part of the conduct pipe at the adjutage, does not turn up at right angles, but with a gentle easy curve; that is, not as at C, but as at L, where the jet plays to a greater height at K: the upright part at G directly resists the water coming from F, whereas the curve at L causes the impulse of the water against it to be oblique; and therefore a less part of its momentum will be destroyed, and consequently the greater remaining force will throw the jet the higher.

A Table of the height to which jets will rise, in feet and decimal parts, from reservoirs of an height of five feet to an hundred and fifty feet.

Rei.	Jet.	Rei.	Jet.	Rei.	Jet.	Rei.	Jet.
5	4,91	31	28,32	57	48,99	83	67,71
6	5,88	32	29,16	58	49,74	84	68,40

30	27,48	56	48,24	82	67,02		

FOUNTAINS.

From what has been said upon the second cause assigned for the obstruction the jet meets with in rising to the height of the reservoir, which is the friction against the sides of the hole and the adjutage, it appears, *ceteris paribus*; that the hole in the adjutage ought to be made in a thin plate of brass, and not through the bore of a tube of any length, because of the quantity of surface in such an adjutage-piece which must greatly retard the jet, and diminish the height.

If the conduit-pipe EFG be not of a proper size to supply water as fast as it can be expended at the adjutage G, the jet will likewise be checked, and it will not rise to the full height. To ascertain the proportion of the conduit-pipe to the bore of the adjutage, is shewn by the following table, made by Mr. Mariotte, Dr. Desaguliers, and others, who, by various experiments, found that if the reservoir be 5 feet high, a conduit-pipe  $1\frac{3}{4}$  inch diameter will admit a hole in the adjutage from  $\frac{1}{4}$  of an inch to  $\frac{3}{4}$  of an inch; and so on, as in the following table.

Height of the reservoir.	Diameter of the ad- jutages.		Diameter of the pipes of conduit.	
	Feet.	Inch.	Inch.	
5		$\frac{1}{4}$ to $\frac{3}{8}$	$1\frac{3}{4}$	
10		$\frac{1}{4}$ to $\frac{1}{2}$	2	
15		$\frac{1}{4}$ to $\frac{1}{2}$	$2\frac{1}{4}$	
20		$\frac{1}{4}$ to $\frac{1}{2}$	$2\frac{1}{2}$	
25		$\frac{1}{4}$ to $\frac{1}{2}$	$2\frac{3}{4}$	
30		$\frac{1}{4}$ to $\frac{3}{4}$	3 or $3\frac{1}{2}$	
40		$\frac{3}{8}$ to $\frac{1}{2}$	$4\frac{1}{4}$	
50		$\frac{3}{8}$ to $\frac{1}{2}$	5	
60		1	$5\frac{3}{4}$	
80		$1\frac{1}{4}$ to $1\frac{1}{2}$	$6\frac{1}{2}$	
100		$1\frac{1}{4}$ or $1\frac{1}{2}$	7 or 8	

Here the jet is supposed to be within 100 or 150 yards of the reservoir; but if the conduit-pipe much exceeds this length, it must be of a larger diameter than what is here assigned: thus, for jets from  $\frac{3}{4}$  of an inch, to those of an inch, and from reservoirs from 40 to 90 feet height, if the distance be from 150 yards to  $\frac{1}{4}$  of a mile, the diameter of the pipe should be of 6 inches; from  $\frac{1}{4}$  of a mile to  $\frac{1}{2}$  miles it must be of 7 inches; and from  $\frac{1}{2}$  miles to 5, it must be 8 inches diameter for the same jets. If it be required to keep any number of jets playing, whose ad-

jutages are given in diameter by one common conduit-pipe, we must find the diameter of an adjutage equal to all the given ones: thus, if there be four adjutages of  $\frac{3}{4}$  of an inch each, then the square of  $\frac{3}{4}$  is  $\frac{9}{16}$ , which multiplied by the number of adjutages 4, makes  $\frac{36}{16}$ , the square root of which is  $\frac{6}{2} = 3$  — the diameter of the adjutage, equal to all the four small ones. A pipe of conduit of 10 inches diameter will supply all the jets, as being a little more than six times as great as the diameter of the one large adjutage now found. After this manner the dimensions of a conduit-pipe may be found for any number of adjutages.

A fountain that shall spout the water in various directions is made as follows: suppose the vertical tube in which the water rises, to be AB (*ibid.* n° 2.) in this fit several other tubes, some horizontal, others oblique, some inclining, others reclining, L, O, P, A, N, &c. then as all water retains the direction of the aperture through which it is spouted, that issuing through A will rise perpendicularly, and that through L, H, N, P, O, will describe arches of different magnitudes, tending different ways.

Or thus: suppose the vertical tube AB (*ibid.* n° 3.) to be stopped at top, as at A; and instead of pipes, or jets, let it be only perforated with little holes all round, or only half its surface; then will the water spout forth in all directions through the little apertures, to a distance proportional to the height of the fall of the water.

A ball, A, if its weight be not too heavy, being laid in the bottom of the cup or basin B (*ibid.* n° 4.) will be taken up in the stream, and sustained at a considerable height, as A; alternately vibrating, or playing up and down, provided the tube BC, through which the water rises, be exactly perpendicular to the horizon.

The ball may be made of a thin plate of brass, or any other light metal; but as its figure of a ball contributes nothing to its reciprocal rise and fall, any other body, not too heavy, may be substituted in place thereof. As it is necessary that the body sustained by the jet, should keep the same precise perpendicular on its descent and rise, since otherwise it would miss the stream, such a fountain should be played in a place free from wind.

A fountain may be made to spout water in manner of a shower, by fitting a spherical

rical or lenticular head AB (*ib. n° 5.*) made of a plate of métal, and perforated at top with a great number of little holes; for the water, rising with a certain velocity towards AB, will there be divided in innumerable little threads, and afterwards be broke and dispersed into small drops.

A fountain may be made to spread the water in form of a cloth, by folding two spherical segments C and D (*ibid. n° 6.*) so close together as to be almost touching one another, with a screw E, to contract or amplify the interstice, or chink, at pleasure: then this spherical head being fitted upon the tube, the water spouting through the chink, will expand itself in manner of a cloth.

The theory of fountains, with regard to the action of air upon water by condensation and rarefaction, may be sufficiently understood from what has been delivered under the articles FLUID, AIR, ENGINE, CONDENSATION, RAREFACTION, and ELASTICITY; whence it appears, that condensed air injected into any vessel containing water, will, by means of its elasticity, cause the water to spout out thro' an adjutage to an height proportionable to the spring of the condensed air. Upon this principle the following fountain AB (*ibid. n° 7.*) depends, where the air is condensed at the top of the water by a syringe, and the air and water retained by the cock at C, so that the fountain cannot play till you open the cock; then the water strongly pressed by the condensed air at SS, goes through the pipe *a*, and the adjutage *b*, with great force, in jets of several figures, according to the spouting-pipes, put on at *b*.

As here the air is compressed by a syringe, in the fountain (*ibid. n° 8.*) the air being only compressed by the concealed fall of water, makes a jet, which, seen for a while, is looked on as a perpetual motion by the ignorant, who think that the same water that fell from the jet, rises again.

The boxes CE, and D Y X, being close, you see only the basin ABW, with a hole at W, into which the water, spouting out at B, falls; but that water going down the hole W, does not come up again at W, but runs down through the pipe WX, into the box D Y X, from whence it drives out the air thro' the ascending pipe YZ, into the cavity of the box CE, where, pressing upon the water that is in it, it forces it out through the

spouting-pipe OB, as long as there is any water in CE; so that this whole play is only while the water contained in CE, having spouted out, falls down through the pipe WX, into the cavity D Y X. The force of the jet is proportionable to the height of the pipe WX, or of the boxes CE and DY, above one another. The height of the water measured from the basin ABW, to the surface of the water in the lower box D Y X is always equal to the height measured from the top of the jet to the surface of the water in the middle cavity at CE. Now since the surface CE is always falling, and the water DY is always rising, the height of the jet must continually decrease, till it is shorter by the height of the depth of the cavity CE, which is emptying, added to the depth of the cavity D Y, which is always filling, and when the jet is fallen so low, it immediately gives over.

The way to prepare this fountain for playing, is as follows: first, pour in water at W, till you have filled the cavity D Y X; then turn the fountain over, and the water will run from the cavity D Y X into the cavity CE, which you will know to be full when the water runs out at B, held down; set the fountain up again, and pour in about a pint of water into the basin ABW, and so soon as it has filled the pipe WX, the fountain will play, and continue so long as there is any water in CE. You may then pour back the water left in the basin ABW, into any vessel, and invert the fountain; which being set upright again, will be set a playing by putting back the water poured out into ABW.

A fountain, which, when it has done spouting, may be turned up like an hour-glass, is made as follows: provide two vessels, AFH and BDG (*ib. n° 9.*) of a capacity proportionable to the time the fountain is required to play without turning up, and placed at so much the greater distance from each other as the water is required to spout the higher: the water contained in the cavity AFH, runs down the curve-pipe CDE, and spouts up through the jet E, by the pressure of the column of water CD; but unless the pipe GF, was open at G, to let the air run up to F, and press at the top of the surface of the water in the cavity A, the water would not run down and spout out at E: there is such another pipe as G K, belonging to the cavity B, through which

Fig. 1. FOUNTAINS.

Fig. 2. FOURCHEE.

which the water of the jet is received into the basin, supplies the cavity B, whilst the fountain stands on the end B; but when the fountain is inverted, it supplies B with air, to let the water descend in the direction GHI, I becoming the spouting-pipe. Wherefore, by turning the machine upside down, the water spouts up through the cock at G, and the vessel AHC, will be the reservoir. Hence, if the vessels AFH and DKB contain just as much water as will be spouted up in an hour's time, we shall have a spouting clepsydra, which may be graduated or divided into quarters, minutes, &c. See the article CLEPSYDRA.

The fountain (plate CVI. n° 1.) is upon the same principle, and of the same kind with n° 8. plate CV. but having double the number of pipes and concealed cavities, it plays as high again. N° 2. must be examined, to see its cavities and pipes, where the basin is A, and the four cavities B, C, D, and E, from which the water from the pipe fG, spouts out to double the height of the fountain; the air at E, which drives it, being doubly condensed. The water going down the pipe i (suppose it three feet long) condenses the air that goes up into the cavity C, through the pipe 2, so as to make it  $\frac{1}{10}$  stronger than the common air; then the water which falling in the pipe 3, from C to D, is capable by the height of its fall, to condense the air at E, so as to make it  $\frac{1}{10}$  stronger, being pushed at C by air already condensed into  $\frac{1}{10}$  less space, causes the air at E to be condensed twice as much; that is, to be  $\frac{1}{5}$  stronger than the common air, so that it will make the water at G spout out with twice the force, and go to twice the height that it would do, if the fountain had been of the make of n° 8. pl. CV. The way to prepare this fountain for playing, is to turn it upside down, and taking out the plugs g, b, to fill the two cavities C and E, and having shut the holes again, set the fountain upright, and pour some water into the basin A, and the jet will play out at G.

Another way of making artificial fountains, is by the rarefaction of the air, in the manner following: AB and CD (*ibid.* n° 3.) are two pipes fixed to a brass-head C, to screw into a glass-vessel E, which having a little water in it, is inverted, till the pipes are screwed on;

then reverting it suddenly, so as to put A the lower end of the spouting-pipe AB, into a jar of water A; and the lower end of the descending pipe CD, into a receiving vessel D, the water will spout up from the jar A, into the tall glass vessel E, from which it will go down at the orifice C, through the descending pipe CD, into the vessel D, till the water is out of A (making a fountain in E) and has emptied itself into D.

The reason of the play in this fountain is this: the pipe CD being 2 feet 9 inches long, lets down a column of water which rarifies the air  $\frac{1}{12}$  part in the vessel E, where it presses against the water spouting at B, with  $\frac{1}{12}$  less force than the water is pushed up the hole A, by the pressure of the common air on the water in the vessel A; so that the water spouts up into E (when the air is rarified  $\frac{1}{12}$ ) with the difference of the pressure of the atmosphere, and the aforesaid rarified air; that is, of 33 to 2  $\frac{3}{4}$ . This would raise the water 2. feet 9 inches: but the length of the pipe A, 9 inches, being deducted, the jet will only rise 2 feet. This may be called a syphon-fountain, where AB is the driving leg, and CD the issuing leg.

A fountain that begins to play upon the lighting of candles, and ceases when they go out, may be contrived as follows: provide two cylindrical vessels AB and CD (*ibid.* n° 4.) connect them by tubes open at both ends KL, FB, &c. so that the air may descend out of the higher into the lower; to these tubes solder candlesticks, H, &c. and to the hollow cover of the lower vessel CF, fit a little tube or jet FE, furnished with a cock G, and reaching almost to the bottom of the vessel. In G let there be an aperture furnished with a screw, whereby water may be poured into CD. Then upon lighting the candles H, &c. the air in the contiguous tubes becoming rarefied thereby, the water will begin to spout through EF.

There are many other artificial fountains made upon these principles; but what are explained may be sufficient, when we have added to it the description of one invented by Dr. Desaguliers to play by the spring of the air, increased by the heat of the sun, which also serves for a dial at the same time.

GNS (*ibid.* n° 5.) is a hollow globe of thin copper, of 18 inches in diameter, supported

supported by a small inverted bason, standing on a frame with four legs A, B, C, &c. which have between them, at the bottom, a large bason of two feet diameter. Along the leg C comes a concealed pipe, going from G, the bottom of the inside of the globe, which pipe comes along HV to join in an upright pipe uI, to make a jet at I. The short pipe Iu going to the bottom of the bason, has a valve at V, under the horizontal part H u, and another valve at V, above the said horizontal pipe, under the cock at K. The north pole N, has a screw to open an hole, whereby to fill the globe with matter. Things thus prepared, and the globe half filled with water, let the machine be set in a garden; and the heat of the sun rarefying the air, as it heats the copper, the air will press hard upon the water, which coming down the pipe GCHVI, will lift up the valve V, but shut the valve u; and the cock being open, spout out at I, and continue to do so for a long time, if the sun shines. At night, as the air condenses again, the outward air pressing the adjutage I, will shut the valve V, but pressing on the bason D u H, it will push up the water, which has been played in the day time through the valve u, and pipe uHG into the globe, so as to fill it up again to the same height that the water was at first, and the next sun-shine will cause the fountain to play again, &c. The use of the cock is to keep the fountain from playing till the time of day that you think proper. A small jet will play six or eight hours. If the globe be set for the latitude of the place, and rectified before it be fixed, with the hour lines or meridians drawn upon it, the hours marked and the countries painted as in the common globe, it will be a good dial; the sun shining upon the same places in this globe, as it does upon the earth itself.

**FOUR-CORNERS**, in the manege. To work upon the four-corners, is to divide (in imagination) the volt, or round, into four quarters: when a horse has made a round or two, either at trot or gallop, he is said to have made the four-corners.

**FOURCHEE**, or **FOURCHY**, in heraldry, an appellation given to a cross forked at the ends. See plate CVI. n° 6.

**FOURCHER**, or **FOURCHING**, in law, signifies the delaying or putting off an action, which might have been brought to a determination in a shorter time.

**FOURCHETTE**, or **FER DE FOUCHETTE**.

See the article **FER**.

**FOURTH**, in music, one of the harmonical intervals, called concords. See the articles **CONCORD** and **INTERVAL**.

It is called fourth, as containing four sounds or terms between its extremes, and three intervals; or as being the fourth in order of the natural or diatonic scale, from the fundamental. The antients called it diatessaron, and speak of it as the principal concord, on whose divisions all the rest depend; but the moderns, so far from allowing it such perfections, find it one of the most imperfect, and even dispute whether it ought to be received among the number of concords at all.

It consists in the mixture of two sounds, in the ratio of 4 : 3; that is, of two sounds produced by two cords, whose lengths, &c. are in that proportion.

*Diminished* **FOURTH**. See **DIMINISHED**.

*Superfluous* **FOURTH**, a discord consisting of two tones major and one minor, called also tritone: it is composed of the ratios 27 : 20, and 4 : 5. See **DISCORD**.

**FOURTH-RATE**. See the article **RATE**.

**FOWEY**, a borough-town of Cornwall, which sends two members to parliament: west long. 5°, and north lat. 50° 26'.

**FOWL**, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such are geese, pheasants, partridges, turkey, ducks, &c. See the articles **GEESE**, **PHEASANT**, &c.

Tame fowl make a necessary part of the stock of a country farm. See the article **POULTRY**.

Fowls are again distinguished into two kinds, *viz.* land and water-fowl; these last being so called, from their living much in and about water: also into those which are accounted game, and those which are not. See the article **GAME**.

**FOWLING**, the art of catching birds by means of nets, bird-lime, decoys, and other devices. See the articles **NET**, **BIRD-LIME**, &c.

**FOWLING** is also used for the pursuing and taking birds with hawks, more properly called falconry. See **FALCONRY**.

**FOWLING-PIECE**, a light gun for shooting birds. That piece is always reckoned best which has the longest barrel, from 5½ to 6 feet, with a moderate bore; tho' every fowler should have them of different sizes, suitable to the game he designs to kill. The barrel should be well polished and smooth within, and the bore of an equal bigness from one end to the other;

other; which may be proved, by putting in a piece of pasteboard, cut of the exact roundness of the top: for if this goes down without stops or slipping, you may conclude the bore good. The bridge-pan must be somewhat above the touch-hole, and ought to have a notch to let down a little powder: this will prevent the piece from recoiling, which it would otherwise be apt to do. As to the locks, choose such as are well filed with true work, whose springs must be neither too strong nor too weak. The hammer ought to be well hardened, and pliable to go down to the pan with a quick motion.

In shooting, observe to do it, if possible, with the wind, not against it; and rather sideways, or behind the fowl, than full in their faces. Observe also to choose the most convenient shelter you can find, as a hedge, bank, tree, or the like. Take care to have your dogs under good command, that they may not dare to stir till you give the word, after discharging your piece: for some ill-taught dogs will, upon only the snap of the cock, presently rush forward, and spoil your sport. If you have not shelter enough, you must creep upon your hands and knees, or even make use of a stalking-horse.

**FOX**, *vulpes*, in zoology, an animal of the dog-kind, which much resembles the common dog in form, and is of the size of a spaniel: it is chiefly distinguished by its long and straight tail, with the tip white. See the articles **CANIS** and **DOG**. The fox is a native of most northern countries. That of Siberia, is about the size of the common kind; but its head is larger, and its tail not only larger and more bushy, but all of one colour. See plate CVII. fig. 1.

A fox in the first year is called a cub; in the second, a fox; and afterwards an old fox. It is a beast of chase, usually very prejudicial to the husbandman, by taking away and destroying his lambs, geese, poultry, &c. The common way to catch him is by gins; which being bated, and a train made by drawing raw flesh across in his usual paths or haunts to the gin, it proves an inducement to bring him to the place of destruction. They are also taken with greyhounds, hounds, terriers, and nets. It is a commendable exercise to hunt these mischievous beasts, the nature of which in many respects is like that of wolves. See the article **HUNTING**.

**FOX-GLOVE**, *digitalis*, in botany. See the article **DIGITALIS**.

**FOY**, or **ST. FOY**, a town of Guienne, in France, thirty-two miles east of Bourdeaux; it is situated under the meridian of London, in  $44^{\circ} 50'$ , north lat.

**FOYLING OF LAND**, the same with following it. See the article **FOLLOWING**.

**FOYLING**, among sportsmen, denotes the footsteps of a stag on grass or leaves.

**FOYNA**, in zoology, a name sometimes given to the martin. See **MARTIN**.

**FRACHES**, in glass-making, flat iron-pans, wherein the new-made vessels are put, to be removed gradually from the fire. See the article **GLASS**.

**FRACTION**, in arithmetic and algebra, is a part or parts of something considered as an unite or integer.

Fractions are distinguished into vulgar or common, and sexagesimal and decimal. See the articles **SEXAGESIMAL** and **DECIMAL**.

Vulgar fractions, called also simply fractions, consist of two parts or quantities, one wrote over the other, with a line between them. The quantity placed above the line is called the numerator of the fraction; and the quantity placed under the line, the denominator. See the articles **NUMERATOR** and **DENOMINATOR**.

Thus,  $\frac{2}{3}$  expresses the quotient of 2 divided by 3; and 2 is the numerator, and 3 the denominator. If the numerator of a fraction is equal to its denominator, then the fraction is equal to unity: Thus

$\frac{4}{4} = 1$ , and  $\frac{a}{a}$  or  $\frac{b}{b}$  are likewise equal to

unity. If the numerator is greater than the denominator, then the fraction is greater than unit. In both these cases, the fraction is called improper. But if the numerator is less than the denominator, then the fraction is less than unit, and is called proper. Thus  $\frac{5}{3}$  is an improper fraction, but  $\frac{3}{4}$  or  $\frac{2}{3}$  are proper fractions. A mixt quantity is that whereof one part is an integer, and the other a fraction; as  $3\frac{2}{3}$ ,  $5\frac{2}{3}$ , and

$a + \frac{a^2}{b}$ . See the articles **CHARACTER**

and **NOTATION**.

**Problem I.** To reduce a mixt quantity to an improper fraction, multiply the part that is an integer by the denominator of the fractional part; and, to the product, add the numerator; then place the former denominator under this sum, and you will have the improper fraction required.

Thus,  $2\frac{3}{5}$ , reduced to an improper fraction, gives  $\frac{13}{5}$ ; for  $2 \times 5 = 10$ , and  $10 + 3 = 13$ , which, divided by the former denominator 5, gives  $\frac{13}{5}$ . In the same manner  $4\frac{1}{2}$ , gives  $\frac{9}{2}$ ; and  $a + \frac{a^2}{b}$ , gives  $\frac{ab + a^2}{b}$ ; and  $a - x + \frac{a^2 - ax}{x} = \frac{a^2 - x^2}{x}$ .

Problem II. To reduce an improper fraction to a mixt quantity, divide the numerator of the fraction by the denominator, and the quotient shall give the integral part; and the remainder, set over the denominator, shall be the fractional part. Thus,  $\frac{12}{5} = 2\frac{2}{5}$ ;  $\frac{ab + a^2}{b} =$

$$a + \frac{a^2}{b}; \frac{ax + 2xx}{a + x} = x + \frac{x^2}{a + x}; \text{ and } \frac{aa + xx}{a - x} = a + x + \frac{2xx}{a - x}.$$

Problem III. To reduce fractions of different denominations to fractions of equal value, that shall have the same denominator; multiply each numerator, taken separately, into all the denominators but its own, and the products shall give the new numerators: then multiply all the denominators into one another, and the product shall give the common denominator. Thus,  $\frac{2}{3}$ ,  $\frac{3}{4}$ , and  $\frac{4}{5}$  are respectively equal to  $\frac{40}{60}$ ,  $\frac{45}{60}$ , and  $\frac{48}{60}$ ; and  $\frac{a}{b}$ ,  $\frac{c}{d}$ , and  $\frac{e}{f}$  are respectively equal to  $\frac{acd}{bcd}$ ,  $\frac{bcd}{bcd}$ , and  $\frac{ccb}{bcd}$ .

Problem IV. To add and subtract fractions, first reduce them to a common denominator (by Probl. III.) then add or subtract the numerators, and the sum or difference set over the common denominator, will be the sum or difference required. Thus,  $\frac{2}{3} + \frac{1}{4} = \frac{8 + 3}{12} = \frac{11}{12}$ ; and  $\frac{3}{4} - \frac{2}{3} = \frac{9 - 8}{12} = \frac{1}{12}$ . In the same manner,  $\frac{a}{b} + \frac{c}{d} + \frac{e}{f} = \frac{adf + bdf + ebd}{bdf}$ ;

and  $\frac{a}{b} - \frac{c}{d} = \frac{ad - cb}{bd}$ ; and  $\frac{x}{2} - \frac{x}{3} = \frac{3x - 2x}{6} = \frac{x}{6}$ . See SUBTRACTION.

Problem V. To multiply fractions; let their numerators be multiplied into one another, to obtain a new numerator, and the denominators into one another, to

obtain a new denominator; and the numerator and denominator so found will be the product required.

Thus,  $\frac{2}{3} \times \frac{4}{5} = \frac{8}{15}$ ; and  $\frac{1}{2} \times \frac{3}{4} = \frac{3}{8}$ .

In the same manner,  $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$ ; and

$$\frac{a + b}{c} \times \frac{a - b}{d} = \frac{a^2 - b^2}{cd}.$$

If a mixt quantity is to be multiplied, first reduce it to the form of a fraction (by Probl. I.) and if an integer is to be multiplied by a fraction, you may reduce it to the form of a fraction, by placing unit under it. Thus,  $5\frac{2}{3} \times \frac{4}{5} = \frac{17}{3} \times \frac{4}{5} = \frac{68}{15} = 4\frac{8}{15}$ , (by Probl. II.) Also  $9 \times \frac{2}{3} = \frac{9}{1} \times \frac{2}{3} = \frac{18}{3} = 6$ ; and, in the

same manner,  $b + \frac{bx}{a} \times \frac{a}{x} = \frac{ba + bx}{a} \times \frac{a}{x} = \frac{a^2b + abx}{ax} = \frac{ab(b + x)}{x}$ .

Problem VI. To divide fractions; first multiply the numerator of the dividend by the denominator of the divisor, and the product will be the numerator of the quotient; then multiply the denominator of the dividend by the numerator of the divisor, and their product will give the denominator of the quotient. Thus,

$$\frac{4}{5} \div \frac{2}{3} = \frac{4}{5} \times \frac{3}{2} = \frac{12}{10} = \frac{6}{5}; \text{ and } \frac{a + b}{a - b} \div \frac{a - b}{a} = \frac{(a + b)a}{(a - b)(a - b)} = \frac{a(a + b)}{a^2 - 2ab + b^2}.$$

These last four problems are easily demonstrated from the definition of a fraction. 1. It is obvious, that the fractions  $\frac{a}{b}$ ,  $\frac{c}{d}$ ,  $\frac{e}{f}$ , are respectively equal to  $\frac{adf}{bdf}$ ,  $\frac{cdf}{bdf}$ ,  $\frac{ebd}{bdf}$ ; since if you divide  $adf$  by  $bdf$ , the quotient will be  $\frac{a}{b}$ ;  $\frac{cdf}{bdf} = \frac{c}{d}$ ; and  $\frac{ebd}{bdf} = \frac{e}{f}$ .

2. Fractions reduced to the same denominator are added by adding their numerators and subscribing the common denominator.

Thus,  $\frac{a}{b} + \frac{c}{b} = \frac{a + c}{b}$ ; for call  $\frac{a}{b} = m$ , and  $\frac{c}{b} = n$ , and it will be  $a = mb$ , and  $c = nb$ ; and  $mb + nb = a + c$ , and  $m + n = \frac{a + c}{b}$ ; that is,  $\frac{a}{b} + \frac{c}{b}$ . After the same manner,  $\frac{a}{b} - \frac{c}{b} = m - n = \frac{a - c}{b}$ .

3. Again,  $\frac{a}{b} \times \frac{c}{d} (=m \times n) = \frac{ac}{bd}$ ; for  $bm = a$ ,  $dn = c$ ; and  $bdmn = ac$ , and  $mn = \frac{ac}{bd}$ ; that is,  $\frac{a}{b} \times \frac{c}{d} = \frac{ac}{bd}$ . 4.

Lastly,  $\frac{a}{b} \div \frac{c}{d}$ , or  $\frac{m}{n}$ , gives  $\frac{ad}{cb}$ ; for  $mb = a$ , and  $mbd = ad$ ;  $nd = c$ , and  $ndb = cb$ : therefore  $\frac{mbd}{ndb} = \frac{ad}{cb}$ ; that is,  $\frac{m}{n} = \frac{ad}{cb}$ .

Problem VII. To find the greatest common measure of two numbers; that is, the greatest number that can divide them both without a remainder. First divide the greater number by the lesser, and if there is no remainder, the lesser number is the greatest common divisor required. If there is a remainder, divide your last divisor by that remainder; and thus proceed, continually dividing the last divisor by its remainder, till there is no remainder left; and then the last divisor is the greatest common measure required. Thus, the greatest common measure of 45 and 63 is 9; and the greatest common measure of 256 and 48, is 16, as appears from the operation at large.

$$\begin{array}{r}
 45 \overline{)63(1} \qquad 48 \overline{)256(5} \\
 \underline{45} \qquad \qquad \underline{240} \\
 18(45(2 \qquad \qquad 16(48(3 \\
 \underline{36} \qquad \qquad \underline{48} \\
 9(18(2 \qquad \qquad 00 \\
 \underline{18} \\
 00
 \end{array}$$

Much after the same manner, the greatest common measure of algebraical quantities is discovered; only the remainders that arise in the operation are to be divided by their simple divisors, and the quantities are always to be ranged according to the dimensions of the same letter. Thus, to find the greatest common measure of  $a^2 - b^2$  and  $a^2 - 2ab + b^2$ , the operation is thus:

$$\begin{array}{r}
 a^2 - b^2 \overline{)a^2 - 2ab + b^2(1} \\
 \underline{a^2 - b^2} \\
 -2ab + 2b^2 \text{ remainder, which} \\
 \text{divided by } -2b \text{ is reduced to} \\
 a - b \overline{)a^2 - b^2(a + b} \\
 \underline{a^2 - b^2} \\
 0
 \end{array}$$

Therefore,  $a - b$  is the greatest common measure required.

The ground of this operation is, that any quantity that measures the divisor

and the remainder (if there is any) must also measure the dividend; because the dividend is equal to the sum of the divisor multiplied into the quotient, and of the remainder added together. Thus, in the last example,  $a - b$  measures the divisor  $a^2 - b^2$ , and the remainder  $-2ab + 2b^2$ ; it must therefore likewise measure their sum  $a^2 - 2ab + b^2$ . You must observe, in this operation, to make that the dividend which has the highest powers of the letter, according to which the quantities are ranged.

Problem VIII. To reduce any fraction to its lowest terms: find the greatest common measure of the numerator and denominator; divide them by that common measure, and place the quotients in their room, and you shall have a fraction, equivalent to the given fraction, expressed in the lowest terms. Thus,  $\frac{3}{9}$  is reduced to  $\frac{1}{3}$ , by dividing the numerator and denominator by the greatest common measure 3. In the same manner  $\frac{75}{125} = \frac{3}{5}$  for  $25 = 4$ , and  $25 = 5$ .

In algebraical terms, the operation is thus:

$$\begin{array}{r}
 \frac{25bc}{25bc} \overline{) \frac{75abc}{125bcx} = \frac{3a}{5x}}; \text{ which is found} \\
 \text{by rejecting the divisor (as being nothing) rejecting the letters } bc \text{ of the} \\
 \text{dividend (as being common to numerator} \\
 \text{and denominator) and dividing the co-} \\
 \text{efficients 75 and 125 by their greatest} \\
 \text{common measure 25; the result of which} \\
 \text{is } \frac{3a}{5x}. \text{ In the same manner, } \frac{156a^2 + 572ab}{a^2 - 2ab + b^2} = \frac{156a^2 + 572ab}{a^2 - 2ab + b^2} \\
 = \frac{11a - 11b}{a^2 - 2ab + b^2} = \frac{a^2 - b^2}{a^2 - 2ab + b^2} \\
 = \frac{a - b}{a + b}; \frac{a^3 - b^3}{a^2 - 2ab + b^2} = \frac{a^2 - ba}{a + b}; \text{ and} \\
 \frac{a^4 - b^4}{a^5 - a^3b^2} = \frac{a^2 + b^2}{a^3}.
 \end{array}$$

When unit is the greatest common measure of the numbers and quantities, then the fraction is already in its lowest terms.

Thus,  $\frac{3ab}{5dc}$  cannot be reduced lower. It

ought also to be remarked, that numbers whose greatest common measure is unit, are said to be prime to each other.

If it is required to reduce a given fraction to a fraction equal to it, that shall have a given denominator; you must multiply the numerator by the given denominator, and divide the product by the former denominator; and this quotient, set over the given denominator, will be the fraction required. Thus, if it

were required to reduce  $\frac{2}{3}$  to an equal fraction, whose denominator shall be 6; find the quotient of  $2 \times 6 \div 3 = 4$ , then will  $\frac{4}{6}$  be the fraction required. In the

same manner,  $\frac{a}{b}$  is reduced to an equal fraction, which has the denominator  $c$ , viz.  $\frac{ac \div b}{c}$ ; for rejecting  $c$  out of both numerator and denominator, there remains  $a \div b = \frac{a}{b}$ .

For the method of reducing vulgar fraction to equal decimal ones, see the article DECIMAL.

It is observable, that when the last figure of the denominator of the fraction happens to be 1, 3, 7, or 9, then the decimal parts can never be precisely equal to the given fraction; yet by continuing the division, you may approximate to its value as near as you please. Thus  $\frac{2}{3} = .666666$ , &c. as far as you please; and, in the same manner,  $\frac{4}{7} = .5714285714$ , &c. Hence it may be farther observed, that these imperfect quotients return again, and circulate without end: in the first example, the circulation begins immediately; but, in the second, it does not begin again till the operation is continued to the seventh place; when the first six figures are repeated over again, constituting what is called the repetend of a decimal fraction. See the articles REPETEND and SERIES.

These repetends sometimes also happen, when other figures, besides those above-mentioned, are the denominator of the fraction. Thus  $\frac{1}{5} = .1666666$ , &c. *ad infinitum*.

**FRACTURE**, in surgery, a rupture of a bone, or a solution of continuity in a bone, when it is crushed or broken by some external cause.

Fractures generally happen when any part of the body, where a bone is situated, receives a violent shock, either by a fall, or a blow with a piece of timber, &c. or by the shot of a gun. There are instances where this accident has happened from an internal disorder, to wit, from the scurvy, a caries, or the venereal disease, which have rendered the substance of a bone so brittle, that it has been fractured without any apparent external accident. See CARIES, SCURVY, &c.

Fractures are distinguished into several classes. First, every fracture is either

simple, that is, when no other parts besides the bone are injured, or compound, as where there is a wound, a dislocation, hæmorrhage, inflammation, fever, caries, or contusion of the bone; or where the bone appears to be fractured in several places at the same time. Other differences arise with regard to the situation of the fracture; sometimes it happens in the cranium, ribs, vertebrae, sometimes in the upper or lower limbs; sometimes in the middle of the bone, and sometimes in either of the extremities. Again, some fractures are transverse, others oblique. In which case it frequently happens that the points of the bones wound the neighbouring parts, pushing quite through the muscular flesh, and common integuments; or at least pricking them grievously, and bringing on pain, inflammation, tumour, and spasm. Violent contusions also may be classed under the head of fractures; for the bones in this case are frequently broke into splinters, by the falling of any heavy body upon the part, or by any violent pressure. To fractures of the bones, we may also very properly add fissures. See the articles FISSURE, CONTUSION, &c.

Fractures of bones are discoverable, 1. By the eye, when the injured part is apparently shorter than the sound; or when the patient cannot make use of it. 2. By the touch, when a preternatural inequality of the bone may be perceived; or that it bends in a part where nature did not intend it should. 3. By the ear, when upon moving the limb, the crushing of the broken bones may be heard. 4. We may strongly suspect a fracture of the part, when it has received a violent blow. And, 5. It is observable that the parts are more subject to this injury in winter than in summer. Lastly, 6. Sometimes, particularly in fractures that are made in a transverse direction, the broken parts of the bone will immediately, of themselves, recover their natural situation, and leave little room to suspect the disorder.

Great variety of mischiefs attend a fractured bone, which differ, 1. With regard to the injured part, and the nature and disposition of the neighbouring parts. 2. With regard to the manner in which fractures are made; for oblique fractures, and those whose splinters and points wound and vellicate the neighbouring parts, are much more painful and dangerous than transverse fractures. 3. We may

may judge of the mischief that is likely to attend a fracture, from the number of pieces into which the bone is broken. And, 4. By observing whether the fracture happened at the middle of the bone, or at its extremities. The principal inconveniencies that attend a fracture are these: the patient loses the use of the limb; the lower part of the limb will be contracted by the muscles, which will make it appear distorted and deformed; the laceration of the periosteum and the vessels of the medulla being in great danger of fistulæ and caries. When the nerves are pricked and irritated by splinters, the patient suffers great pain, convulsions, inflammations, and fever; and if any vessels suffer pressure, the common consequences of a contusion ensue. Sometimes, whilst the bone is uniting, the broken parts are supplied in too plentiful a manner with juices, and the callus is formed irregularly, which occasions a deformity of the limb. See *CALLUS*.

In the cure of fractures, the surgeon's principal care should be to unite the broken bone, to which three things are necessary. 1. That the bone be restored to its natural situation, which is done by extending and replacing it. 2. That after the bone has recovered its natural situation, it be kept there, by giving it rest, and applying proper bandages. Lastly, proper remedies must be used, in order to prevent or remedy the disorders that usually attend this accident. See the articles *INFLAMMATION*, *FEVER*, &c.

When the fractured bones maintain their natural situation, you are under no necessity of extending or replacing the limb, but of applying a proper bandage; but when the fractured parts recede from each other, some degree of extension is necessary. See the article *EXTENSION of fractured limbs*.

Sometimes you will be troubled with splinters of the bone in your way, which render the reduction of the bone very difficult. If the splinters are free, and have no connection with the bone, you must remove them carefully. When they adhere to the principal parts, you should endeavour to replace them with the greatest exactness; and where they cannot be reduced or re-united with the bone, they may be removed by a strong pointed forceps. If they are concealed under the skin, you must endeavour to reduce them to their natural situation: if this cannot be done, make an incision through

the skin, and take them out. See the article *INCISION*.

The bones being properly replaced, the next thing to be done is to secure them in their situation, that they may unite to the best advantage.

To this end two things are chiefly required. 1. To bind it up properly. And, 2. To lay the limb in a convenient posture. The apparatus for securing the situation of the limb is composed of bandages, bolsters, and splints. See the articles *BANDAGE*, *BOLSTER*, and *SPLINT*. In fractures of the lower arm, after you have applied your bandage and dressings, you may suspend it in a scarf or sling, which is to hang from the neck: in fractures of the leg, you may rest the limb upon pillows, or in boxes, placing cushions or pillows under it: these machines are to be fastened to the limb with tapes, that it may remain fixed and immoveable.

*FRÆNUM*, in anatomy, a term applied to some membranous ligaments of the body. As,

*FRÆNUM LINGUÆ*, the ligament under the tongue, which sometimes ties it down too close to the bottom of the mouth; and then requires to be incised or divided, in order to give this organ its proper and free motion. This disorder generally arises in infants soon after their birth, so that they cannot move and exert their tongues in the action of sucking: though it is sometimes also observed in adults. For the operation of cutting the frænum, see the article *TONGUE-TIED*.

Each of the lips has also its peculiar frænum: the upper one under the nose; the under one near the roots of the dentes incisores: these are of the utmost service to us in speaking, and eating and drinking.

*FRÆNUM PENIS*, a ligament of the penis, that ties the prepuce to the lower part of the glans of the penis. See *PENIS*.

There is also a small frænum of the clitoris, by which it is connected to the ossa pubis. See the article *CLITORIS*.

*FRAGA*, a town of Arragon, in Spain, situated under the meridian of London: north lat. 41° 16'.

*FRAGARIA*, the *STRAWBERRY*, in botany, a genus of the *icosandria-pentagynia* class of plants, the corolla of which consists of five roundish, patent petals, inserted in the cup: there is no pericarpium; the common receptacle of the seed is of a roundish, oval figure, plane at the base, pulpy, large, soft, and deciduous; the

seeds

feeds are numerous, small, acuminate, scattered over the superficies of the receptacle, and not deciduous.

**FRAIGHT**, or **FREIGHT**, in commerce. See the article **FREIGHT**.

**FRAIL**, a basket made of rushes, or the like, in which are packed up figs, raisins, &c. It signifies also a certain quantity of raisins, about 75 pounds.

**FRAISE**, in fortification, a kind of defence, consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, or the like, to prevent any approach or scalade.

Fraises differ from palisades chiefly in this, that the latter stand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly so, being usually made a little sloping, or with the points hanging down. Fraises are chiefly used in retrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone-works.

To **FRAISE a battalion**, is to line the musqueteers round with pikes; that, in case they should be charged with a body of horse, the pikes being presented, may cover the musqueteers from the shock of the horse, and serve as a barricade.

**FRAME**, in joinery, a kind of case, wherein a thing is set or inclosed, or even supported, as a window-frame, a picture-frame, &c.

**FRAME** is also a machine used in divers arts; as,

**FRAME**, among printers, is the stand which supports the cases. See the article **CASE**.

**FRAME**, among foundry, a kind of ledge inclosing a board, which, being filled with wetted sand, serves as a mould to cast their works in. See **FOUNDRY**.

**FRAME** is more particularly used for a sort of loom, whereon artificers stretch their linnens, silks, stuffs, &c. to be embroidered, quilted, or the like.

**FRAME**, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called *reticula*. It serves to reduce figures from great to small; or, on the contrary, to augment their size from small to great.

**FRAMING of an house**, among carpenters, denotes all the timber-work therein; namely, the carcase, flooring, partition-

ing, roofing, ceiling, beams, ashlering, &c. all together. See **FLOORING**, &c.

**FRAMPOLE-FENCES**, a privilege enjoyed by the tenants of the manor of Writtel in Essex, whereby they are intitled to the wood growing on the fence, and as many poles as they can reach from the top of the ditch with an axe's helve, towards the repair of their fences.

**FRANC**, or **FRANK**. See **FRANK**.

**FRANCA**, in botany, the same with *frankenia*. See the article **FRANKENIA**.

**FRANCE**, a large kingdom of Europe, situated between 5° west and 7° east long. and between 43° and 51° north lat. being bounded by the english channel and the austrian Netherlands, on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and by the bay of Biscay, on the west. This kingdom was formerly divided into twelve provinces, but at present it is divided into twenty-five general governments, over every one of which is an officer, called an intendant, appointed by the king, who has a power of controuling the governor, and all other officers of justice; and presides over the receivers-general of his generality.

**FRANCFORT**, a city of Germany, situated on the confines of Hesse and Franconia, on both sides of the river Maine: east longitude 7° 30' north lat. 50° 10'.

**FRANCFORT on the Oder**, a city of Germany in the circle of upper Saxony, and marquisate of Brandenburg, situated in east long. 15°, north lat. 52° 22'.

**FRANCHE-COMTE**, the same with the county of Burgundy. See **BURGUNDY**.

**FRANCHE-COMTE**, a province of France bounded by Lorrain on the north; by Alsace and Switzerland, on the east; by La Breis and Bugey, on the south; and by the dukedom of Burgundy, on the west.

**FRANCHISE**, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.

**FRANCHISE** is sometimes used for an immunity, from tribute, in which sense it is either personal or real; that is, belonging to a person immediately, or else by means of this or that place of which he is chief, or a member.

A Franchise may be vested either in bodies

bodies politic, or corporations; in borough towns, or in any single person. There are franchises of different kinds, as the principality of Wales, counties palatine, counties, hundreds, parts of the sea, &c. Besides which there is a franchise of having a leet, manor, or lordship; as also of fairs and markets, felon's goods; as also the goods of fugitives and outlaws; deodands, treasure-trove, waifs, estrays, wrecks, &c.

Franchises and liberties, being usually held by charter, are all said to be derived from the crown, but some lie in prescription without the help of any charter.

**FRANCHISE ROYAL**, seems to be that where the king's writ does not run; but Bracton says, that a franchise royal, is where the king grants to one and his heirs an exemption of toll, &c.

**FRANCHISE** is also used for an asylum or sanctuary, where people are secure of their persons. See **ASYLUM**.

**FRANCHISE of quarters**, a certain place or district at Rome, wherein are the houses of the ambassadors of the princes of Europe; and where such as retire cannot be arrested or seized by the sbirri or sergeants, nor prosecuted at law.

Several of the popes published their bulls and ordinances against the abuse made of this privilege, which rescued so considerable a part of the city, by the enlargement of these places, from their authority, and rendered them a retreat for the most abandoned persons. At last Innocent XI. expressly refused to receive any more ambassadors, but such as would make a formal renunciation of the franchise of quarters.

**FRANCIGENÆ**, in our old law-books, an appellation given to foreigners in general.

**FRANCISCAN MONKS, FRIARS MINOR**, or **GREY FRIARS**, religious of the order of St. Francis, founded by him in the year 1209. See the article **FRIAR**.

The rule of the franciscans, as established by St. Francis himself, is briefly this: they are to live in common, to observe chastity, and to pay obedience to the pope and their superiors.

Before they can be admitted into the order, they are obliged to sell all they have, and give it to the poor: they are to perform a year's noviciate, and when admitted, never to quit the order upon any account. They are to fast from the feast of All-saints, to the Nativity. This order has produced four popes, forty-

two cardinals, and an infinite number of patriarchs. The franciscans had sixty-three monasteries in England, one of which was in the parish of St. Nicholas in London.

**FRANCOLINI**, a town of Italy, situated on the river Po, about nine miles north-east of Ferrara.

**FRANCONIA**, a circle of the german empire, lying between Bohemia on the east, and the electorate of Mentz on the west. Its capital is Nuremburg; and from this country the Franks, who conquered and gave name to the kingdom of France, are said to have come.

**FRANGIPANE**, a kind of exquisite perfume given to the leather of which gloves, &c. are made.

There is likewise a perfumed liquor of the same name, as also a ros solis.

**FRANGULA, BLACK ALDER**, a distinct genus of plants according to Tournefort, but ranked by Linnæus among the rhamnuses. See **RHAMNUS**.

**FRANGULÆ SPECIES**, in botany, the name by which Dillenius calls the maurocena of Linnæus. See **MAUROCENIA**.

**FRANK**, or **FRANC**, meaning literally free from charge and impositions, or exempt from public taxes, has various significations in our antient customs.

**FRANK ALMOIGN**, signifies a tenure by spiritual service, where lands or tenements are held by an ecclesiastical corporation, sole or aggregate, to them and their successors, of some lord and his heirs, in free and perpetual alms.

This is an antient tenure chiefly to be met with in grants to religious houses, colleges, &c. No person can have lands in frank almoign, unless it is by prescription, or on a grant made before the statutes of mortmain; so that the tenure may not be created at this day. Nevertheless the king is not restrained by the statutes, nor a subject licensed or dispensed with by him to make such a grant; and if an ecclesiastical person holds lands at a certain rent, &c. the lord may confirm his estate to hold to him and his successors in frank almoign.

**FRANK CHACE**, is defined to be a liberty of free chace, whereby persons that have lands within the compass of the same, are prohibited to cut down any wood, &c. out of the view of the forester.

**FRANK FEE**, signifies the same as holding lands and tenements in fee simple; that is, to any person and his heirs, and not by such service as is required by antient demesne,

demesne, but is pleaded at common law. See the article **FEE**.

**FRANK FERM**, antiently signified lands changed in the nature of the fee by feoffment, &c. out of the knight's service for other certain yearly services.

**FRANK FOLD**, is where the lord has the liberty of folding his tenants sheep within his manor. See the article **FALDAGE**.

**FRANK-INCENSE**, in natural history, &c. See the article **INCENSE**.

**FRANK LANGUAGE**, or **LINGUA FRANCA**, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

**FRANK LAW**, a word applied to the free and common law of the land, or the benefit a person has by it.

He that for any offence loseth this frank law, incurs these inconveniences, *viz.* He may not be permitted to serve on juries, nor used as an evidence to the truth; and if he has any thing to do in the king's court, he must not approach it in person, but appoint his attorney; his lands, goods, and chattels shall be seized into the king's hands; and his lands be estranged; his trees rooted up, and his body committed to custody.

**FRANK-MARRIAGE**, is where a person, seized in fee of lands or tenements, has given them to another with his daughter, sister, or some woman otherwise of kin to him, in free marriage, by virtue of which the husband and wife have an estate in special tail, and shall hold the land of the donor, discharged of all services, except fealty, to the fifth degree.

**FRANK PLEDGE**, in our law, signifies a pledge or surety for the behaviour of freemen.

According to the antient custom of England, for the preservation of the public peace, every free-born man, at the age of fourteen, except religious persons, clerks, knights, and their eldest sons, was obliged to give security for his truth and behaviour towards the king and his subjects, or else be imprisoned. Accordingly, a certain number of neighbours became interchangeably bound for each other, to see each person of their pledge forth-coming at all times, or to answer for the offence of any one gone away; so that whenever any person offended, it was presently inquired in what pledge he was; and there the persons bound either produced the offender in thirty-

one days, or made satisfaction for his offence.

**FRANK SERVICE**. See the article **SERVICE**.

**FRANK TENEMENT**, is said to be a possession of freehold lands or tenements. See **FREEHOLD** and **TENEMENT**.

**FRANK**, or **FRANC**, an antient coin, either of gold or silver, struck and current in France. The value of the gold-frank was somewhat more than that of the gold crown; the silver-frank was a third of the gold one: this coin is long out of use, though the term is still retained as the name of a money of account; in which sense it is equivalent to the *livre*, or twenty *sols*.

**FRANKENDAL**, a city of Germany, in the palatinate of the Rhine, situated on the west side of the river Rhine, in east long. 8° 15', north lat. 49° 30'.

**FRANKENIA**, **SEA-HEATH**, or **SEA-CHICKWEED**, a genus of the *decandria-monogynia* class of plants, the flower of which consists of five petals, with a plain limb: the fruit is an oval, unilocular capsule, covered by the cup, and containing a great many ovated very small seeds.

**FRANKENSTEIN**, a town of Germany, in the palatinate of the Rhine, and dutchy of Zuebruggen, situated twelve miles north-west of Landau.

**FRANKER**, a town of the United-provinces, in the province of west Friesland, nine miles west of Lewarden.

**FRANKINCENSE**, *olibanum*, in the materia medica. See **OLIBANUM**.

**FRANKS**, **FRANKIS**, or **FRANQUIS**, an appellation given by the Turks, and other nations of Asia, to all the people of the western parts of Europe, to which they give the name of Frankistan.

**FRANSTAT**, or **FRAUSTAT**, a town of Silesia, situated twenty-five miles north-east of Glogaw, subject to Prussia.

**FRASCATI**, or **FRESCATI**, a town of Italy, in the campania of Rome, thirteen miles east of that city, near which place is the tusculum of Cicero, called Grotto Ferrate.

**FRATERCULA**, in zoology, the name by which Gesner calls the arctic duck. See the article **DUCK**.

**FRATERNITY**, in the roman catholic countries, signifies a society for the improvement of devotion.

Of these there are several sorts; as, 1. The fraternity of the rosary, founded by St. Dominic: it is divided into two branches, called the common rosary, and the perpetual

petual rosary; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. See the article ROSARY.

2. The fraternity of the scapulary, whom the blessed virgin, according to the fabbatin bull of pope John XXII. has promised to deliver out of hell the first Sunday after their death. See SCAPULARY.

3. The fraternity of St. Francis's girdle, are clothed with a sack of a grey colour, which they tie with a cord; and, in processions, walk bare-footed, carrying in their hands a wooden cross.

4. That of St. Austin's leathern girdle, comprehends a great many devotees.

Italy, Spain, and Portugal, are the countries where one sees the greatest number of these fraternities, some of which assume the name of arch-fraternities. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to forty poor girls on the feast of St. Jeron their patron.

The fraternity of death, buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

The fraternity of St. Mary of the suffrage, employ their prayers to release souls out of purgatory. The fraternity of mercy, at Lisbon, consists of persons of the greatest quality, the king himself being a member of it; the design of its institution is to procure a great number of masses to the faithful, but chiefly to its own members.

What has been said, may suffice to shew the nature of these fraternities; by entering into which, most of the devotees believe they are much surer of salvation, than they could otherwise be.

FRATERNITY, in a civil sense, a company or gild of certain artificers or traders.

See the articles COMPANY and GILD.

FRATRICELLI, LITTLE BROTHERS, in church history, a sect of heretics who appeared in Italy about the year 1298, and afterwards spread all over Europe. They wore the habit of the franciscan order, and pretended that ecclesiastics ought to have no possessions of their own.

FRATRIAGE, *fratriagium*, the partition among brothers or coheirs, coming to the same inheritance or succession.

Fratriage more particularly signifies a younger brother's inheritance; or whatever the younger sons possess of the father's estate, which, in our antient law,

they are said to enjoy *ratione fratriagii*; and were to do homage for the same to the elder brother, he being bound to do homage to the superior lord for the whole.

FRATRES ARVALES. See ARVALES.

FRATRES CONJURATI, in our antient law-books, &c. signify sworn brothers, or those who took an oath to defend the king against his enemies.

FRATRICIDE, the crime of murdering one's brother. See PARRICIDE.

FRAUD, in law, signifies deceit in grants, or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

A fraudulent conveyance of lands or goods to deceive creditors, as to creditors is void in law. And a fraudulent conveyance in order to defraud purchasers, is also to such purchasers void; and the persons justifying or putting off such grants as good, shall forfeit a year's value of the lands, and the full value of the goods and chattels, and likewise shall be imprisoned.

However, when conveyances are fraudulently made, they are not void to all persons, but only to those that afterwards come to the land as purchasers on good consideration. A general gift made of all the goods of a person, may be reasonably suspected to be by fraud, even though a true debt is owing to the party to whom made; and it is void against other creditors of the donor. Here the several marks of fraud in a gift or grant of goods, are as follow, *viz.* 1. If it be general, without any exception of some things of necessity. 2. If the donor continues to possess and use the goods. 3. If the deed be made in secret. 4. If there be a trust between the parties; or, 5. If made whilst the action is depending.

Where a person is party to a fraud, all that follows thereupon will be intended to be done by him, though fraud shall not be presumed or adjudged to be so, until found by jury.

By the statute of frauds, 29 Car. II. agreements for the sale of lands, leases, &c. are required to be in writing. See 3 & 4 Will. and Mary, c. 14.

FRAUS LEGIS, is where the process of the law is used with a felonious purpose; and a person is turned out of possession of his house, by virtue of a writ of habere facias possessionem, on a false affidavit procured of the service of a declaration in

ejection and judgment had thereon in fraudem legis.

**FRAXINELLA**, in botany, the same with dictamnus. See **DICTAMNUS**.

**FRAXINUS**, the **ASH**, in botany, a genus of trees, belonging to the *polygamia-dioecia* class, in some species of which there is no corolla; in others there is a small one, formed of four slender and acute petals: the fruit is single, of a compressed lanceolate figure, and is what we commonly call the ash-key, several clusters of which are affixed to the same common pedicle.

The wood of this tree is in great use among several artificers, as wheel-wrights, cart-wrights, carpenters, turners, &c. also for making ploughs, harrows, axle-trees, oars, balls, &c. It is said to be as lasting for building as oak, and often preferred before it: though the timber of the trunk greatly excels that of a bough. Some ash is also so curiously veined, that the cabinet-makers equal it to ebony, and call it green ebony; so that the woodmen, who light upon such trees, may have for it what they will. The season for felling this tree, is from November to February; for if cut down too early, or too late, it is liable to the worm. The ash is hurtful to corn-lands, and therefore should be planted either in hedges or clumps, at about nine or ten feet distance.

**FRAY**, among sportsmen. A deer is said to fray its head, when it rubs it against a tree, to cause the pills of the new horns to come off. See the article **HEAD**.

**FREAM**, a name given by farmers to plowed lands worn out of heart, and laid fallow till it recover. See **FALLOWING**.

**FREAM**, among sportsmen, denotes the noise of a boar in rutting time.

**FRECKLES**, *lentigines*, spots of a yellowish colour, of the bigness of a lentile-seed, scattered over the face, neck, and hands. Freckles are either natural, or proceeding accidentally from the jaundice, or the action of the sun upon the part. Heat, or a sudden change of the weather, will often cause the skin to appear of a darker colour than natural, and thereby produce what is called tan, sunburn, and morpew, which seem to differ only in degree; and usually disappear in winter. See the article **TAN**, &c.

Persons of a fine complexion, and such whose hair is red, are the most subject to freckles, especially in those parts which they expose to the air.

To remove freckles, put juice of lemons in a glass-vial, and mixing it with sugar and borax, finely powdered, let it digest eight days, and then use it. Homberg proposes bullock's gall, mixed with alum, and, after the alum has precipitated, exposed three or four months to the sun in a close vial, as one of the best remedies known for the removing of freckles.

**FREDENBERG**, a town of Germany, in the circle of Westphalia, fifty miles west of Cassel.

**FREDERICA**, a town of Georgia, in North America, situated in west long. 81° 30', north lat. 31°, on the island of St. Simons, in the mouth of the river Alatomaha.

**FREDERICKSBURG**, a castle and palace of the king of Denmark, situated in the isle of Zeland, twenty miles north-west of Copenhagen, built upon piles in the middle of a lake.

**FREDERICKSBURG**, a fort upon the gold coast of Guinea, near cape Three-points, subject to the Danes. It lies in west long. 2°, north lat. 5°.

**FREDERICKSHALL**, a strong town of Norway, in the province of Agerhuys, situated on the frontiers of Sweden, thirty miles north of Frederickstad.

**FREDERICKSODE**, a town of Jutland, in the province of Reypen, situated on the little belt in the Baltic-sea, twenty miles west of Odensee.

**FREDERICKSTAT**, a town of Sleswick, or south Jutland, situated on the river Eyder, near the german ocean, thirty-one miles west of Sleswick.

**FREDERICKSTAT**, a town of Norway, in the principality of Agerhuys, situated on a bay of the sea, called the Schagger-rack, near the frontiers of Sweden: east long. 11° 24', north lat. 59°.

**FREE**, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will. See the article **FREEDOM**.

**FREE**, among seamen. The pump is said to free the ship, when it throws out more water than leaks into her. To free the boat, is haling or lading out the water therein.

**FREE-BENCH**, signifies that estate in copyhold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor.

In regard to this free-bench, different manors

manors have different customs, and in the manor of east and west Enbourne in the county of Berks, and in other parts of England, there is a custom, that when a copyhold tenant dies, the widow shall have her free-bench in all the deceased husband's lands, *dum sola & casta fuerit*, whilst she lives single and chaste; but if she is found to be guilty of incontinency, she shall forfeit her estate. Nevertheless, upon her coming into the court of the manor riding backwards on a black ram, with his tail in her hand, rehearsing a certain form of words, the steward is bound by custom to restore her to her free-bench.

**FREE-BORD**, ground claimed in some places beyond or without the fence, and said to contain two foot and an half.

**FREE-CHAPEL**, is properly a chapel of the king's foundation, and by him exempted from the ordinary's visitation or jurisdiction.

**FREE**, or **IMPERIAL CITIES**, in Germany, are those not subject to any particular prince, but governed, like republics, by their own magistrates. See **CITY**.

**FREE-FAIR.** } See the articles { **FAIR**.

**FREE-FEE.** } See the articles { **FEE**.

**FREE-HOLD**, signifies lands or tenements which a person holds in fee-simple, fee-tail, or for term of life.

Freehold is distinguished into freehold in deed, and freehold in law: the first of which signifies the real possession of lands, &c. in fee, or for life; the other is the right that a person has to such lands or tenements before his entry.

**FREE-HOLD** is also extended to such offices as a man holds in fee, or during life. See the article **FEE**.

A freehold, by the common law, cannot commence in futuro, but it must take effect presently, either in possession, reversion, or remainder; and where a person pleads liberum tenementum, or freehold, generally the law intends he has an estate in fee, and not barely for life. Whatever is part of the freehold, goes to the heir; and things fixed thereto, may not be taken as a distress for rent, or in execution, &c. No person shall distrain freeholders to answer for their freehold, or any thing concerning the same, without the king's writ. By the antient laws of Scotland, freeholders are called milites, or knights.

**FREE-MASON.** See the article **MASON**.

**FREE-PART.** See the article **PART**.

**FREE-STATE**, a republic governed by magistrates elected by the free suffrages of the inhabitants.

**FREE-STONE**, a whitish stone dug up in many parts of England, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a kind of the grit-stone, but finer sanded, and a smoother stone, and is called free, from its being of such a constitution as to cut freely in any direction: such is the Portland-stone, and the free-stone of Kent.

**FREE-STOOL.** See **FRID-STOLL**.

**FREE-THINKER.** See the article **DEIST**.

**FREE-WARREN**, the power of granting or denying licence to any one to hunt in such and such ground.

**FREEDOM**, in general, the state or quality of being free. See **FREE**.

**FREEDOM of a corporation**, the right of enjoying all the privileges and immunities belonging to it. See **CORPORATION**.

The freedom of cities, and other corporations, is regularly obtained by serving an apprenticeship; but it is also purchased with money, and sometimes conferred by way of compliment.

**FREEDOM of the will**, that power or faculty of the mind, whereby it is capable of acting or not acting, choosing or rejecting, whatever it judges proper. Of this every man must be sensible, who finds in himself a power to begin or forbear, continue or end several actions, barely by a thought or preference of the mind. The actual exercise of this power, is that which we call volition or willing; and the agent, capable of acting in this manner, is denominated free, and the actions he performs, voluntary. Whereas, on the other hand, wherever any performance or forbearance are not equally in a man's power; wherever doing or not doing will not equally follow upon the preference of his mind, there he is not free, though perhaps the action may be voluntary. To illustrate this, suppose a man to be carried whilst fast asleep into a room where is a person he longs to see, and be there locked fast in, beyond his power to get out; he awakes, and is glad to see himself in so desirable company, which he stays willingly in; that is, prefers his staying to going away. In this case, his stay is voluntary; and yet being locked fast in, he is not at liberty to stay, he has not freedom to be gone. So that liberty does not consist in the preference

ference of the mind, but in the power of conforming to that preference.

**FREEDOM of contrariety**, among moralists, that of choosing either of two opposites, as virtue or vice, good or evil; concerning which the received doctrine is, that mankind have a freedom of contradiction, but not of contrariety; that is, they may abstain from the pursuit of virtue and good, but are incapable of hating them, or of preferring their opposites. See the article **CONTRADICTION**.

**FREEDOM of conscience**. See **TOLERATION**.  
**FREEZE**, or **FRIEZE**, in architecture. See the article **FRIEZE**.

**FREEZE**, or **FRIEZE**, in commerce, a coarse kind of woollen stuff, or cloth, for winter-wear; so called, as being freezeed or naped on one side.

Irish frieze pays, on importation, a duty of  $5\frac{1}{2}\frac{1}{100}$  d. for every yard; and draws back, on being exported,  $4\frac{8}{100}$  d. per yard.

**FREEZING**, in philosophy, the same with congelation. See **CONGELATION** and **FROST**.

Philosophers are by no means agreed as to the cause of this phenomenon. The cartesian account for it by the recess or going out of the ethereal matter from the pores of the water. The corpuscularians, on the other hand, attribute it to the ingress of frigorific particles, as they call them; and Hobbes asserts, that these particles are nothing else but common air, which entangling itself with the particles of water, prevents their motion. Others will have a kind of nitrous salt to be the cause of congelation, by insinuating itself between the particles of water, and fixing them together, like nails. And, indeed, it seems probable that cold and freezing do arise from some substance of a saline nature floating in the air; since all salts, and particularly nitrous ones, when mixed with ice and snow, greatly increase their cold, and even bulk.

Boerhaave observes, that it is extremely difficult to exhibit to the eye the precise degree of cold wherein ice begins to form; since heat and cold, once given to a body, adhere long to it before they quit it. When the air, therefore, is in such a state as keeps Fahrenheit's thermometer at 32 degrees, water will not freeze; because water being 800 times denser than air, retains the warmth considerably longer than air. If any person, there-

fore, is curious to know in what degree of cold water begins to freeze, let him first suspend a thermometer in a free open air on all sides; and then wetting a thin linnen cloth with clear water, and hanging it likewise in the open air, it will grow stiff upon the first access of the freezing cold, and thereby shew when water is beginning to turn to ice. See the article **THERMOMETER**.

By means of freezing, wine, vinegar, and malt-liquors may be reduced to a fourth part of their quantity, without any considerable loss of their essential parts; since only the aqueous parts freeze, leaving the vinous parts concentrated or brought into less compass, and capable of being transported with less expence, and keeping for several years.

**FREEZING MIXTURE**. Mr. Boyle shews in his history of cold, that not only all kinds of salts, but likewise spirits, sugar, and saccharum saturni, mixed with snow, are capable of freezing most fluids; and the same effect was also produced by the mixture of oil of vitriol, or spirit of nitre, with snow.

**FREEZING RAIN**, that which falls in form of ice, or which freezes as soon as it reaches the ground.

**FREEZELAND**, or **FRIESELAND**. See the article **FRIESELAND**.

**FREIGHT**, or **FRAIGHT**, in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel.

The freight of a vessel is usually agreed on either at the rate of so much for the voyage, or by the month, or per ton. Wherever a ship freighted by the voyage, or by the month, is cast away, plundered by pirates, or taken by the enemy, the freight becomes lost; but if the merchant, or any other who hires the ship, agrees by the run, or after such a rate for every piece of the commodities on board, and that part of the goods are saved, it is there held that the ship ought to have her freight, according to the rate of the goods saved. The lading of a ship, in law construction, is bound for the freight; and where goods are put aboard, and the ship has broke ground, a merchant may not afterwards unlade them: for if he then changes his mind, and resolves not to venture, by the marine law, freight is due. Likewise, if the freighter of a ship lade

lade on board any prohibited goods, or unlawful merchandize, whereby the vessel is detained or impeded in her voyage, he shall answer the freight agreed : but where a master freights out his ship, and afterwards takes in goods secretly and unknown to the first laders, he forfeits such freight. In case any ship is freighted out and in, no freight will be due till the voyage is performed ; and here if a vessel be loit in coming home, the freight outwards and inwards are both lost.

If a whole vessel be hired, and the merchant or person who hires it do not give it full load or burden, the master of the vessel cannot, without his consent, take in any other goods without accounting to him for freight. Though the merchant do not load the quantity of goods agreed on in the charter-party, yet he shall pay the whole freight ; and if he load more, he shall pay for the excess. See the article CHARTER-PARTY.

The master may set ashore such goods as he finds in his vessel, which were not notified to him ; or take them at a higher rate than was agreed on for the rest. If a ship be stopped or detained in its course, either through the merchant's or the master's fault, the delinquent shall be accountable to the other. If the master be obliged to reftit his vessel during the voyage, the merchant shall wait, or else pay the whole freight : if the vessel could not be refitted, the master is obliged to hire another immediately, otherwise only to be paid his freight in proportion to the part of the voyage he performed : tho' in case the merchant prove that the vessel, at the time it set sail, was not capable of the voyage, the master must lose his freight, and account for damages to the merchant.

Freight shall be paid for merchandizes which the master was obliged to sell for victuals, refitting, or other necessary occasions, paying for the goods at the rate the rest were sold at where they were landed. In case of a prohibition of commerce with the country whither the vessel is bound, so that it is obliged to be brought back again, the master shall only be paid freight for going. And if a ship be stopped or detained in its voyage by an embargo, by order of the prince, there shall neither be any freight paid for the time of detention, in case it be hired *per month*, nor shall the freight be increased, if hired by the voyage : but the pay and victuals of the sailors, during the deten-

tion, shall be deemed average. See the article AVERAGE.

FREIGHT is also used for the burden, or lading of a ship, or the cargo of goods, &c. which she has on board.

FREIGHT also signifies a duty of fifty sols *per tun* paid to the crown of France by the masters of foreign vessels going in or out of the several ports of the kingdom.

It is to be observed, that all vessels not built in France, are accounted foreign, though belonging to the king's subjects ; and, as such, are liable to the payment of this impost, unless otherwise exempted, or that two thirds of the crew are French. The Dutch and the hans towns are exempted from the duty of freight.

FRENCH, in general, something belonging to France : thus we say, the french language, french customs, polity, &c. The french language is made up of latin, greek, teutonic, and the language spoken by the old Gauls. It is natural, and easily pronounced, and therefore used by most nations of Europe in conversing with foreigners. There are very few compound words in french, which is acknowledged to be to its disadvantage. It has also few diminutives ; but as to purity, easiness, and flexibility, it yields to none.

FRENCH BREAD.

FRENCH COINS.

FRENCH CROWN.

FRENCH WEIGHT, &c.

FRÆNUM, or FRÆNUM, in anatomy.

See the article FRÆNUM.

FRENZY, or PHRENZY, in medicine. See the article PHRENZY.

FRESCO, a method of painting in *relievo* on walls, so as to endure the weather.

It is performed with water-colours on fresh plaster ; or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

The compost should be made of rubbish stones mixt with well-burnt flint, or lime, and water : but the saltness of the lime must be washed out, by pouring water frequently on it. But this should not be done in moist weather.

To prevent the plaster from peeling, strike into the joints of the wall stumps of horse-nails six inches distant from each other. First plaster the walls pretty thick ; then let it dry for some time, the design and colours being first ready prepared. This painting is chiefly performed

formed on walls and vaults newly plastered with lime and sand; and the plaster is only to be put on in proportion as the painting proceeds.

Plaster the wall a second time, about the thickness of half a crown, only so much as you intend to work upon; and while it is wet, work the colours therein, which will incorporate with the plaster so as never to wash out.

The painting must be worked with a free hand, and your colours made high enough at first, as there can be no alteration made after the first painting.

In this work scarce any thing else is used but earths, which still retain their colour, defending it from the burning and salt of the lime. The colours are white, made of lime slacked some time, and white marble dust, red and yellow oker, violet red, verditer, lapis lazuli, smalt, black spanish brown, spanish white, &c. all which are ground and worked up with water.

The brushes and pencils for this work must be long and soft, or else they will rake and raze the painting: the colours must be full and flowing from the brush, and the design or cartoon must be perfect in the paper-copy.

The antients painted on stucco; and we may remark in Vitruvius what infinite care they took in making the incrustations or plastering of their buildings, to render them beautiful and lasting; tho' the modern painters find a plaster made of lime and sand preferable thereto.

**FRESH**, in general, something that is new, pure, and good; or, that has little or no salt in it.

**FRESH DISSEISIN**, in law, such a disseisin as a man may defeat of himself, and by his own power, without the assistance of the king or the law; as where it is of short continuance, *viz.* not above fifteen days. See the article **DISSEISIN**.

**FRESH FINE**, a fine that was levied within a year past. See the article **FINE**.

**FRESH FORCE**, signifies a force newly done; as where a person is disseised of any lands or tenements within a city or borough, or deforced of lands after the decease of his ancestor, to whom he is heir; the person having right may within forty days after the force committed, or title to him accrued, bring his assise or bill of fresh force; and recover the lands. See the article **FORCE**.

**FRESH HAWSE**, among seamen. See the article **HAWSE**.

**FRESH SHOT**, in the sea-language, signi-

fies the falling down of any great river into the sea, by means whereof the sea hath fresh water a good way from the mouth of the river. As this is more or less, they call it a great or small fresh shot.

**FRESH SPELL**, in the sea-phraze, a fresh gang to relieve the rowers in the long-boat.

**FRESH SUIT**, in law, is such a close and active prosecution of an offender, as never ceases from the time of the offence committed or discovered, till he is apprehended.

The benefit and effect of this pursuit of a felon is, that the party pursuing shall have his goods again, which otherwise would be forfeited to the king. A person may be said to make a fresh suit tho' he does not take the thief presently, but some time after the robbery is committed, provided he has used his utmost endeavours to take him; and though the criminal was taken by another person not interested in any thing carried away, yet the party robbed shall be deemed to have made a fresh suit.

**FRESH WATER**. See the article **WATER**.

**FRET**, or **FRETTE**, in architecture, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth. See plate CVI. n<sup>o</sup> 7.

Every return and intersection of these frets must be at right angles, otherwise they lose all their beauty, and become perfectly gothic. Sometimes the fret consists but of a single fillet, which, if well disposed, may be made to fill its space exceedingly well. Frets were very much used by the antients, especially on even flat members, or parts of a building, as the faces of the corona, and eaves of corniches; under the roofs, soffits, &c. and on the plinths of bases, &c. See the articles **CORONA**, **EVE**, &c.

**FRET**, in heraldry, a bearing composed of six bars, crossed, and variously interlaced, as represented in plate CVII. fig. 2.

Some call it the true-lover's knot.

**FRET**, in music, signifies a kind of stop on some instruments, particularly bass-viol and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

**FRET-WORK**, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but is mostly practised

tised in roofs, which are fretted over with plaster-work. The Italians also use fret-works in the mantling of chimneys, with great figures: a cheap piece of magnificence, and as durable almost within doors, as harder matters in the weather.

**FRETTY**, in heraldry, an appellation given to bearings made up of six, eight, or more bars laid across each other, in the manner of frets. See **FRET**.

**FREYSTAT**, a town of Silesia, in Germany, east long.  $17^{\circ} 55'$ , north lat.  $50^{\circ}$ .

**FRIABLE**, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are the free-stone, pumice-stone, &c.

**FRIAR**, or **FRIER**, from the French *frere*, a brother, a term common to monks of all orders, founded on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, *viz.* 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars, or carmelites. From these four the rest of the orders descend. See the articles **FRANCISCANS**, **AUGUSTINES**, &c.

**FRIAR**, in its more peculiar and proper sense, is restrained to such monks as are not priests, for those in orders are generally dignified with the title of father. See **MONK** and **FATHER**.

**FRIAR OBSERVANT**, is a branch of the franciscan friars; thus called, because they are not combined together in any cloister, convent, or corporation, as the conventuals are; but have bound themselves only to observe the rules of their order more strictly than the conventuals do, from whom they separated, out of a singularity of zeal, living in certain places of their own choosing.

**FRIAR'S COUL**, in botany, a name given to several species of arum. See the article **ARUM**.

**FRIBURG**, the capital of a canton of the same name in Switzerland, situated eighteen miles south-west of Bern: east long.  $6^{\circ} 55'$ , north lat.  $46^{\circ} 50'$ .

**FRIBURGH**, a city of Swabia, in Germany, twenty-eight miles south of Strasbourg.

**FRIBURGH**, or **FRIDBURGH**, in our old customs, the same with frank pledge. See the article **FRANK**.

**FRICASSEE**, in cookery, a dish hastily dressed in a frying-pan, with butter, oil,

or the like. Thus we say, a fricassee of pullets, tripe, eggs, &c.

**FRICENTO**, a town and bishop's see of Italy, forty-three miles east of the city of Naples.

**FRICTION**, in mechanics, the rubbing of the parts of engines and machines against each other, by which means a great part of their effect is destroyed.

It is hardly possible to lay down general rules concerning the quantity of friction; since it depends upon a multiplicity of circumstances, as the structure, firmness, elasticity, &c. of the bodies rubbing against each other. Some authors make friction, upon an horizontal plane, equal to one third of the weight to be moved; whilst others have found it to be considerably less.

Be this as it will, the doctrine of friction, as ascertained by the latest experiments, may be summed up in the following manner. 1. When one body insists on another upon a horizontal plane, it presses it with its whole weight; which being equally re-acted on, and consequently the whole effect of its gravity destroyed by the plane, it will be absolutely free to move in any horizontal direction by any the least power applied thereto, provided both the touching surfaces be perfectly smooth. 2. But since we find no such thing as perfect smoothness in the surfaces of bodies, but an evident roughness or unevenness of the parts in their surface, arising from their porosity and peculiar texture, it is easy to understand that when two such surfaces come together, the prominent parts of one will, in some measure, fall into the concave parts of the other; and, therefore, when an horizontal motion is attempted in one, the fixed prominent parts of the other will give more or less resistance to the moving surface, by holding and detaining its parts; and this is what we call friction. 3. Now since any body will require a force proportional to its weight to draw it over a given obstacle, it follows that the friction arising to the moving body will always be in proportion to its weight only, and not the quantity of the surface, by which it bears upon the resisting plane or surface. Thus if a piece of wood four inches wide, and one thick, be laid upon another fixed piece of the same wood, it will require the same weight to draw it along, whether it be laid on its broad or narrow side. 4. For tho' there be four times the number of touching particles on the

the broad side (*ceteris paribus*) yet each particle is pressed with but  $\frac{1}{4}$  of the weight that those are on the narrow side; and since four times the number, multiplied by  $\frac{1}{4}$  of the weight, is equal to  $\frac{1}{4}$  of the number multiplied by four times the weight, it is plain the resistance is equal in both cases, and so requires the same force to overcome it. 5. The reason why friction is proportional to the weight of the moving body, is, because the power applied to move the body, must raise it over the prominent parts of the surface on which it is drawn; and this motion of the body, as it is not upright, so it will not require a power equal to its whole weight; but being in the nature of the motion on an inclined plane, it will require only a part of its own weight, which will vary with the various degrees of smoothness and asperity. 6. It is found by experiment, that a body will be drawn along by nearly one third of its weight; and if the surfaces be hard and well polished, by less than a third part; whereas, if the parts be soft or rugged, it will require a much greater weight. Thus also the cylinder of wood AB, (plate CVII. fig. 3. n<sup>o</sup> 1.) if very smooth, and laid on two well polished supporters, C, D, (having been first oiled or greased) and then charged with the weight of two pounds in the two equal balls, G, H, it will require an additional weight  $x$ , equal to about a third part of the two pounds, to give motion to, or overcome the friction of the said cylinder. 7. Now this additional weight, as it causes a greater weight of the cylinder, will likewise increase the friction, and therefore require the addition of another weight  $y$ , equal to the third part of its own weight: for the same reason, the weight  $y$  will require another  $z$ , a third part less; and so on, *ad infinitum*. Hence, supposing the friction to be precisely a third of the weight, the first weight with all the additional ones, *viz.*  $2, \frac{2}{3}, \frac{2}{9}, \frac{2}{27}, \&c.$  will be a series of numbers in geometrical progression, decreasing. Now the sum of all these terms, except the first, is found, by a well known theorem in arithmetic, to be equal to one pound. So that if the weight of the cylinder be inconsiderable, the readiest way to overcome the friction, would be to double the power G, or H, at once. 8. But tho' we may, at a medium, allow a third part of the weight with which any simple machine is charged, for the friction arising from thence;

yet this is very precarious, and seldom is the case: for if ABCD (*ibid.* n<sup>o</sup> 2.) be a piece of brass of six ounces, and EFGH be also a plate of brass, and both the surfaces well ground and polished, the weight P of near two ounces will be required to draw along the body AC alone; but if AC be loaded with 6, 8, or 10 lb. then a sixth part of the weight will be sufficient to draw it along the plane. On the other hand, if the plane be covered with a linnen or woollen cloth, then a third, or half part, and sometimes more, will be requisite to draw it along on the plane. 9. Yet notwithstanding the difficulty and uncertainty attending the estimation of the quantity of friction, it is still a most useful and necessary enquiry, how, and by what means the friction of any machine may be diminished. In order to this, we must consider friction mechanically, or as a force acting against a power applied to overcome it. Thus suppose AB (*ibid.* n<sup>o</sup> 3.) an upright stem or shaft, turning freely in the socket B fixed in the table or plane IKLM; and AC, DE, two arms fixed in the said shaft, the latter of which, DE, has three pins going into a socket in the middle of heavy weights, F, G, or H, in such a manner, that when a power applied at C moves the lever AC, it causes the lever DE to protrude or thrust along the weights at F, G, or H, in a circular manner upon the table. 10. Now since we suppose the weight, all the while it is in motion, is freely and wholly supported by the plane, it follows that all the resistance it can give to the power applied to C, is only what arises from its friction on the plane. What this friction is, will be found by applying the weight at G, so that BG be equal to AC; for then the power applied to C, acting in a tangent to the circle CRS, that shall just move the weight G, will be equal to its friction. But if the weight be applied at F, because BF is greater than AC, the same power at C, as before, will not move it, by reason its force is here increased by having a greater velocity than the power; as, on the other hand, if placed at H, a less power at C shall move it, because of its having there less velocity than the power, as is evident from the properties of the lever. 11. Hence, we understand, that though the weight of a machine remains the same; yet the friction may be diminished, by contriving that the parts, on which it moves and

rubs,

*Fig. 1. The SIBERIAN FOX.*

*Fig. 2. FRET.*

*Fig. 3. FRICTION*

rub, shall have less velocity than the power which moves it: thus, if the cylinder AB (*ibid.* n° 1.) were to move on the two small pins or gudgeons E, F, the friction would be abated in the proportion of the diameter of the cylinder to that of the pins: 12. The friction on these gudgeons is still farther diminished by causing them to move on the circumference of a wheel: thus, let F be the gudgeon of the cylinder, revolving on the wheel CDE (*ibid.* n° 4.) the velocity of the wheel's circumference will be the same with that of the gudgeon; but the velocity of the wheel's axis AB (which is now to be considered as the rubbing part) is less than that of the wheel, in proportion as its diameter is less than that of the wheel: for example, if the friction of the cylinder moving on its surface, be  $\frac{1}{3}$  part of the weight, and the gudgeon be to the cylinder as 1:10, they will reduce the friction to  $\frac{1}{30}$  part; and if, again, the axis of the wheel be to the wheel as 1:10, the wheel will reduce the friction to  $\frac{1}{300}$  part; and if the axis of this wheel be laid on the perimeter of another wheel, the friction will be reduced to a still lesser part of the weight; so that you may proceed in this manner to diminish the friction *ad infinitum*; and wheels applied in this manner, are called friction-wheels. 13. Besides what has been already said, somewhat farther is necessary to diminish the friction of wheel-carriages. It was before observed, that friction arose chiefly by lifting the body over the prominent parts of the plane on which it is moved; now if we can contrive to move the body along without lifting or sustaining its weight, we shall move it without much friction; and this may be done by laying the body on any moveable circular subject, as rollers, wheels, &c. thus let AB (*ibid.* n° 5.) be the section of an heavy body, laid on a roller EF, upon the plane CD, and drawn by the power P; it is evident, when AB moves, the asperities of its surface will lay hold on those of the roller, and move it likewise; and it is as evident, that when the body AB is drawn against the prominent parts of the roller, they immediately give way, and make no resistance: thus the perpendicular diameter *ab* yields into the situation *ef*, and *cd* succeeds in its place. By this circular motion of the roller, its prominent parts below do only descend

and move upon or over, and are not drawn against the fixed prominent parts of the plane, and so receive no resistance from them. Hence the body AB is conveyed along, without being lifted up, in the same manner as a wheel is moved by a pinion, without any considerable resistance. And this is the true foundation of the doctrine of wheel-carriages. See the article WHEEL-CARRIAGES.

**FRICTION**, in medicine, the rubbing a diseased part, either with or without unguents, oils, &c. Dr. Cheyne greatly recommends friction with a flesh-brush, to persons of weak nerves and sedentary lives; by which means a full and free perspiration would be promoted, and obstructions removed, to the great relief of many valetudinarians.

**FRIDBURG**, an imperial city of Bavaria, in Germany: east longitude 11°; and north lat. 48° 30'.

**FRIDBURG** is also the name of two other towns in Germany, both situated in the circle of upper Saxony, the one nine miles south-west of Dresden, and the other thirty miles west of Leipzig.

**FRIDLAND**, a town of Bohemia, on the confines of Lusatia: east longit. 15° 5', and north lat. 50° 55'.

**FRIDLINGEN**, a town of Swabia, in Germany: east long. 7° 30', and north lat. 47° 35'.

**FRIDSTOL**, mentioned in our ancient writers, among the immunities granted to churches, signifies a seat, chair, or place of peace and security, where criminals might find safety and protection: of these there were many in England, but the most famous was at Beverley, and that in St. Peter's church at York, granted by charter of king Henry I.

**FRIEDBURG**, an imperial city of Germany, sixteen miles north of Francfort on the Main.

**FRIENDLESS MAN**, an old saxon term for an outlaw.

**FRIER**, or **FRIAR**. See **FRIAR**.

**FRIESLAND**, one of the most northern provinces of the united Netherlands, bounded by the German ocean on the north, by Groningen and Overijssel on the east, by the Zuider-sea and Overijssel on the south, and by the same ocean on the west: its chief town is Lewarden.

**East-FRIESLAND**, a province of Westphalia, in Germany, being the north-west part of Germany, bordering on Groningen.

**FRIEZE, FREEZE, or FRIZE**, in architecture, a large flat face, or member, separating the architrave from the cornice, being that part of the entablature between the architrave and cornice. See the articles **ARCHITRAVE**, **CORNICHE**, and **ENTABLATURE**.

This member was by the antients called **zoophorus**, because it was commonly enriched with the figures of animals. The frieze is supposed to be designed to represent the heads of the transverse beams, which sustain the roof or covering.

In the tuscan order it is quite plain, but is enriched with triglyphs in the doric; it is sometimes made arched or swelling in the ionic: in the corinthian and composite it is frequently joined to the architrave by a little sweep, and sometimes to the cornice; and in these richer orders, it is commonly adorned with sculpture, figures, compartments, histories, foliages, festoons, &c. See the articles **TUSCAN**, **DORIC**, **IONIC**, &c.

As to the height of the frieze, it is in general much the same as that of the architrave. The height of the tuscan frieze, according to Vitruvius, who makes it flat and plain, is 30 minutes; but Palladio, who makes it convex and swelling, gives it only 26; Scamozzi makes it plain, but raises the height to 42 minutes. Vitruvius and Vignola, who make the doric frieze flat, only covered with triglyphs give it the height of 30 or 40 minutes: but Palladio and Scamozzi make it 45. The ionic frieze, according to Vitruvius, who makes it flat, only carved with acanthus-leaves, &c. is 30 minutes in height; Vignola makes it 45, and flat like Vitruvius: Palladio, who makes it convex and swelling, calls the height 27; and Scamozzi 28. The height of the corinthian frieze, according to Vitruvius, who enriches it with acanthus-leaves, human figures, &c. is 37 minutes; but Vignola makes it 45, Palladio, 28; and Scamozzi 31  $\frac{1}{2}$ . Lastly, the composite frieze, which, in Vitruvius, is set with cartouches, and carved between them, is, according to that writer, 52  $\frac{1}{2}$  minutes high; but Vignola, who makes it like Vitruvius, gives it but 45 minutes; Palladio, who makes it swelling, has but 30; Scamozzi, 32.

From the variety of their ornaments, friezes obtain various denominations.

**Convex or Pulvinated FRIEZES**, such whose profile is a curve, the best proportion of which is when drawn on the base of an equilateral triangle.

In some the swelling is only at top, as in a console; in others at bottom, as in a balluster. See the articles **CONSOLE** and **BALLUSTER**.

**Flourished FRIEZES**, such as are enriched with rinds of imaginary foliages, as the corinthian frieze of the frontispiece of Nero: or with natural leaves, either in clusters or garlands; or continued, as in the ionic of the gallery of Apollo in the Louvre.

**Historical FRIEZES**, such as are adorned with bas-relievos, representing history, sacrifices, &c. as the arch of Titus at Rome.

**Marine FRIEZES**, such as represent sea-horses, tritons, and other attributes of the sea, as shells, baths, grottos, &c.

**Rustic FRIEZES**, such whose courses are rusticated or embossed, as in the tuscan frieze of Palladio.

**Symbolical FRIEZES**, those adorned with the attributes of religion, as the corinthian of the temple behind the Capitol at Rome, whereon are represented the instruments and apparatus of sacrifice.

**FRIEZE of the capital**. See the article **HYPOTRACHELIUM**.

**FRIEZE, or FREEZE**, in commerce. See **FREEZE** and **FRIZING**.

**FRIGAT**, among seamen, a ship of war, light built, and that is a good sailer.

A frigate has commonly two decks, whence that called a light frigate, is a frigate with only one deck.

**FRIGATOON**, a venetian vessel, commonly used in the Adriatic sea, with a square stern, and carrying only a main-mast, mizen, and bowsprit.

**FRIGID**, is applied to a jejune style, that is unanimated by any ornaments, and consequently without any force or vigour.

**FRIGID ZONE**, in geography. See the article **ZONE**.

**FRIGORIFIC**, in physiology, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which we call cold. See **COLD**.

**FRILL**, in falconry. When a hawk trembles, or shivers, they say, she frills.

**FRINGE TREE**, a name given by some to the chionanthus. See the article **CHIONANTHUS**.

**FRINGILLA**, in ornithology, a comprehensive genus of birds, of the order of the passerines, with the beak of a conic sharp-pointed figure, the two chaps of which mutually receive each other.

To this genus belong the gold-finch, chaff-finch, green-finch, yellow-hammer, canary-bird, linnet, sparrow, &c. See the articles GOLD-FINCH, &c.

**FRINGILLAGO**, a name given by some authors to the parus or titmouse. See the article TITMOUSE.

**FRINGILLARIUS ACCIPITER**, the name by which authors call the sparrowhawk. See the article HAWK.

**FRINWALT**, or **FRIDLAND**, a town of Brandenburg, thirty miles north-east of Berlin, situated on the west side of the river Oder.

**FRIO**, a cape or promontory of Brasil: west lon. 44°, and south lat. 23° 30'.

**FRIPPERY**, a french term sometimes used in our language to signify the trade or traffic of old second-hand cloaths and goods. The word is also used for the place where such sort of commerce is carried on, and even for the commodities themselves. The company of frippers, or fripperers, at Paris, are a regular corporation, of an ancient standing, and make a considerable figure in that city.

**FRISACH**, a town of Bavaria, sixty miles south-east of Salzburg: east lon. 14° 15', and north lat. 47° 20'.

**FRISELAND**, or **FRIESELAND**. See the article FRIESELAND.

**FRISONE**, in ornithology, the same with the coccothraustes, or loxia. See the article LOXIA.

**FRIST**, in the mercantile style, signifies selling goods upon credit, or trust.

**FRIT**, in the glass-manufacture, the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace; or it is the calcined matter to be run into glass. See the article GLASS.

There are three kinds of frit; the first, that made for crystal; the second, or ordinary frit, is that made for the common white or crystalline metal; and the third, that made for green glass.

The frit for crystal is made as follows: take 200 lb of tartre, powdered fine, and sifted; of the salt of polverine 130 lb; mix them well together, and put them in in the calcar, a sort of oven, or reverberatory furnace, which should be first well heated: here let them remain, baking, frying, and calcining, for five hours, during which the workman keeps mixing them with a rake, to make them incorporate. The second, or ordinary frit, is made of bare ashes of polverine, without extracting the salt from them.

The third, for green glass, is made of common ashes, without any preparation.

It may be observed, that glass might be made by immediately melting the materials, without this calcining and making them into frit; but the operation would be much more tedious.

**FRITH**, in its most usual acceptation, signifies an arm of the sea: such are the frith of Forth or of Edinburgh, the frith of Clyde, Murray frith, &c.

**FRITH**, among lawyers, signifies a lawn or plain between two woods.

**FRITH-GILD**, a term antiently used for what is now called a guild-hall, or a company of some corporation: and frithman was one free of such company. See GUILDHALL and COMPANY.

**FRITH** is also used to signify peace. Hence

**FRITH-SOKE**, or **FRITH-SOKEN**, a term formerly used to signify a surety of defence.

**FRITILLARY**, *fritillaria*, in botany, a genus of the *hexandria monogynia* class of plants, the corolla of which is composed of six campanulated, oblong, and parallel petals, with a broad base; the fruit is an oblong, obtuse, trilobate capsule, formed of three valves, and containing three cells; the seeds are numerous, plane, semicircular externally, and placed in a double row.

*Thick* **FRITILLARY**, *fritillaria crassa*, in botany, the same with the asclepias. See the article ASCLEPIAS.

**FRIULI**, a province of Italy, subject to Venice, and bounded by Carinthia in Germany on the north, by Carniola on the east, by the gulph of Venice on the south, and by the Bellunese and Feltrin on the west.

**FRIZE**, or **FRIEZE**, in architecture. See the article FRIEZE.

**FRIZE**, or **FREEZE**, in commerce. See the article FREEZE.

**FRIZING of cloth**, a term, in the woollen manufactory, applied to the forming of the nap of a cloth, or stuff, into a number of little hard burrs or prominences, covering almost the whole ground thereof. See the article FREEZE.

Some cloths are only frized on the back-side, as black cloths; others on the right side, as coloured and mixed cloths, rattsens, bays, freezes, &c.

Frizing may be performed two ways; one with the hand, that is, by means of two workmen, who conduct a kind of

plank that serves for a frizing instrument.

The other way is by a mill, worked either by water, or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equably and regularly. The structure of this useful machine is as follows.

The three principal parts are the frizer or crisper, the frizing-table, and the drawer, or beam. The two first are two equal planks or boards, each about ten feet long, and fifteen inches broad, differing only in this, that the frizing-table is lined or covered with a kind of coarse woollen stuff, of a rough sturdy nap; and the frizer is incrustated with a kind of cement composed of glue, gum arabic, and a yellow sand, with a little aqua vitæ or urine. The beam, or drawer, thus called because it draws the stuff from between the frizer and the frizing-table, is a wooden roller, beset all over with little, fine, short points, or ends of wire, like those of cards used in carding of wool.

The disposition and use of the machine is thus: the table stands immoveable, and bears or sustains the cloth to be frized, which is laid with that side uppermost on which the nap is to be raised: over the table is placed the frizer, at such a distance from it as to give room for the stuff to be passed between them, so that the frizer, having a very slow semicircular motion, meeting the long hairs or naps of the cloth, twists and rolls them into little knobs or burrs, while, at the same time, the drawer, which is continually turning, draws away the stuff from under the frizer, and winds it over its own points.

All that the workman has to do while the machine is a going, is to stretch the stuff on the table, as fast as the drawer takes it off; and from time to time to take off the stuff from the points of the drawer.

The design of having the frizing-table lined with stuff of a short, stiff, stubby nap, is that it may detain the cloth between the table and the frizer long enough for the grain to be formed, that the drawer may not take it away too readily, which must otherwise be the case, as it is not held by any thing at the other end. It were unnecessary to say any thing particular of the manner of frizing stuffs

with the hand, it being the aim of the workmen to imitate, as near as they can, with their wooden instrument, the slow, equable, and circular motion of the machine: it needs only be added, that their frizer is but about two feet long and one broad; and that, to form the nap more easily, they moisten the surface of the stuff lightly, with water mingled with whites of eggs or honey.

**FROBISHER'S STRAITS**, in west Greenland, lie a little to the northward of cape Farewel: west lon. 48°, and north lat. 63°.

**FRODINGHAM**, a market-town of Yorkshire, thirty miles east of York.

**FRODSHAM**, a market-town of Chester, fourteen miles north-east of Chester.

**FROG**, *rana*, in zoology, a genus of amphibious animals, the body of which is broad and short, without a tail, and furnished with four legs.

Besides the common frog, there are a great many other species, the most singular of which is that called the bull-frog, a native of the northern parts of America, with four divided toes on the fore-feet, and five webbed ones on the hinder. This, when the limbs are extended, measures near two feet; the trunk of its body being about eight inches long, and four or five in breadth: it is very voracious, and frequently swallows young ducks, and other water-fowl, before they have strength to shift for themselves. Its croaking is so loud as to resemble the roaring of a bull heard at a distance, whence its name of bull-frog. There is also another very extraordinary species of frog, called the tree-frog, from its living on trees and plants of various kinds: also the green-frog, from its colours; its body is about an inch and a half long.

**FROG**, among farriers, the same with frush. See the article **FRUSH**.

**FROG-FISH**, the *rana piscatrix* of authors. See the article **RAWA**.

**FROME**, a market-town of Somersetshire, nine miles south of Bath.

**FRONDES**, among botanists, denote leaves consisting of several other leaves, and forming the whole of the plant; as is the case of the fern-kind, in which, the fructification being on the back of the leaves, the single leaf makes the whole plant, and is called frondis, not folium.

**FRONT of a battalion**, among military men, is the first rank, or file-leaders. It is likewise called the face or head of a battalion. In like manner

**FRONT** of a *squadron*, is the first rank of troopers.

**FRONT** of a *camp*, the foremost row of tents in the first line, which are the quarter-masters tents in the horse, and sergeants in the foot.

**FRONT** of an *army* consists of a certain number of squadrons and battalions.

**FRONT** of a *place*, or the *TENAILLE*, in fortification, all that is contained between the flanked angles of the two neighbouring bastions, *viz.* the two faces, two flanks, and the curtain.

**FRONT**, in architecture, the principal face or side of a building, or that which is presented to the chief aspect or view.

**FRONT**, in perspective, a projection or representation of the face or forepart of an object, or of that part directly opposite to the eye, which is more usually called the orthography. See *ORTHOGRAPHY*.

*Line* of the **FRONT**. See the article *LINE*.

**FRONT SCALE**. See the article *SCALE*.

**FRONTAL**, in architecture, a little fronton, or pediment, sometimes placed over a little door, or window.

**FRONTAL**, or **FRONTLET**, or **BROW-BAND**, is also used in speaking of the Jewish ceremonies.

This frontal consists of four several pieces of vellum, on each whereof is written some text of Scripture: they are all laid on a piece of calf's leather, with thongs to tie it by.

The Jews apply the leather with the vellum on their foreheads in the synagogue, and tie it round the head with the thongs.

**FRONTALE os**. See **FRONTIS os**.

**FRONTALE**, in medicine, a name for any external medicine, or topic, applied to the forehead: more particularly it means a refrigerating and hypnotic remedy, prepared of cold cephalics, bruised and tied up in a linnen bag, four or five fingers-breadth. It is sometimes used in the same sense with *anacollema*. See the article *ANACOLLEMA*.

**FRONTAL MUSCLES**, in anatomy, two of the four muscles of the cutis of the cranium. See the article *SKULL*.

The frontal muscles are very thin: they are situated under the skin of the forehead, and have both their extremities moveable, excepting only for a few fibres, which arise from the inferior edge of the *os frontis*. They are extended on each side under the eye-lids, near the larger canthus of the eye, beyond the middle of the orbit, towards the lesser canthus;

and extended somewhat obliquely outwards over the *os frontis*: after this, they expand their tendons over the upper part of the cranium, and seem to be joined with the aponeuroses of the occipitales, which are fixed. By this means they are able to move the skin of the forehead and eye-brows. The antagonists to these are the orbiculares palpebrarum, on which they are affixed. See *ORBICULARES PALPEBRARUM*.

**FRONTAL SINUS**. See *SINUS*.

**FRONTATED**, a term used by botanists relating to the leaf of a flower, which grows broader and broader, perhaps terminating in a right line: and is used in opposition to *cuspidated*, that is, when the leaves of the flower end in a point.

**FRONTEIRA**, a town of Portugal, in the province of Alentejo: west lon.  $8^{\circ} 6'$ , and north lat.  $38^{\circ} 50'$ .

**FRONTIER**, the border, confine, or extremity of a kingdom or province, which the enemies find in front, when they would enter the same: thus we say, a frontier town, a frontier province, &c. Frontiers were antiently called marches.

**FRONTIS os**, in anatomy, called also *os coronale*, the bone of the forehead. See the article *FACE*.

This is a bone of the cranium, of an irregular form, double in infants, but in adults usually single: sometimes however, it is divided in these into two parts down to the nose. It is situated in the anterior part of the skull, and forms that part of the face which is called the forehead, from whence it has its name. Its figure is symmetrical, resembling a large shell, almost round. See the article *SKULL*.

The *os frontis* is articulated, by future, to seven other bones; the *ossa parietalia*, *os ethmoides*, *os sphenoides*, *ossa lachrymalia*, *ossa nasi*, *maxillaria*, and the *ossa malarum*. See the articles *SUTURE*, *OSSA PARIETALIA*, &c.

The *os frontis* contains the anterior lobes of the brain, and a portion of the longitudinal sinus; and forms the forehead, the upper parts of the orbits, and a portion of the temples. See *BRAIN*.

In the internal surface of the *os frontis* there is a fovea, or furrow, and an eminence, to which the longitudinal sinus of the *dura mater* adheres: on its external surface are situated the frontal and temporal muscles, and the cartilaginous annule of the *musculus trochlearis* of the eye. See *MUSCULUS TROCHLEARIS*, &c.

**FRONTIGNIAC**,

**FRONTIGNIAC**, a town of Languedoc, in France, situated sixteen miles south-west of Montpellier, and remarkable for producing excellent wine.

**FRONTIGNIAC** is also the name of a fort, situated on the river St. Lawrence, in north America : west longit.  $77^{\circ}$ , and north-lat.  $43^{\circ} 20'$ .

**FRONTISPIECE**, in architecture, the portrait or principal face of a building. See the article **BUILDING**.

**FRONTISPIECE** is also used to signify an ornament fronting the title-page of a book, which, in some measure, should express the subject treated of.

**FRONTLET**, or **FRONTAL**. See the article **FRONTAL**.

**FRONTON**, in architecture, the same with pediment. See **PEDIMENT**.

**FROST**, in physiology, such an excessively cold state of the air, as converts watery fluids into ice. See the articles **FREEZING** and **ICE**.

In very cold snowy weather, not only water, but urine, beer, ale, milk, vinegar, and even wine, are either wholly or in part, converted into ice, though the last but slowly. As to the freezing of expressed oils, a very intense cold may deprive them of their fluidity, so as to be capable of being cut into portions of any figure ; but whether they are convertible into real ice, is not yet determined. In Russia oil freezes much harder than with us, but does not even there become perfect ice. Common anise-seed water, and the like weak spirits, are said to be converted into an imperfect ice in Muscovy ; and the strong spirits into a substance like that of oil. When brandy freezes, a liquid part, much stronger than common brandy, retires to the center of the vessel.

Even solid bodies are liable to be affected by frost : timber is often apparently frozen, and rendered exceedingly difficult to saw. Marble, chalk, and other less solid terrestrial concretions, will be shattered by strong and durable frosts. Metals are contracted by frost : thus, an iron-tube twelve feet long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, it swells or dilates fluids near one tenth of their bulk. Mr. Boyle made several experiments with metalline vessels, exceeding thick and strong ; which being filled with water, close stopped, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently burnt

up with frost, as with the most excessive heat ; and in very strong frosts, walnut-trees, ashes, and even oaks, are sometimes miserably split and cleft, so as to be seen through, and this with a terrible noise like the explosion of fire-arms.

Frost naturally proceeds from the upper parts of bodies downwards ; but how deep it will reach in earth or water, is not easily known, because this depth may vary with the degree of coldness in the air, by a longer or shorter duration of the frost, the texture of the earth, the nature of the juices wherewith it is impregnated, the constitution of its more internal parts as to heat and cold, the nature of its effluvia, &c. Mr. Boyle, in order to ascertain this depth, after four nights of hard frost, dug in an orchard, where the ground was level and bare, and found the frost had scarce reached  $3\frac{1}{2}$  inches ; and in a garden nearer the house, only 2 inches below the surface. Nine or ten successive frosty nights froze the bare ground in the garden  $6\frac{1}{2}$  inches deep ; and in the orchard, where a wall sheltered it from the south sun, to the depth of  $8\frac{1}{2}$  inches. He also dug in an orchard, near a wall, about a week afterwards, and found the frost to have penetrated to the depth of 14 inches. In a garden at Moscow, the frost in a hard season, only penetrates to 2 feet : and the utmost effect that capt. James mentions the cold to have had upon the ground of of Charleton-island, was to freeze it to 10 feet deep : whence may appear the different degrees of cold of that island and Russia. And as to the freezing of water at the above-mentioned island, the captain tells us, it does not naturally congeal above the depth of 6 feet, the rest being by accident. Water also, exposed to the cold air in large vessels, always freezes first at the upper surface, the ice gradually increasing and thickening downwards ; for which reason frogs retire in frosty weather to the bottom of ditches : and it is said, that shoals of fish retire in winter to those depths of the sea and rivers ; where they are not to be found in summer. Water, like the earth, seems not disposed to receive any very intense degree of cold at a considerable depth or distance from the air ; the vast masses of ice found in the northern seas being only many flakes and fragments, which sliding under each other, are, by the congelation of the intercepted water, cemented together.

In cold countries, the frost proves often fatal to mankind ; not only producing cancers, but even death itself. Those who die of it have their hands and feet first seized, till they grow past feeling it ; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, *viz.* by freezing the abdomen and viscera, which on dissection are found to be mortified and black. See the article COLD.

Sharp frosts of long continuance, are very prejudicial to fish in shallow standing waters ; for if the water be deep, or there be either a current or fresh spring in the place, the fish generally escape. Ponds, therefore, should be made large and deep, at least one part of them ought to be considerably deep, to serve as a place of refuge in case of extreme cold. The symptom of mortality in a pond, is the appearance of the fish ; for nothing but the pangs of death can make them move from the bottom in frosty weather. The only effectual method to save fish in this case, is to set great tubs or fats full of water in some out-house, not far from the fire ; then making holes in the ice, the fish will gather about them, as if they came up for fresh air ; and are to be taken out and put into the tubs, where they may be kept till the frost breaks, taking care to freshen the water every twelve hours. Sometimes fish that have been dead to all appearance, and others frozen and enveloped in ice, have been preserved by putting them into water brought to midsummer heat ; for in six or seven hours the ice will be dissolved, and the fish appear as brisk and well as ever ; after which they are to be put into waters, where the frost cannot injure them.

*Hoar-Frost, pruina*, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy crystals of various figures. Hoar-frost, therefore, is nothing but dew, turned into ice by the coldness of the air. See DEW.

**FROTH**, a white, light substance, formed on the surface of fluids, by vehement agitation, consisting of little spherules, or globules.

**FROTH-SPIT**, or **CUCKOW-SPIT**, a name given to a white froth, or spume, very common in the spring, and first months

of the summer, on the leaves of certain plants, particularly on those of the common white field lychinis, or catch-fly, thence called by some spatling poppy.

All writers on vegetables have taken notice of this froth, tho' few have understood the cause or origin of it till of late ; being formed by a little leaping animal, called by some the flea grass-hopper ; by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which containing some air in it, is soon elevated into a small bubble ; before this is well formed, it deposits such another drop, and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see.

**FROTH**, or **FOAM**, in the manege, a moist, white matter, that arises from the mouth of a horse. A horse that, by champing on his bridle, throws out a great deal of froth, is judged to be a horse of mettle and health, and to have a cold fresh mouth.

**FROWER**, an edged tool used in cleaving wood into laths.

**FROZEN**. See the articles **FROST**, **FREEZING**, **ICE**, &c.

**FROZEN-ZONE**. See the article **ZONE**.

**FRUCTIFEROUS**, signifies properly any thing that produces fruit ; but, in a more large and figurative sense, it is used by some, particularly lord Bacon, for such experiments in natural philosophy, as prove advantageous to the experimenter in point of gain or profit.

**FRUCTIFICATION**, among botanists, in a more lax sense, includes the flower and fruit, with their several coverings. See the articles **FLOWER** and **FRUIT**.

Strictly speaking, however, the term fructification signifies only the male and female organs of generation, called the stamina and pistil. See **STAMINA**, **PISTIL**, and **GENERATION**.

**FRUCTISTS**, *fructiste*, in botany, that sort of authors who have attempted the establishing the classes and distinctions of plants upon the fruit, seed, or receptacle of these in plants. Of this list are Cæsalpinus, Morison, Ray, Herman, and Boerhaave.

**FRUGIVOROUS BIRDS**, are such as feed on fruits, either wholly or in part.

The frugivorous birds, according to Mr. Willughby, are a species of terrestrial birds, some of which have crooked bills and claws, yet are of gentler nature, and not rapacious.

**FRUIT**,

**FRUIT**, in general, includes whatever the earth produces for the nourishment and support of man, and other animals, as herbs, grain, hay, corn, &c. See the article **HERBS**, **GRAIN**, &c.

**FRUIT**, more properly, signifies the production of a tree, or plant, for the propagation or multiplication of its kind, in which sense the word takes in all kinds of seeds, with their furniture. But botanists, usually understand by it that part of a plant wherein the seeds are contained. See **PLANT** and **SEED**.

**FRUIT** also implies an assemblage of seeds in a head ; as in a ranunculus, &c. and all kinds of seeds, or grains, whether inclosed in a cover, capsule, or pod ; and whether bony, fleshy, skinny, membranous, or the like.

The fruit in all plants, is the product, or result, of the flower ; or that for the production and nutrition of which the flower was intended.

The structure and parts of different fruit differ in some things, but in all the species, the essential parts of the fruit appear to be only continuations or expansions of those which are seen in the other parts of the tree ; and the same fibres are continued to them from the root. An apple, cut in two transversely, will be found principally composed of four parts. 1. A skin, or rind, which is only a continuation and expansion of the outer bark of the tree. 2. A parenchyma, or pulp, which is an expansion and intumescence of the blea, or inner bark of the tree. 3. The fibres, or ramifications of the woody part of the tree. 4. The core, which is the produce of the pith of the wood, indurated, or strengthened by twigs of the woody fibres intermixed with it. This serves to furnish a proper lodging for the seeds, and filtrates the juices of the parenchyma, or pulp, and conveys them to the seeds.

Of the fibres there are generally reckoned fifteen branches, of which, ten penetrate the parenchyma, and incline to the basis of the flower ; the other five ascend more particularly from the pedicle, or stalk, and meet with the former at the base of the flower ; and to these branches the capsule, or coats of the kernel, are fastened. These branches, being first extended through the parenchyma to the flower, furnish the necessary matter for the vegetation of it, but as the fruit increases, it intercepts the aliment, and

by this means the flower is starved, and falls off.

In a pear, there are five parts to be distinguished ; the skin, parenchyma, ramification, stone and acetarium ; the first three parts are common to the apple : the stone, observed chiefly in choak-pears, is a congeries of stony corpuscles, which are dispersed throughout the whole parenchyma, but in the greatest plenty, and amassed closest together about the center of the acetarium. This seems formed of the stony or calculeous part of the nutritious juice.

The acetarium is a substance of a tart, acid taste, and of a globular figure, inclosed in an assemblage of several of the stony parts before-mentioned.

In plums, cherries, &c. there are four parts, *viz.* a coat, parenchyma, ramification, and stone. The outer part, or shell of the stone, seems formed of the calculeous part of the nutritious juice of the plant ; and the inner part, or kernel, of the pith of the tree, derived thither by feminal branches, which penetrate the base of the stone. The acorn consists of a shell, cortex, and medulla ; the shell consists of a coat and parenchyma, derived from the bark and wood of the tree. The cortex consists of an inner and outer part, the first of which is a duplicature of the inner trunk of the shell ; the second is a softer substance, derived from the same source as the parenchyma of the shell. But authors are not agreed whether the medulla, or pulp of the kernel, doth arise from the pith of the tree, or from the cortical part thereof.

Berries, grapes, &c. contain, besides three general parts, *viz.* coat, parenchyma, and ramification, grains of a stony nature, which are the seeds.

*Use of FRUITS.* Fruits are serviceable in guarding, preserving, and feeding the inclosed seed ; in filtrating the coarser, more earthy and strong parts of the nutritious juice of the plant, and retaining it to themselves, sending none but the most pure, elaborated and spirituous parts to the seed, for the support and growth of the tender delicate embryo, or plantule, therein contained.

The use of fruits, with us, might be rendered much more extensive than it is. Many fruits, which do hurt when eaten raw, would make wines equal in flavour to many of those now obtained at great prices from abroad ; and lands which

will

will not bear corn, yet would bear trees and shrubs, producing such fruits.

Cherries, properly managed, make an excellent wine, and that in very large quantities, and plums also make a very agreeable kind; but that it has an austereness, which must be taken off by mixing a little sugar with it, when in the glass, not before it is drawn off. A coarse plum, a little larger than a damson, is the best kind for this wine, being a sort of plum that grows wild in our hedges. The wine made from it is of a very considerable strength, and affords a pleasant brandy, by distillation, in considerable quantities. Our common garden currants, afford a very agreeable wine; and our gooseberries are not second to any thing. See the articles **BRANDY, WINE, &c.**

The various uses of different fruits in the materia medica, &c. may be seen in the course of this work, each under its proper head.

**Preservation of FRUIT.** In the Philosophical Transactions, n° 237, we have a receipt for preserving fruit and flowers for a whole year, which is as follows. Take salt petre, one pound; bole armoniac, two pounds; common clean sand three pounds: mix them together; and, in dry weather, take fruit or flowers of any sort, not fully ripe, each with its stalk, and put them singly into an open glass, till it be full; cover it close with oil cloth; and in a dry cellar, put each of these glasses four fingers-deep under ground, so that quite round above, as well as below, there may remain two fingers-thick of the mixture.

To preserve quinces, apples, &c. lord Bacon directs us to plunge them in honey; but as that may give them an over luscious taste, to dip them in syrup of wine, boiled to a due height. The conservation of fruit, continues that author, should be tried in vessels filled with fine sand, or powder of chalk; or in flower, the dust of oakwood, &c. Fruits intended for long keeping, he says, should be gathered before they are full ripe, and in a fair day, towards noon, the wind not blowing south, and the moon being under the horizon, and in her decrease.

**First FRUITS.** See **FIRST FRUITS.**

**FRUIT-TREES.** With regard to fruit-trees it may be observed, 1. That the cutting and pruning them, when young, prevent their bearing, though it contributes

to the richness and flavour of the fruit, as well as to the beauty of the tree. 2. That kernel fruit trees come later to bear than stone fruit-trees; the time required by the first before they come to any fit age for bearing, being one with another five years; but when they do begin, they bear in greater plenty than stone-fruit. 3. That stone-fruit, figs, and grapes, commonly bear considerably in three or four years; and bear full crops the fifth and sixth years; and hold it for many years, if well ordered. 4.

That fruit trees in the same neighbourhood will ripen a fortnight sooner in some grounds than in others of a different temperature. 5. That in the same country hot or cold summers set considerably forwards, or put backwards the same fruit. 6. That the fruit on wall-trees generally ripen before those on standards, and those on standards before those on dwarfs.

7. That the fruit of all wall trees planted in the south and east quarters, commonly ripen about the same time, only those in the south rather earlier than those in the east; those in the west are later by eight or ten days, and those in the north, by fifteen or twenty. For the planting, pruning, grafting, &c. of fruit-trees. See the articles **PLANTING, TRANSPLANTING, PRUNING, GRAFTING, ORCHARD, GARDEN, NURSERY, &c.**

**FRUITERY**, a place for the keeping of fruit, a fruit-house, or fruit-loft.

A fruitery should be inaccessible to any thing of moisture, and should be as much as possible so, even to frost.

**FRUITFULNESS**, the quality of bearing plenty of fruit. See **FRUIT.**

**FRUMENTACEOUS**, a term applied, by botanists, to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

**FRUMENTARII**, a kind of soldiers, or archers, under the western empire.

The first time we read of these officers is in the time of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed that they were at first a number of young persons disposed, by Augustus, throughout the provinces, particularly on all the grand roads, to acquaint the emperor, with all expedition, of every thing that happened.

Afterwards they were incorporated into the troops themselves, where they still retained their antient name. As their principal office was the giving intelligence, they were often joined with the curiosi, with whom they agreed in this part of their office. See *CURIOSUS*.

Their name of *frumentarii* is derived from their being also a sort of purveyors to the armies, cities, &c. collecting all the corn from the several provinces to furnish the common-wealth.

**FRUMENTATION**, in roman antiquity, a largess of corn bestowed on the people.

This practice of giving corn to the people was very antient among the Romans; and frequently used to sooth the turbulent humour of the populace. At first the number of those to whom this largess was given, was indeterminate, till Augustus fixed it at two hundred thousand.

**FRUMENTUM SARACENICUM**, in botany, the same with the *fagopyrum*. See the article *FAGOPYRUM*.

**FRUMENTUM INDICUM**, the same with maiz, or indian corn. See *MAIZ*.

**FRUMENTY**, or *FURMETY*, a kind of pottage, made up of wheat, milk, sugar, spice, &c.

**FRUMGYLD**, in old law books, signifies the first payment made to the kindred of a person slain, by way of recompence for his murder.

**FRUMSTOL**, a term antiently used for a mansion-house.

**FRUSH**, or *FROG*, among farriers, a sort of tender horn which arises in the middle of a horse's sole; and, at some distance from the toe, divides into two branches, running towards the heel in the form of a fork.

The frush is a part of a horse's foot, the top of which only should be pared, and that every time the foot is pared, otherwise it is apt to corrupt.

**FRUSTIUM**, in mathematics, a part of some solid body separated from the rest.

The frustum of a cone is the part that remains; when the top is cut off by a plane parallel to the base; and is otherwise called a truncated cone; for finding the surface and solidity of which, see the article *CONE*.

The frustum of a pyramid is also what remains after the top is cut off by a plane parallel to its base, the mensuration of which will be found under the article *PYRAMID*.

The frustum of a globe or sphere is any part thereof cut off by a plane, the solid contents of which may be found by this rule. To three times the square of the semidiameter of the base, add the square of its height; then multiplying that sum by the height, and this product multiplied by .5236 gives the solidity of the frustum. See the article *SPHERE*.

A frustum or portion of any solid, generated by the revolution of any conic section upon its axis, and terminated by any two parallel planes, may be thus compared to a cylinder of the same altitude, and whose base is equal to the middle section of the frustum made by a parallel plane. 1. The difference between such frustum and cylinder is always the same in different parts of the same or of similar solids; when the inclination of the planes to the axis, and the altitude of the frustum are given.

2. In the parabolic conoid, this difference vanishes; the frustum being always equal to a cylinder of the same height, upon the section of the conoid that bisects the altitude of the frustum, and is parallel to its bases. 3. In the sphere, the frustum is always less than the cylinder, by one fourth part of a right-angled cone of the same height with the frustum; or, by one half of a sphere, of a diameter equal to that height; and this difference is always the same in all spheres whatever, when the altitude of the frustum is given.

4. In the cone, the frustum always exceeds the cylinder, by one fourth part of the content of a similar cone, that has the same height with the frustum. See *Mac Laurin's Fluxions*, p. 24. where he likewise compares the frustums of the hyperbolic conoid and spheroid with a cylinder. See also *GAUGING*.

**FRUTEX**, among botanists, denotes a shrub. See the article *SHRUB*.

**FRUTEX ÆTHIOPICUS** and **AFRICANUS**, a name given to several species of pine. See the article *PINE*.

**FRUTICOSE STALKS**, among botanists, those with a hard woody substance. See the article *STALK*.

**FRY**, in zoology, signifies the spawn, or rather young, of fish. See *FISH*.

**FRYTH**, or *FRITH*, in old law books. See the article *FRITH*.

**FUAGE**, in old writers, a tax of 12d. for every fire, levied in the time of Edw. III.

**FUCA**, or **PHUCA**, in ichthyology, a genus of fishes, called by Artdi phycis. See the article **PHYCIS**.

**FUCHSIA**, in botany, a genus of plants, the characters of which are not perfectly ascertained. The flower consists of a single petal, the tube is elevated; the limb is divided into eight segments, and plane; the segments are acuminate, and alternately lower; the fruit is a roundish berry, marked with four furrows, and containing four cells: the seeds are numerous, oval, and placed in a double series.

**FUCUS**, in botany, a genus of submarine plants, belonging to the *cryptogamia* class of Linnæus.

The fucus consists of a tough matter, formed into a kind of leaves, which are flat and variously divaricated; and which have some appearance of fructification, in punctated tubercles, covering oblong vesicles, supposed by Linnæus to be male flowers; and smooth, roundish vesicles, hollow and interwoven with filaments, which appear to him to be female flowers.

There are a great many species of fucus with broader or narrower leaves, and other peculiarities; one of which, the broad-leaved, ferrated fucus, grows to the height of six, eight, or more inches.

**FUDDER**, or **FODDER**, among miners. See the article **FODDER**.

**FUEL**, whatever is proper to burn or make a fire; as, 1. Wood, which should be so felled that cattle may have the browsing of it; for in winter they will not only eat the tender twigs, but even the very moss. The underwood is usually felled for fuel; but if the head or top be used for firing, it is best to begin three or four feet above the timber, if considerable. 2. Fossile and bituminous earths, as turfs and peats. 3. Sulphureous fossils of a firmer texture, as the common coals, Scotch coals, cannel-coal, &c.

It is provided by statute, that wood-fuel shall not be felled under the assize, viz. a faggot bound is to be three feet in length, and have the bond twenty-four inches round, besides the knot. Billets also are to be of a certain length, on certain penalties. See the article **BILLET**.

The fuel, in chemical operations, must be chosen suitable to the intention. The natural sun, in summer, suffices for insulations. A spirit-lamp may be made to give a moderate, or a considerably strong heat, according to the number of

wicks employed. The lighter fuels, such as straw, leaves, twigs, &c. come next in order, after spirit of wine; then oils, wax, rosin, pitch, and, lastly, solid wood, coals, and turf: all which may have their proper furnaces, so as to be burnt in the requisite quantity, and with requisite fierceness or slowness. To excite the greatest degree of heat, the rule is to use the densest fuel in large quantities, which must be blown incessantly with bellows all round the fire wherein the matter to be acted on is lodged.

**FUENTE DUENA**, a town of New-Castile, in Spain, 35 miles south-east of Madrid.

**FUGA VACUI** in the antient schools of philosophy, a supposed aversion in nature to a vacuum. See **VACUUM**.

**FUGALIA**, in roman antiquity, a feast supposed by some to be the same with the regifugium, held on the 24th of February, in memory of the expulsion of the kings, and the abolishing of the monarchical government. Others again, distinguish the fugalia from the regifuge. And others think, that the fugalia was the same with the poplifugia; or the feast of fugia, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery. See **REGIFUGE** and **POPLIFUGIA**.

**FUGAM FECIT**, in law, is when it is found by inquisition that a person fled for felony, &c.

If flight and felony be found on an indictment for felony, or before the coroner, where the murder is committed, the offender shall forfeit all his goods, and the issues of his lands, till he is acquitted or pardoned: and upon finding before justices of oyer, &c. that the offender fled, though he be acquitted on his trial, he forfeits his goods.

**FUGITIVE**, a person obliged to fly his country, or remove from a place where he had some abode, or establishment, on account of his crimes, debts, or other occasions.

**FUGITIVE'S GOODS**, the proper goods of the person that flies on a felony committed by him, which, after the flight, is lawfully found to belong to the king, or lord of the manor.

**FUGITIVES OVER SEA**, persons that go over sea without the king's license, who, unless they are merchants, or eminent persons, forfeit all their goods.

**FUGUE**, in muſic, is when different parts of a muſical compoſition follow each other ; each repeating what the firſt had performed.

There are three kinds of fugues ; the ſimple, double, and counter.

*Single*, or *Simple FUGUE*, is ſome point conſiſting of four, five, or more notes, begun by one ſimple part, and ſeconded by a ſecond, third, fourth, fifth, &c. if the compoſition conſiſt of ſo many ; repeating the ſame, or ſuch like, notes ; (*i. e.* in the ſame proportion) ſo that the ſeveral parts follow, or come in one after another, in the ſame manner ; the leading part ſtill flying before thoſe that follow.

**FUGUE DOUBLE**, or **FUGA DOPPIA**, is when two or more different points move together in a fugue, and are alternately mixed and interchanged by the ſeveral parts. See the article **PART**.

*Counter FUGUE*. See the article **COUNTER**.

**FULCRUM**, in mechanics, the prop or ſupport, by which a lever is ſuſtained. See the article **LEVER**.

**FULD**, a town and abbey of Germany, the abbot of which is a prince of the empire : eaſt long.  $9^{\circ} 35'$ , north lat.  $50^{\circ} 14'$ .

**FULICA**, the **COOT**, in ornithology, a genus of birds, of the order of the gallinæ, with a naked or bald forehead, and divided or cloyen feet : add to this, that all the toes are longer than in whole-footed birds, and have ſemi-circular membranes affixed to their joints.

Of this bird, authors mention ſeveral ſpecies, all diſtinguiſhed by their cloyen toes, and a fleſhy excrescence bare of feathers, and reaching from the bill almoſt to the crown of the head.

**FULIGINOUS**, whatever proceeds from a thick, ſooty ſmoke, ſuch as litharge and lamp-black.

**FULIGNO**, a city of Italy, in the pope's territories, ten miles north of Spoletto.

**FULIGO**, in natural hiſtory, a ſpecies of pumice-ſtone. See **PUMICE**.

**FULIGULA**, in ornithology, the name by which authors call the tuſted duck, with a hanging creſt, a black body, and white belly, and a white ſpot on the wings. It is about the ſize of the common duck.

**FULL-MOON**, *plenilunium*, that phaſis of the moon when, in her oppoſition to the ſun, the whole of her diſc is illuminated ; in which time eclipses of the moon can only happen. See the articles **MOON** and **ECLIPSE**.

**FULLER**, a workman employed in the woolen manufactories, to mill, or ſcour, cloths, ſerges, and other ſtuſs, in order to render them more thick, compact, and durable. See the article **CLOTH**.

Fullers, in conformity to the regulations of the manuſactuſers in France, are obliged to mark their ſtuſs with a particular lead after fulling. They are forbid, by the ſame regulations, to draw out, or tenter-ſtretch, their manuſactuſes, that they may be made greater in length, and narrower in breadth, &c.

**FULLER'S EARTH**, *terra fullonica*, in natural hiſtory, a ſoft, greyiſh, brown, denſe, and heavy marle : when dry, it is of a greyiſh, aſh-coloured brown, in all degrees from very pale to almoſt black, and it has generally ſomething of a greeniſh caſt : it is very hard and firm, of a compact texture, of a rough and ſomewhat duſty ſurface, that adheres ſlightly to the tongue : it is very ſoft to the touch, not ſtaining the hands, nor breaking eaſily between the fingers : it has a little harſhneſs between the teeth, and melts freely in the mouth : thrown into water, it makes no ebullition, or hiſſing, but ſwells gradually in bulk, and falls into a fine ſoft powder. It makes no efferveſcence with aqua fortis.

It is of great uſe in ſcouring cloths, ſtuſs, &c. imbibing all the greaſe and oil uſed in preparing, dreſſing, &c. of the wool, for which reaſon it is made a contraband commodity, and is not to be exported under the penalty of 1s. for every pound weight. See **FULLING**.

**FULLER'S WEED**, in botany, a name ſometimes given to the diſpacus, or teaſel. See the article **DIPSACUS**.

**FULLERY**, a place where cloths, &c. are fullied. See the next article.

**FULLING**, the art or act of ſcouring and preſſing cloths, ſtuſs, ſtockings, &c. to cleanſe, thicken, and render them more firm and ſtrong, which is done by means of a water-mill.

For the deſcription of this mill, ſee plate CVIII. fig. 1. in which, 1. is the track of the wheel, that turns on the outſide ; 2. a front view of the wheel ; 3. the arbour with its leavers, which as they paſs, raiſe the heads of the wooden mallets, and let them fall alternately ; 4. the trough, which in the plate is hid behind the timber work, and is only expreſſed by dots that ſhew its poſition : each trough has at leaſt two, and ſometimes three mallets ; 5. the head of the mallet,

mallet, with three or four notches, which hinder the stuff from sticking under the hammer ; 6. the arm or handle ; 7. the end of the mallet fastened by a pin. 8. In the troughs are laid the cloths, stuffs, &c. intended to be fulled : then letting the current of water fall on the wheel, the mallets are successively let fall upon them, when by their weight and velocity they stamp and press the stuffs very strongly, which by this means become thickened and condensed.

In this operation, fuller's earth is used with some proportion of soap ; but soap alone would do much better, was it not dearer than fuller's earth.

Fulling of stockings, caps, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or those of horses or bullocks. The ingredients generally used on this occasion are fuller's earth, urine, white soap and green soap. But water softened with chalk is far preferable.

The following is M. Colmet's method of fulling with soap, grounded on experiments made by order of the *marquis de Louvois*. Let a coloured cloth of about 45 ells, be laid in the usual manner in the trough of a fulling-mill, without first soaking it in water, as commonly practised in most places. To full this troughful of cloth, fifteen pounds of soap are required, one half of which is to be melted in two pails of river or spring water, made as hot as the hand can bear. Let this solution be poured by little and little, upon the cloth, in proportion as it is laid in the trough : thus it is to be fulled for at least two hours ; after which, let it be taken out and stretched. This done, let the cloth be immediately returned into the same trough, without fresh soap, and there fulled two hours more. Then take it out, wring it well, and express all the grease and filth. After the second fulling, dissolve the remainder of the soap, as the former part, and throw it at four several times on the cloth, not forgetting to take it out every two hours, to undo the plaits and wrinkles it got in the trough. When it is sufficiently fulled, and brought to the requisite quality and thickness, it is scoured out for good in hot water, keeping it in the trough till it be thoroughly clean. As white cloths full more easily than coloured ones, a third part of the soap may be spared.

FULLO, in ichthyology, a name used by several authors for the tench.

FULMINATING, something that thunders, or resembles thunder. See the article THUNDER.

Naturalists speak of fulminating gold, fulminating powder, &c. See the articles AURUM, PULVIS, &c.

FULMINATING LEGION, in antiquity. See the article THUNDERING LEGION.

FULMINATION, in chemistry, is used in a synonymous sense with detonation. See the article DETONATION.

Fulmination in the depuration of the more perfect metals, is, when upon infusing them with lead, a brighter colour succeeds a kind of sulphureous cloud, before appearing in the metals, during the fusion.

FULMINATION, in the romish canon-law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed, that some bull sent from the pope shall be executed.

FULMINATION is also used for the denunciation, or execution of a sentence of anathema, made public with due solemnity. See ANATHEMA.

FUMARIA, in botany, a genus of the *diadelphia hexandria* class of plants, with a polypetalous anomalous flower, the petals of which are oblong and tubulated : the fruit is a small unilocular pod, containing a number of roundish seeds.

This genus comprehends the fumitory, bastard-fumitory, capnoides, cysticapnos, cucularia, corydalis, and capnorchis of authors ; some with a roundish, others with an ovato-acuminated, and others with a very long pod.

The whole plant of fumitory is used in medicine, being accounted good in the scurvy, jaundice, and disorders of the mesentery and spleen.

FUME, in medicine. See FUMIGATION.

FUMER, in zoology, a name sometimes given to the putorius, or pole-cat.

FUMET, a term used by sportsmen for the ordure, or dung, of harts.

FUMIGATION, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded, or softened, by receiving certain fumes for that purpose.

FUMIGATION, in medicine, the application of fumes to particular parts of the body ; as those of fastitious cinnabar, to venereal ulcers. See the article ULCER.

An hystheric fume is made of an ounce of *assa foetida*, and a pound of the best white-wine vinegar, boiled in a pot with a narrow mouth, to which the patient should hold her head, with her mouth open. Steams received this way up the nose, have very sudden and remarkable effects, but this application seems justifiable only in cases where other means cannot be used. See **HYSTERIC**.

A fumigation for a catarrh is made by taking *olibanum*, amber, benjamin, gum guaiacum, and balsam of Tolu, of each two scruples : and making them all into a gross powder to burn.

Where the defluxion is very thin, and has much of its cause in the laxity of the glands, such means may do service, by constringing the parts, and repelling the flux ; but where there is an asthma, and very weak lungs, it may be very inconvenient. See the article **CATARRH**.

To make a fumigation against the falling down of the anus, or fundament. Take frankincense, mastic, amber, and cloves, of each a dram ; red rose-leaves, balaustines, of each two drams ; make them into a gross powder.

This is to be burnt upon a chaffing-dish of coals, under a chair, with a hole in it ; over which the patient is to sit with the bare part to it, after the gut is thrust up ; and by such means continued, will the sphincter at last get strength enough to keep it up, without any such help. In a teneismus it is also of use. See the article **PROLAPSUS**.

A fumigation against the falling down of the womb is made by taking myrrh, mastic, cinnamon, and spikenard, of each a dram ; mint and red roses of each two drams ; cloves, zedoary, and pimento of each half a dram. Make all into a powder to burn.

This is to be used as the preceding ; and in the same weakness it is also good, as that is of service in this.

Fumes from hot aromatic liquors, which are sometimes directed to the same purposes, are hardly so efficacious as those which arise from the burning of dry ingredients, because their moisture prevents their being so immediately restraining.

**FUMITOKY**, *Junaria*, in botany. See **FUMARIA**.

**FUNAMBULI**, in antiquity, rope dancers. See the article **DANCE**.

**FUNCHAL**, the capital of the Madeira-islands, subject to Portugal : west long. 16°, north lat. 32° 33'.

**FUNCTION**, the act of fulfilling the duties of any employment.

Function, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The vital functions are those necessary to life, and without which, the individual cannot subsist ; as the motion of the heart, lungs, &c. The natural functions are such as it cannot subsist any considerable time without them, as the digestion of the aliment, and its conversion into blood. Under animal functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion, without any, or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles, and this action consists chiefly in the shortening the fleshy fibres, which is called contraction, the principal agents of which, are the arteries and nerves distributed in the fleshy fibres. See the articles **ARTERY** and **NERVE**.

In short, all parts of the body have their own functions, or actions peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exercise of them.

**FUNCTION**, in algebra, denotes any compound quantity ; and when one of the component quantities is variable, it is said to be a variable function. See the article **QUANTITY**.

Functions are formed either by addition, subtraction, multiplication, division, involution, or evolution ; as also by the resolution of equations. But besides these, which are called algebraical functions, there are others called transcendental, arising from the management of exponents, logarithms, &c.

For a farther account of functions, the reader may consult Bernoulli, *Oper. T. 3.* also Euler's *Analys. Infinitor.*

**FUND**, in anatomy, signifies the bottom of any cavity in the body ; thus, the fund of the eye is that part possessed by the choroides and retina ; the fund of the uterus, the fund of the bladder, &c. signify also the bottom of these parts. See the articles **EYE** and **UTERUS**.

**FUND**, in commerce, signifies the stocks of the great trading and monied companies. See the article **STOCKS**.

**FUNDS** is also a term adopted by those who speak of the public revenue of nations, to signify the several taxes that have been laid upon merchandizes either by way

of duties of custom, or excise, or in any other manner, to supply the exigencies of the state, and to pay interest for what sums it may have occasion to borrow. Thus we say, such a duty, or such a tax, is a good fund to answer such a purpose.

The funds or taxes of this kingdom, are either temporary or perpetual: temporary ones, are such as are either imposed for a certain number of years, or annually, as the land and malt-taxes: the perpetual funds, are such on which money has been borrowed for the public service, and which are appropriated for the secure and certain payment of the interest of such money, till the discharge of the principal so borrowed. See the articles **DUTY, CUSTOM, TAX, &c.**

**FUNDAMENT**, in anatomy, the same with anus. See the article **ANUS**.

**FUNDAMENTAL**, in general, something that serves as a base or foundation to another.

**FUNDAMENTAL NOTE**, in music, the principal note in a song, or composition, to which all the rest are in some measure adapted, and by which they are swayed: it is otherwise called the key to the song, See the articles **KEY** and **CLEF**.

**FUNDAMENTO**, in the italian music, every part that plays or sings the bass; but more especially the thorough bass, as being the foundation of all harmony.

**FUNDI-BAY**, that situated between New England and New Scotland, in which there is said to be an excellent fishery.

**FUNDULUS**, in ichthyology, a fish otherwise called cobitis. See **COBITIS**.

**FUNDULUS** is also used by Charlton for the gudgeon. See the article **GUDGEON**.

**FUNEN**, the second island for magnitude belonging to the king of Denmark, situated at the entrance of the Baltic sea, and separated from Jutland by the strait called the lesser Belt, and from the island of Zeland by the strait called the great Belt. Its chief town is Odensee.

**FUNERAL RITES**, ceremonies accompanying the interment or burial of any person. See the article **BURIAL**.

These rites differed among the antients according to the different genius and religion of each country. The Egyptians, among the rest of their funeral rites, embalmed their dead. See **EMBALMING**.

Among the ancient Greeks it was usual sometimes, before the interment, to put a piece of money into the mouth of the deceased, which was thought to be Cha-

ron's fare for waiving the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake, composed of flour, honey, &c. which was designed to appease the fury of Cerberus, the door keeper of hell, and to procure the ghost a safe and quiet entrance.

During the time the corpse continued in the house, there stood before the door a vessel of water, the design of which was, that those concerned about the body, might purify themselves by washing; it being the opinion of the Greeks, as well as of the Jews, that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends, were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they divested themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground, and rolled in the dust, or covered their head with ashes; they beat their breasts, and even tore their flesh with their nails, upon the loss of a person they much lamented. When persons of rank, such as public magistrates, or great generals, died, the whole city put on a face of mourning: all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse, were shut up. See the article **MOURNING**. Interring or laying the dead in the ground, seems to have been the most ancient practice among the Greeks; tho' burning came afterwards to be generally used among them. It was customary to throw into the funeral pile those garments the deceased usually wore. The pile was lighted by one of the dead person's nearest relations or friends, who made prayers and vows to the winds to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead person's friends stood by it, pouring libations of wine, and calling upon the deceased. See the article **BURNING**.

When

When Numa reformed the religion of Rome, he ordered that the pontiffs should have the care of the funeral ceremonies ; which, in most respects, were like those of the Greeks already described.

The funeral rites among the Hebrews, were solemn and magnificent : when any person was dead, his relations and friends rent their cloaths ; which custom is but faintly imitated by the modern Jews, who only cut off a bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string ; because the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a speech to the dead in the following terms : " Blessed " be God, who has formed thee, fed " thee, maintained thee, and taken away " thy life. O dead ! he knows your " numbers, and shall one day restore " your life, &c." Then they spoke the elogium, or funeral oration, of the deceased ; after which they said a prayer, called the righteousness of judgment ; then turning the face of the deceased towards heaven, they called out, " Go in " peace."

The antient christians testified their abhorrence of the pagan custom of burning the dead ; and always deposited the body entire in the ground : and it was usual to bestow the honour of embalming upon the martyrs, at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral attire. The exportation, or carrying forth of the body, was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of psalms, was the great ceremony used in all funeral processions among the antient christians.

In the romish church, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy-water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water ; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the *mise-*

*re*, and some other psalms ; and at the end of each psalm a *requiem*. We learn from Alet's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church ; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers : after the office for the dead, mals is said ; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the greek church, are much the same with those of the latin. It needs only be observed, that after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased : after which each of the company eats a bit of bread, and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

**FUNERAL COLUMN**, a column crowned with an urn, wherein the ashes of some deceased person are supposed to be enclosed ; the staff or shaft being beset with tears or flames, the symbols of grief and immortality. See **COLUMN**.

**FUNERAL GAMES**, a part of the ceremony of the antient funerals.

It was customary for persons of quality, among the antient Greeks and Romans, to institute games with all sorts of exercises, to render the death of their friends more remarkable. This practice was generally received, and is frequently mentioned by antient writers. Patroclus's funeral games, take up the greatest part of one of Homer's iliads ; and Agamemnon's ghost is introduced by the same poet in Odyss. *æ*, telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks, mostly consisted of horse-races : the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The garlands, given to victors on this occasion, were usually of parsley, which was thought to have some particular relation to the dead.

Those games, among the Romans, consisted chiefly of processions ; and sometimes of mortal combats of gladiators, around the funeral pile. They, as well as the Greeks, had also a custom, tho' very

very antient, of cutting the throats of a number of captives before the pile, as victims to appease the manes of the deceased. Cæsar relates, that the Gauls had this custom.

The funeral games were abolished by the emperor Claudius.

**FUNERAL HONOURS.** See **HONOUR.**

**FUNERAL ORATION**, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

This custom is very antient, both among the Greeks and Romans. Before the company departed from the sepulchre, they were often entertained with a panegyric upon the dead person, always pronounced by a near relation, or one of the public magistrates.

**FUNGITÆ**, in natural history, a kind of fossil coral, of a conic figure, tho' sometimes flattened and striated longitudinally. See the article **CORAL.**

**FUNGUS**, in surgery, denotes any spongy excrescence. See **EXCRESCENCE.**

In wounds made by a sharp instrument, where there is no disposition of body, the cure is generally performed without any interruption, but from the fungus; and here dry lint alone is generally the best remedy through the whole course of dressing. See **ULCER** and **WOUND.** If ulcers produce a spongy lax flesh, sprouting very high above the surface, it will be necessary to destroy it by some of the escharotics, or the knife. This fungus frequently approaches to a cancerous complexion, and when it rises upon some glands, sometimes actually degenerates into a cancer, as has happened in buboes of the groin. When excrescences have arisen in venereal ulcers, escharotics are to be preferred, and pulvis angelicus, which is a composition of precipitate powder and burnt alum, as it eats deeper, is preferable to precipitate alone. When the excrescence is cancerous, and does not arise from a large cancer, but only from the skin itself, the actual cautery is usually recommended; tho' it is a more secure method to cut away quite underneath, and afterwards to dress with easy applications; but the cases where either of these methods are practicable, very rarely occur.

A fungus in the joints, is a tumour in the articulations of the limbs, without heat or pain, and so soft, that it easily yields to the pressure of the finger; but upon its removal, expands itself immediately, without retaining any marks.

This may be distinguished from the dropsy of the joint, if it be observed that the latter is a distention of the entire joint, and the other arises rather on one side.

The most proper method of cure, is to rub the part affected several times a-day with warm cloths, and then to foment it with the following decoction: take of litharge, half a pound; armenian bole, an ounce; mastich and myrrh, each half an ounce; wine vinegar, a pint: boil these together for a quarter of an hour. Use this decoction warm. See the article **FOMENTATION.**

If none of these medicines answer the purpose, an incision must be made into the tumefied joint, towards the lower and most commodious part, pressing the tumour hard with your fingers, and retaining it with a bandage placed above it, to prevent its giving way. When the member is restored to its pristine form, it may be healed by vulnerary balsams; but to prevent the serum from collecting again, purging and sudorific medicines should be given, and the wound be kept open with tents for some time. See **WOUND.**

**FUNGUS**, in botany, an order of vegetables, extremely different from all others, and belonging to the *cryptogamia* class of Linnæus.

The fungi have, indeed, so little of the common and general appearance of vegetables, that many have denied them to be such, and contended for their being only excrementitious matter, protruded from decaying vegetables of other kinds. But notwithstanding the fungi have neither the colour or texture of other plants, nor leaves nor flowers like them; yet they must be allowed to belong to the vegetable kingdom, as having absolute and perfect seeds, consisting usually of single antheræ, which produce plants like those from which they are collected.

The fungi are extremely different in figure, and in their manner and place of growth; some growing on the ground, some on living trees, and many on decayed wood; and that horizontally or erect. Some are of only a few days duration, others remain for years, and some there are which grow under the surface of the earth in no particular direction.

To the order of fungi belong a great many genera, as agaric, boletus, phallus, lycoperdon, &c. See **AGARIC**, &c.

**FUNICULUS UMBILICALIS**, in anatomy. See **FOETUS** and **NAVEL-STRING.**

**FUNNEL** of a chimney, the shaft or smallest part of the waste, where it is gathered into its least dimensions.

Palladio directs, that the funnels of chimneys be carried through the roof four or five feet at least, that they may carry the smoke clear from the house into the air. See the article CHIMNEY.

He also advises, that chamber-chimneys be not made narrower than ten or eleven inches, nor broader than fifteen; for if too narrow, the smoke will not be able to make its way; and, if too wide, the wind will drive it back into the room.

**FUNNEL-FASHIONED**, or **FUNNEL-SHAPED-FLOWERS**, in botany. See the article INFUNDIBULIFORM.

**FUR**, or **FURR**, in commerce. See **FURR**.

**FURBISHER**, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c. which is chiefly performed with emery. See the article EMERY.

**FURCA** and **FOSSA**, in our old customs, the power of gallows and pit, or a jurisdiction of punishing felons, viz. the men by hanging, and the women by drowning.

**FURCA**, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced his servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor, having his head fastened to the furca, was whipped to death.

**FURCAM ET FLAGELLUM**, the meanest of all servile tenures, the bondman being at the lord's disposal for life and limb.

**FURCHE**, in heraldry, a cross forked at the ends. See the article CROSS.

**FURFUR**, **BRAN**. See the article **BRAN**. From their resemblance to bran, those excrementitious particles which are evacuated with the urine, are also called furfures; and for the same reason this name is also given to the scabies or scurf of the head.

**FURIES**, *eumenides*, *diræ*; certain goddesses whose office it was to punish the guilty after death. These were three in number; Alecto, Megæra, and Tisiphone, who were described with snakes instead of hair, and eyes like lightning, carrying iron-chains and whips in one hand,

and in the other flaming torches; the latter to discover, and the former to punish the guilty; and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tisiphone punished the crimes which sprang from hatred or anger; Megæra, those from envy; and Alecto, those from an insatiable pursuit after riches and pleasure. They were worshipped at Cafina in Arcadia, and at Carmia in Peloponnesus. They had a temple at Athens, near the Areopagus, and their priests were chosen from amongst the judges of that court. At Telphusia, a city in Arcadia, a black ewe was sacrificed to them.

**FURLING**, in the sea-language, signifies the wrapping up and binding any sail close to the yard; which is done by hauling upon the clew-lines, bunt-lines, &c. which wraps the sail close together, and being bound fast to the yard, the sail is furled.

**FURLING-LINES**, on ship-board; small lines made fast to the top-sail, top-gallant-sail, and the mizen-yard-arms, to furl up the sails by.

**FURLONG**, a long measure, equal to  $\frac{1}{2}$  of a mile, or forty poles. See the articles MEASURE, MILE, and POLE.

It is also used, in some law-books, for the eighth part of an acre. See the article ACRE.

**FURLOUGH**, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

**FURNACE**, an utensil, or vessel, proper to contain fire; or to raise and maintain a vehement fire in, whether of coal or wood. See the article FIRE.

There are divers kinds of furnaces, of various forms, and for various purposes. A chemical furnace is a structure of brick, iron, or stone, capable of containing, restraining, and applying fire to vessels, wherein the chemical subjects are to receive the action of fire.

Hence a furnace requires, 1. A fireplace, wherein the fire is to be raised, kept up, and determined; and as artificial fire must be fed by fuel, a chimney becomes necessary to discharge the smoke; an ash-pit, to admit the air; and a door, where the fuel is to be thrown in. 2. In erecting a furnace, care must be taken to build it so as to preserve the strength of the fire, or not to waste it in vain; and this

this by directing it where it is particularly required. 3. A proper place must also be contrived, in which the vessels containing the subjects may receive the requisite degree of heat, for the requisite time to finish the operation.

In the building of furnaces, regard must be had, 1. To the quantity of fire which the fire-place ought to receive, contain, and support. 2. To the matter of the fuel to be used for the purpose. 3. To the degree of heat required in every operation; since in the same fire-place the same quantity of the same fuel may produce different degrees of heat. Whence, 4. The air must always have access to the fire-place; and the force with which the air tends to the fire, under the form of wind or blast, should be computed. 5. The air-vent from the fire should be principally regarded, for if this be wide, the air here diffuses, and loses itself; or acts but little upon the subject, where its force ought to be collected.

The first or most simple chemical furnace, according to Boerhaave, is constructed as follows. Make a hollow box, with a square basis, of sound, dry oak, nine inches wide, and fourteen high. Into this fix a square piece of wainscot, one inch thick, and five inches from the basis, so as to divide the furnace into two parts; the lower whereof, being five inches high, serves for the fire-place; and the upper, eight inches high, is to receive the retort for distillation. This piece of wainscot, serving as a partition, must have a round hole in the middle, five inches over, where the round bottom of the vessel is to rest. Besides this large hole in the partition, there must be four other round holes made in it, each an inch in diameter, that the heat of the fire may rise freely from the fire-place into the second story. On one side of the fire-place there must be a door going upon hinges, and equal in dimensions to the whole side, or nine inches broad, and five high, so as to open easy, and shut close. The whole internal fire surface of this fire-place must be lined with plated iron or copper, to defend the wood from the fire. The door is to have four round holes made in it, each of them an inch in diameter, to admit the external air; and these holes are to be fitted with four cylindrical stoppers, to regulate the fire, by admitting and excluding the air. This

door must be made of seasoned wood, and made to shut extremely close. In the upper part of the furnace, the side above the door must have a square hole cut in the middle, to the top of it, four inches and a half over; the inner edge of which is to be cut away on its three sides to half the thickness of the board, or to the breadth of half an inch. And to the internal sloping surface about this hole, a plate of wood must be so fitted as to make a joint; this being of use to shut the side of the furnace close, when we design to distil, digest, or exhale in a cucurbit, phial, or evaporating glass: whereas the plate of wood being taken away, fits the furnace for distillation by the retort. There must also be another similar plate of wood with a hole in the middle, two inches and a half over, so as to let the neck of the retort pass through it, when fitted into the square hole, instead of the former. A pair of folding-doors should also be made to serve as the flat top, or cover to the furnace; the middle part of which doors must be cut into a round hole of five inches diameter, to let out the neck of the cucurbit, or bolt head, used in digestion. In the last place, there must be a round flat piece of wood, six inches in diameter, to cover this upper orifice, when the furnace is used for distilling by the retort. See a view of this furnace in plate CVIII. fig. 2. n<sup>o</sup> 1. In order to work this furnace, we must be provided with a square flat-bottomed earthen pan, (*ibid.* A) standing upon three feet, about half an inch high; the height of the pan being from the bottom of the furnace to its upper rim three inches and an half: at the bottom of this pan a little sifted ashes must be lightly sprinkled, a quarter of an inch thick; then an ignited coal of dutch turf, first burnt till it yields no longer smoke, is to be laid upon this bed of ashes, and covered by sifting more of the same ashes lightly upon it, whereby an equable, moderate heat may be kept up for near twenty-four hours.

This furnace works without yielding any smoke, or disagreeable smell, and affords so gentle and equable a heat, that in the opinion of Boerhaave, eggs may be hatched by it: tho' it may be raised high enough to make water boil, or higher; and of course will commodiously perform all kinds of digestions and distillations of aqueous and spirituous li-

quors, volatile, alkaline salts, and volatile aromatic salts, or tinctures, exhalations, &c.

If a furnace be required capable of giving a stronger heat, so as to distil in sand, the best contrivance, according to Boerhaave, is the following, for making portable furnaces, these being the most commodious, on account of leaving the chimney of the laboratory free. Let a hollow cylinder, CGHD, (*ibid.* n<sup>o</sup> 2.) be made of thin iron-plate, seventeen inches in diameter, and nineteen inches high; the lower end to be closed, and the upper end open. Let the bottom be supported with three iron feet, twelve inches long; and let the iron bottom be covered on the inside with a copper-plate, lest the salt in the ashes should otherwise soon corrode the iron. Let a grate, *y*, be fixed in this cylinder, so that the upper surface thereof, being parallel to the base of the cylinder, may rise four inches above it. Let the grate be surrounded with a flat ring of plated iron, three inches and an half broad. Let the bars of the grate be flat, half an inch wide, and set at the distance of an inch from each other. This iron rim of the grate must rest upon three pins sticking out by the inside of the furnace, to fix the grate. Let the ash-place, NOPQ, be fitted with an iron door, four inches high, and six inches wide, to move upon hinges, and shut exactly close. At the height of three inches from the upper surface of the grate, let the bottom of the fire-place, TRSV, begin, and make the whole six inches wide, and four inches and an half high.

Next describe an ellipsis, ILMK, with the distance of fifteen inches between the foci, and a perpendicular of five inches from the focus to the circumference; and make a wooden model, bcde, of half such an ellipsis, cut off at the foci. This model is to serve as a core in forming the cavity of the furnace, by adjusting fine brick-work in correspondence to the figure made by revolving such a model about its axis; and thus leaving but little space between the joinings, to be exactly filled up with mortar. But before this is done, let a stopper be made for the fire-place of the same iron-plate, and the same cylindrical surface, and internal substance, as the furnace itself. The top of the cylindrical part of the furnace, KXI, must be cut into a hol-

low, three inches wide, and two deep, on the same side with the door, in order commodiously to receive the neck of the retort in distillation. Lastly, an iron pot must be fitted into the upper opening of the furnace, KXI, and fixed so close and strong with brick and mortar, that the work may neither crack nor let the fire escape; but near the upper rim in this pot, there must be left in the brick-work four vent-holes, made in the form of crescents, an inch over in their widest parts, and two inches in their curvature, to discharge the smoke, and make a draught of air to animate the fire occasionally. And thus you will have a furnace fit for distilling by the cucurbit, retort, or bolt-head, and being portable, it will serve many other operations.

The third furnace, which no laboratory can be without, is a *balneum mariz*, made like the two former, excepting that the distance from the surface of the grate to the bottom of the cylindrical copper-vessel, is only eight inches. See the article *BALNEUM*.

A fourth furnace is also required in a laboratory, to raise a strong fire for the melting of bodies not easily fused; the best furnace for which purpose, is made thus. Let a stone-arch, abcd, (*ibid.* n<sup>o</sup> 3.) be built three feet high, as a basis whereon to raise this furnace; then make an ash-hole, cdef, five inches high; and over that fix a grate, efib, consisting of iron bars, near an inch thick, and set at about an inch distance from each other. Let the bottom of the grate, and the ash-hole, be of a circular figure, twelve inches in diameter, *ab, cd, ef, bi*; and build up the cylinder six inches above the grate; then raise upon it a parabolic cone, kmnl, with an axis of eight inches, and its lower ordinate of six. Over this parabolic cone, build a cylindrical chimney of three inches diameter, and two feet high. In the front of the fire-place, two inches above the grate, make a door five inches wide, and six high, and arch it a-top with the arch of a circle, twelve inches in diameter. At the height of an inch above the arch of the door, make a conical hole in the furnace, two inches wide on the outside, that the operator may look downwards into the fire when any thing is melting, and let a stopper be exactly fitted to this opening. The furnace, *axy4bx3*, must be built with good brick and terras, and

*Fig. 1.*  
FULLING-MILL.

*Fig. 2* CHEMICAL FURNACES.

*Fig. 3.* FURNACE.

*J. Jefferys sculp.*

and have its sides five inches thick, the internal surface thereof being laid smooth with cement.

A fifth furnace, ABCD, (*ibid.* n° 5.) for distilling mineral acids, as those of sea-salt, nitre, alum, vitriol, &c. is directed by Boerhaave to be built in the following manner. Upon the pavement of the laboratory, under the chimney, build up a parallelopiped, twenty inches broad in front, AB, and twenty-eight inches long, BG. Let the cavity be twelve inches wide in front, and twenty-two inches long, which gives the thickness of the wall. Let the parallelopiped be raised eleven inches high. Make a door-way, HKLI, in the middle of the front, rising eleven inches from the ground, and four inches wide, leaving an indentation on the front to receive an iron door; and let it close occasionally. This part of the apparatus regards the ash-hole and air-vent of the furnace. Instead of a grate, here use prismatic iron-bars, an inch wide, and fourteen inches long, placing them an inch asunder, parallel with the breadth of the ash-hole. Now describe an ellipsis in the upper cavity upon this parallelopiped, with the foci twenty-two inches asunder, and the transverse diameter twelve inches; whence the breadth of the fire-place will be at both ends about ten inches. Next let there be a cavity formed, of this elliptical figure, four inches and a half deep, on the inside; and complete the external part of it in a parallelopiped-form. In the front-wall, immediately over the ash-hole, make a door-way, POMN, seven inches wide, and nine inches high; and let the bottom edge of this door-way slope an inch and a half downwards, and let the lower line of the door be three inches above the upper line of the ash-hole. In the other side there must be an arched opening, RSQ, with its lower limit rising ten inches above the grate, being twenty inches long, and twelve inches high; and the elliptical arch with its foci, twenty inches asunder, and its transverse diameter twenty-four. This opening is for the distilling vessels to be put in and taken out. On the internal side, opposite to this opening, at the height of nine inches above the grate, a ledge of about an inch and a half must be left to support the vessels employed in the distillation; and in the middle of the upper part of this wall, there must be a

square hole, three inches wide, and two inches high, for the chimney. The upper elliptical arch must next be made, whose vertex is to rise twenty-one inches above the grate, the axis of the ellipsis twenty-two inches, and the transverse diameter ten. Let such an arch therefore be struck by revolving such an ellipsis about its axis, reaching sixteen inches from the grate.

When this furnace is used for distillation, two alembics are to be placed horizontally, and parallel to each other, so that their bottoms may rest upon the ledge in the opposite wall, whilst their mouths lie parallel to the opening they are put in at; which opening is now to be perfectly closed up with brick and mortar, leaving the necks of the vessels sticking out, whereto earthen pipes being applied, and their other ends fixed to receivers, the operation may be thus begun. See ALEMBIC and DISTILLATION.

For other chemical furnaces, see the article LABORATORY.

FURNACE is also applied to that used in the melting of iron, which authors frequently confound with iron-forges, though there is a considerable difference between them. See the article FORGE.

This furnace is a brick-structure, much in the shape of an egg set on end, wherein the iron-ore, after it has been burnt in a kiln, is put, intermixed with cinders and charcoal, and the whole melted till it trickle down into the receiver underneath. See the article FLUX.

Swedenborg has laid down, from his own experience, certain rules for the construction of metallurgic furnaces, by which they will always be made more advantageous to the proprietor, *cateris paribus*, than any other kind. These rules are, that the chimney be always placed as nearly as may be behind the center of the furnace; that the smaller the depth of the fire-place, provided it be sufficient to hold the coals, the better; that all furnaces must be the better the wider they are forwards; and the higher they are, so as not to lose the benefit of reverberation.

Belows-FURNACE, is one of the two kinds of furnaces used in coinage for the fusion of metals, consisting of a flat hearth at bottom, into which the air may be admitted by a hole, as in the chemical furnaces. On a level with the hearth is a second aperture, which gives passage to the

the pipe of the bellows, from whence the furnace is denominated; about a foot over this is a moveable grate; and over this is the place where the crucible is set, which is square, and made of the same earth with the crucible, of breadth sufficient to bear a range of coals around the crucible. To melt metal in this furnace, they lay a little plate of forged iron over the grate, and on this they set the crucible, which is likewise covered with an iron or earthen lid; then they fill the furnace with charcoal, and when it is well lighted, and the crucible sufficiently hot, they stop the vent-hole: lastly, throwing on fresh coals, they stop the furnace with an iron lid; thus continuing to work the bellows, and supply fresh fuel, till the metal is in fusion.

**Domestic FURNACE.** See OVEN.

**Founder's FURNACE.** See the article FOUNDRY.

**Glass-house FURNACE.** See the article GLASS.

**Glass-painter's FURNACE** is made of brick, nearly square, and about  $2\frac{1}{2}$  feet each way. It is cut horizontally in the middle, by a grate, which sustains the pan or shovel the glass is baked in. This furnace has two apertures, one below the grate, to put the fuel in at; the other above it, through which the workman spies how the action of the colours goes on.

**Hatter's FURNACES** are of three kinds: a little one under the mould, whereon they form their hats; a larger in the scouring-room, under a little copper, full of lees; and a very large one under the great copper, wherein they dye their hats.

**Plumber's FURNACE** is also of three kinds.

In the first they melt the lead whereof the sheets are to be cast, being only a large copper, or receptacle like a copper, made of free-stone, and coated well round with potter's clay, having a little iron-pan at bottom.

In the second they melt the lead to be cast in moulds for pipes, &c. which are not to be soldered.

The third is the tinning furnace, being a square frame of wood, or sometimes a mass of stone-work, with a brick-hearth whereon is made a charcoal fire, which serves them for the applying of thin tin leaves on their works.

**Wind-FURNACE,** the second furnace used in the fusion of metals for coinage. At

bottom it has a hearth made hollow, in manner of a copel, with a vent-hole in the fore part thereof; over the vent-hole is a grate, sealed in the mass of the furnace; over the grate is the place for the crucible, which is usually of forged iron. The fire being lighted, the crucible is put in, with a cover over it, and a capital or cover of earth or iron, is laid likewise over the furnace; and at the top of this capital is a hole, five or six inches in diameter. This is called a wind-furnace, by reason the air entering thro' the vent-hole at bottom, which is always open, serves the same purpose as the bellows in the other furnaces. Gold is generally melted in the bellows-furnace, as requiring an intenser heat before it fuses; but silver and copper are commonly melted in the wind-furnace.

**FURNAGE, or FORNAGE.** See the article FORNAGE.

**FURNES,** a town of Flanders, ten miles east of Dunkirk: east long.  $2^{\circ} 25'$ , and north lat.  $51^{\circ} 10'$ .

**FURNITURE of dials,** certain additional points and lines, such as the ecliptic, circles of declination, azimuths, italian hours, points of the compass, &c. drawn on dial-plates. See the article DIAL.

**FURO,** in zoology, a name given to the viverra, or ferret. See FERRET.

**FUROR UTERINUS,** a disorder peculiar to women, proceeding from an inordinate desire of coition, sometimes attended with melancholy, and sometimes with a maniacal delirium. The patient delights in talking obscenely, and in soliciting men to satisfy their desires both by words and gestures.

It is occasioned by an inflammation of the pudenda, or of the parts in which the venereal stimulus resides, which are chiefly the clitoris and vagina; or in the too great abundance and acrimony of the fluids of those parts; or both these causes may exist together.

In the delirium maniacum, the patient is entirely shameless; but in the melancholicum more reserved, and her folly is confined to fewer objects. If it continues a month or two, the fault of the brain becomes obstinate, for it degenerates into real madness.

The indications of cure are to diminish the heat and sensibility of the affected parts, to cool, sweeten, and dilute the blood, and so render it balsamic; or to pursue both intentions at once. The first

first indication is answered by frequent and copious bleedings: the must likewise be purged with jalap, scammony, or diagridium. Emetics are also good; and emollient clysters should be given; to which add a drachm and a half of sal prunella, or a little vinegar, morning and night. To abate the acrimony, the patient may drink mineral waters, or emulsions with chicken-broth, and feeds of papav. alb. lin. cannabis, &c. and sweetened. In the summer, whey with half a drachm of sal prunel. for each dose. After which she should be kept to a milk diet only.

In a delirium melancholicum, lawful co-ition may be admitted.

**FURR**, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on, and used as a part of dress by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, coney, &c. See the articles **ERMINE**, **SABLE**, &c. Furrs are charged with various duties.

Badger-skins pay, the piece,  $5 \frac{74\frac{1}{2}}{100}$  d. whereof  $5 \frac{17\frac{1}{2}}{100}$  d. is drawn back on ex-

portation. Bear-skins, if black or red, pay each 4s.  $9 \frac{45}{100}$  d. and draw back 4s.  $3 \frac{75}{100}$  d. but if white, each skin pays 9s.  $6 \frac{80}{100}$  d. and draw back 8s.  $7 \frac{60}{100}$  d.

Beaver-skins pay each  $7 \frac{18\frac{1}{2}}{100}$  d. and draw back  $4 \frac{34\frac{1}{2}}{100}$  d. Cats-skins, the hundred,

containing five score, pay 9s.  $6 \frac{20}{100}$  d. and draw back 8s.  $7 \frac{20}{100}$  d. Ermines, the timber, containing forty skins, pay 9s.  $6 \frac{20}{100}$  d. and draw back 8s.  $7 \frac{1}{2}$  d.

Fox-skins, the ordinary kind, pay only  $3 \frac{83}{100}$  d. each, and draws back  $3 \frac{48}{100}$  d. but each black fox-skin pays 2l. 7s.  $10 \frac{80}{100}$  d. and draw back 2l. 3s.  $1 \frac{50}{100}$  d.

Leopard-skins, the piece, pay 5s.  $8 \frac{1}{2}$  d. and draw back 5s.  $4 \frac{68\frac{1}{2}}{100}$  d.

Matrons the timber, containing forty skins, pay 2l. 7s.  $10 \frac{80}{100}$  d. and draw back 2l. 3s.  $1 \frac{50}{100}$  d. Mole-skins, the

dozen, pay  $1 \frac{43\frac{3}{8}}{100}$  d. and draw back  $1 \frac{29\frac{3}{8}}{100}$  d. Otter-skins, the piece, pay

1s.  $2 \frac{36\frac{1}{2}}{100}$  d. and draw back 1s.  $\frac{93\frac{1}{2}}{100}$  d.

Ounce skins, the piece, pay 2s.  $11 \frac{60\frac{1}{2}}{100}$  d. and draw back 2s.  $8 \frac{34\frac{3}{4}}{100}$  d. Sables or

all sorts, the timber, containing forty skins, pay 7l. 3s.  $7 \frac{80}{100}$  d. and draw back 6l. 9s.  $4 \frac{80}{100}$  d. Weazle-skins, the dozen, pay  $\frac{95\frac{1}{2}}{100}$  d. and draw back

$86\frac{1}{4}$  d. Wolf-skins tawed, the piece, pay  $\frac{700}{100}$  s.  $2 \frac{17\frac{1}{2}}{100}$  d. and draw back 6s.  $5 \frac{62\frac{1}{2}}{100}$  d.

Wolf-skins untawed, the piece, pay 5s.  $6 \frac{6\frac{1}{2}}{100}$  d. and draw back 4s.  $11 \frac{51\frac{1}{2}}{100}$  d. If

any furrs be tawed, or otherwise drest, they pay 6s. more for every 20s. value.

**FURRS**, in heraldry, a bearing which represents the skins of certain beasts, used as well in the doublings of the mantles belonging to the coat-armour, as in the coat-armours themselves. See the articles **ERMINE**, **ERMINOIS**, &c.

**FURR**, among carpenters, a piece nailed upon a rafter, to strengthen it when decayed, or to make it straight when it has sunk in the middle.

**FURRING**, among carpenters, is the regular fashioning out any part. When the main piece of the material is scanty, either by defects, wains, or want of thickness; then a piece of the same is put behind it to make good its thickness, which is called a furr.

**FURSTENBURG**, a town and castle of Germany, the capital of a county of the same name, thirty miles north-west of Constance: east lon.  $8^{\circ} 30'$ , and north lat.  $47^{\circ} 50'$ .

**FURSTENFIELD**, a town of Austria and dutchy of Stiria, thirty-six miles east of Gratz: east lon.  $16^{\circ} 46'$ , and north lat.  $47^{\circ} 26'$ .

**FURUNCLE**, or **BOIL**, in surgery, a small resisting tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin.

As there is no part of the body free from being the subject of furuncles, so the whole is sometimes so miserably infested with them, that the patient can hardly tell how to stir himself, or on what part to lie. Not only adults, but also the younger, even new-born infants, are obnoxious to this dreadful disorder, which occasions in them most fatiguing clamour and

and restlessness. Though there is little danger in this disease in adults; yet, in tender infants, it occasions convulsions, and even death itself.

The principal cause of furuncles is a too glutinous and inspissated state of the blood; and, consequently, the greater the inspissation, the worse and more numerous will be the furuncles.

With regard to the cure, it seems to consist chiefly in restoring the stagnating blood to its former circulation and free motion.

When the furuncles are very numerous, or return again, it is proper to use internal purging medicines, and such as attenuate and cleanse the blood. In adults, bleeding is proper, both by the lancet and scarification with cupping; and, at the same time, a strict regimen of diet should be used, drinking frequently and plentifully of a decoction of the woods, and such like attenuators of the blood. The patient should also entirely abstain from drinking fermented and spirituous liquors, particularly wine and its spirit; and from the too frequent use of tobacco. When the disorder is recent, external medicines only will frequently suffice for the whole cure. For this purpose a mixture of honey, acidulated with spirit of vitriol till it has acquired a considerable sharpness, is proper to anoint the furuncles. Of no less virtue is the frequent touching them with mere spirit of vitriol or sulphur. Discutient plasters are also found very serviceable, as those of simple diachylon, de melito, de sperma ceti, vel dialaponis.

But if these medicines prove insufficient to disperse the tumour, it is to be brought to suppuration, by applying a plaster made of honey and flour, or of diachylon with the gums; and where these are insufficient, to make use of the maturating cataplasms recommended under the article PHLEGMON.

When the furuncle is known to be ripe, by its softness and yellow head, recourse is to be directly had to the scalpel; and having made an opening, the corrupted matter contained therein is to be discharged; after this, a plaster of diachylon must be applied, and the ulcer daily cleansed of its matter, till it is healed.

Pustules and pimples arising in the face, are to be treated like furuncles; and, in both cases, the drinking of whey, and the mineral waters, is accounted good for cleansing the blood,

When sucking infants are afflicted with furuncles, it is proper to give the mother, or nurse, some purging medicine, and to order a strict regimen and diet. At the same time the infant should take some gentle laxative medicine, with absorbent powders, to allay the acrimony of its juices. *Heister.*

FURUNCULUS, in zoology, a name given to the ferret. See FERRET.

FURZE, or FURZE-BUSH, in botany. See the article ULEX.

In many countries, where there are dry banks, or dry sand or gravel, that nothing else will grow on, furze makes an extremely good fence; and is propagated either by sets or seeds, especially the latter. It will make a good hedge in three years, if well weeded and carefully kept from cattle, especially sheep; and if clipped, it will thrive extremely, and be very thick; but if let grow at large, it will prove the better shelter, and yield excellent fuel. It proves also an admirable covert for wild-fowl.

Sometimes, indeed, furze over-runs the pasture, or arable-lands; in which case it is to be grubbed up, or it may be destroyed by only marling the lands.

Furze-faggots are used for breeming ships, when in the dock to be cleaned, or under repair.

FUSA, in the Italian music, the same with our quaver. See the article QUAYER.

FUSANUS, in botany, a shrub otherwise called euonymus. See EUONYMUS.

FUSAROLE, in architecture, a moulding or ornament placed immediately under the echinus, in the doric, ionic, and composite capitals.

It is a round member, carved in the manner of a collar, or chaplet, with oval beads; and should always answer exactly under the eye of the volute, in the ionic capital.

FUSEE, in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see the articles CLOCK and WATCH.

FUSEE, or FIRELOCK. See the article MUSQUET.

FUSEE of a bomb. See BOMB.

FUSIBILITY, in natural philosophy, that quality of bodies, which renders them fusible. See the article FUSION.

FUSIBLE COLUMN. See COLUMN.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and

and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in latin *fusus*, a spindle, from its shape. See plate CVIII. fig. 3.

**FUSILIERS**, or **FUSILEERS**, in the military art, are foot-soldiers, armed with fuses, or firelocks. See **FUSEE**.

**FUSILY**, or **FUSILE**, in heraldry, signifies a field, or ordinary, entirely covered over with, or divided into fusils. See the article **FUSIL**.

**FUSION**, the melting of metals, minerals, &c. by means of fire.

Different metals run in different manners from their ores : thus, lead, though extremely fusible in the metal, runs with difficulty from the ore, so as to require a considerable violence of fire. This stubbornness not belonging to the metal, must be attributed to the stony, sulphureous, or other mineral matter with which the ore is mixed ; which matter seems to require a degree of heat capable of vitrifying the lead, before the metal will run : but then the lead thus vitrified, recovers a metallic form again, by coming in contact with the coals. See **LEAD**.

Tin runs from its ore with greater ease than lead, and is therefore smelted in much less furnaces ; but copper requires an intense heat, or a blast furnace ; and iron the greatest heat that can be given in a furnace : and both iron and copper absolutely require immediate contact with the fuel employed. Hence it appears that each metal must have its determinate degree of heat, to run it with advantage from the ore or stone.

In order, likewise, to obtain the metal from the ore to the best advantage, the scoria or slag must be necessarily made to run thin and fluid ; otherwise it entangles or inviscates the metal, and will not let it separate fully. And hence we frequently observe in the assaying of copper-ores, small grains of metal interspersed here and there, among the scoria, that require to be separated by stamping and washing the whole mass ; which labour might have been prevented, by using a proper degree of heat capable of procuring a thin fusion and a suitable flux, so as to have made all the metals fall to the bottom of the crucible ; which it constantly does, when the operation is well performed. See **FLUX**.

It seems principally owing to a defect in the knowledge of fusion, that so many

recrements or slags of metals, antiently thrown as useless from the furnace, have been of late wrought to considerable profit by more skilful workmen : at least it seems more rational to attribute the success to this cause, than to a supposed growth of metals in such slags ; or to believe that lead has grown rich in silver by lying exposed to the open air, while perhaps it is rather owing to the unskilfulness of the former workmen, who were unable to separate all the silver contained in the lead.

All moisture, and too sudden cooling, prove prejudicial to the more ignoble metals after fusion, and sometimes dangerous to the operator : for a little water falling upon melted iron or copper, makes them expand with prodigious violence, and discharge themselves abroad with a force like that of a cannon : and even sudden cooling will often occasion the surface of the metal to crack, and suffer the more internal part, not yet set or fixed, to issue out to a considerable distance ; whence either the loss of the metal or mischief may ensue.

To prevent these ill effects, after copellation it is usual for the operator to throw a quantity of water, all at once, upon the lump of silver, as it lies in the test, at the moment when it begins to grow rigid ; for the water, by its coldness, suddenly makes so thick a cover upon the surface of the silver, that the hotter parts in the inside cannot break through the upper. *Shaw's Chem. Lect.*

**FUST**, the same with the shaft of a column. See the articles **COLUMN** and **SHAFT**.

**FUSTIAN**, in commerce, a kind of cotton stuff, which seems as it were whaled on one side.

Right fustians should be altogether made of cotton-yarn, both woof and warp ; but a great many are made, of which the warp is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse ; with flag or nap, and without it.

The duties on fustians imported, are so high as to amount in a manner to a prohibition : for instance, dutch and milan fustians, the piece, containing two half pieces of fifteen yards the half piece, pay 1 l. 10 s. 9  $\frac{1}{2}$  d. draw back 1 l. 7 s. Holmes and bevernex fustians, the bale, containing forty-five half pieces, pay 15 l. 8 s. draw back 13 l. 10 s. Naples fustians,

fustians, tripe or velure plain, the yard, pay 1s. 11,  $\frac{1}{8}$  d. draw back 1s. 8,  $\frac{1}{8}$  d. Naples fustians, wrought, called sparta velvet, the yard, pay 3s.  $\frac{1}{8}$  d. draw back 2s. 8,  $\frac{4}{8}$  d.

**FUSTICK**, or **FUSTOCK**, a yellow wood, that grows in all the Caribbee-islands, used in dying yellow.

It pays no duty on importaion.

**FUTTOCKS**, in a ship, the timbers raised over the keel, or the encompassing-timbers that make her breadth. Of these there are first, second, third, and fourth, denominated according to their distance from the keel, those next it being called first or ground-futtocks, and the others upper-futtocks: those

timbers, being put together, make a frame-bend.

**FUTURE**, in general, denotes whatever regards futurity, or the time to come. See the article **TIME**.

**FUTURE TENSE**, among grammarians. See the article **TENSE**.

**FUZEE**, or **FUSEE**, in military affairs. See the article **FUSEE**.

**FUZEE**, among fashiers, two dangerous splents, joining from above downwards. They differ from screws or thorough splents in this, that the latter are placed on two opposite sides of the leg. See the article **SPLINT**.

**FUZILIER**, or **FUSILIER**, in the art of war. See the article **FUSILIER**.

## G.

**G**, in grammar, the seventh letter and fifth consonant of our alphabet; but in the greek, and all the oriental languages, it occupies the third place. It is one of the mutes, and cannot be sounded without the assistance of some vowel.

In english it has a hard and soft sound; hard, as in the words *game*, *gun*, &c. and soft, as in the words *gesture*, *giant*, &c. at the end of words, *gh* is pronounced like *ff*, as in the words *rough*, *tough*, &c. The letter *g* is also used in many words where the sound is not perceived, as in *sign*, *reign*, &c.

As a numeral, **G** was antiently used to denote 400; and with a dash over it, thus  $\overline{G}$ , 40,000. In music it is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name gamut. See the articles **CLEF** and **GAMUT**.

As an abbreviature, **G**. stands for *Gaius*, *Gellius*, *gens*, *genius*, &c. **G. G.** for *gemina*, *gestit*, *gesserunt*, &c. **G. C.** for *genio civitatis*, or *Cæsaris*. **G. L.** for *Gaius libertus*, or *genio loci*. **G. V. S.** for *genio urbis sacrum*. **G. B.** for *genio bono*. And **G. T.** for *genio tutelari*.

**GABARA**, or **GABBARA**, in antiquity, the dead bodies which the Egyptians em-

balmed, and kept in their houses, especially those of such of their friends as died with the reputation of great piety and holiness, or as martyrs. See the articles **EMBALMING** and **MUMMY**.

**GABEL**, a word met with in old records, signifying a tax, rent, custom, or service, paid to the king, or other lord.

**GABEL**, or **GAVEL**, among builders. See the article **GAVEL**.

**GABEL**, according to the french duties or customs, a tax upon salt, which makes the second article in the king's revenue, and amounts to about one fourth part of the whole revenue of the kingdom.

**GABIN**, a town of great Poland, forty-six miles north-west of Warsaw: east lon. 20°, and north lat. 52° 35'.

**GABIONS**, in fortification, baskets made of osier-twigs, of a cylindrical form, six feet high, and four wide; which being filled with earth, serve as a shelter from the enemies fire.

They are commonly used on batteries, to screen the engineers, &c. in order to which, one is placed on either side of each gun, room being only left for the muzzle to appear through. They also serve as a parapet on lines, lodgements, &c. when the ground is too hard to dig into.

There are a smaller sort, used on parapets in trenches, &c. to cover the musqueteers;

Fig. 1. GAGES.

Fig. 2. GALLERY.

queteers; which are placed so close, that a musquet can but just peep through.

To render the gabions useless, the enemy endeavours to set them on fire, by throwing pitched faggots among them.

**GABLE**, or **GAVEL**, among builders. See the article **GAVEL**.

**GABLOCKS**, the artificial spurs of gamecocks. See the article **GAME-COCK**.

**GABRES**, or **GAURS**, in the religious customs of Persia. See **GAURS**.

**GAD**, among miners, a small punch of iron, with a long wooden handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

**GAD-FLY**, or **BREEZE-FLY**, names given to the black and yellow bodied cæstrus, a fly nearly as large as the common blue flesh-fly. See the article **OESTRUS**.

**GADUS**, in ichthyology, a genus of malacopterygious fishes; the head of which is usually compressed; the branchiostegæ membrane on each side contains six small bones; and the back-fins are either two or three in number.

This is a large genus, comprehending the whiting, cod, haddock, ling, whistfish, &c. See **WHITING**, **COD**, &c.

**GADWAL**, in ornithology, a species of duck, about the size of a widgeon. See the article **DUCK**.

**GAFOLD-LAND**, in old law-books, land liable to taxes, and let for rent.

**GAGATES**, **JET**, in natural history. See the article **JET**.

**GAGE**, in law-books, the same with surety or pledge. See the articles **SURETY** and **PLEDGE**.

Thus, where a person has taken distress, and being sued in replevin, he shall not only avow the distress, but gager deliverance; that is, put in sureties, or pledges, that he will deliver them. See the article **DISTRESS**.

**GAGE** is also used in a synonymous sense with wage. See the article **WAGE**.

**Mort-GAGE**. See **MORTGAGE**.

**GAGE**, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water, is the ship's gage.

**GAGE**, in joinery, an instrument marked G, in Plate of Joinery, in which the piece of wood *b*, is moveable upon the staff *c*, so as to be set nearer or farther from the tooth *a*, at pleasure. Its use is to draw a line parallel to the straight side of any board, for gaging tenons, and marking stuff to an equal thickness.

**GAGE**, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See **FOUNDERY** and **LETTER**.

There are several kinds of these gages, as the flat-gage, represented in plate CIX. fig. 1. n° 3. and the face-gage and italic-gage, &c. *ibid.* n° 5.

**Sliding-GAGE**, a tool used by mathematical instrument makers, for measuring and setting off distances. It is also of use in letter-cutting, and making of moulds. See plate CIX. fig. 1. n° 4. where *aa* is the beam, *b* the tooth, *cc* the sliding socket, and *dddd* the shoulder of the socket.

**Sea-GAGE**, an instrument invented by Dr. Hales and Dr. Desaguliers, for finding the depth of the sea, the description whereof is this. *AB* (plate CIX. fig. 1. n° 1.) is the gage-bottle, in which is cemented the gage-tube *Ff*, in the brass-cap at *G*. The upper end of the tube *F*, is hermetically sealed, and the open lower end *f*, is immersed in mercury, marked *C*, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass *HG*, pierced with several holes, to admit the water into the bottle *AB*. The body *K*, is a weight, hanging by its shank *L*, in a socket *N*, with a notch on one side at *m*, in which is fixed the catch *l* of the spring *S*, and passing through the hole *L*, in the shank of the weight *K*, prevents its falling out, when once hung on. On the top, in the upper part of the brass-tube at *H*, is fixed a large empty ball, or full-blown bladder *I*, which must not be so large, but that the weight *K* may be able to sink the whole under water.

The instrument, thus constructed, is used in the following manner. The weight *K* being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket *N*, is somewhat longer than the shank *L*, and therefore, after the weight *K* comes to the bottom, the gage will continue to descend, till the lower

part of the socket strikes against the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K; when this is done, the ball or bladder I, instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube Ff, and the height to which it has been forced by the greatest pressure, *viz.* that at the bottom, will be shewn by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shews into what space the whole air in the tube Ff is compressed; and consequently the height or depth of the water, which by its weight produced that compression, which is the thing required.

If the gage-tube Ff, be of glass, a scale might be drawn on it with the point of a diamond, shewing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is not more than 634 feet, which is not half a quarter of a mile.

If, to remedy this, we make use of a tube 50 inches long, which for strength may be a musquet-barrel, and suppose the air compressed into an hundredth part of half an inch; then by saying as 1:99::490:39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the Dr. contrived a new form for his sea-gage, or rather for the gage-tube in it, as follows: BCDF (*ibid.* n° 2.) is a hollow metalline globe communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water, as before; but the degree of compression, or height to which the treacle has been forced, cannot here be seen thro' the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will

receive the mark of the treacle, and shew it, when taken out.

If the tube AB be 50 inches long, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, *viz.* 2½ inches, which correspond to 6600 which is a mile and a quarter. Again, half that space, or 1½ inch, will shew double the former depth, *viz.* 13200 feet, or 2½ miles, which is probably very nearly the greatest depth of the sea.

*Bucket-sea-GAGE*, an instrument contrived by Dr. Hales, to find the different degrees of coolness and saltness of the sea, at different depths; consisting of a common household pail or bucket, with two heads to it. These heads have each a round hole in the middle, near four inches diameter, and covered with valves opening upwards; and that they might both open and shut together, there is a small iron-rod fixed to the upper part of the lower valve, and at the other end to the under part of the upper valve; so that as the bucket descends with its sinking weight into the sea, both the valves open by the force of the water, which by that means has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is brought up full of the lowest sea-water to which it had descended.

When the bucket is drawn up, the mercurial thermometer, fixed in it, is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, else it would be altered by the different temperature of the air.

In order to keep the bucket in a right position, there are four cords fixed to it, reaching about four feet below it, to which the sinking weight is fixed.

*Water-GAGE*, or *HYDROMETER*. See the article *HYDROMETER*.

*GAGES for grinding optic glasses*. See the article *GRINDING*.

**GAGER** and **GAGING**. See the articles **GAUGER** and **GAUGING**.

**GAHALA**, a name given by some to the colocasia, or great egyptian arum. See the article **ARUM**.

**GAIANITES**, *gaianita*, in church-history, a branch of eutyrians. See the article **EUTYCHIANS**.

**GAIETA**, a strong fortified town of the kingdom of Naples, in Italy, thirty-five miles north-west of the city of Naples : east lon.  $14^{\circ} 30'$ . and north lat.  $41^{\circ} 20'$ .

**GAIN**, in commerce, is used in a synonymous sense with profit. See the article **PROFIT**.

**GAIN**, in architecture, the bevelling shoulder of a joist or other timber.

It is also used for the lapping of the end of the joints, &c. upon a trimmer or girder, and then the thickness of the shoulder is cut into the trimmer, also bevelling upwards, that it may just receive the gain, and so the joist and trimmer lie even and level with the surface.

This way of working is used in floors and hearths.

**GAINAGE**, in old law-books, properly signifies the plough-tackle, or implements of husbandry ; but is also used for the grain or crop of ploughed lands.

**GAINERY**, in old law-books, denotes tillage, or the profit thence arising.

**GAINSBOROUGH**, a market-town of Lincolnshire, fourteen miles north-west of Lincoln ; which gives the title of earl to the noble family of Noel.

**GAIOPHRAGMIA**, in natural history, a genus of septariæ, divided by septa or partitions of earthy matter, of which there are several species. See **SEPTARIÆ**.

**GALACTITES**, in natural history, the name by which the antients called a smooth, ash-coloured, indurated kind of clay, said to have been used with success for defluxions and ulcers of the eyes, and as an astringent. See the article **CLAY**.

**GALANGALS**, *galanga*, in the materia medica, the name of two roots kept in the shops, a greater and a smaller ; of which the smaller is by far most esteemed.

The lesser galangal is a small and short root, of an irregular figure, and of the thickness of a man's little finger, seldom met with more than an inch or two long. It should be chosen full and plump, of a bright colour, very firm and sound, and of an acrid and insupportably hot taste.

The larger galangal is brought to us in pieces of two inches or a little more in length, and of near an inch in thickness : its surface is less unequal and tuberoser than the smaller sort, but is far from being smooth ; on the outside it is of a brown colour, with a very faint cast of red, and within it is of a paler colour, and has a much less acrid and pungent taste than the smaller kind. It is to be chosen in the largest, soundest, and heaviest pieces.

The roots of both the galangals, but particularly of the lesser, abound with a volatile, oily, aromatic salt ; the lesser is esteemed an excellent stomachic : it has the credit of being a great cephalic, cardiac, and uterine, but is more particularly recommended in vertigos. The greater galangal possesses the same virtues, but in a less degree. See the article **KÆMPFERIA**.

**GALANT**, or **GALLANT**. See the article **GALLANT**.

**GALANTHUS**, the **SNOW-DROP**, in botany, a genus of the *hexandria-monogynia* class of plants, the flower of which consists of three oblong and obtuse petals ; the fruit is a globose-oval capsule, obtusely trigonal, and containing a great number of roundish seeds.

The galanthus is the same with the narcissus-leucoium of authors, with a large snow-white flower.

**GALATA**, a great suburb belonging to Constantinople, opposite to the seraglio, on the other side of the harbour. It is here that the Greeks, Armenians, Franks, Christians, and Jews inhabit, and are allowed the exercise of their respective worships.

**GALATIA**, the antient name of Amasia, a province of lesser Asia.

**GALATIANS**, or *Epistle to the GALATIANS*. See the article **EPISTLE**.

**GALAXIUS**, a name given by the antients to morochthus. See **MOROCHTHUS**.

**GALAXY**, in astronomy, the *via lactea*, or milky way in the heavens : a tract of a whitish colour, and considerable breadth, which runs through a great compass of the heavens, sometimes in a double, but for the greatest part of its course in a single stream ; and is composed of a vast number of stars, too minute or too remote from the earth, to be distinguished by the naked eye ; but are discovered in all parts of it, in great numbers, by the assistance of the telescope.

**GALBANUM**,

**GALBANUM**, in pharmacy, a gum issuing from the stem of an umbelliferous plant, growing in Persia and many parts of Africa.

It is sometimes met with in the shops in loose granules, called drops or tears, and sometimes in large masses, formed of a number of these blended together; but in these masses some accidental foulness is often mixed with the gum. The single drops usually approach to a roundish, oblong, pear-like form. Galbanum is soft like wax, and, when fresh drawn, white; but it afterwards becomes yellowish or reddish: it is of a strong smell, of an acrid and bitterish taste; it is inflammable in the manner of a resin, and soluble in water like a gum.

It attenuates and dissolves tough phlegm, and is therefore of service in asthma and inveterate coughs: it is also of great service in hysteric complaints; it dissipates flatulencies, promotes the menses, and facilitates delivery and the expulsion of the secundines. It is given in pills and electuaries, and is used externally in form of a plaster, applied to the belly, against habitual hysteric complaints, and on many other occasions.

**GALBULA**, in ornithology, the same with chloreus. See the article **CHLOREUS**.

**GALE**, in the sea-language, a term of various import: when the wind blows not so hard but that a ship may carry her top-sails a-trip (that is, hoisted up to the highest) then they say it is a loom-gale. When it blows very strong, they say it is a stiff, strong, or fresh gale. When two ships are near one another at sea, and there being but little wind blowing, one of them finds more of it than the other, they say that the one ship gales away from the other.

**GALEARII**, in roman antiquity, servants who attended the soldiers in the field, and carried their helmets; whence the name.

**GALEASSE**, a large low-built vessel, using both sails and oars, and the biggest of all the vessels that make use of the latter. It may carry twenty guns, and has a stern capable of lodging a great number of marines. It has three masts, which are never to be lowered or taken down. It has also thirty-two benches of rowers, and to each bench six or seven slaves, who sit under cover. This vessel is at present only used by the Venetians.

**GALENIC**, or **GALENICAL**, in pharmacy, a manner of treating diseases founded on the principles of Galen.

The distinction of galenical and chemical, was occasioned by a division of the practitioners of medicine into two sects, which happened on the introduction of chemistry into medicine; then the chemists, arrogating to themselves every kind of merit and ability, stirred up an opposition to their pretensions, founded on the invariable adherence of the other party to the ancient practice. And though this division into the two sects of galenists and chemists has long ceased, yet the distinction of medicines, which resulted from it, is still retained.

Galenical medicines are those which are formed by the easier preparations of herbs, roots, &c. by infusion, decoction, &c. and by combining and multiplying ingredients; while those of chemistry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, digestion, fermentation, &c.

The late improvements in philosophy, which have retrieved the reputation of galenical pharmacy, have also greatly reformed it. It is now become all mechanical and corpuscular; and instead of qualities and degrees, every thing is now reduced to mechanical affections; to the figures, bulks, gravities, &c. of the component particles, and to the great principle of attraction.

**GALENISTS**, in church-history, a branch of anabaptists, who are said to have adopted several arian opinions concerning the divinity of our Saviour. See the articles **ARIANS** and **ANABAPTISTS**.

**GALEOBDOLON**, in botany, a name given by Dillenius, to the leonurus. See the article **LEONURUS**.

**GALEOLA**, **HEMP-LEAVED DEAD-NETTLE**, in botany, a genus of the *didynamia-gynospermia* class of plants, the flower of which is monopetalous, with the upper lip crenated and arched, and the lower one trifid: the seeds are four in number, and contained in the cup. Both the leaves and seeds of this plant are used in medicine, and said to be discutient and antiseptic.

**GALERITA**, in ichthyology, a species of blennius. See the article **BLENNIOUS**. The galerita is distinguished from the other species of blennius, by a transverse cutaneous crest on the head.

**GALEUS**,

**GALEUS**, in ichthyology, a name by which several species of sharks are called. See the article **SHARK**.

**GALEXIA**, a name used by some for the lamprey. See the article **LAMPREY**.

**GALICIA**, the most north-west province of Spain, bounded by the ocean on the north-west, by the provinces of Asturias and Leon on the east, and by Portugal on the south.

**GALICIA**, or **GUADALAJARA**, a province of Mexico, bounded by new Mexico on the north, by the gulph of Mexico on the east, by Mexico proper on the south, and by the Pacific ocean and gulph of California on the west.

**GALILE**, or **GALILEE**, once a province of Judea, now of Turkey in Asia, was bounded by mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the river Chifon on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles.

**GALILEANS**, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or enrollment of all the subjects of the roman empire.

They pretended that God alone should be owned as master and lord; and in other respects were of the opinion of the pharisees: but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

**GALIUM**, or **GALLIUM**, in botany. See the article **GALLIUM**.

**GALL**, in the animal oeconomy, the same with bile. See **BILE** and **BILIOUS**.

**GALL-BLADDER**, called *vesicula*, and *cystis fellea*, is usually of the shape of a pear, and of the size of a small hen's egg. It is situated in the concave side of the liver, and lies upon the colon, part of which it tinges with its own colour. It is composed of four membranes: or coats: the common coat; a vesicular one; a muscular one, consisting of straight, oblique, and transverse fibres; and a nervous one, of a wrinkled or reticulated surface within, and furnished with an unctuous liquor.

The use of the gall-bladder is to collect the bile, first secreted in the liver, and

mixing it with its own peculiar produce, to perfect it farther, to retain it together a certain time, and then to expel it.

**GALL**, in natural history, denotes any protuberance or tumour produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

The general history of galls is this: an insect of the fly-kind is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the branches of a tree; and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The hole in each of these tumours, through which the fly has made its way, may for the most part be found; and when it is not, the maggot-inhabitant or its remains are sure to be found within, on breaking the gall. However, it is to be observed, that in those galls which contain several cells, there may be insects found in some of them, though there be a hole by which the inhabitant of another cell has escaped.

Oak-galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows stronger, becomes black; and on this property depends the art of making our writing-ink, as also a great deal of those of dying and dressing leather; and other manufactures.

In medicine, galls are found to be very astringent, and good, under proper management, in diarrhoeas, dysenteries, and hæmorrhages of all kinds; they have also a very eminent virtue as a febrifuge. Half a dram, or more, of the powder of Aleppo-galls may be given for a dose, and will often cure an intermittent fever. They are also used externally by way of fomentation in prociptentiæ of the anus: and a decoction of them has been injected in the fluor albus, with very great success.

**St. GALL**, in geography, a town of Switzerland, five miles west of the lake of Constance; forming a republic of itself, but without any territory. Its legislative power is lodged in two councils. It is said to contain 10,000 inhabitants, all employed in the linnen-manufacture.

**GALLANT**, or **GALANT**, a french term adopted into our language, and signifying polite, civil, and well bred, with a disposition to please, particularly the ladies. It also signifies brave or courageous.

**GALLEON**, or **GALLION**, in naval affairs. See the article **GALLION**.

**GALLERY**, in architecture, a covered place in a house, much longer than broad, and usually in the wings of a building; its use being chiefly to walk in.

**GALLERY**, in fortification, a covered walk across the ditch of a town, made of strong beams, covered over head with planks, and loaded with earth: sometimes it is covered with raw hides to defend it from the artificial fires of the besieged. Its sides should be musquet-proof. It ought to be eight foot high, and ten or twelve wide, and the covering to rise with a ridge, that what is thrown upon it by the besiegers with a design to burn it, may roll off. See plate CIX. fig. 2.

Galleries are chiefly used to secure and facilitate the miners approach to the face of the bastion, over the moat, which is already supposed to be filled up with faggots and bavins, and the artillery of the opposite flank dismounted.

**GALLERY of a mine**, is a narrow passage, or branch of a mine carried on underground to a work designed to be blown up.

Both the besiegers and the besieged also, carry on galleries in search of each others mines, and these sometimes meet and destroy each other.

**GALLERY**, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

**GALLERY**, in gardening, a kind of covered walk, in a garden, formed into porticoes or arches, with horn-beams, lime-trees, or the like.

Each pillar of the porticoes or arches ought to be four feet distant from the other, and the gallery twelve feet high,

and ten feet wide, that there may be room for two or three persons to walk in a-breast.

In forming these galleries, it is to be observed, that when the horn-beams are grown to the height of three feet, and the distance of the pillars well regulated; the next thing to be done is; to form the frontispiece: to perform which, the horn-beam must be run up a trellace made for that purpose, which forms the arch, and as it grows up, those bows which overshoot the others, must be cut with the sheers, and in time they will grow strong, and may be kept in form by the sheers.

**GALLEY**, in naval affairs, a low-built vessel, using both sails and oars, and commonly carrying only a main-mast and fore-mast, which may be struck or lowered at pleasure. Such vessels are much used in the Mediterranean, especially by the king of France. See **SHIP**.

*Condemnation to the GALLEYS*, the punishment of being compelled to serve on board these vessels, imposed on certain criminals in France; and that either for life, or for a limited number of years, according to the nature of their crimes.

**GALLEY**, or **GALLY**, in printing. See the article **GALLY**.

**GALLI**, in antiquity, the priests of the goddess Cybele, who were eunuchs, and took their name from Gallus, a river in Phrygia.

When a youth was to be initiated into this order, the custom was to throw off his cloaths, to run crying aloud into the midst of the troop, and then drawing a sword to castrate himself; after this, he ran about the streets, carrying in his hands the marks of his mutilation, which he was to throw into a house, and in that house to put on a woman's dress.

**GALLIAMBIC VERSE**, *Galliambus*, in ancient poetry, a verse consisting of six feet, viz. an anapest, or a spondee; an iambus, or an anapest, or a tribrach; an iambus; a dactyl; a dactyl; an anapest. The word galliambus, is a compound of iambus and gallus, a priest of Cybele. These priests carried about the image of that goddess, in order to get alms, and as a part of their employment was singing verses all over the country, they, by this means, rendered poetry very despicable.

**GALLIARD**, a gay, sprightly, whimsical kind of dance, formerly much used, consisting of very different motions and actions, sometimes running smoothly along,

along, then capering, sometimes along the room, and sometimes across.

This dance was brought from Rome; from whence it was also called *romanesque*.

**GALLIARDA**, the name of a tune that belongs to a dance called a galliard.

It is commonly in triple time, of a brisk and lively humour, and something like a jig.

**GALLICAN**, any thing belonging to France: thus the term gallican church denotes the church of France, or the assembly of the clergy of that kingdom. See the article **CHURCH**.

**GALLICAN BREVIARY**, the breviary used by the church of Agregentum in Sicily: probably so called from its being introduced by St. Gerlan, who was made bishop of Agregentum after the Saracens were driven out of Sicily by earl Roger; and by the other french bishops, brought thither by norman princes.

**GALLICISM**, a mode of speech peculiar to the french language, and contrary to the rules of grammar in other languages.

**GALLINÆ**, in ornithology, an order of birds, the beak of which is conic; and somewhat incurvated, and the upper chap imbricated.

Under this order are comprehended the ostrich, peacock, pheasant, wood-cock, turkey, the common dunghill cock, partridge, &c. See the articles **OSTRICH**, **PEACOCK**, &c.

**GALLINA GUINEENSIS**, the guinea-hen. See the article **GUINEA-HEN**.

**GALLINA PISCIS**, a name given to the gurnard. See the article **GURNARD**.

**GALLINACEOUS**, an appellation given to the birds of the order of the gallinæ. See the article **GALLINÆ**.

**GALLINAGINIS CAPUT**, in anatomy. See **CAPUT GALLINAGINIS**.

**GALLINAGO**, in ornithology, a bird called in english the snipe. See **SNIPE**.

**GALLING**, or **EXCORIATION**, in medicine. See the article **EXCORIATION**.

**GALLING of a horse's back**, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside

of the pannel; and anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or for want of that, with grease: wash the swelling, or hurt, every evening with cold water and soap, and strew it with salt, which should be left on till the horse be saddled in the morning.

**GALLINULA**, in ornithology, a bird, otherwise called tringa. See **TRINGA**.

**GALLION**, or **GALLEON**, in naval affairs, a sort of ships employed in the commerce of the West-Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the *flota*, and the other for Peru, which they call the gallions. See the article **FLOTA**.

By a general regulation made in Spain, it has been established, that there should be twelve men of war, and five tenders, annually fitted out for the armada or galleons; eight ships of six hundred tons burden each, and three tenders, one of an hundred tons, for the island Margarita, and two of eighty each, to follow the armada: for the New Spain fleet, two ships of six hundred tons each, and two tenders of eighty each; and for the Honduras fleet, two ships of five hundred tons each: and, in case no fleet happened to sail any year, three gallions and a tender should be sent to New Spain for the plate.

They are appointed to sail from Cadiz, in January, that they may arrive at Porto-Bello about the middle of April. where the fair being over, they may take aboard the plate, and be at Havannah with it about the middle of June, where they are joined by the *flota*, that they may return to Spain with the greater safety.

**GALLIOT**, a small gally designed only for chace, carrying only one mast, and two or three pattereroes; it can both sail and row, and has sixteen or twenty oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

**GALLIPAGO-ISLANDS**, are situated in the Pacific Ocean on both sides the equator, between 85° and 90°, west long. and about four hundred miles west of Peru.

**GALLIPOLI**, a port-town of european Turkey, situated at the entrance of the Propontis, or Sea of Marmora, about 100 miles south west of Constantinople: east long. 28°, and north lat. 40° 45'.

**GALLIPOLI** is also a port town of the kingdom of Naples, situated on the gulph of Otranto, about twenty-three miles west of that city: east long.  $19^{\circ}$ , and north lat.  $40^{\circ} 25'$ .

**GALLIUM**, *LADIES-BEDSTRAW*, in botany, a genus of the *tetrandria-monogynia* class of plants, the flower of which is a quadrifid single petal, without any tube, and placed flatwise: the fruit consists of two globose bodies, growing close together, but not adhering, and containing each a single kidney-shaped seed. It is said to be an excellent astringent.

**GALLO**, an island in the pacific ocean near the coast of Peru, about 200 miles west of Popayan: west long.  $80^{\circ}$ , and north lat.  $2^{\circ} 15'$ .

**GALLO** is also a town of Italy, ten miles south of Ancona.

**GALLO**, or **PUNTO GALLO**, a sea-port of Ceylon, subject to the Dutch: east long.  $78^{\circ}$ , and north lat.  $6^{\circ}$ .

**GALLON**, a measure of capacity both for dry and liquid things, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: for instance, the wine gallon contains 231 cubic inches, and holds eight pounds averdupois, of pure water: the beer and ale gallon contain 282 solid inches, and holds ten pounds three ounces and a quarter averdupois, of water: and the gallon for corn, meal, &c.  $272\frac{1}{4}$  cubic inches, and holds nine pounds thirteen ounces of pure water.

**GALLOON**, in commerce, a narrow thick kind of ferret, or lace, used to edge or border cloaths, sometimes made of wool, and at others of gold or silver.

**GALLOP**, in the manege, a motion of a horse that runs at full speed, in which making a kind of leap forwards, he lifts both his fore-legs almost at the same time; when these are in the air, just upon the point of touching the ground, he lifts both his hind-legs almost at once.

A horse in galloping forwards, may lead with which fore-leg he pleases, tho' horses do it most commonly with their right fore-leg; but with whatever fore-leg they lead, the hind-leg of the same side must follow it, otherwise their legs are said to be disunited. To remedy this disorder, the rider must stay the horse a little upon the hand, and give

him the spur on the contrary side to that in which he is disunited.

In a circle, a horse is always to lead with the fore-leg, within the turn; otherwise he is said to gallop false; but here too, the hind-leg of the same side must follow.

**GALLOPADE**, in the manege, also termed the fine gallopade, the short gallop, the listening gallop, and the gallop of the school, is a hand-gallop, in which a horse galloping upon one or two treads, is well united, well knit together, and well coupled. Hence it is said, that a horse makes a gallopade, and works with one haunch; that is, instead of going upon one tread, whether right-out, or in a circle, he has one haunch kept in subjection, let the turn or change of the hand be what it will; so that the inner haunch, which looks to the center of the ground is more narrowed, and comes nearer to the center than the shoulder; and thus the horse does not go altogether to that side, and his way of working is a little more than one tread, and somewhat less than two.

**GALLOPAVO**, in zoology, the same with pavo, or the peacock. See the article **PEACOCK**.

**GALLOWAY**, a province of Scotland, which gives the title of earl to a branch of the noble family of Stuart.

It is divided into two districts; the western, called Upper Galloway, being the same with Wigtonshire; and the eastern, or stewartry of Kircudbright, called Lower Galloway.

**GALLOWAY** is also the capital of a county of the same name, in the province of Connaught, in Ireland: west long.  $9^{\circ} 12'$ , and north lat.  $53^{\circ} 12'$ .

It has a good port, and is advantageously situated for a foreign trade.

**New-GALLOWAY**, a borough-town of Scotland, in the county of Wigton, with which, and some other boroughs, it classes.

**GALLOWS**, an instrument of punishment, on which persons convicted of felony, &c. are executed by hanging. It is formed of two pieces of timber fixed in the earth, with a beam fastened to each on the top; or with three pieces of timber fixed in the earth, with three pieces on the top, forming a triangle.

**GALLOWs of a plough**, a part of the plough-head, so called by farmers, from its resemblance to the common gallows, as consisting

consisting of three pieces of timber, whereof one is placed transversely over the heads of the other two. See the article **PLOUGH**.

**GALLS**, in natural history. See **GALL**.

*Harness*-**GALLS**, among farriers. See the article **HARNESS**.

**GALLUS**, the **COCK**, in ornithology, a well-known domestic fowl, the head of which is ornamented with a longitudinal fleshy crest, or comb: the wattles are two, and placed longitudinally on the throat. This, in its natural state, is a very robust and beautiful bird, variegated with a great number of elegant colours. See plate CX. fig. 1. where n° 1. represents the common dunghill-cock, and n° 2. the hen.

**GALLUS MARINUS**, a name very improperly used by some authors for two distinct kinds of fish, the *faber* and *orbis*. See the articles **FABER** and **ORBIS**.

**GALLY**, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed. The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom, called a gally-slice.

**GALLY**, in the sea-language, is a place in the cook-room, where the grates are set up, and in which fires are made for roasting or boiling the victuals.

**GALLY-WORM**, in zoology, the english name of the *julus* of authors. See the article **JULUS**.

**GAMBEZON**, or **GAMBA**, in antiquity, a kind of soft quilted waistcoat, worn under the coat of mail to prevent its hurting the body. It was made of wool or cotton, quilted between two stuffs, and was also called counterpoint.

**GAMBIA**, a great river of Africa, which, running from east to west falls into the Atlantic ocean in 14° north lat. and 15° west long.

It is said to be navigable for sloops 600 miles. About ten leagues up this river is James's Island, a settlement belonging to Great Britain: it is very small, being less than a mile in circumference, but is defended by a fort.

**GAMBOGE**, is a concreted vegetable juice, the produce of two trees, both called by the Indians *caracapulli*, and is partly of a gummy, and partly of a resinous nature. It is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes; and is of

a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East-Indies, called also Cambodja, and Cambogia; and from thence it has obtained its names of cambadium, cambogium, and gambogium.

It is a very rough and strong purge; it operates both by vomit and stool, and both ways with much violence, almost in the instant in which it is swallowed; but yet without griping. It requires caution and judgment in administering it; but those who know how to give it properly, find it an excellent remedy in dropsies, cachexies, jaundice, asthmas, catarrhs, and in the worst cutaneous eruptions.

Its dose is from two or three grains to six, eight, or ten: four grains generally operate briskly without vomiting, and eight or ten grains usually vomit briskly, and afterwards purge downwards.

It is at present much more esteemed by painters in water-colours, than by physicians. *Hill's Mat. Med.*

**GAME**, *ludus*, in general, signifies any diversion, or sport, that is performed with regularity, and restrained to certain rules. See the article **GAMING**.

Games are usually distinguished into those of exercise and address, and those of hazard. To the first belong chess, tennis, billiards, wrestling, &c. and to the latter those performed with cards or dice, as back-gammon, ombre, picquet, whist, &c. See the articles **CHESS**, **BACK-GAMMON**, &c.

**GAMES**, *ludi*, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the olympic, pythian, isthmian, nemæan, &c. games; and, among the Romans, the apollinarian, circenian, capitoline, &c. games. See the articles **OLYMPIC**, **PYTHIAN**, &c.

It was also customary, among the Greeks, for persons of quality to institute games, with all sorts of exercises, as running, wrestling, boxing, &c. at the funerals of their friends, to do them honour, and render their death more remarkable. This practice is frequently mentioned by antient writers, as Miltiades's funeral in Herodotus, Brasidas's in Thucydides, Timoleon's in Plutarch, with many more. Nor was this custom peculiar to later ages, since we find the description of Patroclus's funeral games takes up the greatest part of one of Homer's iliads; and even prior to this, Oedipus's funeral

is said to have been solemnized with sports.

Among the Romans, there were three sorts of games, *viz.* sacred, honorary, and ludicrous. The first were instituted immediately in honour of some deity or hero; of which kind were those already mentioned, together with the *augustales*, *florales*, *palatini*, &c. The second class were those exhibited by private persons, at their own expence, in order to please the people, and to ingratiate themselves with them, to make way for their own preferment: such were the combats of gladiators, the scenic games, and other amphitheatrical sports. The ludicrous games were much of the same nature with the games of exercise and hazard among us: such were the *ludus trojanus*, *tesseræ*, *tali*, *trochus*, &c. See the article TROJAN GAME, &c.

By a decree of the roman senate, it was enacted, that the public games should be consecrated, and united with the worship of the gods as a part thereof; whence it appears, that feasts, sacrifices, and games, made up the greatest part, or rather the whole, of the external worship offered by the Romans to their deities.

Others distinguish the roman games into 1. The equestrian, or curule games, which were the same with the circensian. 2. The gymnical games, wherein were exhibited gladiatorial, and other shews of the like nature: these were sacred to Mars and Minerva. 3. The theatrical entertainments, consisting of tragedies, comedies, balls, &c. these were sacred to Apollo, Bacchus, Minerva, Venus, &c.

**GAME**, in law, signifies birds or prey, taken or killed by fowling, or hunting. There are several statutes for punishing offences committed by persons not qualified by law, to take or destroy the game. The antient laws ordain, that no person shall take pheasants or partridges, with engines in another's ground, without his license, on forfeiture of 10*l.* and persons killing any pheasant, partridge, pigeon, duck, hare, or other game, forfeit 20*s.* for every fowl, hare, &c. 11 Hen. VII. 1 Jac. I. c. 17. Constables having a justice of peace's warrant, may search the houses of suspected persons for game; and in case any be there found, and they do not give a good account how they came by it, such persons shall forfeit for each hare or pheasant, partridge, &c. not under 5*s.* nor exceeding 20*s.* Likewise by another statute, if any

higher, chapman, carrier, inn-keeper, or victualler, shall have in his custody any hares, pheasants, partridges, heath-game, &c. he forfeits for every hare and fowl, 5*l.* unless the same be sent by a person qualified to kill game. The selling or offering game to sale is made liable to the like penalty; and in that case, if any hare, &c. be found in a shop, &c. it is deemed exposing it to sale. Persons not qualified, keeping dogs, nets, or engines to kill game, on their conviction before a justice of peace, shall also pay 5*l.* or be sent to the house of correction for three months, 4 and 5 W. and M. c. 23. 5 Ann. c. 14. 9 Ann. The penalties for destroying game, are recoverable by action, as well as before justices of peace, by 8 Geo. I. c. 19. If a person hunts any game on the land of another, such other cannot justify the killing of his dogs. Where one in hunting starts a hare upon his own land, and then follows and kills such hare in another person's ground, it is lawful, and the game is his own; but where a man starts a hare on another's land, and kills it there, he is subject to an action of trespass.

**GAME-COCK**, a fighting cock, or one kept for sport; in the choice of which, four things are chiefly to be regarded, *viz.* shape, colour, courage, and sharp heel.

1. As to shape, a game-cock must not be chosen either too large, nor too small: the first being generally unweildy, and unactive; the other weak and tedious in fighting. The middle-sized cock is therefore most proper for this purpose, as being strong, nimble, and easily matched; his head ought to be small, with a quick large eye, and a strong beak, which should be crooked, and in colour suitable to the plume of his feathers; the beam of his leg should be strong, and of the colour of his plume; his spurs should be rough, long and sharp; a little bending, and pointing inward. 2. The best colour for a game-cock is either that of a grey, yellow, or red: the pyed pile may pass indifferently; but the white and dun are rarely known to be good for any thing. If his neck be invested with a scarlet complexion, it is a sign of his being strong, lusty, and courageous: whereas a pale and wan complexion denotes him faint and unhealthy. 3. His courage may be known by his proud, upright standing, and  
stately

stately tread in walking; and if he crows frequently in the pen, it is a proof of spirit. 4. His sharpness of heel is known only from observation in fighting; that is, when at every rising he hits to that he draws blood from his adversary; gilding his spurs continually, and at every blow threatening him with immediate death.

To prepare a cock to fight; 1. With a pair of fine shears, cut all his mane off, close to his neck, from the head to the setting of the shoulders. 2. Clip off all the feathers from the tail close to his rump, and the redder it appears, the better is the cock in condition. 3. Spread his wings by the length of the first rising feather; and cut off the rest slope-wise, with sharp points, that in his rising he may therewith endanger an eye of his adversary. 4. Scrape smooth and sharpen his spurs with a pen-knife: and, lastly, see that there be no feathers on the crown of his head, for his opponent to take hold of; and moisten his head all over with your spittle.

**GAME-HEN**, should be of a black, brown, speckled grey, grizzle, or yellow colour: being tufted on the crown denotes courage and resolution; and having the addition of weapons, conduces very much to her excellency. Her body should be big and well poked behind, for the production of large eggs. A general remark is, that a right hen of the game, from a dung-hill cock, will bring forth very good chickens: but the best game cock from a dunghill hen, will never get a bird fit for the game. See the articles **BREEDING**, **HATCHING**, and **CHICKEN**.

**GAME-KEEPERS**, are those who have the care of keeping and preserving the game, and are appointed to that office by lords of manors, &c. who not being under the degree of esquire, may, by a writing under their hands and seals, authorize one or more game-keepers, who may seize guns, dogs or nets used by unqualified persons for destroying the game. Game-keepers are also to be persons either qualified by law to kill the game, or to be truly and properly the servants of the lords or ladies of manors appointing them; and no game-keeper can qualify any person to such end, or to keep dogs, &c. 5 Ann. c. 14. 9 Ann. c. 25. 3 Geo. I. c. 11. The persons qualified to keep guns, dogs, &c. are those who have a free

warren, or 100 l. a year by inheritance, or for life, or a lease for ninety-nine years of 150 l. per annum, also the eldest sons of esquires, &c. 22 and 23 Car. II. c. 25.

A lord of a manor may appoint a game-keeper within his manor and royalty to kill hares, pheasants, partridges, &c. for his own use, the name of whom is to be entered with the clerk of the peace of the county; and if any other game-keeper, or one legally authorized, under colour of his authority, kills game, and afterwards sells it, without the consent of the person that impowers him, he is on conviction to suffer corporal punishment.

**GAMELIA**, γαμηλια, in grecian antiquity, a nuptial feast, or rather sacrifice, held in the antient greek families on the day before a marriage; thus called, from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

**GAMELION**, a poem, or composition in verse on the subject of a marriage, commonly called an epithalamium. See the article **EPITHALAMIUM**.

**GAMELION**, in antient chronology, was the eight month of the Athenian year, containing twenty-nine days, and answering to the latter part of our January, and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

**GAMETRIA**, or **GEMATRIA**. See the article **GEMATRIA**.

**GAMING**, the art of playing or practicing any game, particularly those of hazard, as cards, dice, tables, &c.

Gaming has, at all times, been looked on as a thing of pernicious consequence to the common-wealth; and is, therefore, severely prohibited by law. The statute 33 Hen. VIII. gives justices of peace, and head officers in corporations, a power to enter all houses suspected of unlawful games; and to arrest the gamesters, till they give security not to play for the future. Persons keeping any unlawful gaming-house, are fined 40 s. and the gamesters 6 s. 8 d. a time. If any persons by fraud, deceit, or unlawf I device, in playing either at cards or dice, tables, bowls, cock-fighting, horse-races, foot-races, &c. or bearing a share in the stakes, or betting, shall win any money or valuable thing of another, he shall forfeit

forfeit treble the value thereof : likewise if any person shall play at any of the said games upon tick, and not for ready money, and lose the sum of 100l. on credit, at any one meeting, if the money be not paid down, his security taken for it shall be void, and the winner becomes liable to a forfeiture of treble value of such money won. 16 Car. II. c. 7. Not only all notes, bills, bonds, mortgages, or other securities given for money won at gaming, are declared void ; but also where lands are granted, they shall go to the next person intitled, after the decease of the person so incumbering the same : persons losing by gaming at one time 10l. may recover the money lost, from the winner, by an action of debt brought within three months ; and on the loser's not prosecuting, any other person may lawfully do it, and recover treble the value, with costs. 9 Ann. c. 14. Those who cheat at cards, dice, &c. besides their forfeitures, have inflicted on them such infamy and corporal punishment, as in cases of perjury ; and beating or challenging any other person to fight, on account of money won by gaming, shall forfeit all their goods, and be imprisoned two years : and where persons play that have no visible estates, and do not make it appear that the principal part of their maintenance is got by other means than gaming, they may be bound to their good behaviour by two justices of the peace, &c. Stat. *ibid.* See 2 Geo. II. c. 28. The ace of hearts, pharaoh, basket, and hazard, are judged to be lotteries by cards or dice ; and persons who set up those games, are subject to 200l. penalty. And every adventurer, who shall play, stake, or punt at them, forfeits 50l. Also any sales of houses, goods, plate, &c. in such a way, are void, and the things forfeited to any who will sue for the same. 12 Geo. II. c. 28.

*Laws of GAMING.* These are founded on the doctrine of chances. See the article CHANCE.

Mr. de Moivre, in a treatise de Mensura Sortis, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose  $p$  the number of cases in which an event may happen, and  $q$  the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as  $p$  to  $q$ .

If two gamblers, A and B, engage on this footing, that, if the cases  $p$  happen, A shall win ; but, if  $q$  happen, B shall win, and the stake be  $a$  ; the chance of A

will be  $\frac{pa}{p+q}$ , and that of B  $\frac{qa}{p+q}$  ; conse-

quently, if they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that, if A throw two or more aces at eight throws, he shall win ; otherwise B shall win ; what is the ratio of their chances ? Since there is but one case wherein an ace may turn up, and five wherein it may not, let  $a=1$ , and  $b=5$ . And, again, since there are eight throws of the die, let  $n=8$  ; and you will have  $a+b^n-b^n-nab^{n-1}$ , to  $b^n+nab^{n-1}$  : that is, the chance of A will be to that of B, as 663991 to 10156525, or nearly as 2 to 3.

A and B are engaged at single quoits, and, after playing some time, A wants 4 of being up, and B 6 ; but B is so much the better gamester, that his chance against A upon a single throw would be as 3 to 2 ; what is the ratio of their chances ? Since A wants 4, and B 6, the game will be ended at nine throws ; therefore, raise  $a+b$  to the ninth power, and it will be  $a^9+9a^8b+36a^7bb+84a^6b^3+126a^5b^4+126a^4b^5$ , to  $84a^3b^6+36aa^2b^7+6ab^3+b^9$  ; call  $a$  3, and  $b$  2, and you will have the ratio of chances in numbers, *viz.* 1759077 to 194048.

A and B play at single quoits, and A is the best gamester, so that he can give B 2 in 3, what is the ratio of their chances at a single throw ? Suppose the chances as 2 to 1, and raise  $2+1$  to its cube, which will be  $2^3+32^2+32+1$ . Now since A could give B 2 out of 3, A might undertake to win three throws running ; and, consequently, the chances in this case will be as  $2^3$  to  $32^2+32+1$ . Hence  $2^3=32^2+32+1$  ; or,  $22^3=2^3+32^2+32+1$ . And, therefore,  $2\sqrt[3]{2}=2+1$  ;

and, consequently,  $2=\frac{1}{\sqrt[3]{2}-1}$ . The

chances, therefore, are  $\frac{1}{\sqrt[3]{2}-1}$ , and 1, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4, what is the probability I win both wagers ?

1. The probability of winning the first is  $\frac{3}{5}$ , that

that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is  $\frac{7}{11}$ : therefore, multiplying these two fractions together, the product will be  $\frac{2}{33}$ , which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is  $\frac{31}{33}$ , which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is  $\frac{1}{3}$ , the probability of losing the second is  $\frac{4}{7}$ : therefore multiplying  $\frac{1}{3}$  by  $\frac{4}{7}$ , the product  $\frac{4}{21}$  will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain  $\frac{17}{21}$ , which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: the probability of winning the second is  $\frac{7}{11}$ ; the probability of losing the first is  $\frac{2}{3}$ : therefore, multiplying these two fractions together, the product  $\frac{14}{33}$  is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is  $\frac{2}{3}$ , and the probability of losing the second  $\frac{4}{7}$ : therefore, the probability of losing them both is  $\frac{8}{21}$ ; which being subtracted from 1, there remains  $\frac{13}{21}$ : therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is  $\frac{5}{6}$ , the second is also  $\frac{5}{6}$ , the third  $\frac{5}{6}$ , and the fourth  $\frac{5}{6}$ : therefore the probability of missing it four times together is  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$ ; which being subtracted from 1, there will remain  $\frac{671}{1296}$  for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of

missing it three times would be  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$ ; which being subtracted from 1, there will remain  $\frac{91}{216}$  for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is  $\frac{1}{6}$ , and of missing it the other three times is  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6}$ , it follows that the probability of throwing it the first time, and missing it the other three successive times, is  $\frac{1}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{1296}$ ; but because it is possible to hit it every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing the other three, is  $\frac{4 \times 125}{1296} = \frac{500}{1296}$ ; which

being subtracted from 1, there will remain  $\frac{796}{1296}$  for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other; what is the probability that the event, which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances are as 2 to 1, the probability of the first happening before the second is  $\frac{2}{3}$ , but the probability of its happening twice before it, is but  $\frac{2}{3} \times \frac{2}{3}$  or  $\frac{4}{9}$ : therefore it is 5 to 4 (even does not come up twice before four once).

But, if it were demanded; what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is  $\frac{12}{17}$ , and the probability of throwing it twice is  $\frac{12}{17} \times \frac{12}{17}$ , or  $\frac{144}{289}$ ; therefore, the probability of not doing it is  $\frac{145}{289}$ : therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour, what is the pro-

probability that, taking one card at a venture out of each heap, I shall take out the two aces?

The probability of taking the ace out of the first heap is  $\frac{1}{13}$ , the probability of taking the ace out of the second heap is  $\frac{1}{13}$ ; therefore the probability of taking out both aces is  $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$ , which being subtracted from 1; there will remain  $\frac{168}{169}$ : therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap of thirteen cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be  $\frac{1}{13}$ , and the probability of taking out the two be likewise  $\frac{1}{13}$ ; yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be  $\frac{1}{12}$ ; therefore the probability of taking out the ace, and then the two, will be  $\frac{1}{13} \times \frac{1}{12}$ .

In this last question the two events have a dependence on each other, which consists in this, that one of the events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

If the events in question be  $n$  in number, and be such as have the same number  $a$  of chances by which they may happen, and likewise the same number  $b$  of chances by which they may fail, raise  $a+b$  to the power  $n$ . And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be  $\frac{a+b)^n - b^n}{a+b)^n}$ ; and

that of B's winning will be  $\frac{b^n}{a+b)^n}$ ; for

when  $a+b$  is actually raised to the power  $n$ , the only term in which  $a$  does not occur is the last  $b^n$ : therefore, all the terms but the last are favourable to A.

Thus if  $n=3$ , raising  $a+b$  to the cube  $a^3 + 3a^2b + 3ab^2 + b^3$ , all the terms but  $b^3$  will be favourable to A; and therefore the probability of A's winning will be

$\frac{a^3 + 3a^2b + 3ab^2}{a+b)^3}$ , or  $\frac{a+b)^3 - b^3}{a+b)^3}$ ; and

the probability of B's winning will be  $\frac{b^3}{a+b)^3}$ . But if A and B play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be  $\frac{a+b)^n - nab^{n-1} - b^n}{n+b)^n}$ ; for

the only two terms in which  $aa$  does not occur, are the two last, viz.  $nab^{n-1}$  and  $b^n$ .

**GAMMA AUREUM**, in zoology; a species of the phalenæ, or moths, with deflected wings. See **PHALENA**.

**GAMMARUS**, in ichthyology, a species of the cancer, or crab-fish. See the article **CANCER**.

**GAMMER-LAMB**, or **GIMMER-LAMB**. See the article **GIMMER**.

**GAMMONING**, among seamen, denotes several turns of rope taken round the bowsprit, and reeved through holes in knees of the head, for the greater security of the bowsprit. *Blackley*.

**GAMMUT**, **GAM**, **GAMMA**, or **GAMMA-UT**, in music, a scale whereon we learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders and dispositions. See **NOTE** and **SCALE**.

The invention of this scale is owing to Guido Aretine; tho' it is not so properly an invention as an improvement on the diagram, or scale of the Grecians. See the article **DIAGRAM**.

The gammut is also called the harmonical hand, by reason that Guido made first use of the figure of the hand to demonstrate the progression of his sounds.

Guido, finding the diagram of the antients of too small an extent, added five more chords or notes to it; one below the proslambanomenos of the antients, and four above the nete hyperbolæon. The first he called hypo-proslambanomenos, and denoted it by the letter G, or the greek  $\gamma$ , gamma; which note being at the head of the scale, occasioned the whole scale to be called by the name of gam, or gammut. This scale is divided into three series or columns, the first called durum, the second natural, and the third molle, as represented by the following scheme. See **PROSLAMBANOMENOS**, **NETE**, **DURUM**, **NATURAL**, and **MOLLE**.

The

## The GAMMUT or SCALE of GUIDO.

	ee di	B. dur la	Nat. mi	Molle la
	cc bb	sol fa	re ut	sol la
G	aa	re	la	fa mi
	g	ut	sol	re
	f	la	fa	ut
	e	la	mi	
F	d	sol	re	la
	e	fa	ut	sol
	b	mi		fa
	a	re	la	mi
	G	ut	sol	re
	f	ut	fa	ut
	e	la	mi	
C	d	sol	re	
	c	fa	ut	
	B	mi		
	a	re		
	Γ	ut		

The use of this scale is to make the passages and transitions from B durum to B molle, by means of tones and semitones. The series of B natural standing between the other two, communicates with both, so that to name the chord of the scale by these syllables, if we would have the semitones in their natural places, viz. *b, c,* and *e, f,* then we apply *ut* to *g*; and after *la* we go into the series of B natural, at *fa*; and after the *la* of this, we return to the former at *mi*; and so on. And we may begin at *ut* in *c*, and pass into the first series at *mi*, and then back to the other at *fa*, by which means the one transition is a semitone, viz. *la, fa,* and the other a tone, *la, mi*. To follow the order of B molle, we may begin with *ut* in *c* or *f*, and make each semitone after the same manner. See the articles TONE and SEMITONE.

Hence came the barbarous names of ga-

mut, are, B mi, &c. but what perplexed work is here with so many different syllables applied to each chord, and all to mark the places of the semitones, which the simple letters *a, b, c,* &c. do as well, and with more ease.

Several alterations have been made in the gammut. M. Je Murs particularly added a seventh syllable, viz. *fi*; and the English usually throw out that and *ut*, and make the other serve for all, as will be shewn under the article SOLFAING.

GAMMUT, or GAMM, is also the first or gravest note in the modern scale of music, the reason whereof is shewn under the preceding article.

GANDER, in ornithology, the male of the goose-kind; one of which, it is said, will serve five geese. See GOOSE.

GANG, in the sea-language, the same with crew. See the article CREW.

The company wherewith a ship's boat is manned,

manned, is called the cockswain's crew, or gang. See the article COCKSWAIN.

**GANG-WAY** is the several passages or ways from one part of the ship to the other; and whatever is laid in any of those passages, is said to lie in the gang-way.

**GANG-FISH**, a species of coregonus, with the upper jaw longest and flat, and with fourteen rays in the back fin. See the article COREGONUS.

**GANGEA**, the capital of a territory in the province of Chirvan, in Persia: east long. 46°, north lat. 41°.

**GANGES**, a large river of the hither India, rises in the mountains which separate India from Tartary; and, running from the north-west to the south-east near 1500 miles through the Mogul's dominions, discharges itself by several channels into the bay of Bengal.

This river is worshiped like a god by the superstitious Indians, many thousands of whom annually undertake pilgrimages to it, and carry their dying friends to expire on its banks, and as soon as they die, heave them into the middle of it.

**GANGI**, or **COULER**, a town of Golconda, in the hither India: east long. 79°, and north lat. 16°.

**GANGLIO**, or **GANGLION**, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus; upon the tendons or ligaments in that part, usually without any pain to the patient. Though ganglions so nearly resemble an encysted tumour, that Celsus makes them one and the same; yet their difference may appear, if it were only from their different seats; ganglions being confined to the tendons and ligaments of the hands and feet, whereas encysted tumours are not restrained to any part of the body. See the article ENCYSTED.

With regard to the cause of ganglions, they seem generally to proceed from an inspissation of the viscid juices, which are let out, and lodged betwixt the fibres and membranes, when the tendons and ligaments of those parts have been injured by a fall, blow, strain, contusion, or the like, in which case they gradually increase more or less, as long as the fibres yield; the juices find vent so as to advance to the size of a filbert, walnut, or even a pigeon's egg: some are oblong, round, or oval, with an equal or uneven surface: some of them which are recent, may be easily dispersed; and others, which have

been of long standing, hardly yield to any remedies but the knife.

The inspissated matter of a recent ganglion, may often be happily dispersed by barely rubbing the tumour well every morning with the fasting saliva, and binding a plate of lead on it afterwards for several weeks successively. Many attribute a greater discutient virtue to the lead, when it has first had some mercury rubbed on it. Forelius, and others, advise the use of a plaster of ammoniac and mercury, and often to rub them with oil of sassa. Others write, that a cure may be readily performed, if the patient lays his hand upon a table, and strikes on the tumour with his fist: but care should be taken not to injure the bones, tendons, or other parts of the hand in striking the tumour; and the same care must be taken if there is a necessity of having recourse to caustics or incision, in order to remove them.

See CAUSTIC and INCISION.

**GANGRENE**, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. A gangrene is distinguished from a sphacelus, in as much as this latter is not an incipient but an absolute and perfect corruption, or death of the parts, already made. See the article SPHACELUS.

A gangrene may be discovered generally from the following signs; namely, the inflammation, with its symptoms, which have all along been very violent, do generally undergo a sudden change, as if they were going off. The parts which were before swelled and tense, do now grow soft and flaccid, and upon pressing with the finger on the skin and fat, its impression remains behind, as in an oedema; at length the cuticula separates from the cutis, often rising up in blisters, like those on burns, filled with a reddish, yellowish, and black humour; and the sense of the limb is in some degree diminished. See the article OEDEMA.

The causes of a gangrene, as well as a sphacelus, are either external or internal. Among the internal causes are reckoned an erysipelas, and all other inflammations which rise spontaneously, and can by no means be dispersed, nor brought to suppuration. Inflammations of this kind usually proceed from the blood's being too acrimonious, or corrupted by the bile, or in a scorbutus; or when the circulation of the blood is too quick, or too slow,

by

by reason of old age, or any other weakness; or, lastly, when the patient uses a perverse course of life with respect to diet, and passions of the mind, especially anger, grief, and fear, during the time of the inflammation. By external causes are intended injuries of the air, cold water, and the application of topical remedies externally to the inflamed parts; which are either cooling, astringent, fat, oily, or the like; together with all great external hurts or accidents, which frequently happen to the body through falls, blows, &c. as in wounds, fractures, luxations, &c. See WOUND, FRACTURE, and LUXATION.

A gangrene is for the generality never without danger, because it easily changes into a sphacelus, or intire mortification, which never admits of cure but by taking off the dead parts. But a gangrene which is slight, incipient, and not spread far, but only affects the skin and fat, is not very difficult to cure; especially when it happens in a young and stout patient, in a mild and temperate season, and does little or no injury to the muscles and nerves: but the larger, more violent, and confirmed is the gangrene, and the faster it spreads, the more difficult it is generally to effect a cure, especially in an old or weak patient; or in an ill habit of body, from a dropy, phthisis, or scorbutus: the weather also being too hot, or very cold, or the parts affected being near the thorax, or abdomen, may make the case more dangerous. Nor can this case be neglected without the utmost danger of life, or its suddenly turning into a sphacelus.

Therefore the gangrene must be treated so, that it may not terminate in a sphacelus. For which end, first of all, in plethoric and strong habits, the patient must be bled largely, and the operation repeated at discretion; but in weak habits, it should be omitted. The remainder of the treatment, according to Heister, will consist chiefly in observing the following directions. 1. To be careful in the beginning to prevent all violent external causes of inflammations, too strict a bandage in wounds and fractures, all foreign bodies which are stuck in the part, as thorns, splinters, &c. improper medicines externally applied, as ointments, oils, and plasters, with cooling and astringent things; all which should be removed as soon as possible. 2. The next observation respects chiefly the keep-

ing up the patient's strength, especially in weak and old people. This may be best effected by ordering a diet which not only affords good juices, but is also well accommodated to the age, constitution, and other circumstances of the patient. In weak and old people, the most suitable diet will be soups, strengthening broths, &c. With respect to medicines, the most proper are the corroborants, usually termed cordials, as the spirits, essences, powders, and electuaries of that tribe; especially made up or mixed with confectioned alkermes. It will be proper also, in this case, frequently to apply a sponge to the nose or carpal arteries, which has been dipped in hungary water; also to bind it to the temples. For patients who are of a more warm, sanguine, and bilious habit, soups and ptisans mixed with acid juice of citrons or lemons, will be very proper strengtheners; at the same time, not neglecting other medicines, which are proper to be used in fevers: but the peruvian bark is by many celebrated in this disorder beyond any other internal medicine. 3. The chief and last observation concerning the treatment of a gangrene, is chiefly to discharge the stagnating and corrupted blood from the parts affected as soon as possible, to prevent the neighbouring parts from being affected thereby.

The principal means to effect this are, 1. To make use of proper internal, strengthening medicines. 2. To make scarifications on the part affected, by numerous incisions lengthways, and of a sufficient depth, in order to discharge the stagnating and corrupted blood, and to make way for the ingress of the virtues of the discutient medicines which are applied externally. Lastly, 3. Discutient, stimulating, and balsamic fomentations and cataplasms which resist putrefaction, are to be carefully applied to the disordered part. See FOMENTATION and CATAPLASM.

The fomentation is to be applied hot, several times in a day, to the parts affected, by means of linnen or woollen cloths; and to give a lasting warmth, we may apply a hot tile wrapped up in a thick cloth, or a hot bag of sand.

GANNET, in ornithology, a bird of the larus or gull-kind, frequent on the western coasts of England.

It is equal in size to the common duck. The upper part of the body is of a deep rusty ferrugineous colour, much like

that of the common buzzard ; and the breast and belly are also brown, but paler. It is an extremely singular species, its whole aspect, in some degree, approaching to that of some of the larger birds of prey. See plate CX. fig. 2.

**GANTLET**, or **GAUNTLET**, a large kind of glove, made of iron, and the fingers covered with small plates. It was formerly worn by cavaliers, when armed at all points.

**GANTLET**, in surgery, a kind of bandage for the hand. See **BANDAGE**.

It consists of a swathe four or five yards long, with which they wrap up the hand, and all the fingers, one after another.

**GAOL**, a prison, or place of legal confinement.

Every county has two gaols, one for debtors, which may be wherever the sheriff pleases ; the other for the peace and matters of the crown, which is the county gaol.

If a gaol be out of repair, or insufficient, &c. justices of peace, in their quarter sessions, may contract with workmen for the rebuilding or repairing it ; and by their warrant order the sum agreed on for that purpose, to be levied on the several hundreds and other divisions in the county by a just rate, 11 & 12 Will. III. c. 19. See the article **PRISON**.

**GAOL-DELIVERY**, is where a commission or patent is granted by the king in the nature of a letter, to certain persons, who are thereby appointed his justices, or to two or three of them, authorising them to deliver his gaol, at such a place, of the prisoners contained therein ; and for that end it commands them to meet at such place, at the time they themselves shall appoint, when the sheriff of the county is commanded to bring all the prisoners in the gaol before them, &c. 4 Inst. 168.

The justices of gaol-delivery are empowered by the common law to proceed upon indictments of felony, trespass, &c. and to order execution or reprieve ; they may likewise discharge such prisoners, as on their trials are acquitted, and those against whom, on proclamation made, no evidence has appeared : they have authority to try offenders for treason, and to punish many particular offences by statute. 2 Hawk. 24. 2 Hale's hist. Placit. Cor. 35.

**GAOLER**, the keeper of a gaol or prison. Sheriffs are to make such gaolers for whom they will be answerable : but if there be any default in the gaoler, an ac-

tion lies against him for an escape, &c. yet the sheriff is most usually charged. 2 Inst. 592. Where a gaoler kills a prisoner by hard usage, it is felony. 3 Inst. 52. No fee shall be taken by gaolers, but what is allowed by law, and settled by the judges, who may determine petitions against their extortions, &c. 2 Geo. II. c. 22.

**GAP**, a city and bishop's see of Dauphine, in France, eighteen miles west of Embrun : east longitude  $5^{\circ} 46'$ , north lat.  $44^{\circ} 32'$ .

**GARAGAY**, a rapacious bird of Mexico, about the size of our kite.

**GARBE**, in heraldry, a sheaf of any kind of grain, borne in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

**GARBLER** of spices, an antient officer in the city of London, who is authorized to enter into shops, ware-houses, &c. there to view and search drugs, spices, &c. and see that they be garbled or cleansed from the dross and dust wherewith they are mixed.

**GARBLING** of bow-staves, the sorting them, or separating the good from the bad.

**GARBOARD-STRAKE**, the plank next the keel of a ship, one edge of which is run into the rabbit made in the upper edge of the keel on each side. Blanckley's Nav. Expof.

**GARCINIA**, in botany, a genus of the *icosandra-monogynia* class of plants, called magoistans by Garcias, from whom Linnaeus has given it the name of garcinia. The flower consists of four roundish, patent petals ; and the fruit is a large unilocular, coriaceous berry, containing eight hairy and fleshy seeds, convex on one side, and angular on the other.

**GARD**, or **GUARD**. See **GUARD**.

**GARDA**, a town of the Veronese, in Italy, subject to Venice : east long.  $11^{\circ}$ , north lat.  $45^{\circ} 25'$ .

**GARDANT**, or **GUARDANT**, in heraldry, denotes any beast full faced, and looking right forward. See plate CXI. fig. 2. which represents a lion gardant.

**GARDELEBEN**, a town of Brandenburg, in Germany : east long.  $11^{\circ} 45'$ , north lat.  $52^{\circ} 40'$ .

**GARDEN**, a plot of ground, cultivated and properly ornamented with a variety of plants, flowers, fruit, &c.

Gardens are usually distinguished into flower-garden, fruit-garden, and kitchen-garden ; the first of which, being designed

signed for pleasure and ornament, is to be placed in the most conspicuous part, that is, next to the back front of the house; and the two latter, being designed for use, should be placed less in sight. But tho' the fruit and kitchen-gardens are here mentioned as two distinct gardens, yet they are now usually in one; and that with good reason, since they both require a good soil and exposure, and equally require to be placed out of the view of the house. See KITCHEN-GARDEN.

In the choice of a place proper for a garden, the most essential points to be considered are the situation, the soil, the exposure, water and prospect.

1st, As to the situation, it ought to be such a one as is wholesome, and in a place neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees; and if it be too low, the dampness, the vermin, and the venomous creatures that breed in ponds and marshy places, add much to their insalubrity. The most happy situation is on the side of a hill, especially if the slope be easy, and in a manner imperceptible; if a good deal of level ground be near the house; and if it abounds with springs of water; for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades for ornament, but when it has performed its office, will water the adjacent valleys, and, if it be not suffered to stagnate, will render them fertile and wholesome. Indeed if the declivity of the hill be too steep, and the water be too abundant, a garden on the side of it may frequently suffer, by having trees torn up by torrents and floods; and by the tumbling down of the earth above, the walls may be demolished, and the walks spoiled. It cannot, however, be denied, that the situation on a plain or flat, has several advantages which the higher situation has not: for floods and rain commit no damage; there is a continued prospect of champaigns, intersected by rivers, ponds and brooks, meadows and hills covered with woods or buildings; besides, the level surface is less tiresome to walk on, and less chargeable, than that on the side of an hill, since terrace walks and steps are not there necessary; but

the greatest disadvantage of flat gardens, is the want of those extensive prospects which rising grounds afford.

2dly, A good earth, or soil, is next to be considered; for it is scarce possible to make a fine garden in a bad soil; there are indeed ways to meliorate ground, but they are very expensive; and sometimes when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom. To judge of the quality of the soil, observe whether there be any heath, thistles, or such-like weeds growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby, and whether they are of a faded green, and full of moss, or infested with vermin; if this be the case, the place is to be rejected: but, on the contrary, if it be covered with good grass fit for pasture, you may then be encouraged to try the depth of the soil. To know this, dig holes in several places, six feet wide, and four feet deep; and if you find three feet of good earth, it will do very well; but less than two, will not be sufficient. The quality of good ground is neither to be stony, nor too hard to work; neither too dry, too moist, nor too sandy and light; nor too strong and clayey, which is the worst of all for gardens.

3dly, The next requisite is water, the want of which is one of the greatest inconveniencies that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains, canals, cascades, &c. which are the greatest ornaments of a garden.

4thly, The last thing to be considered, is the prospect of a fine country; and tho' this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable, but unwholesome.

In the laying out and planting of gardens the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. The area of a handsome garden,

den, may take up thirty or forty acres, but not more; and the following rules should be observed in the disposition of it. There ought always to be a descent of at least three steps from the house to the garden; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive. The first thing that should present itself to view, should be an open lawn of grass, which ought to be considerably broader than the front of the building; and if the depth be one half more than the width, it will have a better effect: if on the sides of the lawn there are trees planted irregularly, by way of open groves; the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel walk, on the outside of which should be borders three or four feet wide, for flowers: and from the back of these, the prospect will be agreeably terminated by a slope of ever-green shrubs, which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead thro' the different plantations, gently winding about in an easy natural manner, which will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings, that are twisted about into so many short turns, as to render it difficult to walk in them: and as no garden can be pleasing where there is a want of shade and shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind. Where the borders of the gardens are fenced with walls or pales, they should be concealed with plantations of flowering-shrubs intermixed with lawrels, and other ever-greens, which will have a good effect, and at the same time conceal the fences, which are disagreeable, when left naked and exposed to the sight. Groves are the most agreeable parts of a garden, so that there cannot be too many of them; only that they must not be too near the house, nor be suffered to block up agreeable prospects. To accompany parterres, groves opened in compartments, quincunxes, and arbour-work with fountains, &c. are very agreeable. Some groves of ever-greens should be planted in proper places, and some squares of trees of

this kind may also be planted among the other wood. See *QUINCUNX*, &c.

Narrow rivulets, if they have a constant stream, and are judiciously led about a garden, have a better effect than many of the large stagnating ponds or canals, so frequently made in large gardens. When wilderesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design appear trifling. Buildings, statues, and vases, appear very beautiful; but they should never be placed too near each other: magnificent fountains are also very ornamental; but they ought never to be introduced, except there be water to keep them constantly running. The same may also be observed of cascades and other falls of water. See the articles *CASCADES*, *FOUNTAINS*, &c.

In short, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In the business of designs, the aim should be always at what is natural, great and noble. The general disposition of a garden, and of its parts, ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number and sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. And before a garden is planned out, it ought ever to be considered, what it will be when the trees have had twenty years growth. *Miller's Gard. Dict.*

**GARDENING**, a branch of agriculture, containing the cultivation of gardens. See the preceding article.

The art of gardening affords a variety of delights. It teaches how to dispose fruit-trees, flowers, and herbs to the best advantage, whether for profit or pleasure; and shews how to prepare the soil for sowing the different kinds of seeds, as well as how to treat the plants when grown up. It is a pleasure to behold a person employed, amongst the plants of a spacious garden, in reforming, by proper methods, a growth of natural wildings; to see him cultivate mutual alliances between his plants, by grafting or inoculation, whereby the bad are meliorated, and the good rendered still more perfect. By this means, a plant taken from the wilds of a forest, softens its savage nature, and will sometimes divest itself of its

its thorns, when it happens to be associated with a domestic one.

As to the several parts and operations of gardening, the reader will find them described under the articles **SOWING, PLANTING, TRANSPLANTING, GRAFTING, INOCULATION, PRUNING, NURSERY, HOT-BED, GREENHOUSE, WALK, TERRACE, ALLEY, AVENUE, ARBOUR, GROVE, ESPALIERS, STANDARDS, &c.**

**GARDENING** *a hawk*, in falconry, the putting her on a turf of grass to cheer her.

**GARDIAN, or GUARDIAN.** See the article **GUARDIAN**.

**GARDS, or GUARDS.** See **GUARDS**.

**GARDUS**, in ichthyology, a fish more usually called *sargus*. See **SARGUS**.

**GARGANEY**, in ornithology, a bird of the anas or duck-kind, about the size of the common teal, which in many particulars it greatly resembles. It is distinguished by a green spot in the wings, and a white line over the eyes. See the article **ANAS**.

**GARGARISM**, in medicine, is sometimes taken, in a large sense, for every collution of the mouth; but, strictly speaking, it signifies a liquid medicine, appropriated to affections of the mouth, gums, fauces, larynx, and sometimes of the head, received into the mouth, and there used by way of collution, without deglutition.

Gargarizations, according to Celsus, are made for the sake of alleviation, repression, or evacuation. The first intention is answered by milk and cremor of ptisan, or bran; repression is effected by water wherein lentils, roses, brambles, quinces or dates have been bottled; and evacuant gargarisms are mustard and pepper.

**GARIDELLA, FENNEL-LEAVED NIGELLA**, in botany, a genus of the *decandria-trigynia* class of plants. It has no flower petals; but there are five long, equal, and bilabiate nectaria: the fruit consists of three oblong, compressed, acuminate capsules, formed of two valves, and containing numerous small seeds.

**GARLAND**, a sort of chaplet made of flowers, feathers, and sometimes precious stones, worn on the head, in manner of a crown.

**GARLAND** also denotes ornaments of flowers, fruits, and leaves, intermixed, antiently much used at the gates of temples, where feasts and solemn rejoicings were held; or at any other place where marks of public joy or gaiety were

required, as at triumphal arches, tournaments, &c.

The flowers and greens whereof garlands were composed, were various. The antients made no public entertainment but upon the festivals of the gods; and then the garlands, hymns and songs, were that part of the entertainment the gods were supposed to delight in, according to Athenæus. And in latter ages of antiquity, upon the public festival of any god, they used that particular herb or flower supposed to be sacred to that deity: but, at other times, all such herbs were made use of as the season would best admit of, or as they thought were most conducive to pleasure, health, or refreshment. Garlands were not confined to the head only, but other parts of the body, particularly the breast, were adorned with them.

**GARNET, granatus**, in natural history, a very beautiful gem, of a red-colour, with an admixture of bluish. When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, tho' only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names, according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue: this is a very beautiful gem.

3. The *forane* or *ferain* garnet, that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The *almandine*, a garnet only a little paler than that called the rock-ruby.

Garnets are very properly distinguished into the oriental and occidental kinds, as being found in Europe as well as the East-Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the european ones are common in Italy, Hungary, and Bohemia.

Some authors have supposed the deeper-coloured garnet to be the same with the carbuncle of the antients, from which it really differs; since, on receiving the sun's

fun's beams, it never gives so true a fire-colour as the carbuncle. See the article **CARBUNCLE**.

**Counterfeit GARNET**, or **GARNET-PASTE**, a preparation of glass, the colour of which emulates that of the genuine garnet. See the article **GLASS-MAKING**.

This paste is made three different ways.

1. By mixing two ounces of prepared crystal with six of common red-lead, and adding sixteen grains of manganese, and three grains of zaffer. 2. By adding  $5\frac{1}{2}$  ounces of minium to two of crystal, and then mixing with them fifteen grains of manganese, and four grains of zaffer. 3. By mixing five ounces of minium with two ounces of prepared crystal, and adding fifty-two grains of manganese, and six grains of zaffer. This last makes by far the most elegant garnet-paste.

**GARNET**, in a ship, is a tackle having a pendant coming down from the main-mast, with a block well seized to the main-stay, just over the hatch-way, to which a guy is fixed to keep it steady; and at the other end is a long tackle-block, in which the fall is reeved, that so by it any goods or casks may be hauled and hoisted into or out of the ship. When this garnet is not used, it is fastened along the stay.

**Clew-GARNET**, in a ship. See **CLEW**.

**GARNISH**, in law-books, signifies to warn; in which sense, to garnish the heir, is mentioned in stat. 27 Eliz. c. 3. See the article **GARNISHMENT**.

**GARNISHEE**, is used for the third person or party in whose hands money is attached within the liberties of the city of London, in the sheriff's court there; and he is so called, because he has had garnishment or warning not to pay the money, but to appear and answer to the plaintiff creditor's suit.

**GARNISHMENT**, is a warning given to a person for his appearance, for the better furnishing of the cause and court; as where a person is sued for detaining charters or other writings delivered him by the plaintiff, and another person, upon some certain conditions; and therefore he prays that the other person may be warned to plead with the plaintiff, whether the conditions are or are not performed; which is the praying of garnishment; and interpreted to be either a warning of that other, or a furnishing the court with parties sufficient to determine the cause.

**GARONNE**, a large river of France, which taking its rise in the Pyrenean mountains, runs north-west by the city of Tholouse, divides the provinces of Guienne and Gascony, and visiting the city of Bourdeaux, falls into the bay of Biscay, about sixty miles below that city. It has also a communication with the Mediterranean, by means of the royal canal of Lewis XIV.

The tide flows up this river twenty miles above Bourdeaux.

**GAROSMUS**, in botany, a name by which stinking orach is sometimes called.

**GARRISON**, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection; or even to be subsisted during the winter season: hence, garrison and winter-quarters are sometimes used indifferently, for the same thing; and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it; and where they keep regular guard, as a frontier town, a citadel, castle, tower, &c. The garrison should always be stronger than the townsmen.

Winter-quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard. See **WINTER-QUARTERS**.

**GARRISON-TOWN**, a strong place in which troops are quartered, and do duty, for the security thereof; keeping strong guards at each port, and a main guard in the market-place.

**GARRISON**, in geography, a town of Ireland, in the county of Fermanagh, and province of Ulster: west long.  $8^{\circ} 20'$ , and north lat.  $54^{\circ} 16'$ .

**GARRULUS**, in ornithology, a bird called in the English the roller. See **ROLLER**.

**GARSTANG**, a market-town of Lancashire, ten miles north of Preston.

**GARTER**, a ligature for tying up the stocking; but particularly used for the badge of a noble order of knights, hence denominated the

*Order of the GARTER*, a military order of knighthood, the most noble and antient of any lay-order in the world; instituted by king Edward III. This order consists of twenty-six knights-companions, generally princes and peers, whereof the king of England is the sovereign, or chief. They are a college or corporation, having a great and little seal.

Their

Fig. 1. Order of the GARTER.

Fig. 2. GORE. Fig. 3. GIRONNE. Fig. 4. GARDANT.

Fig. 5 GAUGING ROD.

Their officers are a prelate, chancellor, register, king at arms; and usher of the black rod. They have also a dean with twelve canons, and petty canons, vergers, and twenty-six pensioners, or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor, which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two distinct offices united in one person. Garter carries the rod and scepter at the feast of St. George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See KING at arms.

All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, with the chapel of St. George, and the chapter-house, erected by the founder for that purpose. The habit and ensign of the order are a garter, mantle, cap, george, and collar. The four first were assigned the knights companions by the founder; and the george and collar, by Henry VIII. The garter (see plate CXI. fig. 1. n° 1.) challenges preeminence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes, and absent knights, who, and all other knights elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, HONI SOIT QUI MAL Y PENSE; i. e. "shame to him that thinks evil hereof." The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprize he had undertaken, for recovering his lawful right to that crown, and that the bravery of those

knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle (*ibid.* n° 2.) is the chief of those vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, antiently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs, or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device HONI SOIT, &c. within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver. (*ibid.* n° 3.)

The collar (*ibid.* n° 4.) is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the motto gold. See COLLAR. The manner of electing a knight companion into this most noble order, and the ceremonies of investiture, are as follow. When the sovereign designs to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which passing both under the sovereign's sign manual and signet of the order, are sent to the person by garter principal king at arms, and are in this manner, or to the same effect. "We, with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shewn, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns, thereof, and be ready for your installation upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election,

buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion by garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes. "To the honour of God omnipotent, and in memorial of the blessed martyr St. George, tye about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten, or laid aside; that thereby thou mayst be admonished to be courageous, and having undertaken a just war in which thou shalt be engaged, thou mayst stand firm, valiantly fight, and successively conquer."

The princely garter being thus buckled on, and the words of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a sky-coloured ribbon, (*ibid.* n° 5.) whereunto is appendant, wrought in gold within the garter, the image of St. George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St. George, by whose imitation provoked, thou mayst so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory."

Then the knight elected kisses the sovereign's hand, thanks his majesty for the great honour done him, rises up, and salutes all the companions severally, who return their congratulations. N° 2. *ibid.* exhibits a view of a knight of the garter in the habit of this order. Since the institution of this order, there have been eight emperors, and twenty-eight kings, besides numerous sovereign princes enrolled as companions thereof. Its origin is somewhat differently related: the common account is, that it was erected in honour of a garter of the countess of Salisbury, which she dropped dancing with king Edward, and which that prince picked up; but our best antiquaries think it was instituted on account of the victory over the French at

Cressy, where the king ordered his garter to be displayed as a signal of the battle.

**GARTH**, signifies a little clove, or backside, in the north of England; also a wear. See the article **WEAR**.

**GARTHMAN**, a term formerly used for a fisher-man.

**GARUM**, among physicians, denotes the brine, or pickle, wherein anchovies, herrings, &c. are preserved. See the article **PICKLE**.

**GARYOPHYLLUS**, or **CARYOPHYLLUS**, in botany, &c. See the article **CARYOPHYLLUS**.

**GAS**, among chemists, a term made use of by Helmont, to signify, in general, a spirit incapable of coagulation, such as proceeds from fermented wine.

In particular, it has various significations; thus, gas vitale, is the spirit of our life, the light and the balsam, which preserves from corruption. The gas pingue sulphureum is what is suddenly mortal, being lethiferous exhalations arising principally in caves and mines. Gas sulphuris, the gas or spirit of sulphur, is made by burning sulphur under a glass bell set over a vessel of water, till the water is sufficiently impregnated with the sulphur. The gas sylvestre is that invisible and incoercible spirit which arises from vegetable juices under fermentation. Helmont makes several other distinctions of gas; as the gas ventosum, which is mere air; the gas siccum, which is sublimate de flatibus; the gas salium, and the gas fructuum, which are mere elementary water.

**GASE-HOUND**, or **GAZE-HOUND**. See the article **GAZE-HOUND**.

**GAZCOIN**, or **GASCOIGN**, denotes the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

**GASCONY**, the most south-west province of France, bounded by Guienne, on the north; by Languedoc, on the east; by the Pyrenees, which separate it from Spain, on the south; and by the bay of Biscay on the west.

The inhabitants of this province are remarkable for vaunting and pretending to improbabilities; whence the like pretence, in others, is called a gasconade.

**GASKOIN**, or **GASCOIN**. See **GASCOIN**. **GASSENHOVEN**, or **GUTZENHOVEN**, a town of the Austrian Netherlands, fifteen miles east of Louvain: east long. 5°, and north lat. 50° 55'.

**GAS-**

**GASTALDUS**, or **CASTALDUS**, an officer antiently entertained in the courts of divers princes.

The *gastaldus* was what in Italy and Spain is now called *major domo*, or the master or steward of an household. The *gastaldus* was a comes or count, which shews his office to have been very considerable.

In the laws of Italy we sometimes met with a *gastaldus* in the sense of a carrier, and sometimes as an ecclesiastical officer.

**GASTEROSTEUS**, in ichthyology, a genus of acanthopterygious fishes, distinguished by having only three small bones in the branchiostegæ membrane, and the belly almost entirely covered with oblong bony laminae.

To this genus belong the common stickle-back, the lesser stickle-back, and the great stickle-back. See the article **STICKLE-BACK**.

**GAST-HOUND**, or **GAZE-HOUND**. See the article **GAZE-HOUND**.

**GASTRO-EPIPLOIC VEIN**, a vein that opens into the *vena portæ*. See **VEIN**.

**GASTRIC**, in general, something belonging to the stomach. See **STOMACH**.

**GASTRIC JUICE**, *gastricus succus*, among physicians, a thin, pellucid, spumous, and saltish liquor, which continually distills from the glands of the stomach, for the dilution of the food. See **FOOD**.

**GASTRIC VESSELS**, in anatomy, the arteries and veins of the stomach. See the articles **ARTERY** and **VEIN**.

**GASTRILOQUUS**, the same with *ventriloquus*. See **VENTRILOQUUS**.

**GASTROCNEMIUS**, in anatomy, the name of two thick, pretty broad, and oblong muscles, which form a great part of what is called the calf of the leg. They are situated laterally with respect to each other, under the poples.

**GASTROCNEMIUS** is also the name of one of the extensor-muscles of the foot.

**GASTROMANCY**, *γαστρομαντεία*, a method of divination by water, practised by the antient Greeks in the following manner. They filled certain round glasses with fair water, about which they placed lighted torches: then invoked a dæmon, praying in a low, murmuring voice, and proposed the question to be solved. A chaste and unpolluted boy, or a woman big with child, was appointed to observe with great care and exactness, all the alteration in the glasses; at the same time desiring, beseeching, and com-

manding an answer; which, at length, the dæmon used to return by images in the glasses; which, by reflexion from the water, represented what should come to pass.

**GASTRORAPHY**, *γαστροραφία*, in surgery, the operation of sowing up wounds of the abdomen. See **ABDOMEN**.

There are two cases in which this operation is absolutely necessary; the first is, where the wound is so large, that there is no possibility of retaining the intestines by any other method; for as the intestines are continually pushed forward in the act of inspiration, by the action of the diaphragm and the abdomen, the falling down of the intestines in this case is unavoidable, and therefore the operation is necessary. The other is in large transverse wounds of the abdomen, where the muscles are divided, but the peritonæum is not concerned.

In wounds of the abdomen the chief inquiry is, whether the omentum or intestines are let out. If none of these have burst through the wound, the lips of the wound must be kept as close together as possible with the hands, and the patient kept with his head lying downwards, till the wound is sufficiently secured from letting out the contents of the abdomen. But when the intestines are already fallen out, they must be returned with the greatest expedition, lest they should receive any injuries from the external air. It is first to be examined, however, whether they have received any wound, or not; and whether they preserve their natural warmth and colour: for where they are cold, livid, dry, or wounded, they are not to be returned suddenly, but fomented with warm milk and water, or wraped up for some time in the cawl of some animal newly killed, till they have in some degree recovered their natural heat and colour.

You will easily perceive, that there is some hurt in the intestines, though the wound does not immediately appear, if there is a more than ordinary flaccidity in them; in which case, the rest of the intestines must be pulled gently forward till you find the wound. See the article **INTESTINES**.

If nothing of this sort is the case, but the intestines are in their natural state and condition, they must be instantly returned in the following manner. The patient being placed in a supine posture, and laid on that side that is opposite to

the wound, the intestine must be returned by the aperture of the wound, with the two fore fingers; taking care never to take off one finger, till the other is on the gut. The patient is all the while to hold his breath, and the lips of the wound must be then brought together. If the intestines have been forced through a small wound, and are afterwards distended with wind, that they cannot easily be returned, it is necessary to pull the intestine gently forward, that more of it may come out, and the wind take up less room in any one part. An assistant should then gently dilate the wound as far as may be, either with his hand, or with two hooks fixed in the internal membrane, while the surgeon returns the intestines. When this is done, the wound must be secured first with the hand, and then with the proper dressings; and, in this case, the surgeon may avoid the use of this painful operation. But if the wound is so narrow, that the gut can neither be reduced nor pulled forward, the aperture must be enlarged with the knife.

The operation of gastrotomy, when found necessary, may be performed in the following manner; first pass a strong double, or quadruple thread well waxed through two crooked needles, and with these stitch up both ends of the wound, beginning at one end with the upper lip of the wound, passing the needle thro' the peritonæum, muscles of the abdomen, and the common integuments, from within outwards, leaving only the breadth of a thumb between the stitches, and the mouth of the wound, observing the same method in passing the other needle thro' the lower lip; and, while you are passing the needle with one hand, it will be proper to support the lips of the wound with the other, to prevent the intestines from being wounded. In a wound of two fingers-breadth, one stitch in the middle will be sufficient; but in larger wounds the stitches must be repeated in proportion to their size, leaving a thumb's breadth between each of the sutures, the extremities of the thread are to be left hanging down on each side; and when the suture is finished, while an assistant holds the lips of the wound together, these ends are to be tied in knots, in the following manner. Both ends of the threads are to be taken up, and to be tied in a double knot, passing a small

bolster between the two knots, to prevent the skin from being hurt. Where there are more sutures than one, you must begin at the upper part of the wound, tying them down in order; that before the last is tied, a soft tent of the size of a finger, with a thread fastened to the end of it, may be introduced into the lower part of the wound. This tent will keep a passage open for the evacuation of grumous blood, or matter, which may be collected in the cavity of the abdomen. The wound, when all this is done, must be anointed with some vulnerary balsam, and covered with pledgits of lint, a sticking plaster, and bolsters, securing all with the scapulary bandage.

**GASTROTOMY**, γαστροτομία, in surgery, the cutting open the abdomen and uterus, as in the cæsarian section. See the article CÆSARIAN.

**GATE**, in architecture, a large door, leading, or giving entrance into a city, town, castle, palace, or other considerable building: or a place giving passage to persons, horses, coaches, or waggons, &c. As to their proportion, the principal gates for entrance through which coaches and waggons are to pass, ought never to be less than seven feet in breadth, nor more than twelve, which last dimension is fit only for large buildings. The height of a gate is to be  $1\frac{1}{2}$  of the breadth, and somewhat more; but as for common gates in inns, under which waggons go loaded with hay, straw, &c. the height of them may be twice their breadth.

**Paired GATES**, such as are set up in fences for shutting up the passages into fields, and other inclosures.

These are of two sorts, either of sawed or cleft timber.

**Opening of the GATES** in astrology. See the article OPENING.

**GATE**, in the manege, the going or pace of a horse.

**GATE of the sea**, or **SEA-GATE**, in the sea-language. When two ships are aboard one another, by means of a wave or billow, it is usual to say they are aboard one another in a sea-gate.

**GATE**, in geography, a chain of mountains that run through the middle of the hither Peninsula of India, from south to north.

**GATHER**, in the sea-language, is said of a ship that gets the wind of another.

**GATTON**

**GATTON**, a borough town of Surry, sixteen miles south of London, which sends two members to parliament.

**GAVALI**, a name by which *bdellium* is sometimes called. See *BDELLIUM*.

**GAVEL**, or **GABLE**, among builders. See the article **GABLE**.

**GAVELET**, in law, an antient and special cessavit used in Kent, where the custom of gavel-kind continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his lands and tenements.

In respect to this gavellet the lord was to seek by award of his court from three weeks to three weeks, to find some distress upon the lands, until the fourth court; and if in that time he could find no distress on the premises whereby he might have justice of his tenant; then, at the fourth court, it was awarded, that the lord should take the lands, &c. into his hands, in the name of a distress, and keep it a year and a day without manuring, in which space of time, if the tenant did not come and pay his arrearages, and make the lord amends, then the lord was to go to the next county-court with his witnesses of his own court, and pronounce there the process; after which, by the award of his court, he became intitled to enter and manure those lands or tenements as his own. And if the tenant wanted to re-enjoy his lands, &c. as he did before, he was then obliged to make agreement with the lord for the same.

**GAVELET**, in London, is a writ used in the hustings, given to lords of rents in the city of London.

**GAVELKIND**, a tenure or custom belonging to lands in the county of Kent, by which the lands of the father are, at his death, equally divided among all his sons; or the land of a deceased brother, in case he leaves no issue, among all the brethren. This is by some called antient socage-tenure: the custom came from our saxon ancestors, among whom the inheritance of lands did not descend to the eldest, but to all the sons alike; and the reason why it was retained in Kent is, because the kentish men were not conquered by the Normans in the time of William I.

The particular customs attending this tenure are, that the heir, at the age of fifteen, may give or sell his lands in gavelkind; and tho' the father is attainted of treason and felony, and suffers

death, the son shall inherit. A wife shall be endowed of a moiety of the gavelkind-lands, of which her husband died seised, during her widowhood. Likewise a husband may be tenant by curtesy of half his wife's lands, without having any issue by her; but if he marries again, not having issue, he forfeits his tenancy.

**GAVELMAN**, a tenant liable to pay tribute.

**GAVELMED**, the duty of mowing grass, required by the lord of his customary tenants.

**GAVELCESTER**, the same with **Tolcester**. See the article **TOLCESTER**.

**GAVEREN**, or **WAVEREN**, a town of the Austrian Netherlands, situated on the east-bank of the river Scheld: east long.  $3^{\circ} 35'$ , north lat.  $51^{\circ}$ .

**GAUGE**, or **GAGE**. See **GAGE**.

**GAUGE-LINE**, on the gauging-rod. See the article **GAUGING**.

**GAUGE-POINT**, of a solid measure, the diameter of a circle, whose area is equal to the solid content of the same measure. Thus, the solidity of a wine-gallon being 231 cubic inches, if you conceive a circle to contain so many inches, the diameter of it will be 17.15; and that will be the gauge-point of wine-measure. And an ale-gallon, containing 282 cubic inches, by the same rule, the gauge-point for ale-measure will be found to be 19.15. After the same manner, may the gauge-point of any foreign measure be obtained; and from hence may be drawn this consequence, that when the diameter of a cylinder, in inches, is equal to the gauge-point of any measure, given likewise in inches, every inch in length thereof will contain an integer of the same measure, *e. gr.* in a cylinder whose diameter is 17.15 inches, every inch in height contains one entire gallon in wine measure; and in another, whose diameter is 18.95 inches, every inch in length contains one ale-gallon.

**GAUGER**, a king's officer, who is appointed to examine all tuns, pipes, hog-heads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

There are divers statutes that mention this officer and his office; as by 27 Ed. III. c. 8. all wines, &c. imported are to be gauged by the king's gaugers, or their deputies, otherwise they shall be forfeited, or their value; and on default  
of

of the gauger, that he be not ready to do his office when required, or that he defrauds in doing his office to the damage of the buyer or seller, he shall pay the party grieved his treble damage, lose his office, be punished by imprisonment, and be ransomed at the king's will : and in case less be found in the tun or pipe than ought to be, the value of as much as shall lack, shall be deducted in the payment.

Every gauger shall truly, within the limits of his office, gauge all tuns, butts, pipes, tierces, puncheons, tertians, hogheads, barrels, and rundlets; and mark on the head of every vessel the contents, upon pain to forfeit to the party to whose use the wine, &c. shall be sold, four times the value of that which the vessel marked shall lack of his content : the same forfeiture shall be recovered by an original writ, &c. and every person selling the wine, &c. in the vessel marked, shall allow of the price, the value of the lack of gauge, or default of filling, upon pain of forfeiture to the buyer, double the value, to be recovered with costs as before. No brewer shall put to sale any beer or ale in vessels brought from beyond the sea, within the city of London, or suburbs of the same, or within two miles compass without the suburbs, before the same be gauged, and the true content of every such vessel set upon the same, by the gallon appointed for beer and ale, according to the standard, by the master and wardens of the coopers of London.

**GAUGING**, the art or act of measuring the capacities or contents of all kinds of vessels, and determining the quantities of fluids or other matters contained therein.

The art of gauging is that branch of the mathematics called stereometry, or the measuring of solids ; because the capacities of all sorts of vessels used for liquors, as cubical, parallelopipedal, cylindrical, spheroidal, conical, &c. are computed as though they were really solid bodies, and reduced thereby to some known cubic measure, as gallons, quarts, pints, &c. The principal vessels that come under its operation are pipes, barrels, rundlets, and other casks ; also backs, coolers, vats, &c.

The solid content of cubical, parallelopipedal, and prismatical vessels is easily found in cubic inches, or the like, by multiplying the area of the base by the perpendicular height. And for cylindri-

cal vessels, the same is found by multiplying the area of the base by the perpendicular altitude as before. See the articles CUBE, PARALLELOPIPED, &c.

Casks of the usual form of hogheads, kilderkins, &c. may be considered as segments of a spheroid cut off by two planes, perpendicular to the axis ; which brings them to Oughtred's theorem for measuring ale and wine-casks, which is thus : add twice the area of the circle at the bung, to the area of the circle of the head ; multiply the sum by one third of the length of the cask, the product is the content of the vessel in cubic inches.

But for accuracy, Dr. Wallis, Mr. Caswell, and others, think that most of our casks had better be considered as frustums of parabolic spindles, which are less than the frustums of spheroids of the same base and height, and give the capacity of vessels nearer the truth than either Oughtred's method, which supposes them spheroids ; or than that of multiplying the circles of the bung and head, into half the length of the cask, which supposes them parabolic conoids ; or than that of Clavius, &c. who takes them for two truncated cones, which is farthest off of all.

The common rule for all wine or ale-casks, is to take the diameters at the bung and at the head, by which you may find the area of the circle there ; then taking two thirds of the area of the circle at the bung, and one third of the area of the circle at the head, and adding them together into one sum ; this sum multiplied by the internal length of the cask, gives the content in solid inches ; which are converted into gallons by dividing by 282 for ale, and 231 for wine-gallons.

But gauging, as now practised, is chiefly done by means of instruments called gauging-rods or rulers, which do the business as once, and answers the question without so much calculation, which is no inconsiderable addition both to the ease and dispatch of the work, though it is not so much to be depended on.

The methods of gauging which are mostly used, is by the four-foot gauging-rod and Everard's sliding ruler : the description and uses of both are as follows :

*The four-foot GAUGING-ROD* (plate CXI. fig. 5.) is usually made of box, and consists of four rules, each a foot long, and about three eighths of an inch square, joined together by three brass-joints ; by which means the rod is rendered four feet long

long when the four rules are opened, and but one foot when all are folded together. On the first face of this rod, marked 4, are placed two diagonal lines, one for beer and the other for wine; by means of which the content of any common vessel in beer or wine-gallons, may be readily found, by putting the brafed end of the gauging-rod into the bung-hole of the cask, with the diagonal lines upwards, and thrust this brafed end to the meeting of the head and staves; then with chalk make a mark at the middle of the bung-hole of the vessel, and also on the diagonal lines of the rod, right against or over one another, when the brafed end is thrust home to the head and staves; then turn the gauging-rod to the other end of the vessel, and thrust the brafed end home to the end as before. Lastly, see if the mark made on the gauging-rod, come even with the mark made on the bung-hole, when the rod was thrust to the other end; which if it be, the mark made on the diagonal lines, will, on the same lines, shew the whole content of the cask in beer or wine-gallons. If the mark made on the bung-hole be not right against that made on the rod, when you put it the other way, then right against the mark made on the bung-hole, make another on the diagonal lines; and the division on the diagonal line, between the two chalks, will shew the whole content of the vessel in beer or wine-gallons. Thus, *e. gr.* if the diagonal line of a vessel be  $28\frac{4}{5}$  inches, its content in beer-gallons will be nearly 51, and in wine-gallons 62.

If a vessel be open, as a half barrel, tun, or copper, and the measure from the middle on one side to the head and staves be 38 inches, the diagonal line gives 122 beer-gallons; half of which, *viz.* 61, is the content of the half tub.

If you have a large vessel, as a tun or copper, and the diagonal line taken by a long rule be 70 inches; then every inch at the beginning-end of the diagonal line call 10 inches: thus 10 inches become 100 inches; and every tenth of a gallon call 100 gallons; and every whole gallon call 1000 gallons.

On the second face, 5, are a line of inches and the gauge-line, which is a line expressing the areas of circles (whose diameters are the correspondent inches) in ale-gallons: at the beginning is wrote *Ale-area*. Thus, to find the content of any cylindrical vessel in ale-gallons; seek the

diameter of the vessel in inches, and just against it, on the gauge-line, is the quantity of ale-gallons contained at one inch deep; this multiplied by the length of the cylinder, will give its contents in ale-gallons.

On the third face, 6, are three scales of lines; the first, at the end of which is written *Hoghead*, is for finding how many gallons there are in a hoghead, when it is not full, lying with its axis parallel to the horizon. The second line, at the end of which is written *B. L.* is for the same purpose. The third is to find how much liquor is wanting to fill up a butt, when it is standing; at the end of it is wrote *B. S.* signifying, *butt standing*.

Half way the fourth face of the gauging-rod, 7, there are three scales of lines, to find the wants in a firkin, kilderkin, and barrel, lying with their axes parallel to the horizon. They are distinguished by the letters *F. K. B.* signifying a firkin, kilderkin, and barrel.

The use of the lines on the two last faces is very easy; you have only to put it downright into the bung-hole to the opposite staves, if the vessel, you want to know the quantity of ale-gallons contained therein, be lying; and then where the surface of the liquor cuts any one of the lines appropriated to that vessel, will be the number required.

*Everard's sliding-rule* is principally used in gauging, being ordinarily made of box, a foot long, an inch broad, and  $1\frac{5}{16}$  inch thick, with two small scales to slide in it, which may be drawn out, one towards the right hand, and the other towards the left, till the whole be 3 feet long. See plate CXII.

The principal lines on the instrument are those commonly known by the name of Gunter's line, or Line of numbers, which are here distinguished one from another by certain letters, set at the end of the lines, towards the right hand: thus the lines D are each of them one single line of numbers, beginning at the end of the rule towards the left hand, and from thence continued to the other end. The lines A, B, and C, are called double numbers, each being two lines or radiuses of numbers; the line E is called triple numbers, being three radiuses of numbers: this triple line is equal in length to the double lines, and all to the single line; for all the five begin and end at the same point. On the line A are four brass center-pins, two in each radius; one in each of which

which is marked M B. to signify that the number it is set against, 2150.42, is the cubic inches in a malt-bushel. The other two are marked with A. to signify that the numbers they are set against, 282, are the cubic inches in an ale-gallon. Close to the figure 7, in the first radius on the same line, is a dot marked *f*.i. set exactly over .707, denoting .707 to be the side of a square inscribed in a circle, whose diameter is unity. Close to 9 is another dot, marked *f*e. set over .886, which is the side of a square, equal to the area of a circle, whose diameter is unity. Another dot nigh W, is set over 231, the cubic inches in a wine-gallon; and another near C, is set over 3.141592, the circumference of a circle, whose diameter is unity. The line marked M D. to signify *malt-depth*, is no more than a line of numbers in a reverse order, the number 1 being set directly against M. B. on the first radius, and is of exceeding great use in casting up of malt-gauges.

On the line D. there are four center-pins, the first, marked W G. is the gauge-point of a wine-gallon, *i. e.* the diameter of a cylinder whose height is 1 inch, and content 231 cubic inches, or a wine-gallon, which is 17.15 inches. The second center-pin, marked A G. stands at the gauge-point for an ale-gallon, which is 18.95 inches. The third, M S. stands at 46.3, the side of a square, whose content is equal to the inches of a solid bushel. The fourth, M R. is the gauge-point for a malt-bushel, which is 52.32 inches. The two lines of segments are each numbered from 1, 2, &c. to 100: the first is for finding the ullage of a cask taken as the middle frustum of a spheroid, lying with its axis parallel to the horizon: and the second for finding the ullage of a cask standing.

Again, on one of the narrow sides, noted *e*, are, 1°. a line of inches, numbered 1, 2, 3, &c. to 12, each subdivided into 10 equal parts. 2°. A line, by which, with that of inches, we find a mean diameter for a cask, in the figure of a middle frustum of a spheroid. 3°. A line for finding the mean diameter of a cask in the figure of the middle frustum of a parabolic spindle, which gaugers call the second variety of casks. 4°. One for the third variety, which is of a cask in the figure of two parabolic conoids abutting on a common base.

On the other narrow face, marked *f*. are, 1°. A foot, divided into 100 equal parts,

marked F M. 2°. A line of inches, noted I M. 3°. A line F C. for finding the mean diameter of the fourth variety of casks, which is the middle frustum of two cones, abutting on a common base.

On the backside of the sliding-piece is a line of inches from 13 to 36, when the two pieces are put endwise; and against that, the correspondent gallons, or hundred parts, that any small or like open vessel, from 13 to 36 inches diameter, will contain at one inch deep.

*The uses of the sliding-rule in some parts of arithmetic.*

Problem I. Having two numbers given, to find a third geometrically proportional unto them; and to three, a fourth; and to four, a fifth, &c.

Find one of the numbers given, upon the line B, and set it against the other given number, on the line A; then find the same number on B (which was last counted) upon A; and against this third upon B, is the fourth on A. In like manner, against the fourth on B, you have the fifth on A, &c.

Example. Let it be required to find a third proportional to these two numbers, 2 and 4, which may bear the same proportion to 4, that 4 does to 2?

Draw out the sliding-rod, till 2 upon B stand against 4 upon A; then against 4 upon B, is 8 (the third proportional) upon A; and against this third (*viz.* 8) upon B, is 16 upon A, which is the fourth proportional, &c. Contrariwise, if it were required to find a third proportional to the same numbers, 2 and 4, which may bear the same proportion to 2, that 2 bears to 4? Set 4 in the second radius upon A, to 2 upon B; then against 2 upon A (towards the left hand) is 1, the third proportional; and against 1 upon A, is .5, the fourth upon B: also against this fourth upon A, is .25, the fifth proportional on B, &c.

Problem II. One number being given to be multiplied by another, to find the product. In multiplication, either of whole numbers, mixed or decimal fractions, the proportion is, As 1: the multiplicator:: the multiplicand: the product.

Example. Let it be required to multiply 6 by 4. The proportion then is as 1: 4:: 6: 24. Therefore set 1 upon the line B, to 4 upon the line A; then against 6 upon B, is 24, the product sought, upon A.

*Opposite each*

**Problem III.** One number being given to be divided by another, to find the quotient. In division, both of whole numbers and mixed, the proportion is, as the divisor is to 1, so is the dividend to the quotient.

**Example.** Let it be required to divide 24 by 4, the proportion is, as 4:1::24:6. Therefore set 4 upon B, to 1 upon A; and then against 24 upon B, is 6 upon A, which is the quotient sought.

**Problem IV.** Three numbers being given, to find a fourth in direct proportion.

**Rule.** Set the first number given upon B, to the second upon A, and then against the third number given upon B, is the fourth number sought upon A.

**Example.** If 8 quarters of malt will make 20 barrels of small beer, how many barrels of such beer will 22 quarters make?

Set 8 upon B, to 20 upon A; and then against 22 upon B, is 55 upon A; and so many barrels will 22 quarters make.

**Problem V.** To three numbers given, to find a fourth in an inverted proportion.

**Rule.** Set the third number upon A, to the first (being of the same denomination) upon B; and then against the second number upon A, you have the fourth upon B.

**Example.** If 8 men do any piece of work in 9 days, in how many days can 12 men do the same work?

Set 12 upon A, to 8 upon B; then against 9 upon A, is 6 upon B, which is the answer. For 12 men may do the same work in 6 days, which 8 men will do in 9 days.

**Problem VI.** Betwixt two numbers given to find a mean geometrical proportional.

**Rule.** Set one of the numbers given upon C, to the same number upon D; and then against the other given upon C, is the geometrical mean sought upon D.

**Example.** Let the numbers given be 50 and 72, to find a geometrical mean, &c.

Set 50 upon C, to 50 upon D; and then against 72 upon C, is 60 upon D; so 60 is the geometrical mean betwixt 50 and 72. Or thus, set 72 upon C, to 72 upon D; and then against 50 upon C, is 60 upon D, the mean as before.

To find the square or cube roots of any number, let the lines C and D for the first, and D and E for the second, be applied to one another, so that 10 at the end of D be even with 10 at the end of C; and 10 at the end of D be even with 10 at the end of E; the lines in this case

are like a table, shewing the square or cube roots of any number by inspection; for against any number upon C, you have the square root thereof upon D; and against any number upon E, you have the cube root thereof upon D: &c. *contra*.

*The use of the rule in measuring superficies: and first of a circle.*

**Problem I.** The diameter or circumference of a circle, either being given, to find the other. The circumference of that circle whose diameter is unity, is 3.1415926536; but for practice, the four first figures are sufficient; therefore, as 1:3.1415::the diameter of any circle to its circumference. By the rule thus, set 1 on the line A, against 3.1415 on B; then against any diameter on the line A, you have the circumference on B: &c. *contra*.

Against	$\left\{ \begin{array}{l} 20 \\ 30 \\ 40 \\ 50 \end{array} \right\}$	you have these circumferences	62.851
			94.247
			125.663
			157.079

Or contrariwise against these circumferences	$\left\{ \begin{array}{l} 20 \\ 30 \\ 40 \\ 50 \end{array} \right\}$	you have these diameters	6.366
			9.549
			12.732
			15.915

**Problem II.** The diameter of any circle being given, to find the area (or any part thereof) in inches, or in ale or wine-gallons. 1. For the whole area in inches.

The area of a circle is equal to the product, or rectangle, of half the diameter into half the circumference; that is, if half the diameter be multiplied by half the circumference, the product will be the area: thus, when the diameter is 1, the circumference is 3.1415, the half of which is 1.5707, which multiplied by half the diameter (*viz.* .5) the product will be the area of that circle, whose diameter is 1, *viz.* .785398.

The areas of all circles are in proportion one to another, as the squares of their diameters: therefore, as the square of the diameter of any circle is to the area of that circle, so is the square of the diameter of any other circle to the area thereof. Now as the square of 1 is but 1, is must be as 1:1.785398::square of the diameter of any circle to the area thereof. So .785398 is a fixed multiplier; and if an unit with cyphers be divided by .785398, the quotient will be 1.27324, a fixed divisor: and by either of these numbers may the area of any circle be found, either by multiplication or division. For if the squares of any diameter be multiplied or divided by these

numbers, the product or quotient will be the area in inches, feet, or yards, according as the diameter was measured in inches, feet, &c.

But with more expedition by the rule. Set 1 upon the line D, to .785398 upon C. The rule being thus set, the lines are like a table of circles, areas to all diameters; for against any diameter upon the line D, you have the area thereof upon C. Thus if the diameter is 20, the area is 314.159; if it is 25, the area is 490.87 inches. And on the contrary if the area is 300, the diameter is 19.54; if 400, the diameter is 22.56 inches.

The area in inches divided by 282, the cubic inches in an ale-gallon, or by 231 for wine-gallons, gives the area for either respectively; or you may use any other divisor, according to the measure you want. But without knowing the inches contained in any area, the area in gallons may be found thus: divide .785398 by 282, the quotient will be .0027851 ale-gallons; or by 231, if for wine-gallons, and it gives .0033999. These numbers are the areas of circles in ale and wine-gallons, whose diameters are 1; and are fixed multipliers for finding the area of all circles in either of these measures; for if the square of the diameter of any circle be multiplied by either of these numbers, the product is the area in ale or wine-gallons respectively. If you would effect this by division, the several divisors are thus found: multiply the divisor for finding the area in inches, *viz.* 1.27324, by 282, or 231, the products 359.05 for ale-gallons, and 294.11 for wine-gallons, are the divisors sought. And the square of the diameter of any circle divided by one of these, gives the respective area.

But the area of any circle may be more readily found by the help of fixed numbers, called gauge-points; and these numbers are the diameters of those circles whose content, at 1 inch deep, is equal to the respective gallon to which they belong. They are the square roots of the divisions last mentioned, that for A. G. 18.95, for W. G. 17.15, on the rule: thus, set 18.95 (the gauge-point for ale-gallons) upon D, to 1 upon C; then against any diameter upon D, you have the area upon C. The like for wine-gallons, by the proper gauge-point. Note, when the area of any circle is sought in ale-gallons, if the diameter be more than 18.95 and less than 100, set the gauge-

point upon D, to 1 at the beginning of C. Or when the diameter is less than the gauge-point, or more than 100, then set the gauge-point to 1, in the middle upon C. Lastly, to find any part of the area, set the gauge-point to  $\frac{1}{2}$ , or  $\frac{1}{3}$ , or any other part of 1, then against the diameter you have the like part of the area.

From what has been said, it will not be difficult to use the rule in gauging the areas of all right-lined figures; and when the area is found, the solidity is easily obtained. Thus, for example, the diameter, depth, and content of any cylindrical tun, any two being given, to find the third. In this problem are three questions, all resolved at once setting the rule: 1. By the depth and content to find the diameter. Example. Suppose the depth 40 inches, and the content 1800 ale-gallons, what is the diameter?

Set 40, the depth, upon C, to the gauge-point upon D; then against 1800, the content, upon C, is 127.1 inches, the diameter sought.

2. By the diameter and content, to find the depth, without moving the rule: say As 127.1, the diameter, is to 1800, the content; so is the gauge-point to 40, the depth,

$\left. \begin{array}{l} \text{D} \\ \text{C} \\ \text{D} \\ \text{C} \end{array} \right\} \text{upon}$

3. By the depth and diameter, to find the content, the rule standing as before: say, As the gauge-point is to 40, the depth, so is 127.1, the diameter, to 1800, the content,

$\left. \begin{array}{l} \text{D} \\ \text{C} \\ \text{D} \\ \text{C} \end{array} \right\} \text{upon}$

Note, as a circle is the base of a cylinder, so a triangle, quadrangle, or any other plane superficies, may represent the base of a prism: for if there be planes erected perpendicularly upon the lines which encompass any such superficies, they will generate a solid, which may be called a prism; and the content of any such solid is found by multiplying the area of the base by the altitude, or distance from one base to another.

*The use of the rule in GAUGING of malt.* The duty upon malt is charged upon the bushel, and so proportionably for greater or lesser quantities. The bushel here intended is the winchester-bushel, which contains 2150.42 solid inches, but 2150 will be near enough for practice.

If the area in inches, of any plane figure, be divided by 2150, the quotient shews the bushels and parts of a bushel, which such a figure or vessel contains at

one inch deep. Example. There is a cistern or vat, whose base is a rectangular parallelogram, the length is 72 inches, and the breadth 48 inches, what is the area, at 1 inch deep? Answ. 1.607, that is, 1 bushel and .607 thousand parts of a bushel; For 72 multiplied by 48, is 3456; and this divided by 2150, gives 1.607. But the area of any figure may be more readily found by the lines A and B, upon the rule: thus, as 2150 upon A, is to one of the sides upon B; so is the other side upon A, to the area upon B: so in the example above, set 2150 upon A, to 72 upon B; then against 48 upon A, is 1.607 upon B. Or set 2150 upon A, to 48 upon B; then against 72 upon A, is 1.607 upon B.

The area thus found, being multiplied by the mean depth in inches, gives the content of such a cistern at that depth and so for any quantity of malt upon the floor; but care must be taken in finding the mean depth of any quantity of malt, either in the cistern or upon the floor, by reason of the unevenness of the surface of the malt, and of the bottom of the cistern or floor upon which it was laid; in order to which, take the depth in 6, 8, or 10 places; and add all these depths together, and divide the sum by the number of places in which the depths were taken, the quotient will be the mean depth required. Barley is sometimes steeped in round vessels, and the area of a circle in bushels is thus found: take the diameter in inches; and let the square thereof be multiplied by .0003653, or divided by 2737.47, the product or quotient will be the area sought.

Example. Suppose the diameter of any vessel be 60 inches, this squared is 3600, and this multiplied by .0003653, or divided by 2737.47, gives 1.315, the area required.

But for any round vessel, the rule gives the area in bushels by inspection, by help of a certain number called the gauge-point, which in this case is 52.32 (being the diameter of a circle, whose area is 2150, the solid inches in a bushel). Thus in the example above, the diameter was 60 inches, therefore set the gauge-point (*viz.* 52.32) upon D, to 1 upon C; then against 60 upon D, is 1.315, the area upon C. And the rule being thus set against any diameter upon D, you have the area upon C.

But a cistern, couch, or floor-gauge may

be more speedily and expeditiously cast up by the line M D, signifying malt depth. On this line always find the depth of the cistern, couch, or floor; then say, as the depth upon the line M D, is to the length or breadth upon B, so is the length or breadth upon A, to the content in malt-bushels upon B. Example. Admit a floor whose length is 160, breadth 132, and depth 8.1 inches, what is the content in malt-bushels?

Operation by the rule.

Set the depth 8.1 on M D, to the length 160 on the line B; then against the breadth 132 upon A, you have 79.5 upon B, the content in malt-bushels. Thus,

M D.	B.	A.	B.
as 8.1 :	160 ::	132 :	79.5
Depth. Length. Breadth. Content.			

Or thus:

M D.	B.	A.	B.
as 8.1 :	132 ::	160 :	79.5
Depth. Breadth. Length. Content.			

GAULE, in botany, the same with myrica. See the article MYRICA.

GAUNT-BELLIED, in the manege, is said of a horse whose belly shrinks up towards his flanks.

GAUNTLET, or GANTLET. See the article GANTLET.

GAVOTTA, or GAVOTTE, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains are played twice over. the first has usually four or eight bars, and the second contains eight, twelve, or more. The first begins with a minim, or two crotchets, or notes of equal value, and the hand rising; and ends with the fall of the hand upon the dominant or mediant of the mode, but never upon the final, unless it be a rondeau: and the last begins with the rise of the hand, and ends with the fall upon the final of the mode. See RONDEAU, DOMINANT, &c.

*Tempi di* GAVOTTA is when only the time or movement of a gavotte is imitated, without any regard to the measure, or number of bars or strains.

Little airs are often found in sonatas, which have this phrase to regulate their motions.

GAURS, in matters of religion, an ancient sect of the magicians in Persia. They have a suburb at Ispahan, which is called Gaurabad, or the town of the gaurs, where they are employed only in the meanest and vilest drudgery: but they chiefly abound in kerman, the barrenest province

vince in all Persia, where the mahometans suffer them to live with some freedom, and in the full exercise of their religion. Some years ago many of them fled into India, where their posterity remain to this day.

They are a poor harmless sort of people, zealous in their superstition, rigorous in their morals, and exact in their dealings: they profess the worship of one God alone, the belief of a resurrection, and a future judgment, and utterly detest all idolatry, though the mahometans believe them to be the most guilty of it. It is true, they perform their worship before fire, for which they have an extraordinary veneration, as believing it to be the most perfect emblem of the deity. They have the same veneration for Zoroaster that the Jews have for Moses, esteeming him a prophet sent from God.

**GAWSE, or GAWZE**, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gawzes, and some with gold or silver flowers on a silk ground.

**GAZE-HOUND, or GAST-HOUND**, one that makes more use of his sight than of his nose. Such dogs are much used in the north of England: they are fitter in an open champain country, than in bushy and woody places. If at any time a well-taught gaze-hound takes a wrong way, he will return upon a signal and begin the chase afresh. He is also excellent at spying out the fattest of a herd, and having separated it from the rest, will never give over the pursuit till he has worried it to death.

**GAZELLA**, in zoology, the name of several species of goat: as, 1. The african gazella, called also antelope and dorcas lybica, the horns of which are cylindric and half way arched. 2. The indian gazella, or antelope, with very long, cylindric, and straight horns, annulated at the base. 3. Another species of african gazella, with cylindric, arched, and perfectly annulated horns. This last is a small, but very beautiful species, and greatly resembles the common deer in shape: the horns, which arise from the middle of the forehead, are of a beautiful black colour, and annulated all the way from the base to the very tips. See a figure of it in plate CXIII. fig. 1.

**GAZETTE**, a news-paper, or printed account of the transactions of all the countries in the known world, in a loose sheet or half sheet. This name is with us con-

fined to that paper of news published by authority.

The word is derived from gazetta, a venetian coin, which was the usual price of the first news-paper printed there, and which was afterwards given to the paper itself.

**GAZONS**, in fortification, pieces of fresh earth, covered with grass, and cut in form of a wedge, about a foot long and half a foot thick, to line the outides of works made of earth, as ramparts, parapets, &c. The first bed of 'gazons is fixed with pegs of wood; the second bed should be so laid as to bind the former, by being placed over its joints; and so continued till the works are finished. Betwixt these beds it is usual to sow all sorts of binding herbs, in order to strengthen the rampart.

**GEAR, or About your GEAR**, in the sea-language, a word of command to work on all hands.

**GEASTER**, a name given by Micheli to the lycoperdon. See LYCOPERDON.

**GED**, a bird otherwise called juddock. See the article JUDDOCK.

**GEERS, or CHAINS**, in country-affairs, the trappings and other harness belonging to draught-horses or oxen.

**GEESE**, in ornithology. See GOOSE.

**GEHENNA**, a term mentioned in several parts of scripture, which our english translators have rendered hell. See HELL.

**GELÆOPACHIA**, in natural history, a class of mineral inflammable fluids, of a thicker consistence, and opaque; such is pissasphaltum. See PISSASPHALTUM.

**GELÆOSPILA**, another class of inflammable mineral fluids, of a thinner consistence, and pellucid: such is naphtha. See the article NAPHTHA.

**GELATINOUS**, in pharmacy and medicine, any thing approaching to the glutinous consistence of a gelatina, or jelly. See the article JELLY.

**GELD**, in our old customs, a saxon word signifying money, or tribute: also a compensation for some crime committed. See the article GILD.

Hence wergeld, in our antient laws, was used for the value of a man slain; and orfgeld, of a beast. See ORFGELD.

**Foot-GELD**. See the article FOOT-GELD.

**Horn-GELD**. See the article HORN-GELD.

**Wood-GELD**. See WOOD-GELD.

**GELDABLE LANDS, &c.** See TAXABLE.

**GELDERLAND**, comprehending Zutphen, is a province of the united Netherlands, bounded by the Zuider-sea and Overysse on the north, by Westphalia on the

the east, by Brabant on the south, and by the province of Utrecht on the west.

**GELDER-ROSE**, the name by which some call the opulus, or water-elder.

**GELDING**, the operation of castrating any animal, particularly horses.

This operation consists in cutting out the testicles; in performing which, three things are to be observed: first, regard is to be had to their age; next, to the season of the year; and, lastly, to the state of the moon. For the first, if the operation is to be performed on a colt; he may be gelded at nine or at fifteen days old, if the testicles be come down, in regard the sooner he is gelt the better it will be for his growth, shape, and courage; though a horse may be gelt at any age, if proper care be taken in the cure. As for the second, the best time is about April or May, or else about the latter end of September. And for the third, the wane of the moon is the fittest time for performing this operation.

The manner of gelding is as follows: the beast being calt down on some soft place, the operator takes the stones between his foremost and his great finger, and slitting the cod, presses the stones forth; then taking a pair of nippers, made very smooth, either of steel, box, or brasil-wood, he claps the strings of the stones between them, very near to where the stones are set on, and presses them so hard, that there may be no flux of the blood; then, with a thin, drawing cauterizing iron, made red-hot, sears away the stone.

This done, he takes a hard plaster made of rosin, wax, and washed turpentine, well dissolved together, and melts it on the head of the strings: that being done, he sears them, and melts more of the salve, till such time as he has laid a good thickness of it upon the strings.

This being done to one stone, the nippers are loosened, and the like is done to the other; and the two slits of the cod are then filled with whitesalt, and the outside of the cod is anointed with hogs-grease; and thus they let him rise, and keep him in a warm stable, without tying him up.

If he swells much in his cods or sheath, they chase him up and down; and make him trot an hour in a day, and he soon recovers.

The manner of gelding a hog is as follows: the operator, after having made two cross slits, or incisions, on the midst

of the stones, presses them out, and anoints the sore with tar. But another more general method, yet somewhat more dangerous, if not well done, is first to cut the stone on the top, and after having drawn that one forth, the operator puts in his fingers at the same slit, and, with a lancet, cuts the skin between the two stones, and by that slit presses out the other stone. Then having cleansed out the blood, he anoints the part with fresh grease: and thus there is but one incision made in the cod. Boar-pigs ought to be gelt about six months old; yet they are commonly gelded about three weeks or a month old.

**GELDING of a lamb** may be performed from the age of three days to three weeks or more, in the following manner: one is to hold the lamb between his legs, or in his lap, and turn him on his back, holding his fore-feet upright together (but if any black spots are seen in his flank, he must not be cut at all), then the cutter holding the tip of the cod in his left hand, cuts the lap of it an inch quite away; which done, he, with the foremost fingers and thumbs of both hands, should softly slip down the cod over the stones, to the belly, and with his teeth, holding the left stone in his mouth, he draws it softly out the length of the string; after which he is to draw out the other stone in the same manner; then he spits in the cod, and anoints the lamb's flanks with fresh grease, and so lets him go, and keeps stirring him up and down for two or three hours.

**GELDRES**, a city of Gelderland, situated twenty-three miles south of Nimeguen: east longit.  $6^{\circ} 8'$ , and north lat.  $51^{\circ} 35'$ .

This city, with the territory about it, was yielded to the king of Prussia, by the treaty of Utrecht.

**GELLENHAUSEN**, an imperial city of Germany, governed by its own magistrates; it is situated nine miles north of Hanau: east longit.  $8^{\circ} 50'$ , and north lat.  $50^{\circ} 15'$ .

**GELOSCOPY**, a kind of divination drawn from laughter; or a method of knowing the qualities and character of a person, acquired from the consideration of his laughter.

**GEM, gemma**, in natural history, a common name for all precious stones, of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, pellucid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance, giving fire with steel, not fermenting with acid menstruums, and very difficultly calcinable in the fire. Of this class there are two genera, the chroastasma, and the chroastaces. See **CHROASTASIMA** and **CHROASTACES**.

The bodies composing the class of semipellucid gems, are stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter, debased by earth: however, they are but slightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

Of this class there are two orders: the first of which consists of the semipellucid gems, of but two variegations, and frequently of one plain, simple colour; tho' sometimes veined: this order contains four genera, *viz.* the sardæ, the chalcédonies, the hydrophanæ, and the pramnian. See the articles **SARDAE**, **CHALCEDANII**, **HYDROPHANÆ**, and **PRAMNION**.

The second order of semipellucid gems, consisting of those remarkable for their veins, zones, and variegations, contains also four genera, *viz.* the achatæ, the onyches, the sardoniches, and the cameæ. See the articles **ACHATÆ**, **ONYCHES**, **SARDONYCHES**, and **CAMEÆ**.

Many authors, not only among the ancients but the moderns, are full of the virtues and medicinal properties of precious stones; but their reputation, in this respect, is now not a little fallen. Yet as the fragments of such stones are still preserved by the physicians in some of the most celebrated compositions, as there are certain chemical preparations made of them, as several persons of the greatest candour and experience have related many considerable effects of certain gems, on their own particular observations, and, lastly, as it is no way improbable that some of the softer stones may have some considerable operations on the human body, it might be imprudent indiscriminately to exclude from them any medicinal virtue at all. When much the greater part of their traditional quali-

ties are set aside as fabulous, there will remain some on as real and well warranted a footing, as many of our other medicines.

On such considerations the excellent Mr. Boyle was induced to give us that extraordinary piece of the origin and virtues of gems, the purport whereof is to shew, that such stones were originally in a fluid state, or are made up of such substances as were formerly fluid; and that many of their general virtues are probably derived from the mixture of metalline and other mineral substances, usually incorporated with them; while the great variety and the particular efficacy of their virtues, arise from some happy concurrent substances of that commixture, *e. g.* the peculiar nature of the impregnating liquor, the proportion wherein it is mixed with the petrescent juice, and the like.

To support this hypothesis of the virtues of gems, he shews, that several of them are not simple concretions of any petrescent liquors, but consist also of other adventitious parts, which he argues from the separableness of such substances in some stones, the specific gravity in others, and the different tinctures to be met with in gems of the same species. There may, therefore, be in some gems numberless adventitious corpuscles; and there is reason to think, that some of these corpuscles may be endued with several properties and medicinal virtues.

The stress of what is objected to them is this: the mineral substances they contain are so closely locked up, that they can communicate nothing to the body, and so can have no medicinal operation; being unconquerable by so small a heat, as that of the stomach, and other parts of the body.

This objection might be plausible enough to prevent the ascribing any medicinal virtues to them, *a priori*, but can conclude nothing against what is warranted by so many facts and observations, especially when there are several particulars that obviate this objection. For a vigorous loadstone, though frequently harder than many gems, is known to emit copious effluvia; and there are many which have been found to have a manifest and inconvenient operation on the body, by being wore in the pocket, or long held in the hand.

“The hydrostatical ballance, says Mr. Boyle, is of prime use in discerning  
“genuine

“ genuine gems from counterfeits, which  
 “ but too often pass for true, to the  
 “ prejudice of physicians and their pa-  
 “ tients, and the loss of lapidaries: for  
 “ as there are, perhaps, no qualities of  
 “ bodies more essential than their pon-  
 “ derosity, so there is scarce any where-  
 “ in impostures find more difficulty to  
 “ make a notable alteration without be-  
 “ ing discovered.” See the article *HY-  
 DROSTATICAL BALANCE*.

*Imitation or counterfeiting of GEMS in glass.*

The art of imitating gems in glass, is too considerable to be passed without notice; some of the leading compositions therein, we shall briefly mention upon the authority of Neri. See *GLASS*.

These gems are made of pastes, and are no way inferior to the native stones, when carefully made and well polished, in brightness or transparency, but want their hardness. See the article *PASTE*.

The general rules to be observed in making the pastes, are these. 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work, as will bear the fire well. 3. That the powders be prepared on a porphyry-stone, not in a metal mortar, which would communicate a tinge to them. 4. That the just proportion in the quantity of the several ingredients be nicely observed. 5. That the materials be all well mixed, and if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot: for if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make paste of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty. Take of prepared crystal, ten pounds; salt of polverine, six pounds; sulphur of lead, two pounds; mix all these well together into a fine powder; make the whole with common water into a hard paste; and make this paste into small cakes, of about three ounces weight each, with a hole made in their middle; dry them in the sun; and afterwards calcine them in the straightest part of a potter's furnace. After this, powder them, and levigate them to a perfect fineness on a porphyry, and set this powder in pots in a glass-furnace to purify for three days: then cast

the whole into water, and afterwards return it into the furnace, where let it stand fifteen days, in which time all foulness and blisters will disappear; and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a sea-green, brass simply calcined to a redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in this by the same way of working as the making of coloured glasses; and this is so hard, that they very much approach the natural gems.

The colour of all the counterfeit gems made of the several pastes, may be made deeper or lighter, according to the work for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones, a paler: besides the colours made from manganese, verdigrease, and zaffer, which are the ingredients commonly used, there are other very fine ones which care and skill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron: a very fine green from brass or copper; a sky-colour from silver; and a much finer one, from the granates of Bohemia.

*GEMARA*, in Jewish antiquity, a collection of decisions and determinations on the law, wrote after the Mishna was completed.

It was called gemara, or perfection, because it was considered as so perfect an explication of the law, that after it no farther additions could be made, or any thing more desired. It is otherwise called the talmud. See *TALMUD*.

*GEMATRIA*, or *GEMATRIE*, in Jewish antiquity. See the article *CABBALA*.

*GEMBLOURS*, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Orne, ten miles north-west of Namur: east long. 4° 30', and north lat. 50° 30'.

*GEMELLES*, in heraldry. See the article *BAR-GEMEL*.

*GEMELLUS*, in anatomy, the name of two muscles, both of which are small, flat and narrow, and situated almost transversely one above the other, between the tuberosity of the ischium and the great trochanter, immediately below the pyramiformis, and parted by the tendon of the obturator internus.

The superior and smallest gemellus is fixed

fixed to the lower part of the spine of the ischium, to the superior part of the small ischiatic notch, and is continued under the acetabulum where it is bent downwards. The inferior and largest gemellus, is fixed to the superior and back part of the tuberosity of the ischium, and bending upwards towards the other line, together with it forms a sort of irregular semicircle.

**GEMINATED COLUMN.** See the article **COLUMN**.

**GEMINI**, the **TWINS**, in astronomy, one of the twelve signs of the zodiac, the third in order, beginning with aries. See the articles **SIGN** and **ZODIAC**. This constellation, according to different authors, contains from 24 to 89 stars. It is represented by the figure of two twin-children, looking each other affectionately in the face, and supposed to be Castor and Pollux.

**GEMMA**, *gem*, in natural history. See the article **GEM**.

*Sal* **GEMMÆ**, is the purest and finest fossil salt, and an extremely bright and beautiful fossil. It is considerably hard and firm, and at least as pellucid as rock crystal; but is frequently coloured throughout with a milky-white, which takes off greatly from its lustre; and as crystal is liable to be tinged with red, green and yellow, so as to resemble rubies, sapphires, emeralds, and topazes, so this salt is sometimes tinged with these several colours; but rarely preserves the transparency of crystal under the same circumstances. See the article **SALT**.

**GEMONIÆ SCALÆ**, in roman antiquity, a place for executing criminals, not unlike Tyburn with us. It was situated on the Aventine mount, or tenth region of the city; and was, according to some, a place raised on several steps, from whence they precipitated the criminals. But others will have it to have been a kind of dungeon, to which they descended by steps.

**GEMOTE**, a term used in old laws-books for a court. See the article **MOTE**.

**GEMUND**, a town of Germany, in the circle of Westphalia, and dukedom of Juliers, situated on the river Roer: east long.  $6^{\circ} 15'$ , and north lat.  $50^{\circ} 34'$ .

**GEMUND**, a town of Germany, in the circle of Swabia, and county of Rechsberg, situated on the river Rems: east long.  $9^{\circ} 40'$ , and north lat.  $48^{\circ} 45'$ .

**GEMUND**, a town of Germany, in the circle of Franconia, situated on the river

Maine: east long.  $9^{\circ} 45'$ , and north lat.  $50^{\circ} 8'$ .

**GENA**, the **CHEEK**, in anatomy, that part of the face between the nose and the ears. See the article **FACE**, &c.

**GENÆ QUADRATUS.** See **QUADRATUS**.

**GENAP**, a town of Brabant, situated on the river Dyle, fourteen miles south-east of Brussels.

**GENDARMES**, or **GENS D'ARMES**, in the french armies, a denomination given to a select body of horse, on account of their succeeding the antient gendarmes, who were thus called from their being completely clothed in armour.

The king's body guards, the light horse of the royal house, and the musqueteers, are at present reputed to belong to the gendarmerie.

The grand gendarmes are a troop composed of about 250 gentlemen, who guard the king's person. The king himself is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers. There are besides these, gendarmes of the queen, the dauphin, &c.

**GENDER**, *genus*, among grammarians, a division of nouns, or names, to distinguish the two sexes. See **NOUN** and **SEX**.

This was the original intention of gender; but, afterwards, other words which had no proper relation, either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus *arbor*, in latin, is feminine; but *arbre*, in french, is masculine: and *dens*, in latin, is masculine; but *dent*, in french, is feminine. Nay, a gender has sometimes changed in the same language, according to time and occasion. Thus *alvus*, according to Priscian, was antiently masculine, but afterwards became feminine; and *navire*, was antiently feminine in french, but is now masculine. In english we have no genders; indeed we express the difference of sex by different words; as boar, sow; boy, girl, &c. We have also twenty-four feminines distinguished from the males by varying the termination of the female into *ess*; as actor, actress; prince, princess; heir, heiress, &c. and we have a few words in which the feminine is distinguished from the masculines by the termination *ix*, as executor,

executor, executrix ; administrator, administratrix, &c. which is all our language knows of any thing like genders.

The eastern languages, as well as the vulgar languages of the west, have only two genders, the masculine and the feminine. The greek and latin have besides, the neuter, common, and doubtful gender. This last indeed is not common, for it properly belongs only to the names of some animals, which are promiscuously joined both to masculine and feminine adjectives, to express their male or female, as *bos*, *canis*, *fus*, &c. They have also the epicene gender, which is not a different one, but serves promiscuously for either ; including both the kinds under one single gender and termination : thus *vulpes*, a fox, tho' it signifies either the male or female, is really of the feminine gender, in latin. And so *custodie*, watchmen or centinels, are really feminine, tho' they signify men. This is common to all languages that have them. The latin and greek, in the neuter gender, do not regard them, having no relation to the male or female sex, but what fancy gives them, and the termination of certain words.

The oriental languages frequently neglect the use of genders ; and the persian language has none at all, which is no disadvantage ; the distinction of genders being entirely useless.

**GENEALOGICA ARBOR**, or tree of consanguinity, signifies a genealogy or lineage drawn out under the figure of a tree, with its root, stock, branches, &c.

The genealogical degrees are usually represented in circles, ranged over, under, and aside each other. This the Greeks called *stemmata*, a word signifying crown, garland, or the like.

**GENEALOGY**, *γενεαλογια*, an enumeration of a series of ancestors ; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

**GENEP**, a town in the dutchy of Cleeve, in Germany, situated on the Nierse and Maese, ten miles west of Cleeve : east long.  $5^{\circ} 30'$ , and north lat.  $51^{\circ} 40'$ .

**GENERAL**, an appellation given to whatever belongs to a whole genus. See **GENUS**. Thus we say, general geography, diet, council, averment, issue, &c. See the articles **GEOGRAPHY**, **DIET**, &c.

**GENERAL OFFICERS**, in the army. See the article **OFFICER**.

**GENERAL TERMS**, among logicians, those which are made the signs of general ideas. See **IDEA** and **ABSTRACTION**.

All things that exist, Mr. Locke observes, being particulars, it might be expected that words should be so too in their signification : but we find it quite contrary ; for most of the words that make all languages are general terms. This is the effect of reason and necessity. For, First, It is impossible that every particular thing should have a distinct name, because it is impossible to have distinct ideas of every particular thing ; to retain its name, with its peculiar appropriation to that idea.

Secondly, It would be useless, unless all could be supposed to have these same ideas in their minds. For names applied to particular things, whereof I alone have the ideas in my mind, could not be significant or intelligible to another, who is not acquainted with all those particular things which had fallen under my notice.

Thirdly, It would be of no great use for the improvement of knowledge : which, tho' founded in particular things, enlarges itself by general views ; to which things, reduced into sorts under general names, are properly subservient.

In things where we have occasion to consider and discourse of individuals and particulars, we use proper names : as in persons, countries, cities, rivers, mountains, &c. Thus we see that jockeys have particular names for their horses, because they often have occasion to mention this or that particular horse, when he is out of sight.

Afterwards, observing that a great many things resemble each other in shape, and other qualities, we frame a general idea that takes in only the qualities in which those many particulars agree ; and to this idea we give the name *man*, for example, in which there is nothing new ; that which is peculiar to each individual being left out, and only what is common to all retained. And thus we come to have a general idea, and a general name. By the same method the mind proceeds to more general notions and names, as those of animal, substance, being, thing, and such universal terms as stand for any ideas whatsoever.

As to the signification of general words, it is evident they do not barely signify one particular thing ; neither do they signify

a plurality. But they signify a genus, kind, or sort of things. See the articles ABSTRACTION and GENUS.

**GENERAL** of an army, in the art of war, he who commands in chief. See ARMY. A general ought to be a man of great courage and conduct, to have great experience, and to be of good quality. His conduct appears in establishing his magazines in convenient places ; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off ; in subsisting them ; and in knowing how to take the most advantageous posts, either for fighting or shunning a battle. His experience inspires his army with confidence, and an assurance of victory ; and his quality, by creating respect, augments his authority. By his liberality he gets intelligence of the strength and designs of the enemy, and by this means is enabled to take the most successful measures. A general ought likewise to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline.

The office of a general is to regulate the march and encampment of the army ; in the day of battle to choose out the most advantageous ground ; to make the disposition of the army ; to post the artillery ; and where there is occasion, to send his orders by his aids de camp. At a siege, he is to cause the place to be invested ; to order the approaches and attacks ; to visit the works, and to send out detachments to secure his convoys.

**GENERAL** of horse, and **GENERAL** of foot, are posts next under the general of the army, and these have upon all occasions an absolute authority over all the horse and foot in the army.

**GENERAL** of the artillery, or **Master GENERAL** of the ordnance. See ORDNANCE.

**GENERAL** is also used for a particular march, or beat of drum ; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

**GENERAL** is also used for the chief of an order of monks ; or of all the houses and congregations, established under the same rule. Thus we say, the general of the Franciscans, Cistercians, &c.

**GENERATING LINE**, or **FIGURE**, in geometry, is that which by its motion produces any other plane or solid figure. Thus, a right line moved any way parallel to itself, generates a parallelo-

gram ; round a point in the same plane, with one end fastened in that point, it generates a circle. One entire revolution of a circle, in the same plane, generates the cycloid ; and the revolution of a semi-circle round its diameter, generates a sphere, &c. See the articles CYCLOID, SPHERE, &c.

**GENERATION**, *generatio*, in physiology, the act of procreating and producing a thing which before was not ; or, according to the schoolmen, it is the total change or conversion of one body into a new one, which retains no marks of its former state. Thus, we say, fire is generated, when we perceive it to be where before there was only wood, or other fuel : in the same manner, a chick is said to be generated, when we perceive it where before there was only an egg ; or, the egg is changed into the form of a chick.

In generation, there is not properly any production of new parts ; but only a new modification, or manner of existence, of the old ones.

When almighty God, says Dr. Blair, created the world, he so ordered and disposed of the materies mundi, that every thing produced from it should continue so long as the world should stand. Not that the same individual species should always remain ; for they were in process of time to perish, decay, and return to the earth from whence they came ; but that every like should produce its like, every species produce its own kind, to prevent a final destruction of the species, or the necessity of a new creation. For which end he laid down certain regulations, by which each species was to be propagated, preserved, and supported, till, in order and course of time, they were to be removed hence : for without that, those very beings, which were created at first, must have continued to a final dissolution of all things ; which almighty God of his infinite wisdom, did not think fit. But that he might still the more manifest his omnipotence, he set all the engines of his providence to work, by which one effect was to produce another, by means of certain laws or rules, laid down for the propagation, maintenance, and support of all created beings. This his divine providence is called nature, and these regulations are called the laws or rules of nature, by which it ever operates in its ordinary course ; and whatever recedes from that,

is said to be preternatural, miraculous, or monstrous.

**GENERATION of animals.** According to Aristotle, the males contain the principle, and the females the matter of generation: for though both were furnished indeed, with a feminal liquor, yet the semen of the males alone was prolific. The moderns, on the other hand, as well those who contend for the system of generation from eggs, as they who adopt that of the animalcules in the male-seed, pretend that females have no such feminal liquor at all, and that what was commonly taken for it was some other animal fluid.

There are great and many difficulties which attend the most plausible account of the first formation of the parts of an animal, and the beginning of motion in its fluids: for though both reason and experience convince us, that all the parts of an animal did exist before generation; yet how this matter comes to assume so very different a form, as that of an embryo, is by no means agreed on.

Harvey is of opinion, that all females are furnished with eggs, and that the embryos, or young animals, are formed in the same manner as a chick in the egg of any bird. Generation, according to this celebrated physician, is effected wholly by means of the uterus, or womb; which conceives the foetus by a kind of contagion communicated to it by the male-seed, much in the same way as the load-stone communicates magnetism to iron. This contagion, he thinks, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus, he acknowledges, is the only part that is capable of conceiving the foetus, just as the brain is alone capable of forming ideas and notions. Agreeably to this doctrine of Harvey, Steno, and other anatomists, have pretended to discover certain eggs in the ovaries or testicles of women; which Mr. Buffon denies to be the case, affirming, that there are no such eggs to be found in the testicles or ovaries of women.

We cannot enter into a detail of the reasonings for and against the system of generation from eggs, and shall therefore only observe, that its advocates pretend to have discovered eggs in all the females on which they made observations, that the largest of those found in women did

not exceed the bigness of a pea; that they are extremely small in young girls under fourteen, but that age and commerce with men makes them grow larger; that there are more than twenty such eggs in each ovary or testicle; that they are fecundated in the ovary by the spirituous and volatile part of the male-seed; that they afterwards are detached and fall into the uterus through the fallopian tubes; that here the foetus is formed of the internal substance of the egg, and the placenta of the exterior part. See the article **FOETUS**.

Leewenhock is the author of another system of generation, from animalcules in the male seed. He tells us, he discovered many thousands of these in a drop less than a grain of sand. They are found in the semen of all males whatever, but not in that of females; and are so small, that 3,000,000,000 of them are not equal to a grain of sand, whose diameter is but the hundredth part of an inch. When any of these animalcules gets into an egg, fit to receive it, and this falls into the womb through the fallopian tubes, the humours which distil through the vessels of the womb, penetrating the coats of the egg, swell and dilate it, as the sap of the earth does seed thrown into it. The placenta begins to appear like a little cloud, upon one side of the external coat of the egg; and, at the same time, the spine of the embryo-animalcule is grown so big, as to become visible; and a little afterwards, the cerebrum and cerebellum appear like two bladders; and the eyes stand next goggling out of the head; then the beating of the heart or *punctum saliens*, is plainly to be seen; and the extremities discover themselves last of all.

These animalcules are of different figures, some like tadpoles, and others like eels. In the semen of a man, and in that of a dog, there have been discovered two different kinds of them, the one supposed to be males, and the other females. Some even pretend to have seen animalcules disengage themselves from the membranes that surround them; and that they then appeared perfectly like men, with legs, arms, &c. like those of the human body.

All the advocates for the system of generation from animalcules strongly oppose that from eggs. They contend, that these animalcules cannot be looked

but was lost by alliances with those who had but the usual number of fingers or toes.

He farther observes, that most animals, excepting mankind, have stated seasons for procreation, and that the females go with young some a longer, others a shorter time. Mares go from eleven to twelve months; cows and hinds go nine months, as do also women; foxes and wolves, five months; and bitches go only seven weeks; cats nine weeks; and rabbits but thirty-one days. Most birds are hatched in twenty-one days; the canary birds, and some others, are hatched in thirteen or fourteen days. It appears, therefore, that there is an endless variety in the time and manner of the generation of animals.

Those who desire a more full account of these systems of generation may consult Harvey, Leewenhoek, Buffon, &c.

*Parts of GENERATION.* The parts of generation, in men, are the testicles, vasa deferentia, vesiculæ seminales, and penis. See the article *TESTICLE*, &c.

Those, in women, are the pudendum or vulva, the clitoris, nymphæ, vagina, uterus or womb, ovaries, and fallopian tubes. See the articles *PUDENDUM*, *CLITORIS*, &c.

*GENERATION of Fishes.* The opinion of most naturalists, that the female fishes first deposit their spawn, and that the males afterwards eject the semen upon it, is denied by Linnæus; who thinks it impossible, that the eggs of any animal should be impregnated out of its body. He thinks it much more probable, that the males always eject their semen some time before the females deposit their spawn; and that by swallowing this semen, the spawn is impregnated in the body of the fish. Nay, he tells us, that he himself saw three or four females, in the spawning time, gather about the male, and greedily swallow the semen he ejected. This he observed in some species of the eel, perch, and especially the cyprinus; but he recommends farther enquiry to be made on this subject.

*GENERATION of Insects*, no less than that of birds, is now certainly known to be from eggs; which the female deposits in places, where, at a proper season, they are hatched into animals like their parents; or into maggots, or worms, which, after several transformations, at last appear in the form of their parents. See *INSECT*, *TRANSFORMATION*, &c.

*Extraordinary GENERATION.* Such is that of polypes, from cuttings or pieces of another polype. See *POLYPE*.

*GENERATION of plants.* The impregnation of the female palm-tree by the male, has been known in the most ancient times. Herodotus, the father of history, tells us, that the Greeks called some of these trees male, the fruit of which they bound to the other kind, which bears dates; that the small flies, wherewith the male abounded, might assist in ripening the fruit of the female-tree. The remote age in which Herodotus wrote, sufficiently apologizes for his believing, that what was really brought about by the farina fecundans of the male-flower, was to be attributed to the insects frequently found therein, and which perhaps frequently carry this farina from the male to the female. The process of impregnation, according to Theophrastus, was this: while the male plant was in flower, they cut off a branch of these flowers, and scattered the dust and down therein upon the flowers of the female plant; by which means the female did not cast her fruit, but preserved them to maturity. This has been lately verified at Berlin, where a female palm-tree bore fruit for many years; but the fruit never ripened, and when planted, did not vegetate, merely because there was no male palm in the place: for having procured a branch of male flowers from Leipzig, twenty german miles from Berlin, they suspended it over the female flowers of their tree; and the experiment succeeded so well, that the female tree produced more than an hundred perfectly ripe fruit; and the experiment being repeated, it bore above two thousand ripe fruit, which being planted produced young trees.

It is in the flowers of vegetables only, that the parts subservient to generation are produced; and these flowers are either male, female, or hermaphrodite. male-flowers are those possessed of the organs of generation, analogous to the male parts of animals: such are the stamina and apices, called by Linnæus, filaments and antheræ. The female flowers are only endowed with parts like those, which perform the office of generation in females; and these are the pistil and its appurtenances, which Linnæus divides into three parts, the germen, style, and stigma. The hermaphrodite flower, which constitutes the great bulk

of the vegetable creation, is possessed of all these parts in itself, and is therefore capable of propagating its species without any foreign assistance; which, by many incontestable experiments, it has been found neither the male nor female flower simply is able to do. The impregnation of hermaphrodite flowers, may be performed within their own calyx; but, before a separate female flower can be so, the farina fecundans of the male flower must necessarily be conveyed to it thro' the circumambient air; which is the reason, why the quantity of the produce of such plants is much more precarious, than that of plants which have hermaphrodite flowers: for if, during the flowering of these separate male and female plants, the weather proves either very wet or stormy, their produce of fruit will be very inconsiderable, from the spoiling or hasty dissipation of the male farina. Thus, independent of frosts, the fruit of the nut and filbert-tree will be most numerous in those years, in which the months of January, and February are the least stormy and wet, because at that time their flowers are produced. For the same reasons, a stormy or wet May destroys the chestnuts; and the same weather, in July, prodigiously lessens the crop of maize, or indian corn, as its spikes of male-flowers stand lofty, and at a considerable distance from the female.

Some of the more skilful modern gardeners put in practice, with regard to melons and cucumbers, the very method mentioned by Theophrastus two thousand years ago, in regard to the palm-tree. As these plants, early in the season, are in this climate confined to frames and glasses, the air in which they grow is more stagnant than the open air; whereby the distribution of the farina fecundans, so necessary towards the production of the fruit for the propagation of the species, is much hindered. To obviate the inconvenience thence arising, they collect the male-flowers when fully blown; and presenting them to the female ones by a stroke of the finger, they scatter the farina fecundans therein, which prevents the falling of the fruit before it is ripe.

By far the greater part of plants produce hermaphrodite flowers; but some there are which have separate male and female-flowers growing from the same root, as maize, nettles, box, elm, birch,

oak, beech, hazel, hornbeam, plane-tree, pine, fir, cypress, cedar, melons, cucumbers, gourds, and several others: in many of these, the male and female flowers stand at a considerable distance. There are other plants which produce those necessary organs upon different roots, as the palm-tree, hops, the willow-tree, missetoe, spinach, hemp, poplar, french and dog's mercury, the yew-tree, juniper, and several others. Among these, the valisneria of Linnæus, as to the manner in which its male-flower impregnates the female, is one of the most singular prodigies in nature. It grows in rivulets, ditches, and ponds, in many parts of Europe. The male plant, which is continually covered with water, has a short stalk, upon the top of which its flowers are produced. As this top never reaches the surface of the water, the flowers are thrown off from it, and come unopened to the surface of the water; where, as soon as they arrive, by the action of the air, they expand themselves, and swim round the female flowers, which are blown at the same time. These last have a long spiral foot-stalk, by which they attain the surface of the water, and remaining there in flower a few days, are impregnated by the male-flowers detached from the stalk at the bottom.

It is observable, that the operations of nature are carried on most usually by certain general laws, from which however she sometimes deviates. Thus almost all plants have either hermaphrodite flowers, or male and female flowers, growing from the same root, or male and female flowers from different roots; but there are a few of another class, which from the same root furnish either male and hermaphrodite flowers, or female and hermaphrodite ones: of this kind are the mulberry-tree, the musk or plantain-tree, white hellebore, pelltory, arrach, the ash-tree, and a few others. *Watson*, in *Phil. Transf.* Vol. 47, p. 169—183.

Some object to this theory of the generation of plants, from having observed some plants, which were termed female, growing singly; and though at a very great distance from any male plants of the same kind, producing perfect fruits, which grew when sown. Mr. Miller tells us, he himself was staggered in his opinion, on having observed a female plant of white briony, which grew singly

In a garden, where there were no other plants of the same kind ; which, nevertheless, for several years, produced berries, which grew and flourished perfectly well. This put him upon examining the plant more carefully than he had done before, when a great many male-flowers were found intermixed with the female ones ; and he adds, that he has frequently observed the same in many other plants, which are generally male and female in distinct plants, yet have sometimes both sexes on the same plant.

From what has been said, it appears very plain, that the embryo of the female flower must be impregnated by the farina fecundans, or male dust, in order to render the fruit perfect ; but how, or in what manner, it is performed, is what we can only guess at ; since, in the generation of animals, our greatest naturalists differ widely, as has been shewn above, in their opinions concerning the particular method how it is performed. If, says the reverend Dr. Hales, I may be allowed to indulge conjecture, I would propose it to the consideration of naturalists, whether, from the manifest proof we have that sulphur attracts air, a hint may not be taken to enquire whether this may not be the primary use of the farina fecundans, to attract and unite with itself, elastic or other refined active particles. That this farina abounds with sulphur, and that a very refined sort, is probable from the subtle oil which chemists obtain from the chives of saffron : and if this be the use of it, was it possible that it could be more aptly placed than on the slender points of the stamina, where it might easily, with the least breath of wind, be dispersed in the air ; thereby surrounding the plant, as it were, with an atmosphere of sublimed sulphureous pounce ? These uniting with particles of air, may, perhaps, be inspired at several parts of the plant, and especially at the pistil, and be thence conveyed to the capsula seminalis. And if to these united sulphureous and aerial particles, we suppose some particles of light to be joined (for Sir Isaac Newton has found that sulphur attracts light strongly) ; then the result of these three by far the most active principles in nature will be a punctum saliens, to invigorate the seminal plant : and thus we are at last conducted, by the regular analysis of vegetable nature, to the first

enlivening principle of their minutest origin.

So much for the generation of plants, and the discovery of their different sexes, upon which Linnæus has founded his system of botany, at present so much and so well received. Whoever, therefore, would consider, more minutely, the structure of flowers, and the almost infinite variety of the number and disposition of their parts, may consult Linnæus's *Philosophia Botanica*, lately published, where this subject is treated in a very copious and instructive manner.

But besides this regular and natural generation, many plants may be propagated, by planting cuttings or slips of them in the earth. See **CUTTINGS**.

**GENERATION of Stones.** See the article **LITHOGENESIS**.

**GENERIC NAMES**, among philosophers, the same with general terms. See the article **GENERAL TERMS**, supra.

**GENEROUSA**, among lawyers, the addition for a gentlewoman, who may quash any writ wherein she is termed spinster. See the article **SPINSTER**.

**GENESIS**, among mathematicians, signifies the formation or production of some figure or quantity. See the article **GENERATING**, supra.

**GENESIS**, among divines, a canonical book of the Old Testament, and the first of the pentateuch, or five books of Moses. The Hebrews call it *Bereschith*, or, In the beginning, these being the first words in the book. The Greeks gave it the name of *Genesis*, from its beginning with the history of the creation of the world. It includes the history of two thousand three hundred and sixty-nine years, and besides the history of the creation, contains an account of the original innocence and fall of man ; the propagation of mankind ; the rise of religion ; the general defection and corruption of the world ; the deluge ; the restoration of the world ; the division and peopling of the earth ; and the history of the first patriarchs down to Joseph, at whose death it ends.

It was easy for Moses to be satisfied of the truth of what he delivers in this book, because it came down to his time through a very few hands. For, from Adam to Noah, there was one man (*Methuselah*) who lived to see them both : in like manner, from Noah to Abraham, Shem conversed with them both ; as Isaac also did with Abraham and Joseph, from whom  
there

these things might easily be conveyed to Moses by Amram, who was cotemporary with Joseph. Moses is supposed to have written this book, during his retirement in the land of Midian, before he conducted the Israelites out of Egypt.

**GENET**, **GENNET**, or **JENNET**, in the manege, denotes a small sized, well proportioned spanish horse.

To ride *a la genette*, is to ride after the spanish fashion, so short, that the spurs bear upon the horse's flank.

**GENET** is also the name of a kind of cat, bred in Spain, somewhat bigger than a weasel, of a grey or black colour, but the fur of the black is the most valuable.

**GENETHLIACI**, in astrology, men who erect horoscopes, or pretend to predict what will happen to persons, from the stars which presided at their birth. See the article **HOROSCOPE**.

Nothing can be more absurd than this pretended science, and yet there have been times when princes themselves were greatly infatuated with these sort of people. The assurance with which these cunning fellows predicted future events made them always find dupes, and even after they were expelled from Rome by a decree of the senate, they met with such protection from the credulity of the people, that they still continued unmolested in the city.

**GENETHLIACUM**, or **GENETHLIAC POEM**, verses made on the birth of some prince, or other illustrious person, in which the poet, by a kind of prediction, promises him great advantages, great prosperity, and glorious victories. The same name is also given to verses of this kind, made on the birth of any person whatsoever.

**GENEVA**, a city near the confines of France and Switzerland, on the river Rhone, about sixty miles north-west of Lyons: east long. 6°, north lat. 46° 20'. Geneva is a fortified town, about two miles in circumference, situated at the west end of a lake sixty miles long, and twelve broad, called the lake of Geneva. It is a republic, governed by a council of 200, and a senate of twenty-five members; and is said to contain 30,000 inhabitants.

**GENEVA**, or **GIN**, among distillers, an ordinary malt-spirit, distilled a second time, with the addition of some juniper-berries. See the article **JUNIPER**. Originally, the berries were added to the malt in the grinding; so that the

spirit thus obtained was flavoured with the berries from first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

**GENEVIEVE**, or *St. GENEVIEVE'S DAY*, a festival observed at Paris on the third of January, in honour of St. Genevieve, patroness of the city.

*Nuns of St. GENEVIEVE*. See the article **MIRAMJONES**.

**GENIAL**, an epithet given by the pagans to certain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

**GENICULI**, among botanists, the knots or joints in the stalks of plants; whence they are denominated geniculate plants.

**GENIOGLOSSI**, in anatomy, two muscles which lie immediately under the geniohyoidæus. They arise fleshy from the fore-part of the lower jaw internally, and enlarging themselves, are inserted in the root of the tongue. When these act, they pull the tongue forwards, and thrust it out of the mouth.

**GENIOHYOIDÆUS**, in anatomy, is a muscle which arises in the middle of the chin, above the mylohyoides, and near the synchondrosis of the jaw: its termination is in the base of the os hyoides. See the articles **MYLOHYOIDES**, **SYNCHONDROSIS**, &c.

**GENIPA**, in botany, a genus of the *pentandria-monogynia* class of plants, the flower of which consists of a single, rotated petal; its tube is very short, and of a funnel-like shape; and the limb large, and divided into five deep segments. The fruit is a fleshy berry, of an oval figure, small at each end, truncated, and containing two cells, in which are a number of depressed angulated seeds. See Plate CX. fig. 4.

**GENIS**, a town of Savoy, situated on the river Guier, twelve miles west of Chambery.

**GENISTA**, **GREEN-WEED**, or **DYER'S-WEED**, a genus of the *diadelphia-decandria* class of plants, with papilionaceous flowers; and the fruit a roundish turgid,

turgid, and anilocular pod, containing a single kidney-like seed.

**GENISTA SPARTIUM**, a plant called by Linnæus *ulex*. See the article **ULEX**.

**GENISTELLA**, in botany, the same with the *genista*. See the article **GENISTA**.

**GENITAL**, an appellation given to whatever belongs to the parts of generation. See the article **GENERATION**.

**GENITAL GODS**, *dii genitales*, in roman antiquity, the same with the *indigetes*. See the article **INDIGETES**.

**GENITALIA**, or **GENITARIES**, in anatomy, a name sometimes given to the testes, or testicles of man, on account of their office in generation. See the article **TESTICLE**.

**GENITES**, *gevritus*, among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of *genites* such of the Jews as were issued from parents, who, during the babylonish captivity, had not allied with any gentile family.

**GENITIVE**, in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the genitive case : But in the vulgar tongues, they make use of a sign to express the relation of this case. In english they prefix the particle *of*, in french *de*, or *du*, &c. Though in strictness there are no cases in either of these languages ; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the latin, &c. See the article **CASE**.

In the hebrew tongue, the genitive case is marked in a very different manner from that of the greek and latin ; for whereas in those languages the noun governed is varied, in the hebrew the noun governing undergoes the alteration. See the article **HEBREW LANGUAGE**.

**GENITURA**, in botany, a name used by some for anethum, or dill.

**GENIUS**, a good or evil spirit, or dæmon, whom the antients supposed set over each person, to direct his birth, accompany him in life, and be his guard. See the article **DÆMON**.

The rank and office of the *genii* were inferior to those of the lares ; for the latter were the tutelar gods of a family, whereas the *genii* had the care or government only of single persons, or places.

Apuleius following the sentiment of Plato, gives the following account of the *genii*.

They are spirits who never were engaged in matter, nor were ever joined to bodies. Of these *genii* Plato is of opinion that every man has his own, who watches over him, and is a witness not only of his actions, but of his very thoughts ; and that, when the person dies, the *genius* conducts the soul of which he had the charge, to judgment, and assists at the trial : if the accused person falsifies, the *genius* convicts him ; if he speaks the truth, he confirms it ; and it is upon his evidence that sentence is pronounced.

The antients not only ascribed a *genius* to particular persons, but to places likewise. They allowed a *genius* to provinces and towns, to forests, trees, fountains, and to the sciences. Each person sacrificed once a year to his *genius*, and scattered flowers, and sprinkled wine to him : sometimes they offered leaven or salted dough, or a pig two months old.

It was commonly thought that each person had two *genii* attending him. Flattery introduced the custom of swearing by the *genius* of the emperors, among the Romans, in the decline of that empire. Socrates's *genius* is famous in antiquity. The Mahometans pretend that the *genii* inhabited the world many thousand years before Adam, under the reigns of several princes, who all bore the name of Solomon ; but falling at length into a general corruption, Ebbe was sent to drive them to a remote part of the earth, there to be confined ; that some of that generation, still remaining, they were by Talmurath, one of the antient kings of Persia, who waged war against them, forced to retreat to the famous mountains of Kaf. See the article **ANGEL**.

**GENIUS**, in matters of literature, &c. a natural talent or disposition to do one thing more than another ; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently, and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a *genius* determined not only to a certain art, but to certain parts of that art, in which only they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them

them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules, whilst another displeases though he observes them ; because he has not the happiness of being born with a genius for painting.

A man born with a genius for commanding an army, and capable of becoming a great general by the help of experience, is one whose organical conformation is such, that his valour is no obstruction to his presence of mind, and his presence of mind makes no abatement of his valour. Such a disposition of mind cannot be acquired by art : it can be possessed only by a person who has brought it with him into the world. What has been said of these two arts, may be equally applied to all other professions. The administration of great concerns, the art of putting people to those employments for which they are naturally formed, the study of physic, and even gaming itself, all require a genius. Nature has thought fit to make a distribution of her talents among men, in order to render them necessary to one another : the wants of men being the very first link of society : she has therefore pitched upon particular persons to give them an aptitude to perform rightly some things which she has rendered impossible to others ; and the latter have a greater facility granted them for other things, which facility has been refused to the former. Nature, indeed, has made an unequal distribution of her blessings among her children ; yet she has disinherited none ; and a man divested of all kinds of abilities, is as great a phenomenon as an universal genius.

From the diversity of genius, the difference of inclination arises in man, whom nature has had the precaution of leading to the employments for which she designs them, with more or less impetuosity in proportion to the greater or lesser number of obstacles they have to surmount, in order to render themselves capable of answering this vocation. Thus the inclinations of men are so very different, because they follow the same mover, that is, the impulse of their genius. This, as with the painter, is what renders one poet pleasing, even when he trespasses against rules ; while others are disagreeable, notwithstanding their strict regularity.

The genius of these arts, according to the abbé du Bos, consists in a happy arrangement of the organs of the brain ; in a just conformation of each of these organs ; as also in the quality of the blood, which disposes it to ferment, during exercise, so as to furnish a plenty of spirits to the springs employed in the functions of the imagination. Here he supposes that the composer's blood is heated ; for that painters and poets cannot invent in cool blood ; nay, that it is evident they must be wrapt into a kind of enthusiasm when they produce their ideas. Aristotle mentions a poet who never wrote so well as when his poetic fury hurried him into a kind of frenzy. The admirable pictures we have in Tasso of Armida and Clorinda, were drawn at the expence of a disposition he had to real madness, into which he fell before he died. Do you imagine, says Cicero, that Pacuvius wrote in cold blood ? No, it was impossible. He must have been inspired with a kind of fury, to be able to write such admirable verses.

GENNET, or GENET. See GENET.

GENOA, a city and archbishop's see of Italy, and capital of the republic of the same name, is built on a strand near the sea, and rises gradually to the top of a hill ; the houses, which are lofty and well built, rising like the seats of a theatre, afford a fine prospect at sea. The harbour is large and deep, and the principal street, from one end to the other, resembles a double row of palaces : east long. 9° 30', and north lat. 44° 30'.

This city, which is fortified by a double wall, is six miles round, and contains thirty parish churches, twenty colleges, and as many convents and religious houses. The legislative authority is lodged in the great senate, consisting of the signiory and four hundred noblemen and principal citizens, elected annually out of the freemen. The signiory consists of the doge and twelve other members, who hold their places two years. Four parts in five of the senate must agree to the enacting of laws. The doge is obliged to reside in the palace the two years he is in office ; and after they are expired, he retires to his own house, where his administration is either approved or condemned ; and if the latter, he is proceeded against as a criminal.

The territories of the republic lie in the form of a crescent, along the coast of the

Mediterranean.

Mediterranean, extending 150 miles ; but the country no where reaches above twenty miles from the sea, and in some places not ten.

**GENS D'ARMES.** See **GENDARMES.**

**GENTIAN**, *gentiana*, in botany, a genus of the *pentandria-digynia* class of plants, the flower of which consists of a single petal, tubulated and imperforated at the base ; and at the edge, divided into five segments, various in figure : the fruit is an oblong, cylindric, acuminate capsule, slightly bifid at the top, formed of two valves, and containing only one cell : the seeds are numerous and small ; the receptacles are two, and grow to the two valves of the capsule.

The root of this plant is large, remarkably tough, and of a firm texture. It is brought to us from Germany, where it is in many places cultivated as liquorice is amongst us ; and is to be chosen fresh, tough, of a middle size, free from the small fibres, and well dried ; tho' if it be scorched, it is to be rejected.

This root is one of the best stomachic bitters that the materia medica affords : it procures an appetite, and greatly assists digestion. But if we give credit to some authors, this is one of the least of its virtues ; they have recommended it as a febrifuge and an alexipharmic, and as the most certain remedy for the bite of a mad dog. On this occasion it is not only recommended internally but externally, a cataplasm made of venice-treacle and the powder of this root, being ordered to be applied to the wound. It is also said to be a certain remedy for agues, and one of the best known medicines against the plague.

**GENTILE**, in matters of religion, a pagan, or worshipper of false gods.

The origin of this word is deduced from the Jews, who called all those who were not of their nation, by the name of גוים, *gojim*, i. e. gentes, which in the greek translations of the Old Testament, is rendered by *τα εθνη* ; in which sense it frequently occurs in the New Testament, as in Matt. vi. 32. *All these things the nations or gentiles seek.* Whence the latin church also used gentes, in the same sense as our gentiles, especially in the New Testament. But the word gentes soon got another signification, and no longer meant all such as were not Jews, but those only who were neither Jews nor Christians, but followed the superstitions of the Egyptians, Greeks, Romans,

&c. In this sense it continued among the christian writers, till their manner of speech, together with their religion, was publicly and by authority received in the empire, when gentiles, from gentes, came into use : and then both words had two significations, viz. in treatises or laws concerning religion, they signified pagans, neither Jews nor Christians : and in civil affairs, they were used for all such as were not Romans.

**GENTILE**, *gentilis*, in the roman law and history, a name which sometimes expresses what the Romans otherwise called barbarians, whether they were allies of Rome or not : but this word was used in a more particular sense for all strangers and foreigners not subject to the roman empire, in contradistinction to *provincialis*, or an inhabitant of a province of the empire.

The word is used in this sense in the Greek, but was not introduced into this or the latin tongue, till after christianity was established ; it being taken from scripture.

**GENTLEMAN**, a person of a noble birth, or descended of a family which has long borne arms.

Chamberlayne observes, that in strictness, a gentleman is one whose ancestors have been freemen, and have owed obedience to none but their prince ; on which footing no man can be a gentleman but one who is born such. But, among us, the term gentleman is applicable to all above yeomen ; so that noblemen may be properly called gentlemen. In our statutes, *gentilis homo* was adjudged a good addition for a gentleman. 27 Edw. III. The addition of knight is very antient, but that of esquire or gentleman was rare before 1 Hen. V.

**GENTLEMAN usher of the black rod.** See the article **ROD**.

**GENTLEMAN, or LORD of the bed-chamber.** See the article **BED-CHAMBER**.

**GENTLEMEN of the chapel**, officers whose duty and attendance is in the royal chapel, being in number thirty-two, whereof twelve are priests ; the other twenty, commonly called clerks of the chapel, assist in the performance of divine service. One of the first twelve is chosen for confessor of the household, whose office it is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer the sacrament.

One of the twenty clerks, well versed in music, is chosen first organist, who is  
 § S 2 master

master of the children, to instruct them in music, and whatever else is necessary for the service of the chapel; a second is likewise an organist; a third, a lutanist; and a fourth, a violist.

There are likewise three vergers, so called from the silver-rods they carry in their hands; being a serjeant, a yeoman, and groom of the vestry; the first attends the dean and sub-dean, and finds surplices and other necessaries for the chapel; the second has the whole care of the chapel, keeps the pews, and seats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

**GENTLEMEN PENSIONERS.** See the article **PENSIONER**.

**GENUFLEXION**, among ecclesiastical writers, the posture of kneeling, was a very antient custom in acts of devotion; though the Russians are said to esteem it indecent, and even the dissenters, among us, prefer that of standing.

**GENUS**, among metaphysicians and logicians, denotes a number of beings, which agree in certain general properties, common to them all; so that a genus is nothing else but an abstract idea, expressed by some general name or term. See the articles **ABSTRACTION** and **GENERAL TERMS**.

It is plain, therefore, that by a genus we do not barely signify one particular thing, nor yet a plurality of things; but a sort or kind of things, all agreeing in certain general properties.

Thus animal is said to be a genus in respect of man and brute, in regard man and brute agree in the common nature and character of animal: so a right lined figure of four sides, is a genus in respect of a parallelogram, and a trapezium; and so likewise is substance, in respect of substance extended, which is body; and thinking substance, which is mind.

The method by which the mind advances to form genera is, according to Mr. Locke, as follows. Observing several things that differ from the mind's idea of man, for instance, and therefore cannot be comprehended under that name, to agree with man in some certain qualities by retaining only those qualities, and uniting them into one idea, it gets another more general idea, to which giving a name, it makes a new genus, or a term of a more comprehensive extension. Thus by leaving out the shape, and other properties signified by the word man,

and retaining only a body with life, sense, and spontaneous motion, we form the idea signified by the name animal. By the same way the mind proceeds to body, substance; and at last to being, thing, and such universal terms as stand for any ideas whatever.

This shews the reason why, in defining things, we make use of the genus, namely, to save the labour of enumerating the several simple ideas which the next term stands for: from whence it appears, that genus is no more than an abstract idea comprehending a greater or less number of species, or more particular classes. See the article **SPECIES**.

Genus and species themselves are the workmanship of human understanding; tho' it is not denied that nature, in making things alike, lays the foundation of this sorting and classing, so that every distinct, abstract idea, is a distinct essence: whence in the schools, the word essence has been almost wholly applied to the artificial constitution of genus and species. See the article **ESSENCE**.

In the series of notions rising one above another in the degree of universality, that division which comprehends under it several genera, is called in the schools the higher genus, which denomination continues until we arrive at the last advance of the understanding; when being come to the most general of all ideas that admits not of a superior, it is distinguished by the name of the genus generalissimum. In like manner the several genera comprehended under a higher genus, are in respect of it considered as species; and as these last too have species under them, the inferior divisions are, for distinction's sake, termed lower species. Thus the progression continues, and when we come to the lowest sub-division of all, comprehending only individuals, we call this the species specialissima. All that lie between this and the highest distribution of things are the intermediate genera and species, which are termed each in their turn genus generalius, or species specialior, according as we consider them in the ascending or descending scale of our ideas; or, to speak in the language of logicians, according to their ascent or descent in linea prædicamentali.

**GENUS** is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences,

sciences, as music, rhetoric, anatomy; and natural history.

**GENUS**, in music, by the antients called *genus melodiæ*, is a certain manner of dividing and sub-dividing the principles of melody; that is, the consonant and dissonant intervals, into their concinnous parts.

The moderns considering the octave as the most perfect of intervals, and that whereon all the concords depend, in the present theory of music, the division of that interval is considered as containing the true division of the whole scale. See the articles **SCALE** and **OCTAVE**.

But the antients went to work somewhat differently: the diatessaron, or fourth, was the least interval which they admitted as concord; and therefore they sought first how that might be most conveniently divided: from whence they constituted the diapente and diapason.

The diatessaron being thus, as it were, the root and foundation of the scale, what they called the genera, or kinds, arose from its various divisions; and hence they defined the *genus modulandi* the manner of dividing the tetrachord, and disposing its four sounds as to succession.

The genera of music were three, the enharmonic, chromatic, and diatonic: the two first were variously subdivided, and even the last, tho' that is commonly reckoned to be without any species; yet different authors have proposed different divisions under that name, without giving any particular names to the species, as was done to the other two.

For the characters, &c. of these several genera, see the articles **ENHARMONIC**, **CHROMATIC**, and **DIATONIC**.

**GENUS**, in rhetoric. Authors distinguish the art of rhetoric, as also orations or discourses produced thereby, into three genera, or kinds, demonstrative, deliberative, and judiciary.

To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, funeral harangues, &c. See the articles **PANEGYRIC**, &c.

To the deliberative kind belong persuasions, dissuasions, commendations, &c. To the judiciary kind belong defences and accusations. See the articles **RHETORIC**, **ORATION**, &c.

**GENUS**, in algebra. The antient algebraists divided that art into two genera or kinds, *viz.* the logistic and specious. See **LOGISTIC** and **SPECIOUS**.

**GENUS**, in anatomy, the *genus nervosum*, or nervous kind; or, as others term it, the nervous system, is an expression pretty frequent among anatomists, signifying the nerves considered as an assemblage or system of similar parts, distributed throughout the body. See the articles **NERVE** and **NERVOUS**.

**GENUS**, in natural history, a sub-division of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters.

The genera of animals ought to be established upon the most natural, obvious, and distinctive characters. Thus it would be absurd to range the ox and hog under the same genus, notwithstanding they both have divided hoofs; and it would be equally so to make the roe-deer, rein-deer, and elk, belong to different genera, merely because the figure of their horns differs considerably. Hence the characters of the genera of animals are to be taken from the figure, situation, number, and proportions of their parts; which constitute such a resemblance, as easily distinguishes them from the species of any other genus.

In the class of quadrupeds, besides a general resemblance, the different genera are distinguished from each other by the number and figure of their teeth, the shape of their feet, horns, and the like. See the article **QUADRUPED**.

In the class of birds, the general characters are drawn from the shape of their beak, and the number and disposition of their toes. See the article **BIRD**.

In the class of amphibious animals, the general characters are founded on the number of the crusts or scales on the bellies and tails of the serpent-kind, and on the figure of the tail, and the number and shape of toes in the lizard, frog, and tortoise-kinds. See the articles **SERPENT**, **LIZARD**, &c.

As to the genera of fishes, they are founded on a certain agreement between a number of species, arising from the similitude of their essential external parts; which always consist in the situation of these parts, for the most part also in number, and frequently in their figure and proportion.

The insect-class are distinguished into genera, from the number, figure, &c. of their antennæ, feet, snout, &c.

And the animalcules, as mentioned under the article **ANIMALCULE**.

With

With respect to the vegetable kingdom, all plants and trees are reduced to genera from the consideration of the number, situation, figure, and proportion of the parts of fructification. See the article **FRUCTIFICATION**.

In the same manner, the genera of fossils are established upon the figure, hardness, consistence, inflammability, and other obvious properties of the substances that compose the mineral kingdom. See the article **FOSSILS**.

**GEOCENTRIC**, in astronomy, is applied to a planet or its orbit, to denote it concentric with the earth, or as having the earth for its center, or the same center with the earth. See the articles **EARTH** and **PLANET**.

**GEOCENTRIC latitude of a planet**, is its distance from the ecliptic as it is seen from the earth, which, even though the planet be in the same point of her orbit, is not constantly the same, but alters according to the position of the earth in respect to the planet. For let **BAT** (plate CXIII. fig. 2.) be the orbit of the earth, **PNz** the orbit of the planet, which suppose to be at **P**; from which let fall on the plane of the ecliptic the perpendicular **PE**. In whatever part of her orbit the earth is, this line **PE** will always subtend the angle which measures the geocentric latitude of the planet. Suppose, therefore, the earth at **T**, and venus in **P**, where she comes nearest to the earth, in which position venus is seen in her inferior conjunction with the sun, and her geocentric latitude is measured by the angle **PTE**. But if venus should be in the same situation, **P**, and the earth were at **t**, and from thence venus were observed in her superior conjunction with the sun, where she is at her greatest distance from us, her geocentric latitude would be answerable to **PtE**, which is much less than the angle **PTE**, because the distance **Pt** is greater than **PT**.

What we have here said of the latitude of venus, is likewise true of that of mercury, and upon the same account. See **HELIOCENTRIC** and **LATITUDE**.

**GEOCENTRIC place of a planet**, the place wherein it appears to us from the earth, supposing the eye there fixed: or it is a point in the ecliptic to which a planet seen from the earth is referred.

**GEODÆSIA**, the same with surveying. See the article **SURVEYING**.

**GEOGRAPHICAL MILE**, the same with the sea-mile; being one minute, or the

sixtieth part of a degree of a great circle on the earth's surface.

**GEOGRAPHY**, the doctrine or knowledge of the terrestrial globe; or the science that teaches and explains the properties of the earth, and the parts thereof which depend upon quantity.

Geography, as defined by Varenius, is that part of mixt mathematics, which explains the state of the earth, and of its parts depending on quantity, *viz.* its figure, place, magnitude, and motion, with the celestial appearances, &c. In consequence of this definition, that author divides geography into general and special, or universal and particular.

By universal geography, is understood that part of the science which considers the whole earth in general, and explains its properties without regard to particular countries. This division is distinguished into three parts, absolute, relative, and comparative. The absolute part respects the body of the earth itself, its parts and peculiar properties, as its figure, magnitude, and motion; its lands, seas, and rivers, &c. The relative part accounts for the appearances and accidents that happen to it from celestial causes; and, lastly, the comparative contains an explanation of those properties which arise from comparing different parts of the earth together.

Special or particular geography, is that division of the science which describes the constitution and situation of each single country by itself; and is twofold, *viz.* chorographical, which describes countries of a considerable extent; or topographical, which gives a view of some place, or small tract of the earth. See the articles **CHOROGRAPHICAL** and **TOPOGRAPHICAL**.

Hence the object or subject of geography is the earth, especially its superficies and exterior parts.

The properties of geography, according to the same writer, are of three kinds, *viz.* celestial, terrestrial, and human. The celestial properties are such as affect us by reason of the apparent motion of the sun and stars. These are eight in number. 1. The elevation of the pole, or the distance of a place from the equator. 2. The obliquity of the diurnal motion of the stars above the horizon of the place. 3. The time of the longest and shortest day. 4. The climate and zone. 5. Heat, cold, and the seasons of the year; with rain, snow, wind, and other

other meteors. 6. The rising, appearance and continuance of the stars above the horizon. 7. The stars that pass through the zenith of a place. 8. The celerity of the motion with which, according to the copernican hypothesis, every place constantly revolves. See the articles ELEVATION, POLE, &c.

The terrestrial properties are those observed in the face of each country, and are ten in number. 1. The limits and bounds of each country. 2. Its figure. 3. Its magnitude. 4. Its mountains. 5. Its waters, *viz.* springs, rivers, lakes, and bays. 6. Its woods and deserts. 7. The fruitfulness and barrenness of the country, with its various kinds of fruits. 8. The minerals and fossils. 9. The living creatures there. 10. The longitude and latitude of the place.

The third kind of observations to be made in every country is called human, because they chiefly regard the inhabitants of the place, and these are also ten in number. 1. Their stature, shape, colour, and the length of their lives; their origin, meat, and drink. 2. Their arts, and the profits which arise from them, with the merchandize and wares they barter one with another. 3. Their virtues and vices, learning, capacities, and schools. 4. Their ceremonies at births, marriages, and funerals. 5. The language which the inhabitants use. 6. Their political government. 7. Their religion and church government. 8. Their cities and famous places. 9. Their remarkable histories. 10. Their famous men, artificers, and inventions of the natives.

These are the three kinds of occurrences to be explained in special geography.

In universal geography, the absolute division of the earth, and the constitution of its parts, are examined; and the celestial phenomena in general are to be applied to their respective countries in special geography.

The principles of geography, or those from which arguments are drawn for proving of propositions in that science, are, according to Varenus, of three sorts. 1. Geometrical, arithmetical, and trigonometrical propositions. 2. Astronomical precepts and theorems. 3. Experience, being that upon which the greatest part of geography, and chiefly the special, is founded.

In proving geographical propositions, we are to observe that several properties, and

chiefly the celestial, are confirmed by proper demonstrations; but in special geography, excepting the celestial, almost every thing is explained without demonstration; being either grounded on experience and observation, or on the testimony of our senses: nor can they be proved by any other means. There are also several propositions proved, or rather exposed to view, by the terrestrial globe, or by geographical maps. See the articles GLOBE and MAP.

Other propositions cannot be so well proved, yet are received as apparent truths. Thus, tho' we suppose all places on the globe, and in maps, to be laid down in the same order as they are really on the earth; nevertheless, in these matters, we rather follow the descriptions that are given by geographical writers.

The manner in which we have treated the several geographical articles that occur throughout this work, may be seen under each head, and our division of the science may be seen in the introduction.

Geography is very antient, at least the special part thereof; for the antients scarce went beyond the description of countries. It was a constant custom among the Romans, after they had conquered and subdued any province, to have a map or printed representation thereof, carried in triumph, and exposed to the view of the spectators. Historians relate, that the roman senate, about an hundred years before Christ sent geographers into divers parts to make an accurate survey and mensuration of the whole globe, but they scarce ever saw the twentieth part of it.

Before them, Neco, king of Egypt, ordered the Phœnicians to make a survey of the whole coast of Africa, which they accomplished in three years. Darius procured the Ethiopic-sea, and the mouth of the Indus, to be surveyed; and Pliny relates, that Alexander, in his expedition into Asia, took two geographers to measure and describe the roads; and that from their itineraries, the writers of the following ages took many particulars. Indeed this may be observed, that whereas most other arts and sciences are sufferers by war, geography and fortification alone have been improved thereby. Geography, however, must have been exceedingly defective, as a great part of the globe was then unknown, particularly all America, the northern parts of Europe and Asia, with the Terra Australis,

fralis, and Magellanica ; and as they were ignorant of the earth's being capable to be failed round, and of the torrid zone's being habitable, &c.

The honour of reducing geography to art and system, was reserved for Ptolemy, who, by adding mathematical advantages to the historical method in which it had been treated of before, has described the world in a much more intelligible manner : he has delineated it under more certain rules, and by fixing the bounds of places from longitude and latitude, hath discovered others mistakes, and has left us a method of discovering his own.

There is one thing yet very lame in our geography, the fixing the true longitude of places ; and though several new ways have been lately tried to redress this inconvenience, both from exact pendulums, and from other observations, upon the immersions and emersions of jupiter's satellites, yet they have not altogether proved effectual. See the article LONGITUDE.

The principal writers upon geography, among the antients, are Ptolemy, Pliny, and Strabo : among the moderns, Joannes de Sacrobosco, Cluverius, Heylen, Ricciolus, Weigelius, de Chales, and, above all, Varenius, with Jurin's additions ; to which may be added Leibnecht, Sturmius, Morden, Gordon, Salmon, &c.

**GEOMANCY**, *γομανεια*, according to Polydore Virgil, a species of divination performed by means of chinks made in the ground. Though others think it consisted in making a number of little dots on paper, at random ; and from the various figures which those make, forming a judgment of futurity.

**GEOMETRICAL**, in general, an appellation given to whatever belongs to, or is strictly connected with geometry. See the article GEOMETRY.

**GEOMETRICAL construction of equations.** See the article CONSTRUCTION.

**GEOMETRICAL CURVE.** See CURVE.

**GEOMETRICAL LOCUS**, or PLACE. See the article LOCUS.

**GEOMETRICAL PACE.** See PACE.

**GEOMETRICAL PLANE**, in perspective. See the article PLANE.

**GEOMETRICAL PROGRESSION and PROPORTION.** See PROGRESSION and PROPORTION.

**GEOMETRICAL solution of a problem**, is when it is solved according to the rules

of geometry, and by such lines as are truly geometrical, and agreeable to the nature of the problem. See PROBLEM.

**GEOMETRY**, *γεωμετρια*, originally signified no more than the art of measuring the earth, or any distances or dimensions within it ; but at present, it denotes the science of magnitude in general ; comprehending the doctrine and relations of whatever is susceptible of augmentation or diminution, considered in that light.

Hence, to geometry may be referred the consideration not only of lines, surfaces, and solids ; but also of time, velocity, number, weight, &c.

Plato thought the word geometry an improper name for this science, and accordingly substituted in its place the more extensive one of mensuration ; and, after him, others gave it the title of pantometry, as demonstrating not only the quantities of all manner of magnitudes, but also their qualities, ratios, positions, transformations, relations, &c. And Proclus calls it the knowledge of magnitudes and figures, and their limitations ; also of their motions, and affections of every kind.

**Origin and progress of GEOMETRY.** This science had its rise among the Egyptians, who were in a manner compelled to invent it, to remedy the confusion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their possessions. Thus this invention, which at first consisted only in measuring the lands, that every person might have what belonged to him, was called geometry, or the art of measuring land ; and it is probable, that the draughts and schemes, which they were annually compelled to make, helped them to discover many excellent properties of these figures ; which speculations continued to be gradually improved, and are so to this day.

From Egypt geometry passed into Greece, where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The elements of geometry, written by this last in fifteen books, are a most convincing proof to what perfection this science was carried among the antients. However, it must be acknowledged, that it fell short of modern geometry, the bounds of which, what by the invention of fluxions, and the discovery of the

almost

almost infinite orders of curves, are greatly enlarged. See the articles *CURVE* and *FLUXION*.

We may distinguish the progress of geometry into three ages : the first of which was in its meridian glory at the time when Euclid's Elements appeared ; the second, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this science, which has been carried to its utmost perfection by sir Isaac Newton and Mr. Leibnitz.

*Division of GEOMETRY.* This science is usually distinguished into elementary, and higher or sublime geometry.

The first, or elementary geometry, treats of the properties of right lines, and of the circle, together with the figures and solids formed by them. The doctrine of lines comes first, then that of surfaces, and lastly that of solids.

The higher geometry comprehends the doctrine of the conic sections, and numerous orders of curves. See the article *CONIC SECTIONS* and *CURVE*.

Geometry is again divided into speculative and practical ; the former treating of the properties of lines and figures, as Euclid's Elements, Apollonius's Conic Sections, &c. and the latter shewing how to apply these speculations to the use of mensuration, navigation, surveying, taking heights and distances, gauging, gunnery, &c. See the articles *MENSURATION*, *NAVIGATION*, &c.

We have an excellent treatise on this subject by Dr. Gregory, with additions by Mr. Maclaurin : it is divided into three parts ; the first of which teaches the mensuration of lines and angles. In the second, surfaces are treated of ; and these not only such as are plain, but likewise curve-surfaces, as those of a cylinder, cone, and sphere. The third part treats of solid figures and their mensuration, as sphere, cylinder, cone, &c. See the articles, *SPHERE*, *CYLINDER*, &c.

*Usefulness of GEOMETRY.* The usefulness of this science extends to almost every art and science. It is by the help of it that astronomers turn their observations to advantage, regulate the duration of times, seasons, years, cycles, and epochas ; and measure the distance, motions, and magnitudes of the heavenly bodies. It is by it that geographers determine the figure and magnitude of the whole earth ; and delineate the extent and bearings of kingdoms, provinces, harbours, &c. It is

from this science too, that architects derive their just measures, in the construction of public edifices as well as of private houses. See the articles *ASTRONOMY*, *GEOGRAPHY*, and *ARCHITECTURE*. It is by the assistance of geometry that engineers conduct all their works, take the situation and plans of towns, the distances of places, and the measure of such things as are only accessible to the sight. It is not only an introduction to fortification, but highly necessary to most mechanics, especially carpenters, joiners, mathematical-instrument-makers, and all who profess designing. See *CARPENTRY*, *JOINERY*, *SHIP-BUILDING*, *ENGRAVING*, *DESIGNING*, &c.

On geometry likewise depends, the theory of music, optics, perspective, drawing, mechanics, hydraulics, pneumatics, &c. See *MUSIC*, *OPTICS*, *PERSPECTIVE*, *DRAWING*, *MECHANICS*, &c.

*GEOPONIC*, something relating to agriculture. See *AGRICULTURE*.

*GEORGE*, or *Knights of St. GEORGE*, has been the denomination of several military orders, whereof that of the garter is one of the most illustrious. See *GARTER*.

There is also one of these orders still subsisting at Genoa.

*Religious of the order of St. GEORGE*, form several congregations in Italy and other places.

*St. GEORGE del Mina*, the capital of the dutch settlements, on the Gold-coasts of Guinea, situated seven or eight miles west of Cape-coast-castle, the capital of the british settlements there : west lon. 5°, and north lat. 5°.

*Fort St. GEORGE*, a town and fort on the coast of Cormandel, in the hither India : east lon. 80°, and north lat. 13°.

The town is divided into the White and Black-town. The fort, and White-town, which adjoins to it, are inhabited only by british ; the whole circumference, which is not above half a mile, being surrounded by a stone wall. The outward or Black-town, called Madras, has been lately encompassed by a stone wall and bastions, and is about a mile and a half in circumference ; the whole being almost environed by a river and the sea.

*St. GEORGE's*, the largest of the Bermuda or Summer-islands.

*Cross of St. GEORGE*, a red one in a field argent, which makes part of the british standard. See *CROSS* and *GARTER*.

*GEORGIA*, in Asia, a province bounded by Circassia and Dagestan on the north,

by the Caspian sea on the east, by Armenia or Turcomania on the south, and by Mingrelia on the west.

**GEORGIA**, in America, one of the british plantations, taken out of South-Carolina, from which it is separated by the river Savannah on the north, and bounded by the Atlantic ocean on the east, by the river of St. John, which divides it from spanish Florida, on the south and west.

**GEORGIAN MONKS AND NUNS**, religious of Georgia, in Asia, who follow the rule of St. Basil. See the article **BASIL**.

**GEORGIC**, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry.

The style proper to a georgic must be worked up with a great deal of thought and vigour, that the words may be lively, and every thing the poet describes may immediately rise up to the reader's view. Hesiod and Virgil are the two greatest masters in this kind of poetry. In Virgil's Georgics are contained the most useful rules for husbandry in all its branches. Virgil has infinitely exceeded Hesiod in this sort of writing: he began his Georgics at the persuasion of Mæcenas, and was near seven years about them: they are, with respect to the diction, the most finished of all his works, and even of all the poems that ever were composed in latin. The moderns have produced nothing in this kind, except Rapin's book Of Gardening, and the celebrated poem entitled Cyder, by Mr. Philips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

**GERANITES**, in natural history, an appellation given to such of the semipellucid gems, as are marked with a spot resembling a crane's eye.

**GERANIUM**, **CRANE'S BILL**, in botany, a genus of the *monadelphia-decandria* class of plants, the flower of which consists of five large, patent, oval, and vertically cordated petals; the fruit is a capsule, of the form of a crane's bill.

Geranium stands recommended by authors, as one of the greatest vulneraries and astringents of the vegetable world, particularly for stopping hæmorrhages, excels of the menfes. &c.

**GERARDIA**, in botany, a genus of the *distymania-angiospermia* class of plants, the corolla of which consists of a single lingent petal; the tube is roundish, and

longer than the cup; the upper lip is erect, obtuse, plain, and emarginated; the lower lip is reflected, and divided into three segments: the fruit is an oval capsule, containing two cells, and consisting of two valves; the seeds are oval and single.

This plant is much recommended in gouty disorders.

**GERAW**, a town of Germany, nine miles north-west of Darmstat.

**GERBERA**, in botany, a genus of the *syngenesia-polygamia* class of plants, the general corolla of which is radiated, with very numerous hermaphrodite corollulæ on the disc, which are monopetalous, erect, and divided into three segments at the limb; the stamina are five very short filaments; the seeds are single, oblong, crowned with slender down, and contained in the cup.

**GERFALCON**, or **GYRFALCON**, among sportsmen, a hawk of great force. See the article **HAWK**.

The gerfalcon is the largest of the falcon-kind, with head and eyes like those of the haggard. She is strong armed, having long stretchers and singles; and being of a fierce and hardy nature, is extremely difficult to be reclaimed; but when once she is overcome, she proves an excellent hawk, and will scarce refuse to fly at any thing. See **FALCONRY**.

**GERGENTUM**, a town of Sicily, the Agrigentum of the antients, about fifty-five miles south-east of Palermo: east lon. 13° 30', and north lat. 37° 20'.

**GERMAINS**, or **St. GERMAINS**, a town and royal palace of France, fourteen miles north-west of Paris.

**St. GERMAINS** is also a borough of Cornwall, eight miles west of Plymouth.

It sends two members to parliament.

**GERM**, among gardeners, the same with bud. See the article **BUD**.

**GERMAN**, in genealogy, denotes entire or whole: thus, a brother-german is one both by the father's and mother's side; and cousins-german are the children of brothers or sisters.

**GERMAN**, or **GERMANIC**, also denotes any thing belonging to Germany; as the german empire, german flute, &c.

**GERMANDER**, in botany, the english name of the teucricum of Linnæus. See the article **TEUCRICUM**.

**Water-GERMANDER**, a plant called by botanists scordium. See **SCORDIUM**.

**GERMANY**, an extensive empire of Europe, situated between 5° and 10° east longitude,

longitude, and between 45° and 55° north latitude; bounded by Denmark and the Baltic sea on the north, by Poland and Hungary on the east, by Switzerland and the Alps on the south, and by France, Holland, &c. on the west.

It is divided into ten circles, three of which lie on the north, *viz.* Upper and Lower Saxony, and Westphalia; three on the south, *viz.* Austria, Bavaria, and Swabia; three about the middle, *viz.* Franconia, and the Upper and Lower Rhine; the tenth, which consisted of the dutchy of Burgundy and the seventeen provinces of the Netherlands, have long been detached from the empire. See SAXONY, WESTPHALIA, &c.

There are in Germany upwards of three hundred sovereign princes and states, most of them arbitrary in their respective territories.

GERMEN, or GERM, the same with bud. See the article BUD.

GERMERSHEIM, a town of Germany, subject to France, about ten miles east of Landau: east lon. 8° 15', and north lat. 49° 12'.

GERMINATION, the first sprouting of the seeds of plants. See VEGETATION.

GERONTES, in grecian antiquity, a sort of magistrates of antient Sparta, answering to the areopagites at Athens.

GERTRUDENBURG, a fortified town of the united Netherlands, in the province of Holland, nine miles north of Breda; subject to the prince of Orange.

GERUND, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as, nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*.

Grammarians are very much embarrassed to settle the proper nature and character of gerunds. It is certain they are no verbs, nor distinct moods of verbs, in regard they do not mark any judgment or affirmation of the mind, which is the essence of a verb; besides their having cases, which verbs have not. Some, therefore, will have them to be adjectives passive, whose substantive is the infinitive of the verb: on this footing they are denominated verbal nouns, or names formed of verbs, and retaining the ordinary regimen thereof. See the article NOUN.

The gerunds are derived from active, neuter, and deponent verbs; and, for the most part, they follow their signification;

as, *docendum*, from *doceo*; *currendo*, from *curro*; *loquendum*, from *loquor*.

GESNERIA, in botany, a genus of plants, of the *didynamia* class, the flower of which is monopetalous, tubular, and divided into five segments at the limb; the fruit is a roundish capsule, containing a very great number of extremely small seeds.

GESSEIT, or *Quam diu se bene* GESSE-  
RIT. See the article QUAM DIU.

GESSES, or JESSES, the furniture belonging to a hawk. See JESSES.

GESTATION, among physicians, the same with pregnancy. See the article PREGNANCY.

GESTICULATION, in rhetoric, signifies the affected action of an orator, which is deemed a great fault. See ACTION.

GESTRICIA, a province of Sweden, bounded by Helsingia on the north; by the Bothnic gulph on the east, by Upland on the south, and by Dalecarlia on the west.

GESTU ET FAMA, an antient writ, where a person's good behaviour was impeached, now out of use.

GESTURE, in rhetoric, consists chiefly in the proper action of the hands and face. It is a kind of natural language, that supplies the use of speech in persons born dumb. See the article ACTION.

GETHYLLIS, in botany, a genus of the *decandria-monogynia* class of plants; the corolla of which consists of a single petal; the tube is filiform and very long; the limb is plane, divided into six equal segments, of a lanceolated figure, and but about a third part the length of the tube, the fruit is an oblong, ventricose, triangular capsule, with three cells; the seeds are numerous.

GEVAUDAN, a territory of Languedoc, adjoining to the Cevennes.

GEVER, or St. GOAR, a town of Germany, fifteen miles south of Coblentz.

GEUM, *avens*, in botany, a genus of the *icosandria-pentagynia* class of plants, the corolla of which consists of five roundish petals, with narrow unguis of the length of the cup, and inserted into it; there is no pericarpium; the common receptacle of the seeds is oblong, hairy, and placed on the cup, which is, at that time, reflex: the seeds are numerous, compressed, hispid, and each furnished with a long geniculated style.

GEUM, is also used for saxifrage, *saxifraga*. See the article SAXIFRAGE.

GEX, a town of France, seven miles north-west of Geneva.

**GHEMARA**, or **GEMERA**. See the article **GEMARA**.

**GHENT**, or **GAUNT**, a city and capital of Flanders, thirty miles north-west of Brussels: east lon.  $3^{\circ} 36'$ , north lat.  $51^{\circ}$ . It is a large fortified town, twelve miles in circumference, and defended by a citadel; and yet is a place of no great strength, by reason of the vast extent of ground it takes in.

**GHILIAN**, a town of the french Netherlands, five miles west of Mons.

**GIAGH**, in chronology, a cycle of twelve years; in use among the Turks and Cathayans. See the article **CYCLE**.

Each year of the giagh bears the name of some animal: the first, that of a mouse; the second, that of a bullock; the third, of a lynx or leopard; the fourth, of a horse; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They also divide the day into twelve parts, which they call giaghs, and distinguish them by the name of some animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

**GIALLOLINO**, in natural history, a heavy, friable, fine, yellow ochre, called naples-yellow, and much used among painters, who esteem it a very fine colour. See the article **OCHRE**.

**GIANT**, *gigas*, a person of enormous bulk, or stature.

The reality of giants, and of nations of giants, is much controverted among the learned. Dr. Derham observes, that though we read of giants before Noah's flood, yet there is great reason to think the size of a man was always the same from the creation: for as to the nephilim, or giants, in Gen. vi. the antients vary about them; some taking them for great atheists, and monsters of impiety, rapine, tyranny, and all wickedness, as well as of monstrous stature. And as to those Numb. xiii. represented as men of gigantic size, it is probable the fears of the spies might have added thereto: however this be, it is plain that in both these places giants are spoke of as rarities and wonders of the age, not of the common stature; and such instances we have had in all ages.

**GIANT'S BONES**, in natural history, a name erroneously given to certain fossil bones, vulgarly supposed to have been the bones of giants; but, in reality, are those of the elephant or whale-kind.

**GIANT'S CAUSEWAY**, a vast collection of a black kind of marble, called basalt, in the county of Antrim, in Ireland. See the article **BASALTES**.

**GIAROLA**, in ornithology, a species of lark, with a remarkably long heel.

**GIAROLO**, a species of snipe, with a white tail. See the article **SNIFE**.

**GIBBOUS**, a term in medicine, denoting any protuberance or convexity of the body, as a person hunched, or hump-backed.

**GIBBOUS**, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned, or falcated; and the light one hunched out, convex, or gibbous. See the article **MOON**.

**GIBELINS**, or **GIBELLINS**, a famous faction in Italy, opposite to another, called the **guelphs**.

These two factions ravaged and laid waste Italy for a long series of years, so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The gibelins stood for the emperor against the pope: but concerning their origin and the reason of their names, we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederic II's being excommunicated by pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of guelphs and gibelins arose from a quarrel between two antient and illustrious houses on the confines of Germany, that of the Heniys of Gibeling, and that of the Guelphs of Adorf.

**GIBET**, a kind of gallows, whereon criminals are executed, or hung in chains. See the article **GALLOW**.

**GIBLETS**, *gigeria*, the offals of poultry, particularly of a goose and duck, including the head and neck, heart, liver, pinions, and legs; which the art of cookery has busied itself about, by inventing ragouts, pies, soups, &c. made of them.

**GIBRALTAR**,

**GIBALTAR**, a port-town of Andalusia, in Spain, subject to Great Britain : west lon. 6°, and north lat. 36°.

It stands at the foot of mount Calpe, one of Hercules's Pillars, about sixteen miles north of Ceuta, in Africa, from which it is divided by the Straights, to which it gives name. It is built on a rock, in a peninsula, and can only be approached on the land-side by a very narrow passage between the mountain and the sea : cross this passage the Spaniards have drawn a line, and fortified it, to prevent the garrison's having any communication with the country.

The Straights of Gibraltar are about twenty-four miles long, and fifteen broad.

**GIESEN**, a town of Germany, thirty miles north of Francfort.

**GIFT**, in law, a conveyance, by which either lands or goods are passed : it is of larger extent than a grant, being applied to things moveable and immoveable.

A gift may be by deed, by word, or in law : thus, all a person's goods and chattels, except in some special cases, may be given without deed ; though such a gift is liable to suspicion. When such a gift is made in satisfaction of a debt, it should be done before witnesses of credit ; that the goods and chattels be, at the same time, appraised to the full value ; and that the gift be expressly made in full satisfaction of the debt.

As to gifts in law, where a man is married, all the goods and chattels of his wife belong to the husband ; also, if a person be made executor of a will, by gift in law, all the testator's goods are his, after paying the testator's debts.

And as to deed of gift, all things that lie in livery, as messuages, lands, woods, &c. may be given or granted in fee for life, or years, at first ; and be assigned over forever, afterwards. Such a deed may be made upon condition ; and, if it be of goods and chattels, the delivery of a pence is a good feisin of the whole.

**GIG**, or **GIGG**. See the article **GIGG**;

**GIGANTIC**, something of a monstrous size, like that of giants. See **GIANT**.

**GIGERLÆ**, the same with giblets. See the article **GIBLETS**.

**GIGG**, or **JIGG**, in music, denotes a brisk and lively air ; or an airy kind of dance, to a sprightly measure.

**GIGOT-BRANCH**, in the manege. See the article **BRANCH**.

**GILAN**, a province of Persia, bounded by the Caspian sea on the north. Its ca-

pital is a city of the same name : east lon. 48°, and north lat. 37°.

**GILBERTINES**, a religious order founded in England by St. Gilbert, in the reign of Henry I. The nuns followed the rule of St. Benedict, and the monks, that of St. Augustin. There were many monasteries of this order in different parts of England.

**GILD**, or **GUILD**. See **GUILD**,

**GILDING**, the art of spreading or covering a thing with gold, either in leaf or liquid. See the article **GOLD**.

We have this advantage over the antients, in the manner of using and applying the gold, that the secret of painting in oil, lately discovered, furnishes us with means of gilding works, capable of enduring all the violences of time and weather, which theirs could not.

There are several methods of gilding in use among us, as gilding in water, gilding in oil, gilding by fire, &c. of each of which in order.

*The method of water-GILDING.* Water-gilding requires more preparation than oil-gilding, and is chiefly on wooden works, and those made of stucco ; and these too must be sheltered from the weather. A size is used for this way of gilding made of threads, &c. of parchment or gloves boiled in water to the consistence of a jelly. If the thing to be gilt be of wood, it is first washed with this size, boiling hot, and then set to dry ; and afterwards with white paint mixed up with the same size. Some use Spanish white for this purpose, and others plaster of Paris, well beaten and sifted. This sized paint must be laid on with a stiff brush ; which is to be repeated seldomer or oftener according to the nature of the work, as ten or twelve times in flat or smooth works, but seven or eight will be sufficient in pieces of sculpture. In the former case they are applied by drawing the brush over the work, in the latter by dabbing it. When the whole is dry, they moisten it with fair water, and rub it over with several pieces of coarse linnen, if it be on the flat ; if not, they beat or switch it with several slips of the same linnen, tied to a little stick, to make it follow and enter all the cavities and depressures thereof.

Having thus finished the white, the next thing to be done, is to colour it with yellow ochre : but if it be a piece of sculpture in relievo, they first touch it up, and prepare the several parts, which may have

have happened to have been disfigured, by the small iron instruments, as gouges, chissels, &c. The ochre used for this purpose must be well ground and sifted, and mixed up with the size before-mentioned. This colour is to be laid on hot; and in works of sculpture, supplies the place of gold, which sometimes cannot be carried into all the depressures and cavities of the foliages and other ornaments. A lay is also applied over this yellow, which serves for the ground on which the gold is to be laid: this lay is usually composed of armenian bole, blood-stone, black-lead, and a little fat; to which some add soap, and oil of olives; others, burnt-bread, bistre, antimony, glass of tin, butter, and sugar-candy. These ingredients being all ground down together with hot size, three lays of this composition is applied upon the yellow, the one after the other has been dried; being cautious not to put any into the cavity of the work to hide the yellow.

The brush, used for this purpose, must be a soft one; and when the matter is become very dry, they go over it again with a stronger brush, to rub it down, and take off the small grains that stick out, in order to facilitate the burnishing of the gold. To be prepared for gilding, you must have three sorts of pencils; one to wet, another to touch up and amend, and a third to flatten; also a gilding cushion, for spreading the leaves of gold on when taken out of the book; a knife to cut them, and a squirrel's tail fitted with a handle; or else a piece of fine soft stuff on a stick, to take them up directly and apply them. You are first to begin with wetting your pencils; by which the last lay laid on with water is moistened, that it may the better receive and retain the gold. Then you are to lay the leaves of gold on the cushion, and if whole, you must take up with the squirrel's tail, but if in pieces, with the other instrument, or the knife wherewith they are cut, and lay and spread them gently on the parts of the work you had moistened before. If the leaves, as they frequently do, happen to crack or break in laying on, these breaches must be made up with small bits of leaf, taken up upon the repairing pencil, and the whole work is to be smoothed either with the same pencil, or another something larger; the gold being pressed into the dents, into which it could not be so easily carried by the squirrel's tail.

The work having been thus far gilded, must be set to dry, in order to be burnished or flattened. See BURNISHING and FLATTING.

The last operation is the applying the vermeil in all the little lines and cavities; and to stop and amend any little faults with shell-gold. The composition called vermeil is made of gum gutta, vermilion, and a little of some ruddy-brown, ground together with venetian varnish and oil of turpentine. Some gilders, instead of this, make shift with fine lacca, or dragon's blood, with gum-water.

Sometimes instead of burnishing the gold, they burnish the ground or composition laid on the last before it, and only afterwards wash the part over with the size. This method is chiefly practised for the hands, face, and other nudities in rilievo: which, by this means, do not appear so very brilliant as the parts burnished, though much more so than the parts perfectly flat.

To gild a piece of work, and yet preserve white grounds, they apply a lay of Spanish white, mixed with a weak fish-glue on all the parts of the ground, whereon the yellow or the last lay might run.

*The method of GILDING in oil.* This operation requires much less apparatus than that before-mentioned. The basis or matter whereon the gold is laid, in this method, is the remains of colours found settled to the bottom of the pots in which painters wash their pencils. This matter, which is very viscid or sticky, is first ground, and then passed through a linnen-cloth, and thus laid on the matter to be gilt, after it is washed once or twice over with size; and if it be wood, with some white paint.

When this is almost dry, but yet is still unctuous enough to catch and retain the gold, the leaf-gold is laid on, either whole, if the work be large, or cut to pieces, if smaller: the leaves of gold are taken up and laid on with a piece of fine, soft, well-carded cotton; or sometimes by a palat for the purpose, or sometimes with the knife with which the leaves were cut, according to the parts of the work that are to be gilded, or the breadth of the gold that is to be laid on. As the gold is laid on, they pass over it a coarse stiff pencil or brush, to make it stick and as it were incorporate with the ground; and after this they mend any cracks that may have happened in it, either with the same pencil or one that is smaller,

smaller, as has been shewn before in water-gilding.

This kind of gilding is chiefly used for domes and roofs of churches, courts, banquetting-houses, &c. and for figures of plaster of Paris, lead, &c.

*The method of GILDING with liquid gold.*

This is performed by gold reduced to a calx and amalgamated with mercury, in the proportion of about an ounce of mercury to a dram of gold. To perform this, they heat a crucible red-hot, and then put the gold and mercury into it, stirring them gently about till the gold be found melted, and incorporated into a mass with the mercury. When this is done, they cast them into water, to wash and purify them; and out of that into other waters, where the amalgama, which is almost as liquid as if there were nothing but quicksilver in it, may be preserved a long time for use.

Before they proceed to lay this amalgamated gold on the metal, they first render the metal rough, by washing it over with aqua fortis, or aqua secunda; and afterwards rinse the metal in fair water, and scour it a little with fine sand, and then it is ready for the gold.

They next cover over the metal with the mixture of gold and mercury, taking it up with a slip of copper, or a brush made of brass-wire, spreading it as even as possible, to do which they wet the brush from time to time in fair water. Then they set the metal to the fire, upon a grate, or in a sort of cage, under which stands a pan of coals; and in proportion as the mercury, evaporating and flying off, discovers the places where gold is wanting, they take care to supply them by adding new parcels of amalgama.

Then the work is rubbed over with the wire-brush, dipt in beer or vinegar, which leaves it in a condition to be brought to a colour, which is the last part of the process, and which the gilders keep to themselves as a mighty secret.

*The method of GILDING by fire on metal.*

To prepare the metal, they scratch it well, or rake it; then polish it with a polisher; and afterwards set it to the fire to blue, *i. e.* to heat, till it appear of a blue colour. When this has been done, they clap on the first lay of leaf gold, rubbing it lightly down with a polisher; and expose it thus to a gentle fire. They usually give it but three such lays, or four at the most, each lay consisting of a single leaf for common works, and of

two for extraordinary ones: after each lay, it is set a-fresh to the fire; and after the last lay, the gold is in condition to be burnished.

*To gild paper.* Grind bole-armoniac with rain-water, and give one laying of it; when it is dry, take glair of eggs, and add to it a little sugar-candy and gum-water, which lay over the former, and upon this, when it is dry enough, lay leaf-silver, or leaf-gold.

*To gild the leaves of books.* Take bole-armoniac, eight penny-weight; sugar-candy, two penny-weight: mix and grind them with glair of eggs: then on a bound book (while it is in the press, after it hath been smeared with glair of eggs, and is dried) smear the said composition, let it dry, then rub it well and polish it; then with fair water wet the edges of the book, and suddenly lay on the gold, press it down gently with cotton, let it dry, and then polish it with a tooth.

*GILDING of china or porcelain ware.* See the article PORCELAIN.

*GILL*, a measure of capacity, containing a quarter of a pint. See PINT and MEASURE.

*GILL* is also a name for ground-ivy, which, being infused in ale, makes what is known by the name of gill-ale; a sort of medicated ale, said to be absterive and vulnerary.

*GILLA VITRIOLI*, a name sometimes given to the emetic salt of vitriol. See the article VITRIOL.

*GILLINGEN*, a town of Swabia, eleven miles south of HAILBRON.

*GILLS*, *branchiæ*, in ichthyology. See the article BRANCHIÆ.

*GILOLO*, a large island of the Pacific ocean, lying between 1° south latitude and 2° north latitude, and between 125° and 128° east longitude.

*GILOLO* is also the name of the capital of the above island, situated in 40' north latitude.

*GILT-HEAD*, *aurata*, in ichthyology, the sharp-backed sparus, with a crooked gold-coloured line between the eyes. It is a very beautiful fish, the ground-colour of whose body is an olive-brown, but elegantly variegated with a number of different colours. See SPARUS.

*GILT-VARNISH.* See VARNISH.

*GIN*, or *GENEVA*, among distillers. See the article GENEVA.

*GIN*, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved, that

that goes over the wheel at the top : one end of this rope is seized to an iron-monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight ; and when hove up to a cross-piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into ground : then the monkey's own weight over-hauls the windlafs, in order for its being hooked again to the beetle. See the article *ENGINE*.

**GINGEN**, an imperial city of Germany, twenty miles east of Ulm : east lon.  $10^{\circ}$ , and north lat.  $48^{\circ} 36'$ .

**GINGER**, *zinziber*, in botany. See the article *ZINZIBER*.

The root of this plant is too well known to need any description : it will be sufficient to observe, that it is of the tuberous kind, knotty, crooked, and irregular, and divaricated into many branches, of a pale yellowish colour when broken, and, like the *contrayerva*, of a fibrous structure. This root is of a very hot, acrid, and pungent taste; though aromatic withal, and of a very agreeable smell.

Ginger is too cheap to be sophisticated, and too well known to need any directions about the choice of it ; it may only be observed that the hardest and firmest pieces are the best. The Indians are very fond of ginger ; they eat both the young shoots of the leaves, and the roots themselves, cut small, in their sallads and broths ; and they make an excellent sweet-meat of them, preserving them with sugar. Ginger is an excellent carminative and stomachic ; it assists digestion, expels flatulencies, and takes off colic pains, often almost instantaneously. It is also highly esteemed by some as a cephalic, and is particularly said to strengthen the memory. It is often used as a corrective to purging medicines, and has the credit of being a great provocative to venery, especially in the preserved state. It may be given in powders, from two or three to ten, twelve, or fifteen grains ; but it is seldom given in such large doses, on account of its acrimony. It is used in decoctions from one dram to two or three, to the quart. It is an ingredient in the *venice-treacle*, *mithridate*, and *diacordium*, and in many other of the compositions of the shops ; and is very frequently used in carminative and stomachic powders, in extemporaneous prescription.

*Method of preserving GINGER.* Wash the ginger, and lay it to steep for ten or twelve days, in white-wine and water, stirring them every day ; then to a pound of roots allow two quarts of white-wine, and about a pint of lemon-juice ; boil these together for about a quarter of an hour : then add two pounds and a half of fine sugar, and boil it to a syrup, scumming it as it rises ; then set it by in a glazed pan till the next day, and afterwards boil it again in the syrup, for half an hour ; then set it by till the next day, when boiling it again, let it cool ; repeating this till the ginger is clear : after which put it into glasses, and cover them with paper.

This is a fine sweet-meat for the winter-season.

**GINGER-BREAD**, a richer kind of bread, the flavour and taste whereof are heightened and improved with spices, and particularly with ginger, whence the name.

The preparation of ginger-bread is as follows : grate two penny white loaves into two pounds of almonds well blanched and pounded ; then add two ounces of ginger, finely scraped, liquorice, and anise in powder, of each half an ounce ; add to these five or six spoonfuls of rosemary-water ; and knead all into a paste, with a pound of sugar, mould it, and roll it thin, then print it, and dry it in a stove. Others make it of treacle, citron, lemon, and orange-peel, with candied ginger, coriander, and caraway-seeds, mixed up with as much flour as will make it into a paste.

**GINGER-WINE** is made as follows : take three gallons of water, an ounce of rance-ginger, and three pounds of sugar ; boil them for an hour, and then put into it three lemons, and a little good yeast ; close up the vessel, and let it stand five days : if it has so worked as to be clear in that time, it may be bottled ; if not, let it stand longer, until it has worked sufficiently ; and in ten days after it may be drank.

**GINGIDIUM**, in botany, the name by which some call two different plants, a species of fennel and of thapsia. See the articles *FENNEL* and *THAPSIA*.

**GINGIVÆ**, the *GUMS*, in anatomy, a hard sort of flesh, investing the alveoli, or sockets of the teeth.

The gums consist of the common membrane of the mouth, and the periosteum of the jaws, to which they adhere very closely and firmly. They are furnished with

with a vast number of blood-vessels, whence their florid red colour; and they serve for the covering of the jaws, and the keeping the teeth fast in their sockets.

**GINGLYMUS**, γινγλυμος, one of the three subdivisions of that kind of articulation called diarthrosis. See the articles **ARTICULATION** and **DIARTHROSIS**.

The ginglymus is that juncture of the bones wherein they mutually receive and are received by one another, as is the case of the articulation of the humerus and cubitus. See **HUMERUS**, &c.

The ginglymus is again subdivided chiefly into three kinds; the first is when the same bone at the same extremity receives, and is reciprocally received by another bone, after the manner of an hinge, as that of the cubitus and humerus: the second is when a bone receives another at one of its extremes, and is received into another, as the vertebrae do: the third is that where a bone is received into another after the manner of a wheel, or the axis of the wheel in a box, such is that of the second vertebra of the neck in the first.

**GINSENG**, in botany. See the article **PANAX**.

The root of the ginseng is of an oblong figure, never growing to any great size, being generally about four or five inches long, and its thickness that of one's little finger. It is of a firm texture, its surface is furrowed and wrinkled in different places. It is of a brownish colour on the outside, and somewhat yellowish within; and is so pure and fine, that it seems transparent. The top of the root, when it is sent entire to us, is found composed of knots, or tubera, placed over one another in an irregular manner: these are formed of the bottoms of the decayed stalks of the several preceding years. When the root is fair and entire, it is easy to know by these how old it is; but very old roots not being so much in repute, the people who gather ginseng have often the precaution to cut off some, or even all those knobs, before they dry the root.

Ginseng is of a very agreeable and aromatic smell, tho' not very strong; its taste is acrid and aromatic, and has somewhat bitter in it. It is to be chosen sound and firm, moderately heavy, not too tough, and of a good smell. Before it be bought, it will be prudent to cut every root thro', for the Chinese, of whom we have it, fre-

quently find a way to introduce pieces of lead into it, to increase the weight.

The roots of the ginseng and ninzin are so much alike in their shape, colour, and virtues, that they are frequently mistaken for one another, and by the generality of authors understood to be the same, notwithstanding that they belong to two very different plants, and of two different genera. See the article **NINZIN**.

The Chinese and Tartars collect the root of this plant with infinite pains, at two seasons of the year, spring and autumn. They are forbid to touch them with any iron-instrument, so that they can only clean them with wooden knives. They wash them in a decoction of millet-seed, and afterwards hang them over the fumes of the same liquor, which they boil in considerable quantities for that purpose, in a close vessel, in the upper part of which the root is suspended, over the surface of the liquor: after this they dry it for use, thus it becomes transparent. The small fibres which are taken off, they boil in water, and make an extract of them, which they use in the same intention with the root.

The Chinese value the ginseng so highly, that it sells with them for three times its weight in silver. They, as well as the Asiatics in general, think the ginseng almost an universal medicine: they have recourse to it in all diseases, as the last remedy, and readily give themselves over when it will not cure them; but the virtues most generally ascribed to it, are those of a restorative, a provocative, and a cordial. It is famous in the east for giving strength to those who have disabled themselves by the too free use of women: there they also recommend it greatly in the small-pox, fevers of all kinds, disorders of the stomach and bowels, and tell us that diarrhoeas and dysenteries are cured by it: but they caution people not to give it in too large doses to persons of a florid sanguine constitution, on whatever occasion it may be necessary to them. The European physicians esteem it a good medicine in convulsions, vertiges, and all nervous complaints, and recommend it as one of the best restoratives known.

Its dose is from ten grains to twenty, in powder; and from one dram to two to the pint, in infusions.

**GIOVENAZZO**, a bishop's see in the kingdom of Naples, twelve miles west of Bari.

**GIRACE**, a city and port-town of Calabria, about thirty-six miles north-east of Reggio.

**GIRANDOLE**, a kind of branched candlestick. See the article **CANDLESTICK**.

**GIRDERS**, in architecture, some of the largest pieces of timber in a floor.

Their ends are usually fastened into summers and breast-summers, and joists are framed in at one end to the girders.

The size of girders and summers, upon the rebuilding of London, were ordained by act of parliament, to be in length from ten to twenty-six feet, in breadth from eleven to seventeen inches, and in depth from eight to fourteen inches. It was also ordained by the same statute, that no girder or summer should be less than ten inches in the wall, and that their ends should be laid in loam; as also that they be of good hearty oak, as free from knots as may be, because that will be the least subject to breaking, and may with more safety be relied on in this cross and transverse work.

**GIRDING-GIRT**, in the sea-language. A ship is girt, or hath a girding-girt, when her cable being so tight, or strained, upon the turning of the tide, she cannot get over it, but lies across the tide.

**GIRDLE**, *cingulum*, or *zona*, a belt or band of leather, or other matter, tied about the reins, to keep that part more firm and tight.

The Romans always wore a girdle, to tuck up the tunica, when they had occasion to do any thing: this custom was so general, that such as went without girdles, and let their gowns hang loose, were reputed idle dissolute persons.

It was antiently the custom among us, for bankrupts and other insolvent debtors to put off and surrender their girdle in open court; the reason whereof was, that our ancestors used to carry all their necessary utensils, as purse, keys, &c. tied to the girdle: whence the girdle became a symbol of the estate.

**Virgin-GIRDLE**. It was the custom among the Greeks and Romans, for the bridegroom to untie his bride's virgin-girdle, before he took her to his embraces. See the article **BRIDEGROOM**.

This girdle was made of sheeps-wool; it was tied in the herculean knot, and in bed the husband untied it, as a happy presage of his having as many children as Hercules, who at his death left seventy behind him. The poets attribute to Venus a particular kind of girdle, capable

of inspiring the passion of love. See the article **CÆSTUS**.

**Quicksilver-GIRDLE**, *cingulum sapientie*, in medicine, a sort of belt or girdle, invented by Rulandus, made with woollen-cloth sufficiently impregnated with quicksilver, killed with hog's lard.

This is sewed up in a linnen-cloth, which is applied to the skin, about the hypochondria, in disorders of the itch, phthiriasis, ulcers, and in cases where there is no absolute necessity for exciting a salivation. The patient's body must be kept warm, and defended from the cold of the external air, otherwise the belt, which is of itself highly safe, becomes very dangerous, as the access of the external cold during its use, according to Etmuller, endangers a salivation, petechial fever, or other disorders. Bartholine informs us, that this girdle proves mortal, when applied to patients who are either too young, weakened by diseases, or of a cacochymic habit of body.

**Christians of the GIRDLE**, the christians of Asia, particularly those of Syria and Mesopotomia, who to this day wear a large leathern girdle, being enjoined thereto by Motavakkel, tenth caliph of the family of the Abbassides, in the year 856, as a badge of their profession.

**Order of the GIRDLE**. See **CORDELIER**.

**GIRDLE**, in architecture. See **CINCTURE**.

**GIRGE**, a city of upper Egypt, on the west side of the Nile: east lon. 32°, and north lat. 26°.

**GIRGILIM**, in the materia medica, the same with the *sesamum*.

**GIRKIN**, a term used by gardeners for a small kind of cucumber. See **CUCUMBER**.

**GIRLE**, among sportsmen, denotes the roebuck in its second year.

**GIRONNE**, a large city and bishop's see of Spain, in the province of Catalonia, forty-five miles north-east of Barcelona: east lon. 2° 35', and north lat. 42°.

**GIRONNE**, or **GIRONNY**, in heraldry, a coat of arms divided into girones, or triangular figures, meeting in the center of the shield, and alternately colour and metal. See plate CXI. fig. 3.

**GIRT**, in the mensuration of timber, denotes the circumference of a tree. See the article **TIMBER**.

**GIRT**, among builders, a term sometimes used for fillet. See the articles **FILLET**.

**GIRTHS** of a saddle, the strong canvas-straps, which, being buckled under a horse's belly, serve to fix the saddle. See the article **SADDLE**.

**GISBORN**,

**GISBORN**, a market-town of Yorkshire, fifty miles west of York.

**GISBOROUGH**, another market-town of Yorkshire, thirty-seven miles north of York.

**GISCARA**, in botany, the name of a brasilian species of palm-tree.

**GISON**, or **GEISON**, in jewish antiquity, signifies, according to Josephus, a little wall, about breast high, made round the temple of Jerusalem, and round the altar of burnt sacrifices, to keep the people at a distance. This author, in his books of antiquities, makes the gison three cubits high, and but one in his history of the jewish war.

**GISORS**, a city of Normandy, in France, twenty-eight miles south-east of Rouen : east long.  $1^{\circ} 25'$ , north lat.  $50^{\circ} 10'$ .

**GITHAGO**, a name used by some for a species of lychnis. See **LYCHNIS**.

**GIVEN**, among mathematicians and philosophers, the same with data. See the article **DATA**.

**GIVET**, a town of the bishopric of Liege, twenty miles south of Namur.

**GIUSTANDIL**, a town of european Turkey, in the province of Servia : east long.  $24^{\circ}$ , north lat.  $43^{\circ}$ .

**GIULA**, a city of Hungary, subject to the house of Austria : east long.  $21^{\circ} 35'$ , north lat.  $46^{\circ} 38'$ .

**GLABELLA**, in anatomy, the name by which some call the space between the eye-brows, as being smooth and void of hair.

**GLACIS**, in building, an easy, insensible slope, or declivity.

The descent of the glacis is less steep than that of the talus. In gardening, a descent sometimes begins in talus, and ends in glacis. See the article **TALUS**.

The glacis of the corniche, is an easy imperceptible slope in the cymatium, to promote the descent and draining off the rain-water.

**GLACIS**, in fortification, that mass of earth which serves as a parapet to the covered way, sloping easily towards the champion, or field.

The glacis, otherwise called esplanade, is about six feet high, and loses itself by an insensible diminution in the space of ten fathoms. See **ESPLANADE**.

**GLADDON**, or **GLADWIN**, a plant called by botanists iris. See the article **IRIS**.

**GLADE**, in ornithology. See the article **GLEAD**.

**GLADE**, in gardening and agriculture, an opening and light passage made through

a wood, by lopping off the branches of trees along that way.

**GLADIATORS**, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like our prize-fighters, for a livelihood.

The Romans borrowed this cruel diversion from the Asiatics; and we find that the very priests had their *ludi pontificales*, and *ludi sacerdotales*. As from the earliest ages of antiquity we read that it was customary to sacrifice prisoners of war to the manes of the great men that fell in the engagement, in process of time, they came to sacrifice slaves at the funerals of all persons of condition; but as it would have appeared barbarous to cut their throats like beasts, they were appointed to fight with each other, and to do their best to save their own lives by killing their adversary. See the article **BUSTUARI**.

Hence arose the masters of arms called *lanistæ*, and men learned to fight. These *lanistæ* bought slaves to train up to this cruel trade, whom they afterwards sold to such as had occasion to exhibit shews. Junius Brutus, who expelled the kings, was the first that honoured the funeral of his father with these inhuman diversions at the sepulchre of the deceased; but afterwards they were removed to the circus and amphitheatres; and other persons, besides slaves, would hire themselves to this infamous office.

They were all first sworn that they would fight till death, and if they failed, they were put to death, either by fire, swords, clubs, whips, &c. It was usual with the people, or emperor, to grant them life when they shewed no signs of fear. Augustus decreed, that it should always be granted them.

From slaves and freed men, the wanton sport spread to persons of rank, as we find in Nero's time. And Domitian exhibited combats of women in the night-time: we also read, that dwarfs encountered with one another. Constantine the great first prohibited these combats in the east, but the practice was not entirely abolished in the west before Theodoric king of the Ostrogoths, in the year 500.

When any person designed to entertain the people with a shew of gladiators, he

set up bills in the public places, giving an account of the time, the number and names of the combatants, and the circumstances whereby they were to be distinguished; each having his several badge, which generally was a peacock's feather: they also gave notice what time the show would last; and sometimes gave representations of these things in painting, as is practised among us, by those who have any thing to show at fairs, &c. Upon the day appointed for the show, in the first place the gladiators were brought out all together, and obliged to take a circuit round the arena in a very solemn and pompous manner. After this, they proceeded, *paria componere*, to match them by pairs, in which great care was taken to make the matches equal. The first sort of weapons they made use of were staves, or wooden files, called *rudes*, and the second were effective weapons, as swords, poniards, &c.

The first were called *arma lusoria*, or *exercitoria*; the second, *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited.

They began to fence or skirmish with the first, which was to be the prelude to the battle, and from these, when well warmed, they advanced to the second, with which they fought naked. The first part of the engagement was called *ventilare*, *præludere*; and the second *dimicare ad certum*, or *versis armis pugnare*.

When any received a remarkable wound, either his adversary or the people used to cry out, *babet*, or *hoc habet*. If the vanquished surrendered his arms, it was not in the victor's power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant this boon. The two signs of favour and dislike given by the people, were *premere pollicem*, and *vertere pollicem*, the former of which M. Dacier takes to be a clenching of the fingers of both hands between one another, and so holding the two thumbs upright close together, was a sign of the people's admiration of the courage shewn by both combatants; and at the same time for the conqueror to spare his antagonist's life: but the contrary motion, or bending back of the thumbs, signified the dissatisfaction of the spectators, and authorised the victor to kill the other

combatant downright for a coward. The emperor saved whom he liked, if he was present at the solemnity, in the same manner.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and oftentimes a sum of money, perhaps gathered up among the spectators: but the most common rewards were the *pileus* and the *rudis*; the former being given only to such gladiators as were slaves, for a token of obtaining their freedom; but the *rudis* seems to have been bestowed both on slaves and freemen, with this difference, that it procured the former no more than a discharge from any further performance in public, upon which they commonly turned *lanista*: but the *rudis*, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty. See the articles *PILEUS*, *RUDIS*, and *LANISTA*.

There were divers kinds of gladiators distinguished by the weapons, manner, time of fighting, &c. such were the *andabata*, *cateruarii*, *consummati*, *cubicularii*, *dimachæ*, *ficales*, &c.

**GLADIOLE**, *gladiolus*, in botany, a genus of the *triandria-monogynia* class of plants, the flower of which consists of six petals that unite at their bases: the fruit is an oblong, trilocular capsule, containing a great many triangular seeds.

The root of gladiolus, or the common corn-flag, is accounted discutient, and good in malignant and pestilential cases.

**GLADIUS**, a sword; whence *jus gladii*, or right of the sword, is used in our ancient latin authors, and in our norman laws, for supreme jurisdiction: and it is probably from hence that, at the creation of an earl, he is *gladio succinctus*, to denote his having a jurisdiction over the county.

**GLADIUS-PISCIS**, a fish more usually called xiphias. See the article *XIPHIAS*.

**GLAMA**, a species of peruvian camel, with the back even, and the breast gibbous. See the article *CAMEL*.

**GLAMORGANSHIRE**, a county of south Wales, bounded by Brecknockshire on the north, and by the Bristol channel on the south. Its capital is Landaff.

**GLAND**, in anatomy, a small body, formed by the interweaving of vessels of every kind, covered with a membrane, usually provided with an excretory duct, and destined to separate some particular fluid from

from the mass of blood, or to perfect the lymph. See BLOOD and LYMPH.

Many of the anatomical writers of the very first class, and among these some who have written professedly of the glands, and have made it their peculiar business to examine nicely into their nature, and explain their structure, have yet, from mere difficulty of ascertaining adequate ideas of the term, evaded giving a definition or general description of the glands; and in consequence of this, numberless errors, and an almost inextricable confusion, has crept into the study of this important part of the human structure.

Other authors, who have had more boldness, if not greater abilities than those who have avoided meddling with definitions of these parts, have ventured to establish what they call glands: but these differ so much from one another in what they would establish as general certainty, and have produced such imperfect and erroneous definitions, that they have all either included parts which themselves own not to be glands in the definition, or they have limited the term to some particular ones, and excluded what themselves and every body else allow to be glands out of the number.

Glands are parts of a peculiar structure: they are of various figures, colours, and consistencies, as they are destined to different offices. The antients supposed them formed of a different kind of flesh from that of the rest of the body; but the parts to which they have given the name of glands, though they are as different from one another as possible in figure, size, and colour, yet they are easily known, and distinguished as glands by all the world; notwithstanding the difficulty of giving a definition or even a general character of a gland, which shall include all the true glands, and take in no other parts of the body with them.

Many writers on this subject have asserted, that wherever there is a secretion of any kind performed, there is a gland; but this is not true, for there are many secretions performed in the body, and those even of the largest and most important kind, where there are no glands to perform them: the chyle is secreted in the intestines without the assistance of glands; the semen is secreted in the testicles; and the pituita in the pituitary sinuses of the brain, where there are no

glands at all. On the other hand also it is to be observed, that there are glands received and allowed by all writers as such, which do not appear to perform any secretions at all; and the antients themselves agreed in giving the name of glands to several parts, though they were not assured that they secreted any thing, nor even in some cases believed that they did. But Mery, in several papers in the Memoirs of the Paris Academy, not only proves that all the secretions are not performed by means of glands, but that many of the secretions of most importance to the body are performed without glands. We are to add also, that every beginner in anatomy, at this time, knows a gland to be such when he sees it, without knowing any thing of its use. There are therefore other characters by which a gland may be known, though by its office and use it cannot.

Other writers, of the number of whom is the great Malpighi, in dissections of particular bodies, having found vesicles in the brain, liver, kidneys, and other parts of the body, thence declared them to be glandulous in their structure: but in these cases, the bodies dissected were all morbid ones; and as the same vesicles are not found in healthy ones, nor indeed any thing analogous to them, it is a sufficient proof that they are not natural parts of their structure; and besides, vesicles and glands are different. See VESICLE and VASCULOUS.

It is evident that the antients called certain parts of the human body glands, and that for no other reason but because they found them composed of a peculiar kind of fleshy substance, of a peculiar habit, or external appearance, without paying any the least regard either to their internal structure, their spherical figure, (by which character some define them) or their use.

If it be asked, says Heister, what this particular habit in the glands is? or how we are to know it? the answer is, that the peculiar complication and arrangement of the vessels, from which there arises a form obviously distinguishable at sight from the muscles, the fat, the bones, the membranes, the vessels, and in fine from every other part of the human fabric, which gives a sufficiently certain, determinate and striking notice of it.

The differences of the glands among themselves, as established by many authors, are very numerous: it will not be necessary to

to run into the whole disquisition ; we shall only select a few which are more generally established than the rest, and of more immediate and real use. We shall first divide them into two general kinds, the simple, called also conglobate glands, and the conglomerate. See the articles CONGLOBATE and CONGLOMERATE.

The glands differ also greatly in regard to their consistence: some of them are considerably hard and firm, and others extremely soft and tender: of the latter kind in particular are the glands situated in the articulations of the bones of the several parts of the body.

They differ also very considerably in colour. Some of them are of a pale, whitish, red, or fleshy colour; others of a strong, deep red; others yellowish, or brownish, and some evidently blackish.

Their differences in figure are as considerable also as those in colour: some of them are round, others oval, others oblong, and many others of figures as different as well can be from any one of these regular ones: the pancreas, the thyroide, and the thymus, are instances of this: some of them have obtained their names from their peculiar figure: of this number are the glandula pinealis, the miliaries, and others. See the articles PANCREAS, THYROIDE, THYMUS, &c.

*The uses of the GLANDS* are also as different as their colours or figures: some of them are salival, mucose, and lymphatic; others are mucilaginous, sebaceous, and waxy; others lachrymal, pituitary, &c. and from these their several contents or secretions, they are termed lachrymal, &c. see the articles SALIVAL, LYMPHATIC, MUCILAGINOUS, &c.

*The situation of the GLANDS* is another article in which they differ, and from which many of them have their several names; such are the parotides, maxillares, linguales, thyroide, palatine, labial, jugular, cervical, axillary, inguinal, lumbar, intestinal, mesenteric, renal, &c. See the articles PAROTIDE, MAXILLARY, LINGUAL, &c.

And, finally, the size of the glands is a thing in which they differ most obviously and essentially.

*Of the GLANDS in particular.* The particular glands of the body, or such as are truly and properly of this denomination, are, according to Heister, as follow; and first of the glands of the head.

In the sinuses of the dura mater, and out

of them, at the sides, there are found a number of small glands described by Pacchionius; and there are sometimes others visible in the foveæ of the os frontis, and about the divisions of the vessels, between the dura mater and the arachnoides. These glands seem destined for the secreting of a fluid to moisten the dura mater. Other glands of the brain are the pineal gland, and the pituitary gland. See the articles PINEAL, PITUITARY, DURA MATER, and BRAIN.

In the exterior part of the head, that is, out of the cavity of the skull, we have the parotids, the maxillary glands, the sublinguals, the linguals; the labials, the palatine, and the buccinals, which are distributed here and there about the membrane of the mouth; and are each described in their places. In the orbit also there is the lachrymal glands; under the eyes are the sebaceous or seraceous glands, the tonsils in the fauces, the mucose glands in the pituitary membrane of the nostrils, and the ceruminose glands of the ears, each of which are described under their several heads. See the articles EYE and EAR.

The principal gland of the neck is the thyroides, besides which there are also found in the neck a great number of lesser ones, distributed here and there among the muscles and fat. Their figure, their number, and their situations, vary in different subjects; but in general those in the anterior part of the neck are called jugulars; and those in the hinder part, occipitales and cervicales. The use of these is hitherto uncertain; it is generally supposed that they are of service to the lymphatic vessels, but what sort of use they can be of to them, does not so easily appear. See the articles THYROIDES, JUGULARES, OCCIPITALES, CERVICALES, and NECK.

Ruysh and Morgagni have also described and figured glands in the epiglottis: and Morgagni has described others in the other parts of the larynx, particularly about the arytenoide cartilages, as also in the trachea: but these are often so small, that they are scarce discoverable in dissection.

The oesophagus, especially towards its upper part, has a great number of glands; and it is common to find a little aperture or osculum in the center of each, which has much the appearance of an excretory duct.

In the thorax we meet with the gland thymus;

thymus; as also with the glandulæ bronchiales: these last are very observable glands, situated externally in the larger divisions of the trachea and bronchia. They are of a blackish colour; and their use, like that of many others of the glands of this part of the body, is yet very little known. It had been long supposed that they served to secrete a liquid which they discharged into the bronchia, for the lubricating and moistening these parts; but Vercellonius will have it, that they secrete a fluid whose use is to be assistant in the digestion of our food, and that they discharge it into the oesophagus through certain extremely minute ducts. See the articles THORAX, THYMUS, BRONCHIA, &c. About the fifth vertebra of the back, there is sometimes found in the thorax a remarkable gland adhering to the posterior part of the oesophagus: this is usually called glandula dorsalis. It is, in different subjects, of various sizes. It is often of the size of a kidney-bean; sometimes of that of an almond, and sometimes considerably larger; in others, it is much less than the smaller, and sometimes it is wholly wanting; or at least so extremely minute and inconsiderable, that the best dissectors are not able to find it. Sometimes also two glands are found in this part in the place of one. Vercellonius is of opinion, that this gland is also placed there for the secretion of a fluid serving to assist the digestion of our food in the stomach: but Fantonus, and some others, suppose, that these glands discharge a fluid of a mucous nature into the cavity of the oesophagus: several authors affirm, that in dogs these glands are found tumid, and inhabited by a number of oblong and slender red worms. See DORSUM, VERTEBRA, and OESOPHAGUS. In the abdomen there are very considerable numbers of glands: the largest of them is the pancreas; after this in size come the glandulæ renales, or capsulæ atrabiliaræ; after these the mesenterics, and the intestinals of Brunner and Peyer in the intestines. See ABDOMEN, &c. The glands of the stomach are very easily distinguishable in dogs and hogs; but in human subjects, it is difficult to find them: many anatomists have doubted them. Morgagni, however, discovered them so fairly in human subjects, that there is no doubt left about them.

About the vertebra of the loins, near

where the receptaculum chyli is situated, and about the os sacrum, and the divisions of the iliac vessels, are many glands of various sizes and figures: they are commonly called lumbares, sacræ, and iliacæ, and they have numerous lymphatics entering into them, and discharging their contents into the receptaculum chyli. The lumbar glands have been sometimes found swelled to the bigness of a man's fist.

In the concave part of the liver, about the ingress of the vena portæ and the neck of the gall-bladder; as also about the spleen, near the ingress of the vessels, there are frequently found conglobate glands, of about the bigness of a kidney-bean: these are called by authors hepatic glands, cystic glands, and by other names formed from the names of the parts they are near; and they seem to serve the lymphatic vessels. See LIVER.

About the left orifice of the stomach, there sometimes also is found, according to Vercellonius, a gland which he says is equal to a kidney-bean in size; he also says that it has ducts opening into the cavity of the stomach. In hogs this gland is very conspicuous, but in human subjects it is not so.

Many authors have told us, that in the omentum, in every part where the fat lies, there are a number of glands whose office it is to secrete it. Dissection shews us a few about that part where it is joined to the pylorus; and as to the rest, it is not necessary that there should be glands, because there is fat: for that may be, and is, indeed, in great abundance secreted immediately from the arteries.

In the gall-bladders of oxen there are often found a number of small glands of a yellow colour, not unlike the ceruminous glands in the auditory passage. In human subjects the same kind of glands are also sometimes found. The bladder and the ureters have also sometimes a number of small glands, but they are very indeterminate in number and size, and are not always indeed found in the same place, especially about the ureters. Those about the bladder are usually situated towards the neck of it, and are sometimes tolerably conspicuous.

In the parts of generation of man there occur, 1. The glandulæ Cowperii. 2. The glandulæ Littri. And, 3. The odorous glands of Tyson. See PENIS.

As to the latter ones, those of them which are situated in the interior part of the prepuce, are much more obvious than those about the coronæ penis, where it is very difficult to distinguish them from the nervous papillæ of the same part.

4. We meet with the prostratæ. 5. The glands of the vesiculæ feminales: but these are rarely seen distinct. Terraneus also describes six small glands in the urethra virilis. See the articles PREPUCE, PROSTRATÆ, VESICULÆ SEMINALES, and URETHRA.

In the parts of generation in women, we are to refer to the number of the glands.

1. Those which Morgagni discovered in the nymphæ: these have a very near alliance with the glandulæ odoriferæ of the penis in men. 2. Authors tell us of glands in the female as well as the male urethra: but the dissector will find only little foramina and ducts in the place of them. 3. About the extremity of the urethra, however, in the vagina, there are sometimes found evident glands, situated beneath them: these, as well as the glands of the nymphæ, are often very turgid in the time of parturition. 4. The vesicles sometimes met with near the internal orifice of the uterus, and taken by some for a new ovary, are not properly glands, tho' some people have been very positive that they were such; having nothing of the habit and peculiar appearance of glands, and being in truth only vesicles. 5. Some have also maintained that there are glands in the uterus, by which the menstrual discharges are secreted; but this notion arises only from the false hypothesis, that where there are no glands, there can be no secretion. See the articles VAGINA and UTERUS.

Among the glands which belong to the articulations, and the extremities, we are to mention first the axillary ones. 2. The inguinal glands; these last, being situated on each side in the groin near the crural vessels, are in various diseases apt to grow tumid, and inflamed. Abscesses are often formed in them; but their use in the body is not easily understood. 3. The glands, called from their discoverer glandulæ haverianæ, in the articulations: they are also called from the matter they secrete glandulæ mucosæ. These are the softest of all the glands in the body; they secrete a mucous soft fluid, which serves to lubricate the joints, and render their motions easy, and to

prevent their growing dry, and cohering together.

About the scapula, the flexure of the elbow, the hand, the knee, and the foot, there are also found here and there some small glands; as also in some places between and among the muscles: but as their number and situation, as well as their size and figure, are very uncertain and variable, it is not necessary to recount them here.

We are, however, yet to speak of the cutaneous glands. Verheyen tells us, that Steno had discovered, that there is a gland situated under every distinct pore of the skin, from whence there arises a vessel for the conveyance of the matter of sweat, which terminates at the surface of the cutis: and hence Verheyen, though he does not say that he had ever seen any of these glands himself, ventures to give them a place among the parts he describes; and calls them subcutaneous glands. The pores of the skin are so extremely numerous, that if, according to these authors, there were a gland belonging to every one of them, the glands must be almost infinite in number. But in dissection, when the cutis has been carefully cleared from the fat that is under it, it is certain no such glands are seen, either in the separated fat, or on the lower surface of the cutis: there are indeed always found little portions of the fat here and there insinuating themselves into the little foveolæ, or holes in the cutis; but pieces of fat will be distinguished from glands, with very little difficulty by an expert anatomist. From this, and from innumerable searches after these glands, it appears, that there are indeed no such glands as those called subcutaneous. See the article CUTIS.

GLANDERS, in the manege, a disease in horses, consisting of a thick, slimy, corrupt humour, running from the nostrils, of a different colour, according to the different degrees of malignity, or as the infection has been of a shorter or longer continuance; being white, yellow, green, black, or bloody.

Authors ascribe this disease to various causes: some to infection; others, to a disorder of the lungs; others, to the spleen; some to the liver; and others, to the brain. After it has been of so long a standing, as that the matter is become of a blackish colour, which is usually in  
its

its last stage, they suppose it to come from the spine; and hence they call it the mourning of the chine.

Kernels and knots are usually found under the caud in this disorder; and as these grow bigger and more inflamed, so the glands increase more.

For the cure of the glander's, Mortimer gives the following receipt.

Take a pint of children's chamber-lye, two ounces of oil of turpentine; half a pint of white wine vinegar; four ounces of flower of brimstone; half a handful of rue: boil this composition till it comes to a pint, and give it to the horse fasting; and let him fast after it six hours from meat, and twelve from water.

**GLANDIVES**, a city and bishop's see of Provence, in France, situated on the river Var, twenty-six miles north-west of Nice: east long.  $6^{\circ} 40'$ , north lat.  $44^{\circ}$ .

**GLANDULAR**, or **GLANDULOUS**, among anatomists. See **GLANDULOUS**.

**GLANDULE**, **GLANDULA**, a term used by anatomists to express a small gland. See the article **GLAND**.

**GLANDULOUS**, something abounding with, or partaking of the nature of glands. See the article **GLAND**.

**GLANDULOUS BODY**, *glandulosum corpus*, a name by which some call the prostate. See the article **PROSTATA**.

**GLANDULOUS ROOTS**, among gardeners, &c. denote such tuberosc ones as are connected together by small fibres. See the article **ROOT**.

**GLANIS**, γλάνις; a fish called in english, the sheat-fish: it is a species of silurus with four cithi on the lower jaw. See **SILURUS**.

**GLANS**, **ACORN**, in natural history. See **ACORN**.

**GLANS**, in anatomy, the anterior extremity of the penis, called by other different names, as the head of the penis, the nut of the penis, and the balanus of the penis. See the article **PENIS**.

The glans is composed of the epidermis and the corpus cavernosum, which is continuous with the urethra. See the articles **EPIDERMIS** and **CORPUS**, &c.

Its surface is very smooth and polished, and is very sensible to the touch, which is owing to a multitude of nervous papillæ distributed all over it; and are most obvious when the penis is erected. In the front of it is the urethra, and immediately under is inserted the frænum or frenulum of the penis. The posterior extremity of the glans, with its neck be-

hind, is distinguished by the name of the corona. See the article **CORONA**.

**GLANS** is also used to denote the tip or extremity of the clitoris, from its resemblance both in form and use to that of the penis. The principal difference consists in this, that it is not perforated as is the glans of the penis. This glans is also covered with a preputium formed of the inner membrane of the labia. See the article **CLITORIS**.

**GLANS** is also taken for strumous, or scrophulous tumors.

It also signifies a suppository, or pessary.

**GLANUS**, or **GLANIS**. See **GLANIS**.

**GLAREA**, in natural history, a kind of impalpable sand. See the article **SAND**.

**GLARIS**, the capital of one of the cantons of Switzerland, of the same name; the inhabitants of which are both protestant and popish: it is situated thirty-five miles south-east of Zurich, in east long.  $9^{\circ}$ , and north lat.  $47^{\circ}$ .

**GLASGOW**, a large city of Scotland, in the shire of Lanerkschire, or Clydesdale; situated on the river Clyde, twenty miles north-west of Lanerk, and forty miles west of Edinburgh, in  $4^{\circ} 8'$ , west long. and  $55^{\circ} 5'$ , north lat.

This is one of the most elegant towns in Scotland. It has an university, and a good foreign trade.

**GLASS**, vitrum, a transparent, brittle, factitious body, produced by the action of fire upon a fixt salt and sand, or stone, that readily melts.

The chemists hold, that there is no body but may be vitrified, or converted into glass; being the last effect of fire, as all its force is not able to carry the change of any natural body beyond its vitrification.

*Antiquity and history of GLASS.* When, or by whom, the art of making glass was first found out is uncertain: some will have it invented before the flood; but without any proof. Neri traces the antiquity of this art as far back as the time of Job: but Dr. Merret will have it as ancient as either pottery, or the making of bricks: because that a kiln of bricks can scarce be burnt, or a batch of pottery be made, but some of the bricks and the ware will be at least superficially turned to glass; so that it must have been known at the building of Babel, and as long before as the making of bricks was used. It must have been known, consequently, among the Egyptians, when the Israelites were employed by them in making bricks:

Of this kind, no doubt, was that fossil glass mentioned by Ferrant. Imperat. to be found under-ground in places where great fires had been. The Egyptians indeed boast, that this art was taught them by the great Hermes. Aristophanes, Aristotle, Alexander Aphrodiseus, Lucretius, and John the divine, put us out of all doubt, that glass was in use in their days.

Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea, who, being obliged to continue there, and dress their victuals, by making a fire on the ground, where there was great plenty of the herb kali; that plant burning to ashes, its salts mixed and incorporated with sand, or stones fit to vitrify, and produced glass: that this accident being known, the people of Sidon, in that neighbourhood, assayed the work, improved the hint, and brought it into use; and that this art has been improving ever since.

Venice, for many years, excelled all Europe in the fineness of its glasses, but of late the French and English have excelled the Venetians, so that we are no longer supplied with this commodity from abroad.

*Nature and characters of GLASS.* Naturalists are divided in what class of bodies to rank glass: some making it a concrete juice; others a stone; others again rank it among semi-metals; but Dr. Merret observes, that these are all natural productions, whereas glass is a factitious compound, produced by fire, and never found in the earth, but only the sand and stone that form it; that metals are formed by nature into certain species; and that fire only produces them, by its faculty of separating heterogeneous, and uniting homogeneous bodies: whereas it produces glass, by uniting heterogeneous matter, viz. salt and sand, of both which it evidently consists; 100 lb weight of sand yielding above 150 lb of glass.

The same learned doctor gives us a precise and accurate enumeration of the several characters, or properties of glass, whereby it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by strong fire. 3. When fused, tenacious and coherent. 4. It does not waste nor consume in the fire. 5. When

melted, it cleaves to iron. 6. When it is red hot, it is ductile, and may be fashioned into any form; but not malleable; and capable of being blown into a hollowness, which no mineral is. 7. Frangible when thin, without annealing. 8. Friable, when cold. 9. Diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissoluble by cold and moisture. 12. Only capable of being graven or cut with a diamond, or other hard stone, and emery. 13. Receives any dye or colour both externally and internally. 14. Not dissoluble by aqua fortis, aqua regia, or mercury. 15. Neither acid juices nor any other matter extract either colour, taste, or any other quality from it. 16. Admits of polishing. 17. Neither loses weight nor substance by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open glass being filled with water in the summer-time, will gather drops of water on the outside, just so far as the water on the inside reaches; and a person's breath blown on it will manifestly moisten it. 22. Little glass balls filled with water, mercury, and other liquor, and thrown into the fire; as also drops of green glass being broken, will fly asunder with a great noise. 23. Neither wine, beer, nor any other liquor, will make it musty, or change its colour, or rust it. 24. It may be cemented, as stones and metals. 25. A drinking-glass, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glass is more or less full, and will make the liquor frisk and leap.

*Materials for making of GLASS.* The materials whereof glass is made, we have already mentioned to be salt and sand, or stones. The salt here used, is procured from a sort of ashes, brought from the Levant, called pulverine, or rochetta; which ashes are those of a sort of water-plant, called kali, cut down in summer, dried in the sun, and burnt in heaps, either on the ground, or on iron-grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use. See KALI and PULVERINE. To extract the salt, these ashes, or pulverine, are powdered and sifted, then put into boiling water, and there kept till one third of the water be consumed; the whole

whole being stirred up, from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted : then the vessel is filled up with new water, and boiled over again, till one half be consumed ; what remains is a sort of lee, strongly impregnated with salt. This lee, boiled over again in fresh coppers, thickens in about twenty-four hours, and shoots its salt ; which is to be laded out, as it shoots, into earthen pans, and thence into wooden fats to drain and dry. This done, it is grossly pounded, and thus put in a sort of oven, called calcar, to dry. It may be added, that there are other plants, besides kali, which yield a salt fit for glass : such are the alga or sea-weed, the common way-thistle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c. See the articles *ASHES*, *SALT*, *EXTRACTION*, *ALGA*, &c.

The sand or stone, called by the artists Tarso, is the second ingredient in glass, and that which gives it the body and firmness. These stones, Agricola observes, must be such as will fuse ; and of these such as are white and transparent are best ; so that crystal challenges the precedence of all others. See the articles *CRYSTAL* and *TARSO*.

At Venice they chiefly use a sort of pebble, found in the river Tesino, resembling white marble, and called cuogolo. Indeed Ant. Neri assures us, that all stones which will strike fire with steel, are fit to vitrify : but Dr. Merret shews, that there are some exceptions from this rule. Flints are admirable ; and when calcined, powdered, and seared, make a pure white crystalline metal : but the expence of preparing them makes the masters of our glass-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used ; which should be white, and small, and well washed, before it be applied : such is usually found in the mouths and sides of rivers. Our glass-houses are furnished with a fine sand for crystal, from Maidstone, the same with that used for sand-boxes, and in scouring ; and with a coarser for green glass from Woolwich. For crystal glass, to 200 lb of tarso, pounded fine, they put 130 lb of salt of polverine ; mix them together, and put them into the calcar, a sort of reverberatory furnace, being first well heated. Here they remain baking, frying, and calcining, for five hours, during which

the workman keeps mixing them with a rake, to make them incorporate : when taken out, the mixture is called frit, or bollito. See the articles *FRIIT* and *BOLLITO*.

It may be further observed, that glass might be made by immediately melting the materials without thus calcining, and making them frit : but the operation would be much more tedious.

A glass much harder than any prepared in the common way may be made by means of borax, in the following manner. Take four ounces of borax, and an ounce of fine white sand, reduced to powder, and melt them together in a large close crucible set in a wind furnace, keeping a strong fire for half an hour : then take out the crucible, and when cold, break it ; and there will be found at the bottom a hard, pure glass, capable of cutting common glass almost like a diamond. This experiment duly varied, says Dr. Shaw, may lead to some considerable improvements in the art of glass, enamels, and artificial gems. It shews us an expeditious method of making glass without the use of fixed salts, which has generally been thought an essential ingredient in glass, and which is the ingredient that gives common glass its softness ; and it is not yet known, whether calcined crystal, or other substances, being added to this salt, instead of sand, it might not make a glass approaching to the nature of a diamond. See the article *GEM*.

*Kinds of GLASS*. Of these materials we have many sorts of glass made, which may principally be distinguished according to their beauty ; as the crystal flint glass, the crystal white glass, the green glass, and the bottle glass. Again these sorts are distinguished by their several uses ; as plate or coach-glasses, looking-glasses, optic-glasses, &c. which are made of the first sort. The second sort includes crown-glass, toys, phials, drinking-glasses, &c. The third sort is well known by its colour, and the second by its form.

*Bleas coloured GLASS* is made thus : put into a pot crystal frit, thrice washed in water ; tinge this with manganese prepared into a clear purple : to this add alumen cativum sifted fine in small quantities, and at several times ; this will make the glass grow yellowish, and a little reddish, but not blackish, and always dissipates the manganese. The last time you add manganese, give no more of the alumen cativum, unless the colour

be too full. Thus will the glass be exactly of the colour of the balas-ruby.

**Red GLASS.** A blood-red glass may be made in the following manner: put six pounds of glass of lead, and ten pounds of common glass into a pot glazed with white glass: when the whole is boiled and refined, add, by small quantities, and at small distances of time, copper calcined to a redness, as much as, on repeated proofs, is found sufficient: then add tartar in powder by small quantities at a time, till the glass is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

**Yellow GLASS.** It is a necessary remark in glass-making, that the crystal-glass made with salt that has an admixture of tartar will never receive the true gold yellow, though it will all other colours: for yellow glass, therefore, a salt must be prepared from poverine, or pot-ashes alone, to make the glass.

**Furnaces for the making GLASS.** In this manufacture, there are three sorts of furnaces, one called calcar, is for the frit, the second is for working the glass, the third serves to anneal the glass, and is called the leer. See FURNACE.

The calcar A, (plate CXIII. fig. 3.) resembles an oven ten feet long, seven broad, and two deep: the fuel, which in England is sea coal, is put into a trench on one side of the furnace; and the flame reverberating from the roof upon the frit, calcines it. The glass-furnace, or working-furnace B, is round, of three yards diameter, and two high; or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part C is properly called the crown, and is made in that form. Its use is to keep a brisk fire of coal and wood, which is never put out. The mouth of it is called the bocca. There are several holes in the arch of this crown, through which the flame passes into the second vault, or partition, and reverberates into the pots filled with the ingredients above-mentioned. Round the insides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the boccas D, or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in, while he works out of the other. Through the working holes the metal is taken out of the pots, and the

pots are put into the furnace, and these holes are stopped with moveable covers made of lute and brick, to screen the workmens eyes from the scorching flames. On each side of the bocca, or mouth, is a boccarella, or little hole, out of which coloured glass, or finer metal, is taken from the piling pot. Above this oven, there is the third oven or leer, about five or six yards long, where the vessels, or glass, is annealed, or cooled: this part consists of a tower, besides the leer F, into which the flame ascends from the furnace. The tower has two mouths, through which the glasses are put in with a fork, and set on the floor or bottom: but they are drawn out on iron pans, called fraches, through the leer, to cool by degrees; so that they are quite cold by the time they reach the mouth of the leer, which enters the sarosel, or room where the glasses are to be stowed.

But the green glass furnace is square; and at each angle it has an arch for annealing, or cooling the glasses. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnet holes, for the fire to come from the furnace to bake the frit, and to discharge the smoke. Fires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick, and the inner part to bear the fire is made of a sort of fuller's earth, or tobacco-pipe clay, of which earth they also make their melting-pots.

Mr. Blancourt observes, that the worst and roughest work in this art, is the changing the pots, when they are worn out, or cracked. In this case the great working hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, thro' the flames, by the hands only. For this work, the man guards himself with a garment made of skins, in the shape of a pantaloons, that covers him all but his eyes, and is made as wet as possible: the eyes are defended with a proper sort of glass.

**Instruments for making of GLASS.** The instruments made use of in this work, may be reduced to these that follow. A blowing pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glass,

glass, after it is blown, and to cut off the former. Scissars to cut the glass when it comes off from the first hollow iron. Shears to cut and shape great glasses, &c. an iron ladle, with the end of the handle cased with wood, to take the metal out of the refining pot, to put it into the workmens pots. A small iron ladle, cased in the same manner, to skim the alkalic salt, that swims at top. Shovels, one like a peel to take up the great glasses ; another, like a fire-shovel, to feed the furnace with coals. A hooked iron fork, to stir the matter in the pots. An iron rake for the same purpose, and to stir the frit. An iron fork, to change or pull the pots out of the furnace, &c.

*Working or blowing round GLASS.* The tools thus provided, the workman dips his blowing pipe into the melting-pot, and by turning it about, the metal sticks to the iron more firmly than turpentine. This he repeats four times, at each time rolling the end of his instrument, with the hot metal thereon, on a piece of iron G, over which is a vessel of water which helps to cool, and so to consolidate, and to dispose that matter to bind more firmly with what is to be taken next out of the melting-pot. But after he has dipt a fourth time, and the workman perceives there is metal enough on the pipe, he claps his mouth immediately to the other end of it H, and blows gently through the iron tube, till the metal lengthens like a bladder about a foot. Then he rolls it on a marble stone I, a little while, to polish it, and blows a second time, by which he brings it to the shape of a globe of about eighteen or twenty inches diameter. Every time he blows into the pipe, he removes it quickly to his cheek, otherwise he would be in danger, by often blowing, of drawing the flame into his mouth ; and this globe may be flattened by returning it to the fire, and brought into any form by stamp-irons, which are always ready. When the glass is thus blown, it is cut off at the collet, or neck, which is the narrow part that stuck to the iron. The method of performing this, is as follows : the pipe is rested on an iron bar, close by the collet : then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which with a slight blow, or cut of the shears K, will immediately separate the collet.

After this is done, the operator dips the iron rod into the melting-pot, by which he extracts as much metal as serves to attract the glass he has made, to which he now fixes this rod at the bottom of his work, opposite to the opening made by the breaking of the collet. In this position, the glass is carried to the great bocca, or mouth of the oven, to be heated and scalded, by which means it is again put into such a soft state, that by the help of an iron instrument, it can be pierced, opened, and widened without breaking. But the vessel is not finished, till it is returned to the great bocca ; where it being again heated thoroughly, and turned quickly about with a circular motion, it will open to any size, by the means of the heat and motion. And by this means we come to learn the cause why the edge of all bowls and glasses, &c. are thicker than the other parts of the same glasses, because in the turning it about in the heat, the edge thickens ; and the glass being as it were doubled in that part, the circumference appears like a selvage.

If there remains any superfluities, they are cut off with the shears L ; for till the glass is cool, it remains in a soft, flexible state. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguished, keeping it turning ; because that motion prevents any settling, and preserves an evenness in the face of the glass, where, as it cools, it comes to its consistency ; being first cleared from the iron rod by a slight stroke by the hand of the workman.

If the vessel conceived in the workman's mind, and whose body is already made, requires a foot, or a handle, or any other member or decoration, he makes them separate ; and now assays to join them with the help of hot metal, which he takes out of the pots with his iron rod : but the glass is not brought to its true hardness, till it has passed the leer, or annealing oven, described before.

*Working, or blowing, of window or table GLASS.* The method of working round glass, or vessels of any sort, is in every particular applicable to the working of window or table-glass, till the blowing iron has been dipt the fourth time. But then instead of rounding it, the workman blows, and so manages the metal upon the iron-plate, that it extends two or three feet in the form of a cylinder.

This

This cylinder is put again to the fire, and blown a second time, and is thus repeated till it is extended to the dimensions required, the side to which the pipe is fixed diminishing gradually till it ends in a pyramidal form; so that to bring both ends nearly to the same diameter, while the glass is thus flexible, he adds a little hot metal to the end opposite the pipe, and draws it out with a pair of iron pincers, and immediately cuts off the same end with the help of a little cold water, as before.

The cylinder being now open at one end is carried back to the bocca, and there, by the help of cold water, it is cut about eight or ten inches from the iron pipe, or rod; and the whole length at another place, by which also it is cut off from the iron rod. Then it is heated gradually on an earthen table, by which it opens in length, while the workman, with an iron tool, alternately lowers and raises the two halves of the cylinder, which at last will open like a sheet of paper, and fall into the same flat form in which it serves for use; in which it is preserved by heating it over again, cooling it on a table of copper, and hardening it twenty-four hours in the annealing furnace, to which it is carried upon forks. In this furnace, an hundred tables of glass may lie at a time, without injury to each other, by separating them into tens, with an iron shiver between, which diminishes the weight by dividing it, and keeps the tables flat and even.

This was the method formerly made use of for blowing plate-glass, looking-glasses, &c. but the workmen, by this method, could never exceed fifty inches in length, and a proportional breadth, because what were larger were always found to warp, which prevented them from reflecting the objects regularly, and wanted substance to bear the necessary grinding. These imperfections have been remedied by an invention of the Sieur Abraham Thevart, in France, about the year 1688, of casting or running large plates of glass in the following manner.

*Casting, or running of large looking-Glass plates.* The furnace G, (plate CXIV.) is of a very large dimension, environed with several ovens, or annealing furnaces, called carquasses, besides others for making of frit, and calcining old pieces of glass. This furnace, before it is fit to run glass, costs 3500*l*. It seldom

lasts above three years, and even in that time it must be refitted every six months. It takes six months to rebuild it; and three months to refit it. The melting-pots are as big as large hogheads, and contain about 2000 weight of metal. If one of them bursts in the furnace, the loss of the matter and time amounts to 250*l*. The heat of this furnace is so intense, that a bar of iron laid at the mouth thereof becomes red hot in less than half a minute. The materials in these pots are the same as described before; and A is the man breaking the frit for that purpose. When the furnace is red hot, these materials are put in at three different times, because that helps the fusion; and in twenty-four hours they are vitrified, refined, settled, and fit for casting. H is the bocca, or mouth of the furnace, K is the cistern that conveys the liquid glass it receives out of the melting-pots in the furnace to the casting table. These cisterns are filled in the furnace, and remain therein six hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pully marked I, and placed upon a carriage with four wheels marked L, by two men P, P. This carriage has no middle piece; so that when it has brought the cistern to the casting table M, they slip off the bottom of the cistern, and out rushes a torrent of flaming matter O, upon the table: this matter is confined to certain dimensions by the iron rulers N, N, N, which are moveable, retain the fluid matter, and determine the width of the glass; while a man R, with the roller Q resting on the edge of the iron rulers, reduceth it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trussles for the convenience of moving to the annealing furnace; into which, strewed with sand the new plate is shoved, where it will harden in about ten days. After this, the glass needs only be ground, polished, and foliated for use.

*Grinding and polishing of plate GLASS.* Glass is made transparent by fire, but it receives its lustre by the skill and labour of the grinder and polisher, the former of whom takes it rough out of the hands of the maker.

In order to grind plate-glass, they lay it horizontally upon a flat stone-table, (pl. CXV.) made of a very fine grained free-stone; and for its greater security they plaster

plaster it down with lime, or stucco : for otherwise the force of the workmen, or the motion of the wheel, with which they grind it, would move it about.

This stone-table is supported by a strong frame, A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground, is laid another rough glass not above half so big, and so loose as to slide upon it; but cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel, to which this plank is fastened; and from the weights laid upon it, to promote the grinding, or friture, of the glasses. The whole is covered with a wheel, B, made of hard light wood, about six inches in diameter; by pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand : After that a finer sort of sand as the work advanceth, till at last they must pour in the powder of pumice. As the upper or incumbent glass polishes, and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a mill by the artists, and is used only in the largest size glasses; for in the grinding of the lesser glasses, they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glass to an exact plainness, it is turned over to the care of the polisher, who with the fine powder of tripoli-stone, or emery, brings it to a perfect evenness and lustre. The instrument made use of in this branch, is a board, c, c, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist in working this roller, is assisted with a wooden hoop, or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

*Grinding and polishing of optic GLASSES.*  
See GRINDING and POLISHING.

*Foliating of GLASS.* See FOLIATING.

*Axungia of GLASS.* See AXUNGIA.

*Painting in GLASS.* The antient manner of painting in glass was very simple and consequently very easy; it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called mosaic work. See MOSAIC.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, basilics, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree; having first laid on the colours. The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours. See the article COLOUR.

For black, Take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce; reduce them to powder, and mix them. For blue, Take powder of blue, one pound; sal nitre, half a pound; mix them and grind them well together. For carnation, Take red chalk, eight ounces; iron scales and litharge of silver, of each two ounces; gum arabic, half an ounce; dissolve in water; grind all together for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, Take red lead, one pound; scales of copper, one pound; and flint, five pounds; divide them into three parts; and add to them as much sal nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, Take silver, an ounce; antimony, half an ounce; melt them in a crucible; then pound the mass to powder; and grind it on a copper plate; add to it yellow-oker, or brick-duit calcined again, fifteen ounces; and grind them

well together with water. For purple, Take minium, one pound ; brown stone, one pound ; white flint, five pounds ; divide them into three parts, and add to them as much sal nitre as one of these parts ; calcine, melt, and grind it as you did the green. For red, Take jet, four ounces ; litharge of silver, two ounces ; red chalk, one ounce ; powder them fine ; and mix them. For white, Take jet two parts ; white flint, ground on a glass very fine, one part ; mix them. For yellow, Take spanish brown, ten parts ; leaf silver, one part ; antimony, half a part ; put all into a crucible, and calcine them well.

In the windows of antient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is intirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one third of a line ; though this was more or less according to the nature of the colour ; the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glass, tho' already coloured, they could shew other kind of colours where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till such time as they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By this means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all ; and this was the manner by which they

wrought their lights, and heightenings, on all kinds of colour.

The first thing to be done, in order to paint, or stain glass, in the modern way, is to design, and even colour the whole subject on paper. Then they choose such pieces of glass as are clear, even, and smooth, and proper to receive the several parts, and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass ; always taking care that the glasses may join in the contours of the figures, and the folds of the draperies ; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again : which done, applying every part of the design upon the glass intended for it, they copy, or transfer, the design upon this glass with the black colour diluted in gum water ; by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black ; and repeat it several times, according as the shades are desired to be heightened, with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing-off the colour in the respective places with a wooden point, or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum-water, much as in painting in miniature ; taking care to apply them lightly for fear of effacing the out-lines of the design ; or even, for the greater security, to apply them on the other side ; especially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay, till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates therewith by the fire ; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very

little. When the painting of all the pieces is finished, they are carried to the furnace, or oven, to anneal, or bake the colours.

The furnace here used is small, built of brick, from eighteen to thirty inches square; at six inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition, is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep; and five or six inches less every way than the perimeter of the furnace. On the one side hereof is a little aperture, through which to make trials, placed directly opposite to that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed, in the following manner. First, the bottom of the pan is covered with three strata, or layers, of quick lime pulverized; those strata being separated by two others of old broken glass, the design whereof is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder, an inch deep; and over this, they lay another range of glasses, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthen ware, closely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to serve as chimnies. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually completed. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimnies. During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace, and pan, to see whether the yellow be perfect, and the

other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

*GLASS of lead*, a glass made with the addition of a large quantity of lead; of great use in the art of making counterfeit gems. See the article *GEM*.

The method of making it is this. Put a large quantity of lead into a potter's kiln; and keep it in a state of fusion, with a moderate fire, till it is calcined to a very grey, loose powder: then spread it on the kiln, and give it a greater heat, continually stirring it, to keep it from gathering into lumps: continue this several hours, till the powder become of a fair yellow: then take it out, and sift it fine: this is called calcined lead. Take of this calcined lead fifteen pounds, and crytalline or other frit, twelve pounds; mix these as well as possible together; put them into a pot, and set them in the furnace for ten hours; then cast the whole, which will now be perfectly melted, into water; separate the loose lead from it; and return the metal into the pot; and after standing in fusion twelve hours more, it will be fit to work.

This glass is capable of all the colours of the gems in great perfection.

*GLASS porcelain*, the name given by many to a modern invention of imitating the china-ware with glass. See *PORCELAIN*. The method of making it, as given by Mr. Reamur, who was the first that carried the attempt to any degree of perfection, is as follows.

The glass vessels to be converted into porcelain, are to be put into large vessels, such as the common fine earthen dishes are baked in; or, into sufficiently large crucibles: the vessels are to be filled with a mixture of fine white sand, and of fine gypsum; or plaster-stone, burnt into what is called plaster of paris; and all the interstices are to be filled up with the same powder, so that the glass vessels may no where touch either one another, or the sides of the vessels they are baked in.

The vessel is to be then covered down, and luted, and the fire does the rest of the work: for this is only to be put into a common potter's furnace, and when it has stood there the usual time of baking the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted

into a white opaque substance, which is a very elegant porcelain, and has almost the properties of that of china.

**GLASS** of *chalcedony*, a mixture of several ingredients with the common mixture of glass, which will make it represent the semi-opaque gems, the jaspers, agates, chalcedonies, &c. See **GEM**.

**GLASS** of *antimony* may be deprived of its emetic quality by digesting it with pure spirit of vinegar till the menstruum be highly tinged. See **ANTIMONY**.

Mr. Boyle says, that if you abstract this liquor, and digest good rectified spirit of wine on the remaining powder, an excellent tincture against several diseases may be obtained. See **TINCTURE**.

**Duties** on **GLASS**. Balm-glasses, on importation, pay per gross, 2s. 5 $\frac{98\frac{1}{2}}{100}$ d; and

draw back on exportation, 2s. 3 $\frac{84\frac{3}{8}}{100}$ d.

Burning-glasses, on importation, pay, per dozen, 11 $\frac{99\frac{1}{4}}{100}$ d. and draw back on

exportation, 11 $\frac{13\frac{3}{4}}{100}$ d. Perspective-glasses,

the piece not exceeding three feet in length, pay 8s. 1 $\frac{17\frac{5}{8}}{100}$ d. on importation; and draw back 7s. 4 $\frac{5\frac{5}{8}}{100}$ d. on exportation.

Perspective-glasses exceeding three feet in length, pay 16s. 2 $\frac{1\frac{5}{8}}{100}$ d. on importation; and draw back 14s. 9d. on exportation. Small perspective-glasses the dozen, pay on importation 8s. 1 $\frac{17\frac{5}{8}}{100}$ d.

and draw back on exportation, 7s. 4 $\frac{5\frac{5}{8}}{100}$ d. Vials the hundred, pay on importation,

4s. 11 $\frac{96\frac{1}{2}}{100}$ d. and draw back on exportation, 4s. 7 $\frac{68\frac{3}{4}}{100}$ d.

Water-glasses the dozen pay on importation, 3s. 11 $\frac{97\frac{5}{8}}{100}$ d.

and draw back on exportation, 3s. 8 $\frac{5\frac{5}{8}}{100}$ d. Broken glass the 112 lb. pays on importation, 1s. 1 $\frac{13\frac{3}{8}}{100}$ d.

and draw back on exportation, 1s. 6 $\frac{1}{100}$ d.

Coarse drinking-glasses, the dozen pay on importation

11 $\frac{99\frac{1}{4}}{100}$ d. and draw back on exportation,

11 $\frac{13\frac{3}{4}}{100}$ d. Flanders-drinking glasses per

hundred, pay on importation, 8s. 3 $\frac{93\frac{3}{4}}{100}$ d.

and draw back on exportation, 7s. 8 $\frac{81\frac{1}{4}}{100}$ d.

French drinking-glasses per hundred, pay on importation, 10s. 1 $\frac{83\frac{3}{4}}{100}$ d. and draw

back on exportation, 6s. 5 $\frac{56\frac{1}{4}}{100}$ d. Venice

drinking-glasses the dozen pay on importation, 5s. 11 $\frac{95\frac{1}{2}}{100}$ d.

and draw back on exportation, 5s. 6 $\frac{82\frac{1}{2}}{100}$ d. Flanders coarse

hour-glasses, the gross pay on importation, 19s. 11 $\frac{8\frac{5}{8}}{100}$ d.

and draw back on exportation, 18s. 6 $\frac{7\frac{1}{2}}{100}$ d. Flanders fine

hour-glasses pay per dozen, on importation, 6s. 7 $\frac{9\frac{5}{8}}{100}$ d.

and draw back on exportation, 6s. 2 $\frac{2\frac{5}{8}}{100}$ d. Venice hour-

glasses, the dozen, pay, on importation, 19s. 11 $\frac{8\frac{5}{8}}{100}$ d.

and draw back on exportation, 18s. 6 $\frac{7\frac{1}{2}}{100}$ d. Looking glasses of

crystal, small, n<sup>o</sup> 6. pay per dozen on importation, 9s. 11 $\frac{92\frac{1}{2}}{100}$ d.

and draw back on exportation, 9s. 3 $\frac{37\frac{1}{2}}{100}$ d. Middle

fort, the dozen pay on importation, 19s. 11 $\frac{8\frac{5}{8}}{100}$ d.

and draw back on exportation, 18s. 6 $\frac{7\frac{1}{2}}{100}$ d. Looking-glasses of crystal,

the dozen n<sup>o</sup> 11, 12. pay on importation, 14l. 19s. 9 $\frac{7\frac{5}{8}}{100}$ d.

and draw back on exportation, 13l. 18s. 5 $\frac{2\frac{5}{8}}{100}$ d.

**GLASTONBURY**, a market-town of Somersetshire, five miles south of Wells.

**GLASTONBURY-THORN**, in botany, a species of mephilus, or medlar.

**GLATZ**, the capital of a county of the same name in Bohemia, 100 miles east of Prague: east long. 16° 8', north lat. 50° 25'.

**GLAUBER'S SALT**, a cathartic or purging salt, thus made. Take of the cake

that remains after the distillation of Glauber's spirit of sea-salt; dissolve it in hot water, and filter the solution through paper. Then reduce the salt into crystals. It is given in doses, from half an ounce to an ounce. See **SALT**.

Glauber's salt, called by some sal mirabile, is nearly allied to Epsom salt. See **EPSOM**.

**GLAUCEO**, among physicians, the same with glaucoma. See **GLAUCOMA**.

**GLAUCION**, in ornithology, a very elegant fresh-water fowl, of the anas or duck-kind, nearly of the size of the common wild duck: its eyes are bright and very piercing in their aspect, and the iris of a fine gold-yellow. See **ANAS**.

**GLAUCIDIUM**, in zoology, the same with glaucus. See the article **GLAUCUS**.

**GLAUCIS SPECIES**, in botany, a name by which botanists call two distinct plants, the *isnardia* and *peplis*. See the articles *ISNARDIA* and *PEPLIS*.

**GLAUCIUM**, in botany, the same with *chelidonium*, or *celandine*. See the article *CHELIDONIUM*.

**GLAUCODES**, a name used by some for two distinct plants, the *glaux* and *peplis*.

**GLAUCOMA**, in medicine, the change of the crystalline humour of the eye into an azure-colour, proceeding from its dryness and condensation, as some affirm; but Heister rather thinks, it arises from an opacity of the vitreous humour, which becomes of a whitish-green colour: for in a suffusion, an opaque body is placed behind the pupil, or is next to the uveous part. Sennertus says, it may be known from a very remarkable whiteness appearing in the eye, and lying deep behind the pupil; which makes every thing appear as if seen through a smoky cloud. It is said to be incurable when inveterate; but that the medicines prescribed for a *gutta serena*, are best also in this case. See the article *GUTTA SERENA*.

**GLAUCUS**, in ichthyology, the name of two distinct fishes, the one a species of *scomber*, with the second ray of the hinder back-fin longest; and the other a species of *squalus*, with a triangular cavity in the hinder part of the back, but without any foramina beside the eyes. This last is the blue shark.

**GLAUX**, in botany, a genus of the *pentandria-monogynia* class of plants, the flower of which consists of a single, campanulated, erect, and permanent petal, divided into five roundish segments: the fruit is a large, globose, but acuminate and unilocular capsule, formed of five valves, and containing five roundish seeds.

**GLAUX** is also the name by which some call the *astragalus*, or milk-vetch. See the article *ASTRAGALUS*.

**GLAZIER**, an artificer who works in glass. See the article *GLASS*.

The principal part of a glazier's business consists in fitting panes and plates of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same.

**GLAZING**, the polishing or crusting over earthen-ware, by running melted lead or litharge over it.

The common ware is glazed with a composition of 50 lb. clean sand, 70 lb. lead-ashes, 30 lb. wood-ashes, and 12 lb. salt,

all melted into a cake. With this mixture they glaze it over, and then set it in an earthen glazing pan; taking care that the vessels do not touch one another. As several colours are used for this purpose, we shall give the following receipts, from Smith's Laboratory. 1. For a black, take lead-ashes, 18 parts; iron-filings, 3; copper-ashes, 3; and zaffer, 2: this, when melted, will make a brown black; and if you would have it blacker, put some more zaffer to it. 2. For blue, take lead-ashes, 1 lb. clear sand or pebble, 2 lb. salt, 2 lb. white calcined tartar, 1 lb. Venice or other glass, 16 lb. and zaffer, half a pound: mix them well together; and after melting quench them in water, and then melt them again; which operation is to be repeated several times; and if you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two. 3. A brown glazing may be given with a mixture of lead-glass, 12 parts, and common glass and manganese, of each one part. 4. A citron-yellow may be made of 6 parts of red-lead, 7 parts of fine red brick-duft, and 2 parts of antimony, all melted together. 5. A flesh-colour, with 12 parts of lead-ashes, and 1 of white glass. 6. For a green-colour, take 8 parts of litharge, 8 parts of Venice glass, 4 parts of brass duft, and melt them together for use; or melt together 2 parts yellow-glass, with as much copper-duft. 7. For a gold-yellow, take of antimony, red-lead, and sand, an equal quantity, and melt them into a cake. 8. For a fine purple-brown, take lead-ashes, 15 parts; clear sand, 18; manganese, 1; white glass, 15 measures; and 1 of zaffer. 9. For a fine red, take antimony, 2 lb. litharge, 3 lb. ruft of iron calcined, 1 lb. and grind them to a fine powder. 10. For a fine white glazing, take 2 lb. of lead, 1 lb. of tin, and calcine them to ashes; of which take 2 parts; of calcined flint or pebble, 1 part; of salt, 1 part; and mixing them well together, melt them into a cake. At Rotterdam, they make a fine shining white glazing, by melting together 2 lb. clean tin-ashes, 10 lb. lead-ashes, 2 lb. fine Venice-glass, and  $\frac{1}{2}$  lb. tartar. 11. A yellow glazing is made of 4 ounces of red-lead, and 2 ounces of antimony, melted together. 12. For a fine yellow, take red-lead, 3 pints; antimony and tin, of each 2 lb. then melting them into a cake, grind it fine; and repeating this

several times, you will have a good yellow.

**GLEAD**, or **GLADE**, in ornithology, a name used in some parts of the kingdom for the milvus, or kite. See **MILVUS**.

**GLEAM**, among falconers, is said of a hawk, when she casts or throws up filth from her gorge.

**GLEBE**, among miners, signifies a piece of earth, wherein is contained some mineral ore. See the article **ORE**.

**GLEBE**, in law, the land belonging to a parish church, besides the tithes.

When a parson or vicar has caused any of his glebe-lands to be manured and sown, at his own charge, with corn or grain, he may by will devise all the profits and corn growing upon the said glebe; and in case he dies without disposing thereof, his executors shall have the same.

**GLECHOMA**, in botany, the name by which Linnæus calls ground-ivy, a plant belonging to the *didynamia-gymnospermia* class, the flower of which is monopetalous and ringent: there is no pericarpium; the seeds, which are oval and four in number, being contained in the cup. The flowers are moderately large, and of a beautiful blue. See **GROUND-IVY**.

**GLEDE**, or **GLEAD**. See **GLEAD**.

**GLEDITSIA**, in botany, a genus of the *dioccia-hexandria* class of plants, the flower of which consists of four petals, and is arranged in the form of an amen-tum: the fruit is a very large pod, separated by partitions into distinct cells, which are full of a pulpy matter: the seeds are solitary, roundish, hard and shining.

**GLEET**, in medicine, the flux of a thin limpid humour from the urethra.

Many imagine that the prodigious increase of certain gleet at particular times, lasting only for two or three days, and then suddenly abating to their wonted quantity, is inconsistent with a purulent discharge; and, therefore, conclude a gleet to be nothing but a præternatural excretion from the relaxed vessels of the urethra. For the cure of venereal gleet, the use of a bougie is recommended, as are astringent injections, beginning with weak ones, and gradually increasing their strength. Aitken recommends milk, drank morning and evening for some time; then mineral waters, whether chalybeate or vitric, for fifteen or twenty days; and afterwards balsamics, to deterge and cicatrize the ulcers concealed

in the urethra; and, last of all, astringents, to dry up the ulcers, and recover the tone of the parts; such as infusions of the leaves of mint, horehound, agrimony, plantain, shepherd's purse, sage, &c. Turner recommends the cold bath, Spaw, Pyrmont, and Bristol waters. Heister, for an injection, recommends lime-water, with a little sugar of lead, or lime-water, with a little camphorated spirit of wine. Turner, when there is any suspicion of a remaining virulence, adds calomel to the lime-water.

**GLENE**, γληνη, in anatomy, a shallow cavity of any bone, which receives another bone in articulation. It also signifies the cavity or socket of the eye.

**GLENOIDES**, the name of two cavities, or small depressions, in the inferior part of the first vertebra of the neck.

**GLSUM**, a name antiently given to amber. See the article **AMBER**.

**GLIS**, in zoology, a name given by some to the common rat, as also to the rell and dor-mouse. See **MUS** and **RAT**.

The flesh of the rell-mouse is recommended for a bulimy; and its fat, rubbed on the feet, is said to procure sleep.

**GLISCHROMICTHES**, in natural history, the name by which Dr. Hill calls the tougher and more viscid loams. See the article **LOAM**.

Of this genus there are several species.

1. The greyish-white glischromictes, of a dense and compact texture: this raises a great effervescence with aqua-fortis, and makes a very valuable brick; but requires too much working, that it is seldom used alone. 2. The pale yellow glischromictes: this raises no effervescence with aqua-fortis, but makes a fine red brick. 3. The yellowish-brown glischromictes, which raises no effervescence with aqua-fortis, and makes a very good brick, but is seldom used alone. 4. The reddish-brown glischromictes. It raises no effervescence with aqua-fortis, and tho' used in brick-making, makes but a soft and coarse kind.

**GLISSA**, a fish of the tunny-kind, of a very delicate taste. See **THYNNUS**.

**GLISTER**, in surgery, the same with clyster. See the article **CLYSTER**.

**GLOBE**, in geometry, the same with sphere. See the article **SPHERE**.

**GLOBE**, in practical mathematics, an artificial spherical body, on the convex surface of which are represented the countries, seas, &c. of our earth; or the face of the heavens, the circles of the sphere, &c.

*&c.* That with the parts of the earth delineated upon its surface, is called the terrestrial globe; and that with the constellations, *&c.* the celestial globe. These globes are placed in frames, with other appurtenances, as represented in plate CXVI. fig. 1. and 2. Their principal use, besides serving as maps to distinguish the outward parts of the earth, and the situation of the fixed stars, is to illustrate and explain the phenomena arising from the diurnal motion of the earth. See the article DIURNAL.

*Construction and description of the GLOBES.*

The globes commonly used are made of pasteboard, or paper, fitted to a spherical mold. After this covering is formed to the artificer's mind, it is divided, by incision, along the middle, and taken off the mold in the form of two caps, or hemispheres. These are next fitted upon a wooden axis, with iron-poles; and, being firmly sewed together, are afterwards pasted over with a composition made of whiting and glue, till the globe become perfectly spherical and smooth. This done, a map of the earth, or of the heavens, is projected in several gores, which being pasted on, the whole is coloured and varnished. Thus finished, the globe is hung in a brazen meridian, moveable within a wooden horizon, and fitted with a horary circle, quadrant of altitude, *&c.*

There are ten principal circles represented upon globes, *viz.* six greater and four lesser ones. The greater circles are the horizon, meridian, equinoctial, as it is called on the celestial, and equator on the terrestrial globe, the ecliptic drawn along the middle of the zodiac, and the two colures. See the articles HORIZON, MERIDIAN, *&c.*

The lesser circles, of principal use, are the two tropics and two polar circles. See CIRCLE, TROPIC, and POLAR.

Of these circles some are fixed, and always obtain the same position; others moveable, according to the position of the observer. The fixed circles are the equator and ecliptic, with their parallels and secondaries; which are usually delineated upon the surface of the globes. The moveable circles are the horizon, with its parallels and secondaries.

The horizon is that great and broad wooden circle surrounding the globe, and dividing it into two equal parts, called the upper and lower hemispheres. It has two notches, to let the brazen meridian

slip up and down, according to the different heights of the pole. On the flat side of this circle are described the twelve signs, the months of the year, the points of the compass, *&c.* The brazen meridian is an annulus or ring of brass, divided into degrees, as represented in the figure. It divides the globe into two equal parts, called the eastern and western hemispheres. The quadrant of altitude is a thin pliable plate of brass, answering exactly to a quadrant of the meridian. It is divided into 90°, and has a notch, nut and screw, to fix to the brazen meridian in the zenith of any place; where it turns round a pivot, and supplies the room of vertical circles. The hour-circle is a flat ring of brass, divided into twenty-four equal parts, or hour-distances; and on the pole of the globe is fixed an index, that turns round with the globe, and points out the hours upon the hour-circle. Lastly, there is generally added a compass and needle upon the pediment of the frame.

The surface of the celestial globe may be esteemed a just representation of the concave expanse of the heavens, notwithstanding its convexity; for it is easy to conceive the eye placed in the center of the globe, and viewing the stars on its surface; supposing it made of glass, as some globes are: also that if holes were made in the center of each star, the eye in the center of the globe, properly placed, would view thro' each of the holes the very stars in the heavens represented by them.

As it would be impossible to have any distinct notion of the stars, in respect of their number, order, and distances, without arranging them in certain forms, called constellations, this the first observers of the heavens took care to do; and these, like kingdoms and countries upon the terrestrial globe, serve to distinguish the different parts of the superficies of the celestial globe. See CONSTELLATION.

The stars, therefore, are all disposed in constellations under the forms of various animals, whose names and figures are represented on the celestial globe; which were first invented by the ancient astronomers and poets, and are still retained for the better distinction of these luminaries.

*Problems on the celestial GLOBE. 1. To rectify the globe.* Raise or elevate the pole to the latitude of the place; screw the quadrant of altitude in the zenith; set the

the index of the hour-circle to the upper XII; and place the globe north and south by the compass and needle; then is it a just representation of the heavens from the given day at noon. 2. *To find the sun's place in the ecliptic.* Find the day of the month in the calendar on the horizon, and right against it is the degree of the ecliptic which the sun is in for that day. 3. *To find the sun's declination.* Rectify the globe, bring the sun's place in the ecliptic to the meridian, and that degree which it cuts in the meridian is the declination required. 4. *To find the sun's right ascension.* Bring the sun's place to the meridian, and the degree of the equinoctial cut by the meridian, is the right ascension required. 5. *To find the sun's amplitude.* Bring the sun's place to the horizon, and the arch of the horizon intercepted between it and the east or west point, is the amplitude, north or south. 6. *To find the sun's altitude for any given day and hour.* Bring the sun's place to the meridian; set the hour-index to the upper XII; then turn the globe till the index points to the given hour, where let it stand; then screwing the quadrant of altitude in the zenith, lay it over the sun's place, and the arch contained between it and the horizon, will give the degrees of altitude required. 7. *To find the sun's azimuth for any hour of the day.* Every thing being done as in the last problem, the arch of the horizon contained between the north point, and that where the quadrant of altitude cuts it, is the azimuth east or west, as required. 8. *To find the time when the sun rises or sets.* Find the sun's place for the given day; bring it to the meridian, and set the hour-hand to XII; then turn the globe till the sun's place touches the east part of the horizon, the index will shew the hour of its rising: after that, turn the globe to the west part of the horizon, and the index will shew the time of its setting for the given day. 9. *To find the length of any given day or night.* This is easily known, by taking the number of hours between the rising and setting of the sun for the length of the day; and the residue, to 24, for the length of the night. 10. *To find the hour of the day, having the sun's altitude given.* Bring the sun's place to the meridian, and set the hour-hand to XII; then turn the globe in such a manner, that the sun's place may move along by the quadrant of altitude (fixed in the zenith) till it

touches the degree of the given altitude; where stop it, and the index will shew on the horary circle the hour required. 11. *To find the place of the moon, or any planet, for any given day.* Take Parker's or Weaver's ephemeris, and against the given day of the month you will find the degree and minute of the sign which the moon or planet possesses at noon, under the title of geocentric motions. The degree thus found being marked in the ecliptic on the globe by a small notch, or otherwise, you may then proceed to find the declination, right ascension, latitude, longitude, altitude, azimuth, rising, southing, setting, &c. in the same manner as has been shewn for the sun. 12. *To explain the phenomena of the harvest moon.* In order to this we need only consider, that when the sun is in the beginning of aries, the full moon on that day must be in the beginning of libra: and since when the sun sets, or moon rises, on that day, those equinoctial points will be in the horizon, and the ecliptic will then be least of all inclined thereto, the part or arch which the moon describes in one day, viz.  $13^{\circ}$ , will take up about an hour and a quarter ascending above the horizon; and, therefore, so long will be the time after sun-set, the next night, before the moon will rise. But at the opposite time of the year, when the sun is in the autumnal, and the full moon in the vernal equinox, the ecliptic will, when the sun is setting, have the greatest inclination to the horizon; and, therefore,  $13^{\circ}$  will in this case soon ascend, viz. in about a quarter of an hour; and so long after sun-set will the moon rise the next day after the full: whence, at this time of the year, there is much more moon-light than in the spring; and hence this autumnal full moon came to be called the harvest moon, the hunter's or shepherd's moon: all which will be clearly shewn on the globe. 13. *To represent the face of the starry firmament for any given hour of the night.* Rectify the globe, and turn it about, till the index points to the given hour; then will all the upper hemisphere of the globe represent the visible half of the heavens, and all the stars on the globe will be in such situations as exactly correspond to those in the heavens; which may therefore be easily found, as will be shewn in the sixteenth problem. 14. *To find the hour when any known star will rise, or come upon the meridian.* Rectify the globe,

globe, and set the index to XII; then turn the globe till the star comes to the horizon or meridian, and the index will shew the hour required. 15. *To find at what time of the year any given star will be on the meridian at XII at night.* Bring the star to the meridian, and observe what degree of the ecliptic is on the north meridian under the horizon; then find in the calendar on the horizon the day of the year against that degree, and it will be the day required. 16. *To find any particular star.* First find its altitude in the heavens by a quadrant, and the point of the compass it bears on; then, the globe being rectified, and the index turned to the given hour, if the quadrant of altitude be fixed on the zenith, and laid towards the point of the compass on which the star was observed, the star required will be found at the same degree of altitude on the said quadrant, as it was by observation in the heavens.

**Problems on the terrestrial GLOBE.** 1. *To find the latitude of any place.* Bring the given place to the brazen meridian, and observe what degree it is under, for that is the latitude required. 2. *To rectify the globe for any given place.* Raise the pole so many degrees above the horizon, as are equal to the latitude of the place; then, finding the sun's place, bring it to the meridian; and proceed, as directed in problem 1. on the celestial globe. 3. *To find the longitude of a given place.* Bring the place to the brazen meridian, and observe the degree of the equator under the same, for that expresses the longitude required. 4. *To find any place by the latitude and longitude given.* Bring the given degree of longitude to the meridian, and under the given degree of latitude you will see the place required. 5. *To find all those places which have the same latitude, or longitude, with those of any given place.* Bring the given place to the meridian, then all those places which lie under the meridian have the same longitude: again, turn the globe round on its axis; then all those places, which pass under the same degree of the meridian with any given place, have the same latitude with it. 6. *To find all those places where it is noon at any given hour of the day, in any place.* Bring the given place to the meridian; set the index to the given hour; then turn the globe, till the said index points to the upper XII; and observe what places lie under the brass meridian, for to them it is noon

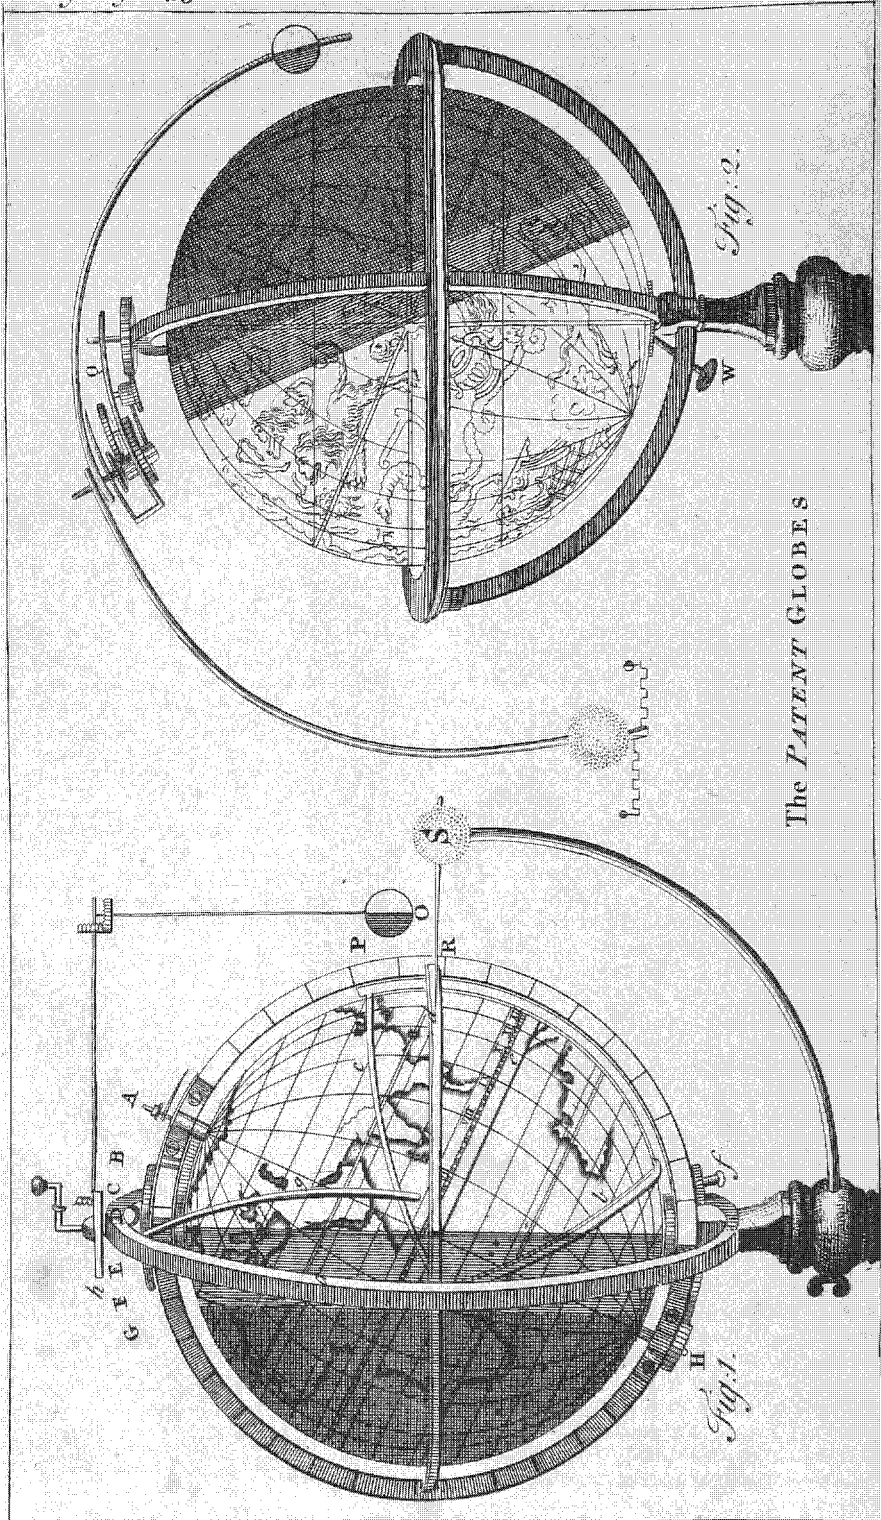

at that time. 7. *When it is noon at any one place, to find what hour it is at any other given place.* Bring the first given place to the meridian, and set the index to the upper XII; then turn the globe till the other given place comes to the meridian, and the index will point to the hour required. 8. *For any given hour of the day in the place where you are, to find the hour of the day in any other place.* Bring the place where you are to the meridian, set the index to the given hour, then turn the globe about, and when the other place comes to the meridian, the index will shew the hour of the day there, as required. 9. *To find the distance between any two places on the globe in english miles.* Bring one place to the meridian, over which fix the quadrant of altitude; and then laying it over the other place, count the number of degrees thereon contained between them; which number multiply by  $69\frac{1}{2}$ , (the number of miles in one degree,) and the product is the number of english miles required. 10. *To find how any one place bears from another.* Bring one place to the brass meridian, and lay the quadrant of altitude over the other; and it will shew on the horizon the point of the compass on which the latter bears from the former. 11. *To find those places to which the sun is vertical in the torrid zone, for any given day.* Find the sun's place in the ecliptic for the given time, and bring it to the meridian, and observe what degree thereof it cuts; then turn the globe about, and all those places which pass under that degree of the meridian, are those required. 12. *To find what day of the year the sun will be vertical to any given place in the torrid zone.* Bring the given place to the meridian, and mark the degree exactly over it; then turn the globe round, and observe the two points of the ecliptic which pass under that degree of the meridian: lastly, see on the wooden horizon on what days of the year the sun is in those points of the ecliptic; for those are the days required. 13. *To find those places in the north frigid zone, where the sun begins to shine constantly without setting, on any given day between the 21st of March and the 21st of June.* Find the sun's place in the ecliptic for the given day; bring it to the general meridian, and observe the degrees of declination; then all those places which are the same number of degrees distant from the pole, are the places required to

be found. 14. *To find on what day the sun begins to shine constantly without setting, on any given place in the north frigid zone, and how long.* Rectify the globe to the latitude of the place; and, turning it about, observe what point of the ecliptic between aries and cancer, and also between cancer and libra, coincides with the north point of the horizon; then find, by the calendar on the horizon, what days the sun will enter those degrees of the ecliptic, and they will satisfy the problem. 15. *To find the place over which the sun is vertical, on any given day and hour.* Find the sun's place, and bring it to the meridian, and mark the degree of declination for the given hour; then find those places which have the sun in the meridian at that moment; and among them, that which passes under the degree of declination, is the place desired. 16. *To find, for any given day and hour, those places wherein the sun is then rising and setting, or on the meridian; also those places which are enlightened, and those which are not.* Find the place to which the sun is vertical at the given time, and bring the same to the meridian, and elevate the pole to the latitude of the place; then all those places which are in the western semicircle of the horizon have the sun rising, and those in the eastern semicircle see it setting; and to those under the meridian, it is noon. Lastly, all places above the horizon are enlightened, and all below it are in darkness or night. 17. *The day and hour of a solar or lunar eclipse being given, to find all those places in which the same will be visible.* Find the place to which the sun is vertical at the given instant, and elevate the globe to the latitude of the place; then in most of those places above the horizon will the sun be visible during his eclipse; and all those places below the horizon, will see the moon pass through the shadow of the earth in her eclipse. 18. *The length of a degree being given, to find the number of miles in a great circle of the earth, and thence the diameter of the earth.* Admit that one degree contains  $69\frac{1}{2}$  english statute miles; then multiply 360 (the number of degrees in a great circle) by  $69\frac{1}{2}$ , and the product will be 25020, the miles which measure the circumference of the earth. If this number be divided by 3.1416, the quotient will be 7963 $\frac{86}{100}$  miles, for the diameter of the earth. 19. *The diameter of the earth being known,*

*to find the surface in square miles, and its solidity in cubic miles.* Admit the diameter be 7964 miles; then multiply the square of the diameter by 3.1416, and the product will be 199250205 very near, which are the square miles in the surface of the earth. Again, multiply the cube of the diameter by 0.5236, and the product 264466789170 will be the number of the cubic miles in the whole globe of the earth. 20. *To express the velocity of the diurnal motion of the earth.* Since a place in the equator describes a circle of 25020 miles in twenty-four hours, it is evident that the velocity with which it moves is at the rate of  $1042\frac{1}{2}$  in one hour, or  $17\frac{3}{10}$  miles per minute. The velocity in any parallel of latitude, decreases in the proportion of the co-sine of the latitude to the radius. Thus for the latitude of London,  $51^{\circ} 30'$ , say,  
As radius 10.000000  
To the co-sine of lat.  $51^{\circ} 30'$  9.794149  
So is the velocity in the } 2.232046  
equator,  $17\frac{3}{10}$  }  
To the velocity of the city } 2.032195  
of London,  $10\frac{8}{10}$  }  
That is, the city of London moves about the axis of the earth at the rate of  $10\frac{8}{10}$  miles every minute of time. But this is far short of the velocity of the annual motion about the sun; for that is at the rate of 60000 miles per hour, or about 1000 miles each minute, supposing the diameter of the annual orbit to be 82 millions of miles.

**Patent-GLOBES**, those with Mr. Neale's improvements, for which he obtained his majesty's letters-patent. The terrestrial globe, with the improvements of this ingenious artist, is represented in plate CXVII. fig. 1. the earth being supposed in that part of its orbit where the north pole A is at its nearest approach to the sun S, which accordingly by the index or ray SR, points to the tropic of cancer; *b* is a moveable circle, which, set to the latitude of a given place, will cause the semicircle *c* to point out the zenith of the said place; *d* represents the ecliptic, *e* the equator, and *f* a screw by which the annual motion may be separated from the diurnal; *g* is a semicircle which always moves at  $90^{\circ}$  distance from the moon, and thereby becomes the lunar horizon for the northern hemisphere; *b* is an inclined plane on which the stem of the moon PO moves, thereby causing the moon itself to shew its several latitudes, nodes, &c. and by this plane

The PATENT GLOBES

plane moving the contrary way, in a little more than 19 of the annual revolutions of the globe, is shewn the retrograde motion of the nodes.

This globe is mounted with the horizon *a* fixed vertically, and placed so as to move upon its own axis *AH*, whereby it represents the diurnal motion of the earth. Hence if the globe be turned round its own axis, by means of the winch at top, the ray from the sun will, in this situation, describe the tropic of cancer: the whole arctic circle will be taken into the enlightened hemisphere, and that of the antarctic circle will be involved in darkness. Let us now suppose the globe turned thirty times about by the winch, the north pole will then be situated as at *B*, and the index from the sun will point to the sign leo on the ecliptic *d*: after turning the globe thirty times more, the north pole will be removed to *C*, and the index advanced to virgo; and in this manner may the phenomena of the earth's annual motion be traced through all the signs of the ecliptic and seasons of the year; the index or pointer describing a spiral line, which every day at noon, or turn of the globe, falls at the distance of about fifteen minutes from that of the preceding day. When the earth is so far advanced in its orbit, that the index *SR* points to the equator, the reason will appear very clear why the days and nights are then equal all the world over; for both poles are now seen in the horizon, which, being the boundary of light and darkness, bisects all the parallels of latitude, and causes an equal distribution of day and night throughout the whole earth.

If the rotation of the globe be continued, the observer will see the north pole descend just as many degrees below the horizon, as the pointer has advanced south of the equator; and when it is arrived at the tropic of capricorn, all that part of the globe within the arctic circle will be involved in continual darkness, whilst that within the antarctic circle enjoys uninterrupted day.

At the distance of 90° from the moon, as has been already observed, is placed a semicircle, which being fixed on the center of the moon's motion, always moves round with her; thereby shewing, throughout her course, all those countries in the northern hemisphere to which she is at any particular time rising, those where she is then setting, and those to

whom she is then due south; as also the exact difference of time between the rising or setting of the sun and moon.

The celestial globe (*ibid.* fig. 2.) is mounted not quite so differently from the common globes, as the terrestrial one; its horizon being as usual, and the globe moveable to the latitude of any country; only instead of those upright pillars to support the horizon, as in common ones, here semicircles are fixed on the pedestal, and from the pole of the equator a motion is conveyed to the pole of the ecliptic; where two arms or indices are placed, on which are fixed the artificial sun and moon. These, as the globe is turned about its axis by the winch *W*, keep their exact motions over the same, by means of the wheel-work at *Q*, in like manner as those luminaries do in the heavens; so that being once set right by an ephemeris, they will remain so, and thereby shew the rising and setting of these luminaries, with the length of the day and night, together with the true cause of all the vicissitudes of the seasons; and how, notwithstanding their apparent motion from east to west, they really move from west to east; the moon, in a very little more than twenty-nine days and a half; and the sun, in a year. See EARTH, SUN, and MOON.

To the center of the sun two jointed stems are occasionally screwed on, and to these are fixed mercury and venus; which by the said joints may be set to their proper stations, and thereby several entertaining problems may be solved. From what has been said it is evident, that the usual problems on the common globes, and most of those with the orrery, may be solved by these curious machines.

*Problems peculiar to the patent-GLOBES.*

1. *To rectify these globes.* This, on the celestial globe, is performed in the same manner as on the common globes. But the terrestrial globe admits of no such rectification; for instead of raising or lowering the pole of the globe itself, according to the latitude of the place, we must here rectify a moveable brass-horizon, so as that the given place shall be in the zenith of the said horizon. 2. *To rectify the sun or moon, according to these globes.* Having found the sun's place in the ecliptic, in the common way, turn the sun about by its stem till it is directly opposite to the same sign and degree of the ecliptic upon the globe. The same

may also be done with respect to the moon, having first found her place by an ephemeris for that day. 3. *To shew on these globes the cause of an eclipse of the sun or moon.* This is self-evident on either globe, by turning them by the winch till the two luminaries come in conjunction with, or opposition to each other, provided they happen to be in or near the nodes. 4. *To explain the reason why they happen no oftener.* This will appear no less evident, by setting the moon to any considerable latitude, and turning the globe till she comes in conjunction with the sun; for then the pointer from the sun will be seen to pass either above or below her, according as she is in north or south latitude; so that there can be no eclipse of the sun, when the moon is not in or near her nodes. 5. *To exhibit a natural representation of the retrograde motion of the moon's nodes.* This is done by only turning the globe with the winch, and observing that the place where the moon crosses the ecliptic, in its motion round the earth, is every time in different places; which are found to be retrograde, or contrary to the order of the signs; that is, they move backward through all the signs from east to west. 6. *The day and hour of a solar eclipse being given, to find all those places on the globe to which the same will be visible.* Turn the globe till the given day comes opposite to the sun, and the place where you are to the pointer; set the index to 12, then turn the globe till the index points to the given hour; set the moon in conjunction with the sun: then all the places above the solar horizon are those to which the eclipse will be visible. 7. *To find the same in a lunar eclipse.* Proceed as in the last problem; only instead of the moon's being in conjunction, she must now be in opposition; and instead of viewing all the countries on that side of the horizon towards the sun, you must survey those on the opposite side; for they are the countries to which the lunar eclipse will be visible. 8. *To exhibit the phases of mercury and venus.* Set them to any given station within the enlightened hemisphere of the celestial globe; and it may be observed, that their different phases in those several stations will be in all respects analogous to those of our moon. 9. *To demonstrate, that in a certain latitude, the inhabitants may observe the sun, moon, mercury, and venus all rising together on a particular day; and yet, on the*

*same day, may see the moon set twelve hours before the sun, mercury fourteen hours after the moon, and venus six hours after all three.* Rectify the globe to the latitude of  $66\frac{1}{2}$ ; let the moon rise near the tropic of capricorn, the sun at the beginning of aries, mercury about fifteen degrees in aries, and venus about eighteen degrees in taurus, with five or six degrees of north latitude; then turn the globe about, and you will find by the index the difference of time sought for. 10. *To find the height of the diurnal arch of the luminaries and planets aforesaid, on any given day.* The globe being rectified, screw the quadrant of altitude to the zenith of the place, which bring to the meridian; then turn about the globe to the given day, and the degree of the quadrant, each respectively pass over, is the height of their arches sought. 10. *To shew why neither mercury nor venus can be seen on the meridian of London at midnight, as all the other planets at certain times are.* Set these two planets to their greatest elongation or distance from the sun; and, by turning the globe about, the impossibility of the thing will be evident.

**GLOBULAR**, in general, an appellation given to things of a roundish figure, like that of a globe.

**GLOBULAR CHART**, a name given to the representation of the surface, or of some part of the surface of the terrestrial globe upon a plane, wherein the parallels of latitude are circles nearly concentric, the meridians curves bending towards the poles, and the rhumb-lines are also curves. See the article **CHART**.

**GLOBULARIA**, in botany, a genus of plants of the *tetrandria-monogynia* class, the proper flower of which is formed of a single petal, tubular at the base, and divided into five segments at the limb; the universal corolla is nearly equal; there is no pericarpium, but the proper perianthium closes at its top, and contains the seed, which is single, and of an oval figure.

Of this genus there are several species, among which that called by some the *alypum* of Montpellier, is a violent cathartic and emetic, and is sometimes given in dropshes with success; but it ought to be used with great caution: its bark contains its principal virtues.

**GLOBULE**, a diminutive of globe, frequently used by physicians in speaking of the red spherical particles of the blood. See the article **BLOOD**.

**GLOCESTER**, the capital of Gloucestershire, ninety miles west of London: west lon.  $2^{\circ} 16'$ , and north lat.  $51^{\circ} 50'$ . It is a bishop's see, and sends two members to parliament.

**GLOGAW**, a city of Silesia, situated on the river Oder, forty-five miles north-west of Breslaw: east lon.  $16^{\circ} 8'$ , and north lat.  $51^{\circ} 40'$ .

*Lesser* **GLOGAW**, a town of Silesia, fifty miles south of Breslaw.

**GLORIA PATRI**, among ecclesiastical writers. See **DOXOLOGY**.

**GLORIOSA**, **SUPERB LILLY**, in botany, a genus of the *hexandria-monogynia* class of plants, the flower of which consists of six oblongo-lanceolated, undulated, and very long petals, reflex nearly to the base; the fruit is an oval pellucid capsule, containing three cells, and numerous globose seeds, disposed in a double series.

**GLOSS**, in matters of literature; denotes an exposition or explication of the text of any author, whether in the same language, or any other; in which sense it differs little from commentary. See the article **COMMENTARY**.

**GLOSS**, among artificers, the lustre or brightness set upon cloth, silk, and the like. See the articles **CLOTH**, **SILK**, &c.

**GLOSSARY**, *glossarium*, a sort of dictionary, explaining the obscure and antiquated terms in some old author; such are Du Cange's latin and greek glossaries, Spelman's Glossary, and Kennet's Glossary at the end of his Parochial Antiquities.

**GLOSSOCOMON**, in surgery, an instrument, or sort of case, contrived by the ancient surgeons, for containing a fractured leg or thigh.

**GLOSSOCOMON**; in mechanics, the name by which Hiero calls a machine, composed of several dented wheels with pinions, and used for raising great weights.

**GLOSSOGAPHE**, in botany, a name used by some for fumitory.

**GLOSSOPETRA**, in natural history, a genus of extraneous fossils, so called from their having been supposed the tongues of serpents turned to stone, though they are really the teeth of sharks, and are daily found in the mouths of those fishes, wherever taken. See **FOSSILS**.

The several sizes of teeth of the same species, and the several different species of sharks, furnish us with a vast variety of these fossil teeth. Their usual colours are black, bluish, whitish, yellowish, or brown. In shape they are usually some-

what approaching to triangular; some are simple, and others have a smaller point on each side the large one; many of them are quite straight, but they are frequently met with crooked, and bent in all the different directions, some inwards, some outwards, and some sideways: they are also of various sizes, the larger ones being four or five inches long, and the smaller less than a quarter of an inch. See plate **CXXIV. fig. 1.**

They are found with us in the strata of blue clay, and are very plentiful in the clay-pits of Richmond, and some other places; but they are no where so common as in the island of Malta.

**GLOTTIS**, in anatomy, the mouth or aperture of the larynx, through which the air ascends and descends in respiring. It is of an elliptic figure, and furnished with cartilages and muscles, by means of which it is occasionally dilated or straitened, so as to give that wonderful variety of notes, of which the voice is capable, in speaking and singing. See the article **LARYNX**.

**GLOTTIS**, in ichthyology, a name sometimes given to the limosa. See the article **LIMOSA**.

**GLOUCESTER**, or **GLOCESTER**. See the article **GLOCESTER**.

**GLOVE**, a covering for the hand and wrist. Gloves, with respect to commerce, are distinguished into leathern-gloves, silk-gloves, thread-gloves, cotton-gloves, worsted-gloves, &c. Leathern gloves are made of chamois, kid, lamb, doe, elk, buff, &c.

Foreign gloves, on their importation, pay the following duties, *viz.* gloves of Canary, Milan, or Venice, unwrought, the dozen pair, pay 4s. 9  $\frac{4}{8}$  d. draw back 4s. 3  $\frac{7}{8}$  d. Those of Canary, Milan, or Venice, wrought with gold or silver, the dozen pair, pay 19s. 1  $\frac{8}{8}$  d. draw back 17s. 3d. French gloves, the gross, pay 1l. 13s. 10  $\frac{12}{100}$  d. draw back 1l.

1  $\frac{8}{100}$  d. French, wrought with gold or silver, the dozen pair, pay 2l. 14s. 1  $\frac{8}{8}$  d. draw back 1l. 12s. 3d. Spanish gloves, plain, the dozen pair, pay 3s. 7  $\frac{8}{100}$  d. draw back 3s. 2  $\frac{81}{100}$  d. Silk-gloves knit, the dozen pair, pay 11s. 5  $\frac{4}{100}$  d. draw back 10s. 6d. More or every pound weight 1s. 10  $\frac{5}{100}$  d. draw back 1s. 10  $\frac{5}{100}$  d. Those of Vandon, the

dozen pair, pay 2s. 4  $\frac{72\frac{1}{2}}{100}$ d. drawback  
2s. 1  $\frac{87\frac{1}{2}}{100}$ d. And more for such as are

made of leather, for every 20s. value,  
upon oath, 6s.

**GLOUTIUS**, in anatomy, a muscle more  
usually called the glutæus major.

**GLOW-WORM**, the english name of an  
insect, called by zoologists cicindela.  
See the article **CICINDELA**.

**GLUCKSTAT**, a fortified town of Ger-  
many, situated on the east side of the ri-  
ver Elbe, thirty miles north-west of  
Hamburgh: east lon. 9°, and north lat.  
54° 20'.

**GLUE**, among artificers, a tenacious vis-  
cid matter, which serves as a cement to  
bind or connect things together.

Glues are of different kinds, according to  
the various uses they are designed for, as  
the common glue, glove-glue, and parch-  
ment-glue; whereof the two last are more  
properly called size. See **SIZE**.

The common or strong glue is chiefly  
used by carpenters, joiners, cabinet-  
makers, &c. and the best kind is that  
made in England, in square pieces of a  
ruddy brown colour; and, next to this,  
the flanders-glue. It is made of the skins  
of animals, as oxen, cows, calves, sheep,  
&c. and the older the creature is, the  
better is the glue made of its hide.  
Indeed, whole skins are but rarely used  
for this purpose, but only the shavings,  
parings, or scraps of them; or the feet,  
sinews, &c. That made of whole skins,  
however, is undoubtedly the best; as that  
made of sinews is the very worst.

*The method of making GLUE.* In making  
glue of parings, they first steep them two  
or three days in water; then washing them  
well out, they boil them to the consistence  
of a thick jelly; which they pass, while  
hot, through ozier-baskets, to separate  
the impurities from it, and then let stand  
some time, to purify it further: when all  
the filth and ordures are settled to the  
bottom of the vessel, they melt and boil  
it a second time. They next pour it into  
flat frames or moulds, whence it is taken  
out pretty hard and solid, and cut into  
square pieces or cakes. They afterwards  
dry it, in the wind, in a sort of coarse net;  
and at last string it, to finish its drying.  
The glue made of sinews, feet, &c. is  
managed after the same manner; only  
with this difference, that they bone and  
scour the feet, and do not lay them to  
steep.

The best glue is that which is oldest;  
and the surest way to try its goodness, is  
to lay a piece to steep three or four days,  
and if it swell considerably without melt-  
ing, and when taken out resumes its for-  
mer driness, it is excellent.

A glue that will hold against fire or wa-  
ter, may be made thus: mix a handful  
of quick-lime with four ounces of linseed-  
oil; boil them to a good thickness, then  
spread it on tin-plates in the shade, and  
it will become exceeding hard, but may  
be easily dissolved over a fire, as glue,  
and will effect the business to admiration.

*Method of preparing and using GLUE.* Set  
a quart of water on the fire, then put in  
about half a pound of good glue, and  
boil them gently together till the glue be  
entirely dissolved and of a due consistence.  
When glue is to be used, it must be made  
thoroughly hot; after which, with a  
brush dipped in it, besmear the faces of the  
joints as quick as possible; then clapping  
them together, slide or rub them length-  
wise one upon another, two or three  
times, to settle them close; and so let  
them stand till they are dry and firm.

*Fish-GLUE*, a name sometimes given to  
ichthyocolla. See **ICHTHYOCOLLA**.

**GLUME**, *gluma*, among botanists, a kind  
of cup, consisting of two or three mem-  
branous valves, which are often pellucid  
at their edges. This sort of cup belongs  
to the grasses.

**GLUTÆUS**, in anatomy, the name of  
three muscles, which form the buttocks,  
and from their size are called maximus,  
medius, and minimus. They all arise  
in the external surface of the ilium, if-  
chium, and os sacrum: the termination  
of the first, or greatest, is about four  
fingers-breadth from the great trochanter,  
and the terminations of the two others  
are in this trochanter.

**GLUTINATIVE MEDICINES**, the same  
with agglutinants. See **AGGLUTINANTS**.

**GLYCINE**, **SCARLET-PEA**, in botany, a  
genus of the *diadelphia-decandria* class of  
plants, with a papilionaceous flower, and  
an oblong bilocular pod, containing a  
number of kidney-shaped seeds, of a scar-  
let colour, spotted with black.

**GLYCONIAN VERSE**, in ancient poetry,  
consists of three feet, whereof the first is  
a spondee, the second a choriambus, and  
the last a pyrrhichius; or the first may be  
a spondee, and the other two dactyls.

Thus, *Mens re-|gnum bona pos-|sidet.*  
or, *Mens re-|gnum bona |possidet.*

**GLYCYRRHIZA**,

**GLYCYRRHIZA, LIQUORICE**, in botany, a genus of the *diadelphia-decandria* class of plants, with a papilionaceous flower, consisting of four petals; the fruit is an oblong, compressed, and unilocular pod, containing a few kidney-shaped seeds.

For the description and medicinal virtues of liquorice, see the article **LIQUORICE**.

**GLYPH**, in sculpture and architecture, denotes any canal or cavity, used as an ornament.

**GLYSTER, or CLYSTER**, among physicians. See the article **CLYSTER**.

**GMELENA**, in botany, a genus of the *didynamia-angiospermia* class of plants, the flower of which is campanulated, and also divided into four segments; the fruit is a globose unilocular berry, surrounding a bilocular nut or kernel.

**GNAPHALIUM, CUDWEED**, in botany, a genus of the *syngenesia-polygamia-superflua* class of plants, with numerous hermaphrodite flowers on its disc, and a few female ones on the verge; there is no pericarpium; the seeds, which are oblong, single, and crowned with down, being contained in the cup.

Cudweed is esteemed drying and astringent, and recommended in dysenteries, hæmorrhages, and all kinds of fluxes; but the modern pharmacy makes little use of it.

**GNAPHALIUM** is also used by some for filago. See the article **FILAGO**.

**GNAPHALOIDES**, the name of a plant called by Linnæus *micropus*. See the article **MICROPUS**.

**GNAT**, in zoology, an insect of the fly-kind, called by authors *culex*. See the article **CULEX**.

There are several species of gnats, distinguished partly by their size, and partly by the different colours with which they are variegated, as black, brown, grey, yellow, &c. They belong to the order of two-winged flies.

**GNESNA**, the capital city of great Poland, situated one hundred and ten miles west of Warsaw: east lon.  $18^{\circ}$ , and north lat.  $53^{\circ}$ .

It is the see of an archbishop, who is always primate of Poland. See the article **POLAND**.

**GNIDIA**, in botany, a genus of the *ostandria-monogynia* class of plants, the flower of which consists of four petals, inserted into the cup; there is no pericarpium; the seed is single, and retained in the bottom of the cup.

**GNOME** is often used in a synonymous sense with apophthegm. See **APOPTHHEGM**.

**GNOMES, gnomi**, certain invisible people, who, according to the cabbalists, inhabit the inner parts of the earth. They are supposed small in stature, and the guardians of quarries, mines, &c. See the article **CABBALISTS**.

**GNOMON**, in dialling, the style, pin, or cock of a dial; which, by its shadow, shews the hour of the day. The gnomon of every dial represents the axis of the world. See **DIAL** and **DIALLING**.

**GNOMON**, in geometry. If, in a parallelogram ABCD (pl. CXIX. fig. 1. n<sup>o</sup> 1.) the diameter AC be drawn; also two lines EF, HI, parallel to the sides of the parallelogram, and cutting the diameter in one and the same point G, so that the parallelogram is, by these parallels, divided into four parallelograms, then are the two parallelograms DG, BG, through which the diameter does not pass, called complements; those through which the diameters pass, EH, FI, are called the parallelograms about the diameter; and a gnomon consists of the two complements, and either of the parallelograms about the diameter, viz. GD + HE + EI, or GD + FI + GB.

**GNOMON**, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun. Thus, in the right-angled triangle ABC *ibid.* n<sup>o</sup> 2. are given, AB the length of the style, BC the length of its shadow, and the right angle ABC. Hence, making CB the radius, we have this analogy for finding the angle ACB, the sun's altitude, viz. BC:AB::radius:tangent of the angle C.

By means of a gnomon, the sun's meridian altitude, and consequently the latitude of the place, may be found more exactly than with the smaller quadrants. See the article **QUADRANT**.

By the same instrument, the height of any object GH may be found; for as DF (*ibid.* n<sup>o</sup> 3.) the distance of the observer's eye from the gnomon, is to DE, the height of the style; so is FH, the distance of the observer's eye from the object, to GH, its height.

**GNOMON** of a globe, the index of the hour-circle. See the article **GLOBE**.

**GNOMONIC**, something belonging to a gnomon. See the preceding article.

**GNOMONIC COLUMN**. See **COLUMN**.

**GNOMONIC PROJECTION**. See the article **PROJECTION**.

**GNOMONICS**,

**GNOMONICS**, *gnomonica*, the art of dialling, or of drawing sun and moon-dials, on any given plane. See the articles **DIAL** and **DIALLING**.

**GNOSTICS**, in church-history, christian heretics so called, it being a name which amongst all the antient heretics affected to take, to express that new knowledge and extraordinary light, to which they made pretensions; the word gnostic signifying a learned, or enlightened person.

St. Epiphanius ascribes the origin of the gnostics to Simon Magus, and says that they acknowledged two principles, a good and a bad. They supposed there were eight different heavens, each of which was governed by its particular prince: the prince of the seventh heaven, whom they named Sabaoth, created the heavens and the earth, the six heavens below him, and a great number of angels. In the eighth heaven they placed their Barbelo, or Barbéro, whom they sometimes called the father and sometimes the mother of the universe. All the gnostics distinguished the creator of the universe from God, who made himself known to men by his Son, whom they acknowledged to be the Christ. They denied that the Word was made flesh; and asserted that Jesus Christ was not born of the virgin Mary, that he had a body only in appearance, and that he did not suffer in reality. They neither believed a resurrection, nor a judgment to come; but imagined that those who had not been instructed in their maxims, would return into the world, and pass into the bodies of hogs and other of the like animals. They had several apocryphal books, as the Gospel of St. Philip, the Revelations of Adam, the Gospel of Perfection, &c.

**GO** is sometimes used, in a special signification, in our law; as *to go without day*, is to be dismissed the court.

**Go**, in ichthyology, a name sometimes given to the sea-gudgeon.

**GOA**, a city and sea-port of the hither India, situated in an island of the river Mandoua, and subject to the Portuguese: east lon. 73° 20', and north lat. 15° 20'.

**GOAD**, a pointed stick, or rod, armed with a sharp iron-pin at the end, to prick oxen or other cattle forwards.

**GOAL**, or **GAOL**. See **GAOL**.

**GOARING**, or **GOREING**, in the sea-language. See **GOREING**.

**GOAT**, *capra*, in zoology, a quadruped of the order of the pecora. See the article **CAPRA**.

The common goat with carinated and arcuated horns, is nearly of the size of the sheep, only that the wool of the latter makes it appear larger. The furr of the goat is of a pale dun, and the hairs rigid and waved, but not curled as in the sheep. It is a native of most parts of Europe. The buck goat has under his jaws two wattles or tufts like a beard. The female also resembles the male, and is valued if she have large teats, a great udder, and no horns, or at least very small ones. These animals require almost nothing to keep them. Their milk is esteemed the greatest nourisher of all liquids, women's milk excepted, and very comfortable to the stomach. The young kids also are very good for the table, and may be managed in all respects like lambs.

**GOAT'S BEARD**, *tragopogon*, in botany, See the article **TRAGOPOGON**.

**GOAT'S EYE**, *agias*, among antient physicians. See the article **ÆGIAS**.

**GOAT-FISH**, *caprifiscus*, in ichthyology. See the article **CAPRISCUS**.

**GOAT'S RUE**, *galega*, in botany. See the article **GALÉGA**.

**GOAT'S STONES**, a name by which some call orchis. See the article **ORCHIS**.

**GOAT-SUCKER**, *caprimulgus*, in ornithology, a species of hirundo. See the article **HIRUNDO**.

**GOAT'S THORN**, the same with tragacanth.

**Gobelins**, a celebrated manufactory for tapestry, established by Mr. Colbert, at Paris, in 1667. See **TAPESTRY**.

**GOBIO**, a species of cyprinus, with the upper jaw longest, and two cirri at the mouth.

**GOBIONARIA**, a species of gobius. See the next article.

**GObIUS**, in ichthyology, a genus of acanthopterygious fishes, with five small bones in the membrane of the gills, and the belly-fins of which grow together into a funnel-shape.

To this genus belongs, 1. The sea-gudgeon, or variegated gobius with fourteen rays in the hinder back-fin; it grows to eight inches in length, and is tolerably thick in proportion: it is very beautifully variegated with brown, white, yellow, green, blue, and black. See pl. CXXIII. fig. 1. n° 1. 2. The paganellus, or gobius with a yellow transverse line on the top of the first back-fin: it grows to about six inches in length, and is tolerably thick in proportion (*ibid.* n° 2.) 3. The jozo, or gobius with the ventral

fin blue, and the rays of the back-fin as-  
furgent. 4. The aphua, or apya-cobi-  
tes, or small gobius with a great many  
rays in the second back-fin : its length is  
only an inch and half. (*ibid.* n<sup>o</sup> 3.)

**Gobi**us is also a name used by different  
authors for several other distinct fishes.  
*viz.* 1. The cyprinus with the upper  
jaw longest, and two cirri at the mouth :  
this is the gobius fluviatilis. 2. The  
pearch with eight or nine black transverse  
lines on each side. And, 3. The smooth  
cottus with two spines on the head. See  
the article **CYPRINUS**, **PEARCH**, &c.

**GOBLET**, a large drinking-cup of a round  
figure, without either foot or handle.

**GOBONE**, or **GOBONY**, in heraldry, the  
same with componed. See **COMPO**ned.

**GOCHT**, a town of Westphalia, about  
seven miles south of Cleves.

**GOD**, *Deus*, the supreme being, the first  
cause or creator of the universe, and the  
only true object of religious worship.

The Hebrews called him Jehovah; which  
name they never pronounced, but used  
instead of it the words Adonai, or Eloe-  
him. See the articles **ADONAI**, **ELOHIM**,  
and **JEHOVAH**.

God, says sir Isaac Newton, is a relative  
term, and has respect to servants. It  
denotes, indeed, an eternal, infinite, ab-  
solutely perfect being : but such a being  
without dominion, would not be god.  
The word god frequently signifies lord,  
but every lord is not god. The domi-  
nion of a spiritual being, or lord, consti-  
tutes god ; true dominion, true god ; the  
supreme, supreme ; pretended, pretend-  
ed. From such true dominion it follows  
that the true God is living, intelligent, and  
powerful ; and from his other perfec-  
tions, that he is supreme, or supremely  
perfect. He is eternal and infinite, om-  
nipotent and omniscient ; that is, he en-  
dures from eternity to eternity, and is  
present from infinity to infinity. He go-  
verneth all things that exist, and knows all  
things that are to be known. He is not  
eternity or infinity, but eternal and infi-  
nite. He is not duration and space, but  
he endures and is present : he endures al-  
ways, and is present every where ; and  
by existing always and every where, con-  
stitutes the very things we call duration  
and space, eternity and infinity. He is

omnipresent, not only virtually, but sub-  
stantially ; for power without substance  
cannot subsist. All things are contained  
and move in him, but without any mu-  
tual passion ; that is, he suffers nothing

from the motions of bodies, nor do they  
undergo any resistance from his omni-  
presence.

It is confessed, that god exists necessarily ;  
and by the same necessity he exists always  
and every where. Hence also he must be  
perfectly similar ; all eye, all ear, all brain  
all arm, all perception, intelligence, and  
action ; but after a manner not at all cor-  
poreal, not at all like men ; after a man-  
ner altogether unknown to us. He is de-  
stitute of all body, and bodily shape,  
and therefore cannot be seen, heard, or  
touched ; nor ought to be worshipped un-  
der the representation of any thing corpo-  
real. We know him only by his pro-  
perties, or attributes, by the most wise  
and excellent structure of things, and by  
final causes : but we adore and worship  
him only on account of his domini-  
on ; for God, setting aside dominion,  
providence, and final causes, is nothing  
else but fate and nature.

The plain argument, says Mr. Mac-  
laurin, for the existence of the deity, obvi-  
ous to all, and carrying irresistible con-  
viction with it, is from the evident con-  
trivance and fitness of things for one an-  
other, which we meet with throughout all  
parts of the universe. There is no need  
of nice or subtle reasonings in this mat-  
ter ; a manifest contrivance immediately  
suggests a contriver. It strikes us like a  
sensation ; and artful reasonings against  
it may puzzle us, but it is without shak-  
ing our belief. No person, for example,  
that knows the principles of optics and  
the structure of the eye, can believe that  
it was formed without skill in that sci-  
ence ; or that the ear was formed without  
the knowledge of sounds ; or that the  
male and female in animals were not  
formed for each other, and for continu-  
ing the species. All our accounts of na-  
ture are full of instances of this kind.  
The admirable and beautiful structure of  
things for final causes, exalt our idea of  
the contriver : the unity of design shews  
him to be one. The great motions in  
the system, performed with the same fa-  
cility as the least, suggest his almighty  
power, which gave motion to the earth  
and the celestial bodies with equal ease as  
to the minutest particles. The subtilty  
of the motions and actions in the internal  
parts of bodies, shews that his influence  
penetrates the inmost recesses of things,  
and that he is equally active and present  
every where. The simplicity of the laws  
that prevail in the world, the excellent  
disposition

disposition of things, in order to obtain the best ends, and the beauty which adorns the works of nature, far superior to any thing in art, suggest his consummate wisdom. The usefulness of the whole scheme, so well contrived for the intelligent beings that enjoy it, with the internal disposition, and moral structure of those beings themselves, shew his unbounded goodness. These are the arguments which are sufficiently open to the views and capacities of the unlearned; while, at the same time they acquire new strength and lustre from the discoveries of the learned. The deity's acting and interposing in the universe, shew that he governs, as well as formed it; and the depth of his counsels, even in conducting the material universe, of which a great part surpasses our knowledge, keep up an inward veneration and awe of this great being, and dispose us to receive what may be otherwise revealed to us, concerning him. It has been justly observed that some of the laws of nature now known to us, must have escaped us, if we had wanted the sense of seeing. It may be in his power to bestow upon us other senses, of which we have at present no idea; without which it may be impossible for us to know all his works, or to have more adequate ideas of himself. In our present state, we know enough to be satisfied of our dependency upon him, and of the duty we owe to him, the lord and disposer of all things. He is not the object of sense; his essence, and indeed that of all other substances, is beyond the reach of all our discoveries: but his attributes clearly appear in his admirable works. We know, that the highest conceptions we are able to form of them, are still beneath his real perfections; but his power and dominion over us, and our duty towards him, are manifest.

Though God has given us no innate ideas of himself, says Mr. Locke, yet having furnished us with those faculties our minds are endowed with, he hath not left himself without a witness; since we have sense, perception, and reason, and cannot want a clear proof of him, as long as we carry ourselves about us. To shew, therefore, that we are capable of knowing, that is, being certain that there is a God; and how we may come by this certainty, I think we need go no farther than ourselves, and that undoubted knowledge we have of our own existence. I think it is beyond question, that man has a clear

perception of his own being: he knows certainly that he exists, and that he is something. In the next place, man knows, by an intuitive certainty, that bare nothing can no more produce any real being, than it can be equal to two right angles. If, therefore, we know there is some real being, it is an evident demonstration, that from eternity there has been something: since what was not from eternity, had a beginning; and what had a beginning, must be produced by something else. Next it is evident, that what has its being from another, must also have all that which is in and belongs to its being from another too: all the powers it has, must be owing to, and received from the same source. This eternal source then of all being, must be also the source and original of all power; and so this eternal being must be also the most powerful.

Again, man finds in himself perception and knowledge: we are certain then that there is not only some being, but some knowing intelligent being in the world. There was a time then, when there was no knowing being, or else there has been a knowing being from eternity. If it be said, there was a time when that eternal being had no knowledge; I reply, that then it is impossible there should have ever been any knowledge: it being as impossible that things wholly void of knowledge, and operating blindly, and without any perception, should produce a knowing being, as it is impossible that a triangle should make itself three angles bigger than two right ones. Thus, from the consideration of ourselves, and what we infallibly find in our own constitutions, our reason leads us to the knowledge of this certain and evident truth, that there is an eternal, most powerful, and knowing being, which whether any one will call God, it matters not. The thing is evident; and from this idea, duly considered, will easily be deduced all those other attributes we ought to ascribe to this eternal being.

From what has been said, it is plain to me, that we have a more certain knowledge of the existence of a God, than of any thing our senses have not immediately discovered to us. Nay, I presume I may say, that we more certainly know that there is a God, than that there is any thing else without us. When I say, we know, I mean, there is such a knowledge within our reach, which we cannot miss, if

we will but apply our minds to that, as we do to several other inquiries.

It being then unavoidable for all rational creatures to conclude, that something has existed from eternity, let us next see what kind of thing that must be. There are but two sorts of beings in the world, that man knows or conceives; such as are purely material, without sense or perception; and sensible perceiving beings, such as we find ourselves to be. These two sorts we shall call cogitative and incogitative beings; which, to our present purpose, are better than material and immaterial.

If then there must be something eternal, it is very obvious to reason, that it must necessarily be a cogitative being; because it is as impossible to conceive that bare incogitative matter should ever produce a thinking intelligent being, as that nothing of itself should produce matter. Let us suppose any parcel of matter eternal, we shall find it in itself unable to produce any thing. Let us suppose its parts firmly at rest together; if there were no other being in the world, must it not eternally remain so, a dead unactive lump? is it possible to conceive that it can add motion to itself, or produce any thing? Matter then, by its own strength, cannot produce in itself so much as motion. The motion it has, must also be from eternity, or else added to matter by some other being, more powerful than matter. But let us suppose motion eternal too; but yet matter, incogitative matter, and motion could never produce thought. Knowledge will still be as far beyond the power of nothing to produce. Divide matter into as minute parts as you will, vary its figure and motion as much as you please, it will operate no otherwise upon other bodies, of proportionable bulk, than it did before this division. The minutest particles of matter, knock, repel, and resist one another, just as the greater do, and that is all they can do: so that if we suppose nothing eternal, matter can never begin to be: if we suppose only matter and motion eternal, thought can never begin to be: for it is impossible to conceive, that matter, either with or without motion, could have originally in and from itself, sense, perception, and knowledge, as is evident from hence, that then sense, perception, and knowledge must be a property eternally inseparable from

matter, and every particle of it. Since, therefore, whatsoever is the first eternal being, must necessarily be cogitative; and whatsoever is first of all things, must necessarily contain in it, and actually have at least all the perfections that can ever after exist; it necessarily follows, that the first eternal being cannot be matter. If, therefore, it be evident, that something must necessarily exist from eternity, it is also as evident, that that something must be a cogitative being. For it is as impossible that incogitative matter should produce a cogitative being, as that nothing, or the negation of all being, should produce a positive being, or matter.

This discovery of the necessary existence of an eternal mind, sufficiently leads us to the knowledge of God: for it will hence follow, that all other knowing beings that have a beginning, must depend on him, and have no other ways of knowledge or extent of power, than what he gives them; and therefore if he made those, he made also the less excellent pieces of this universe, all inanimate bodies, whereby his omniscience, power, and providence will be established; and from thence all his other attributes necessarily follow.

With respect to christians, it need only be just mentioned, that they were very early divided in opinion, as to the nature and essence of the supreme Being; a great part worshipping three persons in the unity of the godhead, whilst others absolutely rejected a trinity of persons, and asserted the unity of the divine nature, both as to person and substance. See the articles ARIAN and TRINITARIAN.

With respect to the theology of the pagans, it is thought by most learned men, that they acknowledged but one God; and that the many different divinities worshipped by them, were but attributes and actions of one and the same God. This may probably be true of the wiser heathens; and indeed there are many strong and beautiful passages in pagan authors, to prove that these acknowledged but one God. Thus Pythagoras taught the unity of God, and defined him to be a mind penetrating and diffusing itself through all the parts of the universe, from which all animals receive life: and Plato called God the being which is; and whenever he mentions the deity, it is always in the singular number.

It is a celebrated division of the heathen gods into *dei majorum gentium*, and *dei*

*minorum gentium* ; that is, into the superior and inferior gods. Another division was taken from their place of residence ; thus there were celestial, terrestrial, infernal, marine, and sylvan gods. They were also divided into animal and natural gods : the animal gods were mortals, who had been raised to divinity by ignorance and superstition (see *APOTHEOSIS*) ; and the natural gods, the parts of nature, such as the stars, the elements, mountains, rivers, &c. There were also deities, who were supposed to preside over particular persons : some had the care of women in child-birth ; others, the care of children and young persons ; and others were the deities of marriage. Each action, virtue, and profession had also its particular god : the shepherds had their Pan ; the gardeners, their Flora ; the learned, their Mercury and Minerva ; and the poets, their Apollo and the Muses. See the articles *GENII*, *LARES*, *PENATES* ; &c.

**GODALMIN**, a market-town of Surry, thirty miles south-west of London.

**GOD-BOTE**, an ecclesiastical fine imposed for offences against God.

**GODDES**, a heathen deity of the female sex.

The antients had almost as many goddesses, as gods ; such were Juno, the goddess of air ; Diana, the goddess of woods, &c. and under this character were represented the virtues, graces, and principal advantages of life, Truth, Justice, Piety, Liberty, Fortune, Victory, &c.

It was the peculiar privilege of the goddesses to be represented naked on medals ; for it was supposed that the imagination must be awed and restrained by the consideration of the divine character.

**GOD-FATHERS**, and **GOD-MOTHERS**, persons who at the baptism of infants, answer for their future conduct, and solemnly promise that they will renounce the devil and all his works, and follow a life of piety and virtue, and by this means lay themselves under an indispensable obligation to instruct them, and watch over their conduct.

This custom is of great antiquity in the christian church, and was probably instituted to prevent children being brought up in idolatry, in case their parents died before they arrived at years of discretion.

The number of god-fathers and god-mothers is reduced to two, in the church of Rome ; and three, in the church of

England : but formerly they had as many as they pleased.

**GOES**, a port town of Zeland, in Holland, ten miles east of Middleburgh.

**GOGET**, a name sometimes given to the sea gudgeon. See the article *Gobi*.

**GOGMAGOG-HILLS** lie three miles south-east of Cambridge : remarkable for the intrenchments cast up on them.

**GOITO**, a city of Italy, ten miles north-west of Mantua.

**GOLCONDA**, the capital of a province of the same name, in the hither India : east lon. 77°, and north lat. 16°.

**GOLD**, *aurum*, a yellow metal, the heaviest, purest, most ductile, and shining, and on these accounts the most valuable of all metals. See the article *METAL*.

Gold is the most frequently found native of all the metals ; and is indeed very rarely found in a state of ore, that is, divested of its metallic form, by it particles being penetrated by, and intimately mixed with sulphur : and in the few instances in which it is found thus, it never constitutes a peculiar ore, but is found intermixed among the ores of other metals ; and most frequently among those of silver, or those of which, though some other be the predominant metal, yet there is a large quantity of silver among it, in which the gold lies in its state of ore. See the article *ORE*.

Native gold, though free from the penetrating sulphurs which reduce metals to ores, is yet very seldom found pure, but has almost constantly an admixture of silver with it, and very frequently of copper : when it has copper in it, it is easily discovered, if in any considerable quantity, by its hardness : the silver is not so easily detected in it. Native gold is sometimes found in pure masses of considerable size, many having been found of more than a pound weight : these masses are met with in the gold-mines, and are called *aurum obryzum*, or *obryzum*, but they are very rare : such, however, have been sometimes found in the german mines. See the article *MINE*.

Its more common appearance, in its more loose state, is in form of what is called gold-dust : this is native gold in smaller masses, usually indeed very small, mixed among the sands of rivers. This is found in many parts of the world, but the greatest quantity of it is from Guinea : some of it is to be met with in the beds of some of the rivers in Scotland. Native gold, in a middle state as to size between these

two kinds, is also found in the cliffs or perpendicular fissures of the solid strata in the mountains of Chili. These fissures are filled up partly with reddish marle, partly with native gold immersed in a debased crystalline stone, of a bluish hue; and partly with loose native gold, which is usually found in flat pieces, from the size of a pea to that of a horse bean: the quantity however, so far as has been yet discovered, is not great.

These, though not unfrequent in those parts of the world where there is gold, are, however, far from being its most common appearance; for it is generally and in the greatest abundance found bedded in masses of hard stone, which lie at vast depths; being often dug at a hundred and fifty fathoms: there is no peculiar stone in which the gold is found in those places, but it is met with indiscriminately in several kinds; some soft, some harder, and even in earths. The richest masses are usually of a whitish, and somewhat bright, but opaque stone, which is a debased crystal, containing a large quantity of a white earth: this is often tinged in part also with black, and sometimes with other colours: yet thro' all the different stains the nature and texture of the stone may be easily discovered to be the same; and often the whole variety of colours will be found in one mass. In this stone, the gold lies in a very beautiful form, and a great variety of figures; some parcels of it are variously divaricated, or in form of small branched figures, but these are very rare. Others are variously interwoven in narrower, or broader veins; and others in small flat spangles, intermixed with specks of black: the stone in which this is lodged will very readily give fire with steel, and will not at all ferment with aqua fortis.

Besides this, however, there are many other stones in the mines of Peru, which hold considerable quantities of gold, visible in large or smaller specks; and these are of all colours, but usually white or reddish: the gold in these is usually in small spangles, but there is no certainty either in the size of the masses of pure native gold in this, or any other state; that of the coasts of Guinea, usually called gold-dust, and commonly finer than the smaller sands, yet sometimes affords pieces of three or four ounces weight; and the lumps of *aunum obryzum*, as it is called, have been found

between twenty and thirty pound weight: these things, however, are not common.

*Properties of GOLD.* The chemists tell us, that gold is composed of two substances; the one an extremely pure and simple matter, of the nature of mercury, and the other, which, they say, fixes or destroys the fluidity of this, an equally pure and simple substance, extremely subtle, and of the nature of sulphur. We are not, says Dr. Hill, to take all this upon the credit of those who affirm it; for by all the trials that have been made, gold seems the most simple of all substances. It is the heaviest of all known bodies; and it is the most ductile of all the metals. See the articles *GRAVITY* and *DUCTILITY*.

It is wholly incapable of rust, and is not sonorous when struck upon. It requires a strong fire to melt it, remaining unaltered in the degree of heat that fuses tin or lead, but running with a less vehement one than is necessary to the fusing of iron, or copper. It does not retain its colour, till the time of its melting, but becomes ignited and white, before it runs, and when in fusion it appears of a pale, bluish, green colour on the surface. It amalgamates the most readily of all the metals with quicksilver. When in a state of fusion, it very easily, and very intimately blends itself with silver, and when mixt with that metal, will also run into a mass with iron. Either silver or gold may indeed be mixed singly with this metal, by fusion, but it is much more easily done with regard to gold, when before blended with silver. It much more easily mixes with copper, and the other metals; and very readily with some of the semimetals, as with the regulus of antimony: common fire carried to its utmost vehemence, has no further effect on gold than the fusing it. It will remain ever so long in its fiercest heat, and come out at last unaltered, and with its whole weight. Exposed to the focus of the strongest burning-glasses, it sparkles and flies off in small masses, which if recovered on paper, and examined afterwards, are found to be pure unaltered gold; but if the heat be managed very nicely, and the same gold again and again exposed to it, it is affirmed that a part of the gold will at length go off in fumes, and the remainder will be found to be a substance of a deep blue, with some admixture of purple; and approaching to the nature

of vitriol, rather than of gold, of which it wants the malleability, and the specific gravity.

The proper solvent of gold is aqua regia: this menstruum owes its power upon this metal to the sea salt it contains; that being almost the only salt which has the quality of acting upon gold. The effect of this menstruum affords us one test for this metal; if we require another, we may have recourse to a fusion with antimony: for if pure gold and antimony be blended together, the antimony upon keeping up the fire to a great height will be driven off in fumes, and will leave the gold, if pure, unaltered in weight; whereas, if it contained any mixture of another metal, the antimony would have taken it away with it, not excepting even silver itself. See the articles *AQUA REGIA* and *ANTIMONY*.

If a quantity of salt of tartar, or any other fixed alkali, be thrown into a solution of gold, the metal is precipitated in form of a powder, which has an explosive power greater than that of gunpowder, or the pulvis fulminans of the chemists. This powder, from its property, is called aurum fulminans. See the article *AURUM*.

Gold is greatly the most divisible of all bodies. If melted with a hundred thousand times its weight of silver, it will perfectly and equally blend itself with that metal: any grain of the melted mass being cut off, will be found on assaying, to contain its due and proportionate quantity of the gold in it; and a single drop of a solution of gold in aqua regia, will communicate a metalline taste to a pint of spirit of wine, if mixed with it.

It is to be observed, that aqua regia, tho' the general and common solvent of gold, is not the only one. Hunkel long since discovered, that it might be dissolved by the fumes arising from a mixture of oil of tartar, and oil of vitriol; and a menstruum in the common liquid form, may be produced from these which will have the same power. Mercury also is a true solvent of this metal by amalgamation; and the hepar sulphuris, or liver of sulphur, on being fused with it, takes it up so perfectly, that it will be carried into a lac sulphuris, either in the solution or precipitation. See *AMALGAMATION*. The chemical character to express gold is a circle with a point in the center thus,  $\odot$ . They intend this as a symbol of perfection and simplicity; the circle

being the most uniform of all figures; and comprehending the greatest space under the smallest superficies. See the article *CHARACTER*.

Numberless have been the attempts to convert other metals into gold; but as nothing is so hard to communicate by art as gravity, they are hitherto, and are likely always to be without success. See the article *PHILOSOPHER'S STONE*.

The degradation of gold seems as highly difficult as the making it: some industrious people have gone so far towards this, as to bring gold to a state in which no reducing fluxes they were acquainted with, could restore it again: but this is no proof that others might not have been invented that would have done it. The vapour of phosphorus, indeed, in a manner calcines gold into a sort of unmalleable matter of the appearance of a calx; and the same thing may be done by a long and gentle calcination of gold, that has been amalgamated with mercury: but people are able to reduce gold in this state, produced by either means, into pure malleable gold again.

*Method of imitating GOLD.* Dr. Shaw thinks the following method of Mr. Homberg, for treating copper with quicksilver, preferable in imitating gold for the making watches, buckles, cane-heads, snuff-boxes, &c. to any other.

If an amalgam be boiled in river-water for two hours; and then the quicksilver be distilled off, and cohobated once; then the remaining copper, being now fused, will be of a beautiful gold colour, and more ductile than copper, so as to become well fitted for watch-work, gilding, and the finer machines and utensils. See the article *AMALGAM*.

For the methods of separating and refining GOLD, see the articles *ASSAYING*, *COPELLING*, *CEMENTATION*, *DEPART*, *REFINING*, *ORE*, and *WASHING*.

*GOLD, in medicine.* The virtues of gold in medicine, however highly extolled by some writers, seem altogether imaginary. The Greeks never paid much respect to it in this way. Geoffroy tells us, that they never used it in medicine at all; but he seems mistaken, for Dioscorides prescribes the filings of this metal to those who had swallowed mercury. It first got footing as a medicine among the Arabians, and we find them prescribing it to be beat into thin leaves as an ingredient in

in many of their compositions. They tell us, that it is a cordial, and that it has great virtues against palpitations of the heart, nervous complaints, and melancholy. The chemists go farther, and talk of aurum potable as an universal medicine: but there seems no great credit to be given to any thing that has been said upon this head; and the present practice allows its use as an ornament only to medicines, not as a medicine itself: the only preparation of it that has been received on the footing of a medicine by rational people, is the aurum fulminans, and that has been of late proved to be a very mischievous one. For this, and the other preparations of gold, see the article **AURUM**.

**GOLD-WIRE**, a cylindrical ingot of silver, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little, round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See the article **WIRE**.

It may be observed, that before the wire be reduced to this excessive fineness, it is drawn through above an hundred and forty different holes, and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

**GOLD-WIRE flattened**, is the former wire flattened between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is without spinning, in certain stuffs, laces, embroideries, &c. See the article **STUFF**, &c.

**GOLD-THREAD, or SPUN GOLD**, is a flattened gold, wrapped or laid over a thread of silk, by twisting it with a wheel and iron bobbins.

*Manner of forming GOLD-WIRE, and GOLD-THREAD, both round and flat.* First, an ingot of silver, of twenty-four pounds, is forged into a cylinder, of about an inch in diameter: then it is drawn thro' eight or ten holes, of a large, coarse wire-drawing iron, both to finish the roundness and to reduce it to about three-fourths of its former diameter. This done, they file it very carefully all over to take off any filth remaining on the forge; then they cut it in the middle; and thus make two equal ingots thereof, each about twenty-six inches long, which they draw through several new holes, to take off any inequalities the file may

have left, and to render it as smooth and equable as possible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking some gold leaves, each about four inches square, and weighing twelve grains, they join four, eight, twelve, or sixteen of these as the wire is intended to be more or less gilt; and when they are so joined, as only to form a single leaf, they rub the ingots reeking hot with a burnisher. These leaves being thus prepared, they apply over the whole surface of the ingot, to the number of six, over each other, burnishing or rubbing them well down with the blood-stone, to close and smoothe them. When gilt, the ingots are laid anew in a coal fire; and when raised to a certain degree of heat, they go over them a second time with the blood-stone, both to folder the gold more perfectly, and to finish the polishing. The gilding finished, it remains to draw the ingot into wire.

In order to this, they pass it through twenty holes of a moderate drawing iron, by which it is brought to the thickness of the tag of a lace: from this time the ingot loses its name, and commences gold wire. Twenty holes more of a lesser iron leaves it small enough for the least iron; the finest holes, of which last scarce exceeding the hair of the head, finish the work.

To dispose the wire to be spun on silk, they pass it between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two, is rendered quite flat, but without losing any thing of its gilding, and is rendered so exceedingly thin and flexible, that it is easily spun on silk thread, by means of a hand wheel, and so wound on a spool or bobin.

**GOLD-LEAF, or BEATEN GOLD**, is gold beaten with a hammer into exceeding thin leaves, so that it is computed, that an ounce may be beaten into sixteen hundred leaves, each three inches square, in which state it takes up more than 159052 times its former surface. See the article **DUCTILITY**.

This gold they beat on a block of black marble, about a foot square, and usually raised three feet high: they make use of three

three sorts of hammers, formed like mallets, of polished iron: the first, which weighs three or four pounds, serves to chafe, or drive: the second, of eleven or twelve pounds, to close; and the third, which weighs fourteen or fifteen pounds, to stretch and finish. They also make use of four moulds of different sizes, *viz.* two of vellum, the smallest whereof consists of forty or fifty leaves, and the larger of two hundred: the other two, consisting each of five hundred leaves, are made of bullocks guts well scoured, and prepared. See **MOULD**.

*Method of preparing and beating GOLD.*

They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them: after they have been hammered here a while with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould, out of which they are taken, divided into four, as before, and laid in the last, or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper books, prepared with a little red bole for the gold to stick to; each book ordinarily contains twenty-five gold leaves. There are two sizes of these books; twenty-five leaves of the smallest only weigh five or six grains, and the same number of the largest, nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold wire-drawers to gild their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. withal. See **GILDING**.

**GOLD-FINCH**, in ornithology, the english name of a species of fringilla, with the wings variegated with black, yellow, and white. See the article **FRINGILLA**. The common gold-finch is a very elegantly coloured bird, somewhat smaller than the common sparrow. But besides this, there are several other species, as the Greenland gold-finch, with a black

spotted head, about the size of the common linnet; and the greenish yellow gold-finch, nearly of the size represented in plate CXVIII. fig. 1.

This last is a most elegant bird; the fore-part of its head, and the upper part of the throat being covered with fine scarlet-coloured feathers, the top of the head ash-coloured, and the upper part of the body a yellowish green.

**GOLD-COIN**. See the article **COIN**.

*Washing of GOLD-ORE*. See the article **WASHING of Ore**.

**GOLD-SIZE**. See the article **SIZE**.

**GOLD-SMITH**, or as some choose to express it, *silver-smith*, an artist who makes vessels, utensils, and ornaments in gold and silver.

The goldsmith's work is either performed in the mould, or beat out with the hammer, or other engine. All works that have raised figures, are cast in a mould, and afterwards polished and finished: plates, or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beat, not cast. The business of the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted: but there are now invented flattening-mills, which reduce metals to the thinness that is required, at a very small expence. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy, to be able to assay mixed metals, and to mix the alloy.

The goldsmiths in London employ several hands under them for the various articles of their trade: such are the jeweller, the snuff-box, and toy-maker, the silver turner, the gilder, the burnisher, the chaser, the refiner, and the gold-beater. See the article **JEWELLER**, &c.

Goldsmiths are superior tradesmen: their wares must be assayed by the wardens of the company of this name in London, and marked: and gold is to be of a certain touch. No goldsmith may take above one shilling the ounce of gold, besides what he has for the fashioning, more than the buyer may be allowed for it at the king's exchange; and here any false metal shall be seized and forfeited to the king. The cities of York, Exeter, Bristol,

Bristol, &c. are places appointed for the assaying wrought-plate of goldsmiths; also a duty is granted on silver-plate of six-pence an ounce, &c. Plate made by goldsmiths, shall be of a particular fineness, on pain of forfeiting 10*l*. and if any parcel of plate sent to the assayers is discovered to be of a coarser alloy than the respective standards, it may be broke, and defaced; and the fees for assaying are particularly limited.

*Burnished GOLD*, that smoothed or polished with a burnisher. See the articles *BURNISHER*, and *BURNISHING*.

*Mosaic GOLD*, that applied in pannels, on proper ground, distributed into squares, lozenges, and other compartments, part whereof is shadowed to heighten, or raise the rest. See the article *MOSAIC*.

*Shell-GOLD*, that used by the illuminers, and wherewithal we write gold letters. It is made of the pareings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aqua fortis, they put it in shells, where it sticks. To use it they dilute it with gum-water, or soap-water.

*Pure GOLD*, that purged by fire of all its impurities, and all alloy. See *ALLOY*. The moderns frequently call it gold of twenty-four caracts, but in reality there is no such thing as gold so very pure, and there is always wanting at least a quarter of a caract. Gold of twenty-two caracts, has one part of silver, and another of copper; that of twenty-three caracts has half a part, *i. e.* half a twenty-fourth of each. See *CARACT*.

*Standard value of GOLD COIN*. See *COIN*.

*GOLD*, in heraldry, is one of the metals, more usually called by the french name *or*. See the articles *METAL* and *OR*.

*Laws relating to GOLD manufactures*. Gold and silver beaten, wrought in papers, for the printers, are prohibited to be imported by 1 Richard III. Gold and silver thread, lace, fringe, or other works made thereof, are prohibited to be imported by the 10th of Anne. Upon oath, that the goods were actually made after the first of July, 1712, of plate, wire-spun upon silk, and security given that they shall not be re-landed in Great-Britain, &c. the exporter of gold lace, thread, and fringe, is to have the following allowance, *viz.* gold-lace, thread, or fringe, the pound weight averdupois, 6*s.* 8*d.*

*GOLDEN*, something that has a relation to gold, or consists of gold, is valuable, or the like; as,

*GOLDEN-BULL*. See the article *BULL*.

*GOLDEN-CALF*, in jewish antiquity, a figure which the Israelites cast in gold, and set up in the wilderness to worship during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of; as in Exod. xxxii.

*GOLDEN-FLEECE*, in the antient mythology, the skin, or fleece, of the ram upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; which being sacrificed to Jupiter, its fleece was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monstrous dragon that never slept; but was at last taken and carried by Jason, and the Argonauts.

*Order of the GOLDEN-FLEECE*. See the article *FLEECE*.

*GOLDEN-NUMBER*, in chronology, a number shewing what year of the moon's cycle any given year is. See *CYCLE*. From what has been said under cycle of the moon, it appears that the golden number will not shew the true change of the moon for more than three hundred and twelve years, without being varied. It is to be observed, that the golden number is not so well adapted to the Gregorian as to the Julian calendar; the epact being more certain in the new style, to find which, the golden number is of use. See the article *EPACT*.

The rule for finding the golden number is already given under *CYCLE of the moon*, or *lunar CYCLE*, of which rule take this example for the year 1754

$$\begin{array}{r} \text{Add} \quad 1 \\ 19) 1755 (92 \\ \underline{171} \\ 45 \\ \underline{38} \\ 7 \text{ Golden N}^{\circ}. \end{array}$$

*GOLDEN-ROSE*. The pope annually consecrates a golden rose on the fourth Sunday in Lent, which is sent to princesses, or to some church, as a mark of his peculiar affection.

*GOLDEN-RULE*, in arithmetic, is also called the rule of three, and the rule of proportion. See *PROPORTION*, and *RULE OF THREE*.

*GOLDINGEN*, a city of Poland, in the dutchy of Courland, sixty miles west of

- of Mittau : east long. 22°, and north lat. 57°.
- GOLNAW**, a city of Brandenburg-Pomerania, fifteen miles north-east of Stetin : east long. 15°, north lat. 53° 40'.
- GOLPS**, in heraldry, are roundles of a purple tincture, called by the French *torceaux*, adding their peculiar colours.
- GOLTBERG-EARTH**, *goltbergenfis terra*, a species of bole. See **BOLE**.
- GOMATUS**, in ichthyology, the same with the gurnard. See **GURNARD**.
- GOMBRON**, the greatest sea-port town in Persia, situated on the strait at the entrance of the gulph of Persia, opposite to the island of Ormus : east long. 55° 30', north lat. 27° 30'.
- GOMERA**, one of the Canary-Islands, subject to Spain, and situated west of Teneriff : west long. 18°, north lat. 28°.
- GOMORRO-ISLANDS**, situated between 10° and 13° south lat. on the eastern coast of Africa.
- GOMPHOSIS**, *γομφωσις*, in anatomy, a species of articulation, wherein one bone is set in the other, like a nail or peg ; as the teeth within the jaws. See the article **ARTICULATION**.
- GOMPHRENA**, the **PURPLE EVERLASTING FLOWER**, in botany, a genus of the *pentandria-digynia* class of plants, the flower of which is divided into five parts, and erect : the petals are subulated and permanent : the fruit is a thin, roundish crust, with one cell, in which are contained a single, large, roundish seed, with an oblique end. It is a native of both East and West-Indies ; and the flower is usually of a beautiful purple colour.
- GONAGRA**, among physicians, signifies the gout in the knee. See **GOUT**.
- GONARCHA**, in antiquity, a dial delineated on several surfaces, or planes, some horizontal, others erect, oblique, &c. See the article **DIAL**.
- GONDOLA**, in naval architecture, a flat kind of boat, very long and narrow, chiefly used on the canals at Venice.
- GONDOLA-SHELL**, in natural history, a species of *dolium*, with an extremely wide mouth. See **DOLIUM**.
- GONFANON**, or **GONFALON**, a kind of banner, carried in the processions of the principal churches at Rome.
- GONGER**, in ichthyology, the same with conger. See the article **CONGER**.
- GONGOLARA**, in botany, the same with the *arica marina*, or sea-heath. See the article **FUCUS**.

**GONORRHOEA**, in medicine, an involuntary efflux of the seminal juices, and some other recrementitious matter. Authors take notice of three species of gonorrhoeas ; the first is a simple gonorrhoea, or perpetual efflux of the seminal juices, without any virulence : the second is a venereal, or virulent gonorrhoea, so called, though improperly, from its similitude to the preceding : the third is an involuntary efflux of a viscid white, or whitish fluid from the urethra, in consequence of a venereal gonorrhoea ill cured, or too frequently repeated. The first species of this disorder arises from a want of a due tone in the solid parts, and by a preternatural relaxation of the vessels containing the seed, and of the parts adjacent to them. See **GLEET**. This gonorrhoea is either mild or benign, or of a malignant kind. The latter consists in a discharge of matter of various colours, accompanied with heat and exulceration ; and in scorbutic, or cacochymic patients, as also those afflicted with the stone, this disorder is generally attended with a pain in discharging the urine, which in such patients is of an acrimonious quality : but in a gonorrhoea of a mild or a benign kind, a whitish liquor all of one colour, is discharged without pain, heat, or exulceration ; and frequently proceeds from a redundancy of the seminal fluid, arising from high living in an unmarried state, or its acrimony in cacochymic, scorbutic, or arthritic patients, as well as from the weakness of, and want of due tone in the femal vessels. The cure of a benign gonorrhoea is highly difficult ; nor can any other reason be assigned for this disorder, than that there is a preternatural efflux of impure humours from all parts of the body to those parts infected, which are already too much weakened, and have their tone destroyed. Besides, the parts subservient to generation, which are in this disorder affected, consist entirely of nerves and nervous coats ; and it is not without the greatest difficulty that the energy of medicines penetrates to them. In the cure, the following intentions are to be pursued. First, the redundancy of impure serum, if there are any such in the body, is, by means of proper laxatives, to be evacuated and derived from the parts affected. Then the too much relaxed and flaccid parts are to be strengthened by proper corroborating medicines, both of the external

ternal and internal kind. The former of these intentions is answered by such laxatives as operate in a double manner, such as the pilulæ balsamicæ of Becher, which are not only purgative, but highly corroborating. To answer the other intention, the following powder must be used. Take of cuttle-bone, one ounce; of red coral, amber, the species of hyacinth, and the bark of cascarilla, each two drams; make into a powder, one dram of which is to be taken every morning and evening in a decoction of barley, prepared with some almonds. At the same time the following epithem may be applied to the region of the pubes and perinæum, especially during the nighttime. Take of herbs, baum, mint, and basil; of the leaves of red roses, and balaustins, each one handful; of pomgranate-bark, cloves, nutmegs, cardamoms, and mastich, each half an ounce: mix together, and put into a small bag to be boiled in red French wine. These measures are to be seconded by an accurate regimen, being chiefly such as is prescribed below for the virulent gonorrhœa. In the cure of a malignant gonorrhœa, regard is to be had to the constitution of the patient: when he is hot, and of a delicate constitution, he ought, especially in the beginning of the distemper, to abstain from hot substances, purgatives, sudorifics, diuretics, &c. The following preparation may be frequently exhibited in this disorder. Take of mint, three handfuls; of venice turpentine, one ounce; of peruvian balsam, half an ounce: distil with three pints of rhenish wine. The dose is from one to two ounces: and the following may be used as a succedaneum. Take of rose-water, and rectified spirit of wine, each half a pint; and of the balsam of life, fifty drops. Mix all together.

A virulent gonorrhœa, or clap, being the second species of this disorder, proceeds from impure coition with an infected person.

This distemper begins, and makes its progress, in the following manner.

The patient, sooner or later, according as the person with whom he has had conversation, was more or less infected, and according to his constitution, by which he may be more or less disposed to receive the infection, is first seized with an unusual pain in the genitals; and a kind of sensation like a rotation of

his testicles. Afterwards, if the prepuce constantly covers his glands, there appears an eruption, or pustule, which, by its size, colour and figure, resembles a spot of the measles. Presently after appears a weeping matter like semen, which daily changes colour, and becomes more purulent, and more yellow, till, at length, if the disorder be highly virulent, it assumes a greenish hue, or appears like a thin sanious matter, mixt with blood. The pustule at length becomes an ulcer, called a shanker. See SHANKER.

Those whose glans is uncovered, seldom have such a pustule, and are less liable to imbibe the infection. The running brings on a heat, or smarting in making water, which is most violent, when it is over, for then it seems to burn the whole duct of the urethra.

Another symptom is the corde, or contraction of the frænum, by which the penis is bent downwards. There is likewise, when the penis is erected, great pain, as if compressed transversely with a strong hand. This chiefly happens in the night, when the patient is warm in bed: sometimes the urethra being eaten, and excoriated with long running: of acrimonious pus, nature breeds a soft spongy flesh, to supply the defect, which daily increasing, forms caruncles, or carnosities so far as to plug up the urinary passage, and stop up the urine. However, the little adjoining ulcers continue to pour forth a kind of an ichor. It also happens, through some violent motion, or the ill timed use of astringents, that the sanies, which should be carried off by the gonorrhœa, is translated to the scrotum, and causes one or both of the testicles to swell, and inflame with intolerable pain: the running at the same time decreasing, while the scalding of the urine is as great as ever.

To these symptoms may be added the phimosis, and the paraphimosis. There are also sometimes watery bladders, called crystallines, and at length buboes of the glands in the groin. See PHIMOSIS, PARAPHIMOSIS, BUBO, and POX.

Women are not so subject to such a variety of symptoms as men: their chief complaint being a difficulty of urine, and a running; however, they are liable to shankers and venereal warts, as well within as on the outward parts of the labia pudendi; as also to buboes in the groin: as for the coarctation of the

sphincter vaginae, purring as it were the external orifice, this is not a phimosis, though by some improperly so called.

This disorder proceeding from an infection of a malignant gonorrhoea, or the lues venerea, is first conveyed to the genitals, and afterwards thro' the pores to the lymph, or feminal liquor; the due crasis and natural mixture of which it destroys, by inducing partly a caustic and corroding, and partly a putrid state thereof: hence arise the pains, the heats, the tumours, the inflammations, and the exulcerations of the genitals. For at first the glans only is infected whilst in coition, the poison insinuating itself into the pores; after which, it soon proceeds to the glands of the urethra, then to the prostate, and afterwards to the vesiculæ seminales. The regimen, during the time of the cure, according to Boerhaave, requires the patient to abstain from all oily food; and he must also avoid every thing, which by its acrimonious quality stimulates to venery; such as spices, bulbous roots, flesh, eggs, fish, and fermented liquors: for as the inflation of the penis retards the cure, it is of the utmost consequence to be avoided; as are also every thing else that inflames the fancy, or provokes to venery, as amorous dalliance with women, &c. Water and whey are the best drinks; and seeds and summer fruits the best aliment. All possible care must be taken that cold never reach the penis, and that it be kept always moist, lest the pores contracting repel the flux of matter. An emollient and somewhat antiseptic cataplasm will be beneficial. In the cure, Sydenham's method of purging the patient till the symptoms were abated is now justly laid aside. Turner's last method, which he made use of himself, is as follows: Take two drachms of quicksilver; one drachm of gum guaiacum; and beat them, together with a little spirit of lemon, till the globules of the mercury disappear: afterwards add half a drachm of the pills of colocynth with aloes: beat it into a mass; of which make up twenty-four pills. Two of these pills containing half a scruple of the mercury, may be taken night and morning; or according to the operation; one only for a week or ten days, unless the patient complains of his gums, or a sore mouth: for then the mercury must be left out.

If the cordee does not remit, a scruple of sal prunella may be taken, with as much fine sugar between whites, in a draught of the following apozem: Take of mercurial water two pounds; of the solution of gum arabic, and syrup of marshmallows, of each one ounce; make it into an apozem, or decoction. The mercurial water is common river-water, in two quarts of which four ounces of quicksilver have been boiled to a quart. The patient may drink of the apozem through the whole course.

And now, as there is occasion, the pills are continued for a week, or ten days more, but at night only; and in the morning is given the quantity of a nutmeg of the following electuary: Take virgin-honey, an ounce and a half; balsam of capivi, six drachms; powder of the root of jalap, and sal prunella, of each one drachm, which make into an electuary. The patient must drink a draught of the apozem as well after the electuary as after the pill. See the article ELECTUARY.

There is no danger of the running being stopt while his body is kept open by these means; but when the quantity grows less, and the colour whiter, and feels more tenacious, the pill is laid aside, and the electuary kept to some days longer, night and morning. If it purges too much, the jalap is left out, and the rhubarb substituted instead thereof. When it proves tedious, boiled turpentine is given by way of farther agglutinating, and drying the gleet. See the article GLEET.

When the cordee and dysury are very stubborn, or the running more virulent than ordinary, the genitals are to be smeared every night quite up to the groin, with the weaker blue ointment, and the pill without the quicksilver is given early in the morning in a large dose, or a draught of the infusion of senna. This method will succeed in three weeks, or a month's time, if the patient is governable.

In the place of mercurials given internally, Astruc directs the use of crude quicksilver, as in the common unction to be rubbed upon the parts, as about the body of the penis, especially under the urethra, to the perinaeum, and so on to the pubes and testicles, by which the mercury, insinuating itself through the pores into the lymphatic vessels,

instantly

instantly conveyed into the glandules and subdues the poison lodged therein, taking away all the symptoms without any disturbance to the *primæ viæ*, the stomach and guts.

If there is no discharge from the penis of any virulent matter, it is called the gonorrhœa sicca, or dry clap; the symptoms of which are a dysury, or difficulty of making water, and after, from the increase of the inflammation and tumefaction, an ischury, or total suppression of urine. See the articles DYSURY, and ISCHURY.

In the cure of the dry clap, Astruc advises plentiful bleeding in the beginning, to take off the tension, and to abate the inflammation; as also emollient decoctions of mallows, linseed, &c. in milk, to foment the parts: but perhaps it might be better to make a pulice of these ingredients, after Boerhaave's method, to lay to the parts affected; or, which is best of all, to use them one after the other.

Astruc advises also lenient clysters, cooling emulsions, and pilsans, with sal prunella and anodynes, between whiles. During the continuance of the inflammation, no mercurials must be used, and if the symptoms increase, threatening an abscess in the perinæum, it is to be forwarded as much as possible, by suppurative pulices, and the matter discharged.

The symptoms of this disease being all separately treated of under their several heads, for the cure and method of treating each, see the articles TUMOUR, BUBO, CARUNCLE, GLEET, SHANKER, PHIMOSIS, PARAPHIMOSIS, CRYSTALLINE, PORRI, CONDYLOMATA, CRISTÆ, &c.

When the gonorrhœa has continued a long while, or long enough for the poisonous matter to make its way into the blood; or by astringents given unseasonably it cannot make its exit; then the patient is infected with the pox. See the article POX.

The third species of this disorder requires the very same treatment with the simple and virulent: but here the least time must not be lost; the affected part must be kept in a constant state of laxity, by the most emollient applications; and the contagious matter must with all possible expedition be drawn out: for the whole cure depends upon the total discharge of the infectious matter, together with the pus, which it has introduced; and if this task is not performed,

a pox is greatly to be apprehended. Wherefore, if this disease continues but for a little time, recourse must be had to all the severities of a salivation. For though salivating does not at all cure either of the two former kinds of gonorrhœa, this species of the disease, having its seat in the glandulæ cowperianæ of the urethra, so that the pus discharges itself by their excretory duct into the urinary duct, is much more susceptible of the power of mercury.

GONALGIA, a term of much the same import with gonagra. See GONAGRA.

GOOD, in general, whatever is apt to cause or increase pleasure, or diminish pain in us; or, which amounts to the same, whatever is able to procure, or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

By pleasure and pain, says Mr. Locke, I would be understood to mean of body or mind, as they are commonly distinguished; though, in truth, they are only different constitutions of the mind, sometimes occasioned by a disorder in the body, and sometimes by thoughts of the mind. Pleasure and pain, and their causes good and evil, are the hinges upon which our passions turn; so that by reflecting on the various modifications or tempers of mind, and the intestine sensations which pleasure and pain, good and evil, produce in us, we may thence form to ourselves the ideas of our passions. See PASSION, HAPPINESS, &c.

Metaphysical GOOD, the same with perfection. See PERFECTION.

Moral GOOD, denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations.

The same principle, or law of our natures, which determines us to pursue any one end, or species of good, prompts us to pursue every other end, or species of good of which we are susceptible, or to which our Maker has given us an original propension. But amidst the great multiplicity of ends or goods, which form the various ingredients of our happiness, we perceive an evident gradation, or subordination; and in the accommodation of our actions thereto, consists their moral goodness. Thus, the goods of the body, or of the external senses, seem to hold the lowest rank in this gradation or scale of goods. These we have in common with brutes; and

when, at any time, they come in competition with goods of a higher order, the unanimous verdict of mankind gives the preference to these last. Next to sensual goods come those arising from social connections, as fame, fortune, power, civil authority, and the like, which are chiefly valuable, as being the means of procuring natural or moral good, but principally the latter. Goods of the understanding are still superior, as taste, knowledge, memory, judgment, &c. And the highest are the moral goods of the mind, directly and ultimately regarding ourselves, as command of the appetites and passions, prudence, fortitude, benevolence, &c. These are the principal ingredients of our happiness.

Moral good is of so singular and sublime a nature, that when the mind is in pursuit of it, though it should prove unsuccessful in its aims, it can rest in the conduct without repining, or being dejected at the ill success: nay, the pleasure attending the consciousness of upright aims, and generous efforts, absorbs the disappointment, and makes inferior ends disappear, as of no amount in the great aggregate or surplussage that remains. See the article HAPPINESS.

**GOOD BEARING**, in law, denotes much the same with good behaviour.

**GOOD BEHAVIOUR**, in law, an exact carriage and behaviour to the king and his people.

A justice of peace may, at the request of another, or where he himself sees cause, demand surety for the good behaviour; and to that end the justice may issue out his warrant against any persons whatsoever, under the degree of nobility; but when it is a nobleman, complaint is to be made in the court of chancery, or king's bench, where such nobleman may be bound to keep the peace. Infants and feme-coverts, who ought to find surety by their friends, may be bound over to their good behaviour; as also lunatics, that have sometimes lucid intervals, and all others who break the peace, or being suspected to do it, by affrays, assaults, battery, wounding, fighting, quarrelling, threatening, &c. A person may be likewise bound to his good behaviour for a scandalous way of living, keeping bawdy-houses, gaming-houses, &c. and so may common drunkards, whoremongers, common whores, cheats, libellers, &c. He who demands

surety for the peace, on any violence offered, must take an oath before the justice, that he goes in fear of his life, or some bodily harm, &c. and that it is not out of malice, but from a regard to his own safety.

**GOODS, bona**, in law, the same with chattels. See the article CHATTELS.

**GOODS**, among distillers, a term for spirits of any kind. See the article SPIRITS.

*Alloting of GOODS.* See ALLOTING.

*Consignment of GOODS.* See the article CONSIGNMENT.

*Running, &c. of GOODS.* See RUNNING, &c.

**GOOD-HOPE**, or *Cape of GOOD HOPE*, the most southern promontory of Africa, where the Dutch have built a good town and fort: east long. 16° and south lat. 34° 15'.

**GOOLE**, in law-books, signifies a breach in a sea bank, or wall.

**GOOSE**, *anser*, in ornithology, a well-known bird of the anas-kind, with the back of a greyish brown colour, the belly and edges of the wing-feathers white.

Geese are fowls of great profit, both for food, for their feathers, and for their grease. For the gathering of their feathers, some authors advise their being pulled twice a year, *viz.* in March and August; yet this is certainly an unprofitable as well as a cruel practice; for the goose on being incapable of flight, easily falls a prey to the fox, and other ravenous creatures, and by uncloathing her, you occasion her getting cold, which suddenly kills her. 'Tis therefore, most adviseable to stay till moulting time, or till you kill her, and then all her feathers may be made use of at pleasure.

**GOOSE-BERRY**, *grossularia*, or *ribes*, in botany. See the article RIBES.

The best way of raising these useful bushes is by cuttings, observing always to take the handsofshoots, and that from branches that bear most fruit. These are to be planted in February. See the article CUTTINGS.

There are a great many sorts of gooseberry, among which the white holland kind is the fairest, and best bearer of all others; the berries being large, transparent, and well tasted. The english yellow gooseberry is known every where, and fittest for culinary uses while green. The hedge-hog gooseberry is large, well-tasted, and extremely hairy. There is also a sort of green gooseberry, that is a very pleasant fruit,

Goose-

**Goose-berries** taken in season, produce a delicious wine, very proper for summer repasts. Also, if thoroughly pressed, with an addition of water, and well fermented, they yield in distillation the best brandy of any of our fruits, and little inferior to french brandy.

**GOOSE-DUNG**, in agriculture. See the article **DUNG**.

**GOOSE-NECK**, in a ship, a piece of iron fixed on the end of the tiller, to which the laniard of the whip-staff, or the wheel rope comes, for steering the ship.

**GOOSE-WING**, in the sea-language. When a ship sails before, or with, a quarter-wind on a fresh gale, to make the more haste, they launch out a boom, and sail on the lee-side; and a sail so fitted, is called a goose-wing.

**GOR**, the capital of a province of the same name, in the East-Indies, subject to the Mogul: east long.  $85^{\circ}$ , north lat.  $31^{\circ} 15'$ .

**GORCE**, in law-books, denotes a kind of wear. See the article **WEAR**.

**GOR-COCK**, a bird, otherwise called a moor-cock. See **MOOR-COCK**.

**GORCUM**, a city of the United Provinces, situated in that of Holland, on the river Waal, twenty-two miles east of Rotterdam: east long.  $4^{\circ} 50'$ , north lat.  $51^{\circ} 50'$ .

**GORDIAN KNOT**, in antiquity, a knot made in the leathers or harness of the chariot of Gordius, king of Phrygia, so very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he who untied this knot, should be master of Asia. Alexander having undertaken it, was unable to accomplish it, when fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished, or eluded the oracle.

**GORE**, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point. See plate **CXI**. fig. 4.

**GORE**, in law, signifies a narrow slip of ground.

**GOREING**, in the sea-language, sloping. A sail is cut goreing, when it is cut sloping by degrees, and is broader at the

clew than at the earing, as all topmasts and top-gallant sails are.

**GOREL**, the title of the prince of Georgia, in Asia. See **GEORGIA**.

**GORGE**, *gula*, in architecture, the narrowest part of the tuscan and doric capitals, lying between the astragal, above the shaft of the pillar and the annulets. See **TUSCAN** and **DORIC**.

It is also used for a concave moulding, larger, but not so deep as a scotia, which serves for compartments, &c. See the article **COMPARTMENT**.

**GORGE**, in fortification, the entrance of the platform of any work.

In all the out-works, the gorge is the interval betwixt the wings on the side of the great ditch, as the gorge of a ravelin, half-moon, &c. These, it is to be observed, are all destitute of parapets; because, if there were any, the besiegers, having taken possession of the work, might use it to defend themselves from the shot of the place; which is the reason, that they are only fortified with palisades, to prevent a surprize.

The gorge of a bastion is nothing else but the prolongation of the curtains from their angle with the flanks, to the center of the bastion where they meet. When the bastion is flat, the gorge is a right line, which terminates the distance between the two flanks. See the articles **BASTION** and **FORTIFICATION**.

**GORGED**, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is also used when the gorge, or neck of a peacock, swan, or the like bird, is of a different colour or metal, from the rest.

**GORGED**, among farriers, &c. signifies the same as swelled; in which sense they say, the legs of a horse are gorged; the paster joint is gorged; you must walk him out to disgorge his shoulder.

**GORGERIN**, in architecture, the same with gorge. See the article **GORGE**.

**GORGONA**, the name of two islands, one in the pacific ocean on the coast of Peru: west long.  $79^{\circ}$ , north lat.  $3^{\circ}$ ; the other in the Mediterranean, twenty-five miles west of Leghorn.

**GORGONIUM**, in botany, a name sometimes given to eryngium. See the article **ERYNGIUM**.

**GORGONS**, in antiquity, a warlike female nation of Lybia, in Africa, who had

had frequent quarrels with another nation of the same sex, called Amazons.

**GORITIA**, or **GORITZ**, a town of Carniola, in Austria, near the confines of the territories of Venice: east long.  $14^{\circ}$ , north lat.  $46^{\circ} 20'$ .

**GORLITZ**, a city of Upper Saxony, in Germany, fifty miles east of Dresden: east long.  $15^{\circ} 6'$ , north lat.  $51^{\circ} 12'$ .

**GOSHAWK**, the english name of the yellow-legged falcon, with a brown back, and a white variegated breast. See the article **FALCON**.

It is a large and very beautiful bird, which preys upon the pheasant, mallard, wild goose, hare, and coney, and will even venture to seize on a kid or goat. She ought to be kept with great care, as being very choice and dainty.

**GOSLAR**, an imperial city of Lower Saxony, in Germany, thirty miles south of Brunswick: east long.  $10^{\circ} 30'$ , north lat.  $52^{\circ}$ .

**GOSPEL**, the history of the life, actions, death, resurrection, ascension and doctrine of Jesus Christ.

The word is saxon, and of the same import with the latin term *evangelium*, or the greek *εὐαγγέλιον*, which signifies glad tidings, or good news; the history of our blessed saviour being the best news ever published to mankind.

This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John; who from thence are called evangelists. The christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

The antient fathers endeavoured to find out divers mysteries in there being but four genuine canonical gospels. St. Jerom, in particular, says, that as there are four parts of the world, and four principal winds, it was also proper there should be four gospels in the church, as four columns to support it, and four breathings of life to render it immortal. They thought they found the figure of the four evangelists in the beginning of the prophecy of Ezekiel, and in the ninth chapter of the Revelations, where mention is made of four living creatures, the first having the face of a man; the second of a lion; the third of an ox; and the fourth of an eagle; and for this

reason the evangelists are usually painted with these symbols.

**GOSSYPIMUM**, **COTTON**, in botany, a genus of the *monadelphia-polyandria* class of plants, the flower of which consists of five plane and patent petals, growing together at their bases, and vertically cordated: the fruit is a roundish capsule, containing four cells, with a great number of oval seeds, surrounded with a fine downy matter. See **COTTON**.

**GOSTAVIN**, or **GOSTIVIN**, a town of great Poland: east long.  $20^{\circ}$ , north lat.  $52^{\circ} 45'$ .

**GOTHA**, the capital of the dutchy of Saxe-Gotha, in Upper Saxony; east long.  $10^{\circ} 36'$ , north lat.  $51^{\circ}$ .

It is subject to the duke of Saxe-Gotha, brother of her royal highness the princess dowager of Wales.

**GOTHIC**, in general, whatever has any relation to the Goths: thus, we say gothic customs, gothic architecture, &c. See the article **ARCHITECTURE**.

Gothic architecture is far removed from the manner and proportions of the antique; having its ornaments wild and chimerical, and its profiles incorrect. However, it is frequently found very strong, and appears very rich and pompous, as may be seen in several of our english cathedrals. This manner of building was, originally, very heavy and coarse; but is since run into the opposite extreme, being slender, rich, and delicate to a fault. In the gothic architecture, we see high vaults raised on slender pillars; and every thing crowded with windows, roses, crosses, figures, &c.

**GOTHIC CHARACTER**, or **LETTER**. See the article **LETTER**.

**GOTHIC COLUMN**. See **COLUMN**.

**GOTHLAND**, the most southern province of Sweden, being a peninsula surrounded on three sides by the Baltic Sea. It is subdivided into east and west Gothland, Smaland, Halland, Bleken and Schonen.

**GOTHLAND**, is also an island of the Baltic, situated between the province of Gothland and Livonia.

**GOTTENBURG**, a port-town of Sweden, situated without the Sound, on the coast of the Schaggerack Sea, near the entrance of the Baltic.

**GOTTINGEN**, a city of Germany, in the circle of Lower Saxony, and dukedom of Brunswick: east long.  $9^{\circ} 45'$ , north lat.  $51^{\circ} 32'$ .

**GOTTORP**,

**GOTTORP**, a city of the dukedom of Sleswic, in Denmark, and capital of the territories of the duke of Holstein-Gottorp : east long.  $10^{\circ}$ , north lat  $54^{\circ} 40'$ .

**GOUDE**, a city of the united Netherlands, in the province of Holland, ten miles north-east of Rotterdam.

**GOUDHURST**, a market-town of Kent, nine miles south-west of Maidstone.

**GOVERNMENT**, in general, is the polity of a state, or an orderly power constituted for the public good.

Civil government was instituted for the preservation and advancement of men's civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some sort of civil authority : but as men are seldom unanimous in the means of attaining their ends, so their difference in opinion in relation to government, has produced a variety of forms of it. To enumerate them, would be to recapitulate the history of the whole earth. But they may, in general, be reduced to one of these heads : either the civil authority is delegated to one or more, or else it is still reserved to the whole body of the people ; whence arises the known distinction of government into monarchy, aristocracy, and democracy. See the articles **ARISTOCRACY**, **DEMOCRACY**, &c.

Mr. Hooker thinks, that the first government was arbitrary, and administered by a single person ; till it was found by experience, that to live by one man's will, was the cause of all men's misery : and this, he concludes, was the original of inventing laws. The Roman, and most of the grecian states, were built upon the republican plan ; but when the Goths, and other northern nations, destroyed the roman empire, and extended their conquests into far distant countries, they established, wherever they came, a mixed form of government. The preservation of this constitution depending upon the ballance between the king, nobility, and people, the legislative power was lodged in these three states, called by different names in different countries ; in the north, diets ; in Spain, cortes ; in France, estates ; and in Britain, parliaments. The excellency of this mixed government, consists in that due poize or ballance between rule and subjection, so justly observed in it, that by the necessary concurrence of the nobility and com-

mons, in the making and repealing all laws, it has the main advantage of an aristocracy, and a democracy, and yet is free from the disadvantages and evils of either of them. This mixed form of government is, however, now driven almost out of Europe, in some parts of which we can hardly find the shadow of liberty left, and in many, there is no more than the name of it remaining. France, Spain, Portugal, Denmark, and part of Germany, were all, an age or two ago, limited monarchies, governed by princes, well advised by parliaments or cortes, and not by the absolute will of one man. But now all their valuable rights and liberties are swallowed up by the arbitrary power of their princes : whilst we in Great Britain have still happily preserved this noble and antient gothic constitution, which all our neighbours once enjoyed. There is such a due ballance of property, power and dominion in our constitution, that, like the antient government of Sparta, it may be called an empire of laws, and not of men ; being the most excellent plan of limited monarchy in the world.

Governments are commonly divided into two classes, arbitrary and free governments ; but there are many different sorts of each. Thus the governments of France and Spain are generally called arbitrary ; tho' they differ as much from the governments of Turkey and other eastern empires, where absolute despotism prevails, as they do from the government of England, and other european nations, where liberty is said to flourish in its fullest perfection.

**GOVERNMENT** is also a post or office which gives a person the power or right to govern or rule over a place, a city, or province, either supremely or by deputation.

**GOVERNMENT** is also used for the city, country, or place to which the power of governing is extended. In France there are thirty-eight governments of provinces independent of each other ; and besides these there are twelve grand governments, which are those of the isle of France, Burgundy, Normandy, Guienne, Brittany, Champaign, Languedoc, Picardy, Dauphiny, Provence, Lyonois, and Orleanois : but these last are only so many classes of governors or governments, contrived for the better and easier regulating the seats, &c. of the many governors, bailiffs, provosts, &c. who are obliged to assist at the general estates.

GOVERN-

**GOVERNMENT**, in grammar, a part of construction usually called regimen. See **CONSTRUCTION** and **REGIMEN**.

**GOVERNOLO**, a town of Italy, ten miles south-east of Mantua.

**GOUGE**, an instrument or tool used by divers artificers; being a sort of round hollow chissel, for cutting holes, channels, grooves, &c. either in wood or stone. See the article **JOINERY**.

**GOURD**, *cucurbita*, in botany. See the article **CUCURBITA**.

Gourd-seeds are of the number of the four greater cold seeds. They are esteemed cooling and diuretic, and are used in emulsions, and some compositions of the shops. They are good in fevers, and in all disorders arising from an acrimony of the blood or humours. Emulsions of these, and the other cold seeds, are anodyne, and are generally used to take off stranguries occasioned by blisters.

We have our gourd-seeds from Holland. They should be chosen large and plump, fresh, and full of pulp, and of a good taste.

**Bitter GOURD**, a name given to the colocynthis. See the article **COLOCYNTHIS**.

**Indian GOURD**, the same with the crescentia of botanists. See **CRESCENTIA**.

**GOURDY LEGS**, in horses, the disorder otherwise called grease. See **GREASE**.

**GOUST**, or **GOUT**, signifies taste or skill in poetry, painting, &c.

**GOUT**, *arthritis*, in medicine, as defined by Boerhaave, a very painful disease, whose seat is in the joints and ligaments of the feet, and whose principal times of invasion are the spring and autumn.

This disease, according to the forementioned author, seldom invades any patient till he is upwards of thirty; and men are more subject to it than women; as also all persons of acute parts that follow their studies too close, especially in the night-time, with an intense application of mind. Likewise those who live high, and indulge their appetites; drinking plentifully of rich generous wines; or who use acids too freely, or white eager wines; or who have been addicted too early to venereal pleasures; or whose bodies are large, gross, and full. Those are liable to it whose sweaty feet are too suddenly chilled; or who suffer their feet to sweat in wet shoes and stockings. Hence hunting and riding in the cold are pernicious. It may likewise be received by contagion, and is hereditary, descending from father to son.

In treating of this disease we shall, from the authority of Sydenham, first give an account of what that writer calls the regular gout, and afterwards of what he calls the irregular: by the latter is meant a gout which, by the preposterous use of improper medicines, has been turned out of its natural course; or, by reason of the patient's weakness, cannot attain to its proper and genuine symptoms.

The regular gout makes its onset in the following manner. It usually seizes the patient in the latter end of January, or beginning of February, all of a sudden, without any previous notice, unless the patient has been troubled with crudities of the stomach, and indigestion for some weeks before: the body likewise, in many, seems to have been puffed up with wind, with a kind of heaviness, which daily increases, till at length the fit comes thundering on; a few days before which there is a torpor, and, as it were, a descent of wind down the muscles of the thigh, with a kind of spasmodic affection of them. Likewise the day before the fit, the appetite is more voracious, but not natural.

Though the patient seems to go to bed in good health, yet commonly about two in the morning, he is alarmed by a pain which most frequently affects the great toe, sometimes the heel, the ankle, or the calf of the leg, which pain resembles that of dislocated bones: there is likewise a sensation, as if water, almost cold, was poured on the membranes of the part affected. Soon after a shivering and shaking supervene, with a feverish disorder. The pain, which at first was tolerable, becomes more violent, as the shaking decreases, and grows more intense every hour till night; and then it is at the height, settling itself about the little bones of the tarsus and metatarsus, whose ligaments it affects. Now there seems to be a violent extension of the ligaments; or there is a sensation of their being lacerated: sometimes they seem to be pressed or squeezed together. At this time the parts affected become so exceeding sensible, that they cannot bear the weight of the sheet, nor the shaking of the room by a person walking about, unless he threads very softly. This always happens at the accession of the fit. About twenty-four hours after this, the patient perceives the part to be swelled, and the pain much abated.

The next day, or perhaps two or three days

days afterwards, if the gouty matter is copious, the part affected is a little in pain. In a few days, the other foot begins to be affected in the same manner; and if the pain has ceased in the first, the weakness which it left behind soon vanishes: the same tragedy is now acted over again. Sometimes when the gouty matter is in great plenty, it attacks both feet at once, but it generally seizes one after the other.

After both feet have been tormented, the fits which follow are out of rule, both as to the time of invasion and the duration; only the pain grows more intense at night, and remits in the morning. From a series of those small fits arises what is called a fit of the gout, which is longer or shorter, according to the patient's age. This happens to the more vigorous, and whom the gout seldom visits, in fourteen days; to persons advanced in years, who have often felt its rage, two months: but those who are debilitated with age, or the long stay of the disease, it does not leave till summer; which being pretty far advanced, drives it away.

When the fit goes off, there is an intolerable itching in the affected foot, chiefly between the toes, from which, and from the feet, fall branny scales, as if the patient had swallowed poison: the disease thus terminated, the patient's good habit of body and appetite return in proportion to the severity of the pain in the last fit, and in the same proportion the next fit will be either accelerated or retarded: for if the last was very severe, the next will not come on in less time than a solar revolution.

Such is the regular gout and its genuine symptoms: but when it is disturbed by incongruous medicines, and the patient is worn out by the long continuance of the disease, it becomes irregular, and the substance of the body is as it were changed into a fomes of the disease, and nature becomes unequal to the task of conquering the disease thus changed in the accustomed manner.

The feet were at first the seat of the disease, but now it attacks the hands, wrists, elbows, knees, and other parts of the body: sometimes it so distorts the fingers, as to make them resemble a bunch of parsnips; and at length stoney concretions appear about the ligaments of the joints, which breaking through the skin, resemble chalk, or crab's eyes.

Sometimes the gouty matter invades the elbows, and creates a whitish swelling of the size of an egg, which soon assumes a red colour, and becomes inflamed: sometimes it affects the thigh in such a manner, as if a great weight was hung thereon; and yet without any remarkable pain: from thence it descends to the knee, which it attacks more roughly, hindering all motion.

Now the gout afflicts the patient all the year, except for two or three months in summer; and the particular fit which did not last above a day or two, continues ten or fifteen days: the patient is disturbed with sickness as well as pain; his limbs begin to be contracted and unfit for motion; and if he attempts any exercise beyond his strength, the fomes of the disease will attack the viscera in a more dangerous manner.

The curative intention, according to Wrintringham, requires, first, that the primæ viæ be set free from a load of indigested crudities, and the viscera be restored to their pristine vigour; secondly, that the fluid stagnating in, and stuffing up the smaller vessels, may be expelled the body, and a free passage through the contracted vessels be restored.

The first intention may be answered by vomits and gentle cathartics repeated as occasion requires; by bitters, aromatics, antiscorbutic medicines; by alkaline fixed salts, taken in small quantities for a long time; by aliments and drinks that are nourishing, light, easy of digestion, quickly assimilated, and taken in due quantity; by powerful exercise often repeated, and long continued; and especially by riding in a dry, serene, pure air; by frictions; by motion of the affected parts; by going to sleep at early hours.

The second intention may be answered partly by the preceding, as well as by procuring gentle sweats; by bathing in natural and artificial baths; by sweating in a bagnio; or by the use of volatile salts, and copious drinking of attenuating liquors, actually hot, in the morning while in bed, in order to procure a sweat; as also by mercurial purges, taking a large quantity of diluents after them; by frictions of the whole body, especially the parts affected, with hot, dry, linnen-cloths, till a redness appear; by cold baths; and the like.

To abate the excessive pain in the part affected, Boerhaave says, that if there be

an absolute necessity, opiates may be given internally, and the patient may drink plentifully of hot whey, or any other liquor of the like nature. Externally emollients and anodynes may be used, laid on pretty hot; or the part affected may be beat with nettles; or it may be anointed with terebinthinated balsam of sulphur; or tow may be burnt thereon.

Sydenham says, that tho' there is nothing of any moment to be done in the fit; yet that it will be proper to abstain from flesh for some days, and to live on water-gruel, or such-like diet, but no longer than the stomach is averse to flesh, for fear of bringing on a disturbance of the animal spirits: but then great care should be taken in the diet, both as to quantity and quality. See the article DIET.

Dr. Cheyne advises, that as soon as the pain is almost gone, and the swelling and weakness only remain, nothing can be better than warm stomachic and spicey purges, dosed and repeated, according to the strength of the patient. This being premised, if the patient's strength is impaired, and flesh wasted, he advises asses milk with pearl, half a pint or a pint in the morning early, or at five or six o'clock in the afternoon; and to keep up the appetite which the milk commonly palls, and to prevent its cooling effects on the stomach, a light bitter made of gentian, cinnamon, and orange-peel, only the last double to the other two, infused in sherry or white-wine, and taken two hours before meals, may be used most conveniently.

Out of the fit, Sydenham prescribes a medium of diet to be observed; the patient should eat no more than the stomach will digest, nor should he be so abstemious as to defraud the parts of such a proportion of aliments as is necessary to maintain their strength and vigour. As to the quality of the food, the patient's palate is to be consulted, but he should dine upon one dish of meat only; he should, however, not eat any thing that is sharp, salted, or seasoned with spices: he should eat no suppers, but instead thereof drink a draught of good small-beer. The most suitable drink is such as is not so strong as wine, nor so weak as water: of this sort is the London table-beer, or water with a little wine; but when the gouty matter has seized the whole body, he must abstain from all fermented liquors, though ever so mild and

small, and use the following decoction only. Take of the root of sarsaparilla, six ounces; sassafras wood, china root, and the shavings of hartshorn, each two ounces; liquorice root, an ounce; boil them together in two gallons of spring-water for half an hour. Afterwards infuse them upon hot ashes, close covered for twelve hours: then boil them till a third part of the liquor is exhaled, and as soon as it is taken off the fire, infuse therein half an ounce of aniseeds for two hours. Lastly, strain it off and let it rest till it become clear, and put it up into bottles for use.

Regard must likewise be had to the symptoms, which in the fit endanger the patient's life. The most common is a weak and languid stomach, attended with sickness and gripes, as if from wind. In this case nothing is better than a glass of canary drank now and then, together with exercise; but if the symptom will not yield to this, give twenty drops of the thebaic tincture in spirituous alexiterial water, provided the head is not attacked, and let the patient compose himself to rest. If the symptom will not yield to this, sweating is prescribed, as also in a diarrhoea, when laudanum fails: but if there is a translocation of the gouty matter to the lobes of the lungs, and the pain has left the joints, this symptom is to be treated as a peripneumony. See the article PERIPNEUMONY.

If the nephritic pains should come upon the gout, let the patient omit all other medicines, and drink a large quantity of posset-drink, in which the leaves and roots of mallows and marsh-mallows have been boiled. Then let a clyster be given, and afterwards a dose of laudanum. When the gout has seized on the head, Dr. Cheyne orders it to be treated as any other violent head-ach, or an inflammation of the brain and its membranes. In young and strong constitutions, mercurial and antimonial vomits will do wonders; likewise gentle stomach-purges are to be poured down continually, that is two or three spoonfuls every third hour, till the effect is obtained. See the articles HEAD-ACH and VOMIT.

Pitcairn asserts, that the gout may be cured in the same manner as the lues venerea, by a salivation, and a decoction of the woods; and Cheyne allows, that a full and free salivation will cure the gout for several years, but then it shatters the constitution so much, that the future fits be-

come worse for it : but however this is no objection against a common mercurial course, which Dr. James, after repeated trials, has found very efficacious in the cure of the gout, of which the several cases published in his treatise of the gout, are a sufficient testimony.

Cheyne likewise observes, that a dram of powdered sulphur, or flower of brimstone, taken regularly in a spoonful of milk, has prevented the fit for many years. It moves the body gently once or twice a day. Musgrave, to bring the gout back from the noble parts to the joints, had a great opinion of the alcohol martis. See the article ALCOHOL.

If this does not excite a pain in the joints in four or five days, recourse must be had to externals ; such as the cephalic plaster, ceratum viride, or hat-case ; or the parts must be stung with nettles.

De Sault, supposing the gout depends on the want of perspiration, proposes warm baths, exercise, avoiding cold as much as possible, clean linnen and other cloaths, moderate eating, abstinence from suppers, frictions, tranquillity of mind, and a milk diet, as preservatives against it. He recommends garlic in the summer, and steel and the peruvian bark in the winter. When the stomach is attacked, he lets blood at the ancles, and applies epispastics of different kinds to the feet ; and then endeavours to procure a general sweat. When the pain is very violent, he blunts it by applying a cloth dipt in liquid laudanum, and exhorts the patient to ule exercise after this.

Cheyne says, that mercurial vomits are not only proper for the gout in the stomach, but that they are absolutely necessary, as well as the mercurial purges, when the gout becomes fixed to and permanent in a part, as also when it is dispersed all over the habit like a rheumatism ; that these active medicines must first render the humours fluid, which gum guaiac, with diaphorantimony, will afterwards carry off.

GOUT-WORT, in botany, a term sometimes used for angelica. See ANGELICA.

GOUTY-LAND, among farmers, denotes a moorish, cold and black soil, abounding with springs.

In Staffordshire this sort of land is ordered much in the same manner as heathy land, only that it is usually burnt deeper. It bears little but oats, white oats upon the gouty, and black oats upon the black cold land.

The turf of these grounds burnt, and carried upon rye or barley-lands, is esteemed a better improvement than dung. See the article HEATHY LAND.

GOWN, *toga*, a well known garment, worn by divines, lawyers, &c. who are therefore called gown-men, or gentlemen of the gown.

The citizens of antient Rome all wore gowns, *togæ* ; whence the appellation given them of *gens togata*. See the articles TOGA, PRÆTEXTA, &c.

GRABATARII, in church-history, a name antiently given to persons who deferred receiving of baptism, till on their death-bed.

GRABOW, or GRUBOW, a town of Lower Saxony, and dutchy of Mecklenburg : east longitude  $11^{\circ} 36'$ , north lat.  $53^{\circ} 32'$ .

GRACE, *gratia*, among divines, signifies any unmerited gift which God bestows on mankind.

Divines distinguish grace into habitual and actual : the first resides stably in us, is fixed in the soul, and remains till it is expunged by some grievous wilful sin. This is also called justifying grace, as it makes us appear innocent and righteous in the sight of God ; and sanctifying grace, as it makes us holy and devoted to God. Actual grace is that which God gives us for the special performance of some particular good thing, as to convert us, to enable us to resist a particular temptation, &c.

Grace is also divided into natural and supernatural : the natural including the gifts of being, life, of rational faculties, an immortal soul, &c. and the supernatural, is considered as a gift conferred on intelligent beings in order to their salvation.

GRACE, in geography, a city of Provence, in France, fifteen miles south-west of Nice : east long.  $6^{\circ} 50'$ , north lat.  $43^{\circ} 40'$ .

ACT of GRACE, an act of parliament for a general and free pardon, and for setting at liberty insolvent debtors.

DAYS of GRACE, in commerce. See DAY.

GRACE is also a title of dignity given to dukes, archbishops, and in Germany, to barons and other inferior princes.

GRACE of God, or By the GRACE of God, a formula used by sovereign princes, to express their independence. Thus in speaking of his britannic majesty, the formula runs thus : " George, by the " grace of God, king of Great Britain, " &c."

**GRACES**, *gratiae*, among canonists, the same with provisions. See **PROVISION**.

**GRACES**, in heathen mythology, three goddesses, whose names were Aglia, Thalia, and Euphrosyne; that is, shining, flourishing, and gay; or according to some authors; Palitheia, Euphrosyne, and Ægiale. Some make them the daughters of Jupiter, and Eurynome, or Eunomia, the daughter of Oceanus; but the most common opinion is, that they were the daughters of Bacchus and Venus.

They are sometimes represented dressed, but more frequently naked, to shew, perhaps, that whatever is truly graceful, is so in itself, without the aid of exterior ornaments. They presided over mutual kindness and acknowledgment; bestowed liberality, eloquence, and wisdom, together with a good grace, gaiety of disposition, and easiness of manners.

**GRACILIS**, in anatomy, a muscle of the leg, so called from its slenderness: it arises from the symphondrosis of the os pubis.

**GRACULUS**, the JACKDAW, in ornithology, a species of corvus. See the articles **CORVUS** and **JACKDAW**.

**GRACULUS PALMIFES**, a species of pelican, called in english the shag. See **SHAG**.

**GRADATION**, in general, the ascending step by step, or in a regular and uniform manner.

**GRADATION**, in architecture, a flight of steps, particularly in ascending from the cloister to the choir, in churches.

It also denotes an artful disposition of several parts, as it were by steps and degrees, after the manner of an amphitheatre; so that those placed before, are rather serviceable than the contrary, to those behind.

**GRADATION**, in logic, a form of reasoning, otherwise called sorites. See the article **SORITES**.

**GRADATION**, in painting, a gradual and insensible change of colour, by the diminution of the tints and shades.

**GRADATION**, in rhetoric, the same with CLIMAX. See the article **CLIMAX**.

**GRADISKA**, a city of Slavonia, situated on the river Save, twenty-five miles west of Zolga: east long. 18°, north lat. 46° 33'.

**GRADO**, in the italian music, the same with degree. See the articles **DEGREE** and **CONJOINT**.

**GRADO**, in geography, an island of the Adriatic sea, thirty-five miles north-east of Venice.

**GRADUAL**, *graduale*, in ecclesiastical writers, a book containing prayers to be used after the epistle.

The romanists still give the name gradual to a verse sung after the epistle.

**GRADUAL PSALMS**. See **PSALMS**.

**GRADUATE**, a person who has taken a degree in the university. See **DEGREE**.

**GRADUATION**, in mathematics, the act of graduating or dividing any thing into degrees, or equal parts.

**GRADUS**, a degree. See **DEGREE**.

**GRAFFER**, a term met with in law-books, signifying a notary or scrivener.

**GRAFFIUM**, a term also found in law-books, for a register or chartulary of deeds and other evidences.

**GRAFT**, or **GRAFF**, in gardening, a cion or shoot of a tree inserted into another, so as to make it yield fruit of the same nature with that of the tree from whence the graft was taken.

In the choice of grafts, the following directions should be carefully observed:

1st. That they are shoots of the former year. 2dly. That they are taken from healthy fruitful trees. And, 3dly. That you prefer those grafts which are taken from the lateral or horizontal branches, to those taken from the perpendicular shoots. These grafts should be cut off from the trees before the buds begin to swell, which is generally three weeks or a month before the season for grafting; therefore when they are cut off, they should be laid in the ground with the cut downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying: if a small joint of the former year's wood be cut off with the cion, it will preserve it the better; and when it is grafted, this may be cut off; for the grafts must be cut to a proper length before they are inserted into the stocks; but till then, the shoots should remain their full length, as they were taken from the tree, which will preserve them better from striking. If these grafts are to be carried to a considerable distance, it will be proper to put their cut ends into a lump of clay, and to wrap them up in moss, which will preserve them fresh for a month or longer: but these should be cut off earlier from the trees, than those which are to be grafted near the place where the trees are growing. For the choice of stocks for grafting, see the article **STOCK**.

**GRAFTING**, or **ENGRAFTING**, is the taking a shoot from one tree, and insert-

[ ing it into another ; in such a manner, as that both may unite and become one tree. See GRAFT, *supra*.

The use of grafting is to propagate any curious sorts of fruit, so as to be certain of the kinds ; which cannot be done by any other method : for as all the good fruit have been actually obtained from seeds, the seeds of these, when sown, will, many of them, degenerate, and produce such fruit as are not worth cultivating : but when shoots are taken from such trees as produce good fruit, these will never alter from their kind, whatever be the stock or tree on which they are grafted ; for tho' the grafts receive their nourishment from the stocks, yet they are never altered by them, but continue to produce the same kind of fruit as the tree from which they were taken.

*General directions for GRAFTING.* All such trees as are of the same genus, *i. e.* which agree in their flower and fruit, will take upon each other ; for instance, all nut-bearing trees may be safely grafted on each other ; as may also the plum-bearing trees, under which head I reckon not only the several sorts of plums, but also the almond, peach, nectarine, apricot, &c. which agree exactly in their general characters by which they are distinguished from all other trees : but many of these are very subject to emit large quantities of gum from such parts of the trees as are deeply cut and wounded, which, in the tender trees of this kind, *viz.* peaches and nectarines, being more common and hurtful, it is found to be the surest method to bud or inoculate them. See INOCULATION.

All such trees as bear cones will do well upon each other, tho' they may differ in one being ever-green, and the other shedding its leaves in winter ; as is observable in the cedar of Libanus, and the larch-tree, which are found to succeed upon each other very well : but these must be grafted by approach ; for they abound with a great quantity of resin, which is apt to evaporate from the graft, if separated from the tree before it be joined with the stock, whereby they are often destroyed ; as also the laurel on the cherry, or the cherry on the laurel. All the mast-bearing trees will also take upon each other, and those which have a tender soft wood, will do well if grafted in the common way ; but those of a more

firm contexture, and that are slow growers, should be grafted by approach.

By strictly observing this rule we shall seldom miscarry, provided the operation be rightly performed and at a proper season, unless the weather should prove very bad. It is by this method that many kinds of exotic trees are not only propagated, but also rendered hardy enough to endure the cold of our climate in the open air ; for being grafted upon stocks of the same sort that are hardy, the grafts are rendered more capable of enduring the cold ; as has been experienced in most of our valuable fruits now in England, which were formerly transplanted hither from more southerly climates.

*Methods of GRAFTING.* We shall now give the methods of grafting, only first observing, that before the operation is begun, the following tools and materials ought to be provided, *viz.* a small hand-saw, to cut off the heads of large stocks ; a good strong knife with a thick back, to make clefts in the stocks ; a sharp pen-knife to cut the grafts ; a grafting chisel, and a small mallet ; bafs strings or woollen yarn ; and a quantity of clay, which should be prepared a month before it is used, in the following manner : get some strong, fat loam ; then take some new stone-horse dung, and break it in amongst the loam ; if you cut a little straw or hay very small, and mix amongst it, the loam will hold together the better ; and if there be a quantity of salt added, it will prevent the clay from dividing in dry weather ; this compound should be well stirred together, and water put to it in the manner of making mortar ; after which it should be moistened afresh, and stirred every other day ; but it ought to be remembered, that it should not be exposed to the frosts, or to drying winds. Of late years, some have made use of another composition for grafting, which they have found to answer the intention of keeping out the air, better than the clay just prescribed. This is composed of turpentine, bees-wax, and rosin, melted together, which when of a proper consistence, may be put on the stock round the graft, in the same manner as the clay is usually applied ; and tho' it be not above a quarter of an inch thick, yet it will keep out the air more effectually than the clay ; and as cold will harden it,

it, there is no danger of its being hurt by froit, which is very apt to caule the clay to cleave and sometimes fall off; and when the heat of summer comes on, this-mixture will melt and fall off without any trouble; but you must be careful not to apply it too hot, lest you injure the grait.

There are several ways of grafting, the principal of which are the following.

**GRAFTING in the rind**, also called crown-grafting, and shoulder-grafting, is only proper for large trees, where either the head or the large branches are cut off horizontally, and two or four cions put in, according to the size of the branch or stem: in doing of this the cions are cut flat on one side, with a shoulder to rest upon the crown of the stock; then the rind of the stock must be raised up, to admit the cion to enter about two inches between the wood and the bark of the stock, so as the shoulder of the cion may meet, and closely join the crown of the stock; and after the number of cions are inserted, the whole crown of the stock should be well clayed over, leaving two eyes of the cions uncovered. This method of grafting was formerly much more in practice than it is at present: its discontinuance was occasioned by the ill success with which it has been attended, from the cions being frequently blown out by strong winds, after they had made large shoots; which has sometimes happened after they have had five or six years growth; so that whenever this method is practised, there should be stakes fastened to support the cions, till they have almost covered the stock. This method of grafting is generally performed about the latter end of March, or the beginning of April.

**Cleft-GRAFTING**, also termed stock or slit-grafting, is practised upon stocks or trees of a smaller size, from an inch to two inches or more in diameter, and may be used with success where the rind of the stock is not too thick. This method of grafting is to be performed in the months of February and March; and in doing it, the head of the stock or branch must be cut off with a slope, and a slit made the contrary way in the top of the slope, deep enough to receive the cion, which should be cut sloping like a wedge, so as to fit the slit made in the stock, being careful to leave that side of the wedge which is to be placed outward, much

thicker than the other; and in putting the cion into the slit of the stock, great care must be taken to join the rind of the cion to that of the stock; for if these do not unite, the grafts will not succeed: when this method of grafting is used to stocks which are not strong, it will be proper to make a ligature of bals to prevent the slit of the stock from opening; then the whole should be clayed over, to prevent the air from penetrating the slit, so as to destroy the grafts; only leaving two eyes of the cions above the clay for shooting.

**Whip-GRAFTING**, also called tongue-grafting, is most commonly practised of any by the nurserymen near London, especially for small stocks; because the cions much sooner cover the stocks in this method than in any other. This is performed by cutting off the heads of the stocks sloping; there must then be a notch made in the slope toward the upper part downwards, a little more than half an inch deep, to receive the cion, which must be cut with a slope upward, and a part left in this slope like a tongue; which tongue must be inserted into the slit made in the slope of the stock, so as that the two rinds of both cion and stock may be equal and join together exactly; then there should be a ligature of bals to fasten the cion, so as that it may not be easily displaced; and afterwards clay it over, as in the former methods.

**Root-GRAFTING**, consists in grafting a fine fruitful branch upon a root. The manner of performing it, is to take a graft of the tree you design to propagate, and a small piece of the root of another tree of the same kind, or very near it, or pieces of roots cut from such tree as you transplant, and whip-graft them, binding them well together. This tree may be planted where you would have it stand, for the piece of root will draw sap and feed the graft, as the stock does in the other methods.

**GRAFTING by approach**. See **INARCHING**.  
**Escutcheon GRAFTING**. See the article **INOCULATION**.

**GRAIES**, a market-town of Essex, situated on the river Thames, seventeen miles east of London.

**GRAIL**, the same with gradual. See the article **GRADUAL**.

**GRAIN**, all sorts of corn, as wheat, barley, oats, rye, &c. See the articles **CORN**, **WHEAT**, &c.

**GRAIN** is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight troy. See the article **WEIGHT**.

A grain-weight of gold-bullion is worth two-pence, and that of silver but half a farthing.

**GRAIN** also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-grained, or against the grain, is contrary to the fibres of wood, &c.

**GRAINING-BOARD**, among curriers, an instrument called also a pummel, used to give a grain to their leather. See the article **CURRYING**.

**GRAMEN**, GRASS, in botany. See the article **GRASS**.

**GRAMEN JUNCEUM**, a name used by Morison for a species of plantain.

**GRAMINEOUS CROWN**, in antiquity, the same with the obsidional one. See the article **CROWN**.

**GRAMINEOUS HERBS**, those with narrow oblong leaves, without any pedicle.

**GRAMINIFOLIA**, a plant called by Linnaeus zannichellia. See **ZANNICHELLIA**.

**GRAMMAR**, *грамматика*, the art of speaking and writing any language with propriety.

Grammar is usually divided into four parts, orthography, etymology, syntax, and prosody. See **ORTHOGRAPHY**, &c. Many are of opinion, that grammar is an art or science antecedent to languages; which, according to them, ought to be accommodated to these original principles. But just the reverse of this is true. Languages were by no means made for grammar, but that for them. It serves to teach languages to those who are ignorant of them; and, therefore, should be accommodated to the genius of each language in particular. In a philosophical view, indeed, there are some circumstances indifferently essential to them all; but this natural agreement is so much altered by the different customs of various languages, as to be for the most part utterly unknown. A just and exact method of grammar, therefore, can be only that, which, supposing a language introduced by custom, without attempting any alteration in it, furnishes certain observations called rules, to which the methods of speaking used in this language, may be reduced; and this collection of rules is what is called grammar.

Grammar, says lord Bacon, is of two kinds; the one having relation to speaking, the other to writing: for, as Aristotle well observed, words are the signs or marks of thoughts, and letters of words. See the articles **LANGUAGE**, **LETTER**, **WORD**, &c.

According to the same noble author, grammar holds the place of a conductor, in respect of the other sciences; and tho' the office be not noble, it is extremely necessary; especially as the sciences, in our times, are chiefly derived from the learned languages. It is of less use in maternal languages, than in learning the foreign ones; but is most of all serviceable in the dead ones, or such as are only preserved in books.

*Philosophical GRAMMAR*, one proposed by lord Bacon, not upon any analogy which words bear to each other, but such as should diligently examine the analogy or relation betwixt words and things. He disapproves of too curious an enquiry about the imposition and original etymology of names. This he thinks an elegant, and as it were a waxen subject, that may be handsomely wrought and twisted, but is attended with little truth and advantage. But, says he, it would be a noble kind of grammar, if any one, well versed in languages, both the learned and vulgar, should treat of their various properties; shewing wherein each of them excelled, and fell short: for thus languages might be enriched by mutual commerce; and one beautiful image of speech, or one grand model of language, for justly expressing the sense of mankind, formed, like the Venus of Apelles, from the excellencies of several. And thus, at the same time, we should have some considerable marks of the genius and manners of people and nations, from their respective languages. See farther remarks on this subject in Bacon's *Doctrine of Delivery*, Sect. 7.

**GRAMMAR** is also used for a book containing the rules of this art, methodically digested; of which there are multitudes indeed, but few good ones.

**GRAMMAR** is likewise used in a synonymous sense with elements, as a geographical grammar, &c.

**GRAMMARIAN**, one that is skilled in, or teaches grammar.

Antiently the name grammarian was a title of honour, literature, and erudition; being given to persons accounted learned in any art or faculty whatever. But it

is otherwise now, being frequently used as a term of reproach, to signify a dry plodding person, employed about words and phrases, but inattentive to the true beauties of expression and delicacy of sentiment. The antient grammarians, called also philologers, must not be confounded with the grammatists, whose sole business was to teach children the first elements of language. Varro, Cicero, Meffala, and even Julius Cæsar, thought it no dishonour to be ranked among grammarians, who had many privileges granted to them by the roman emperors.

**GRAMMATICAL**, in general, something belonging to grammar. See the article **GRAMMAR**.

**GRAMMONT**, a town of the austrian Netherlands, in the province of Flanders, situated on the river Dender: east lon.  $3^{\circ} 30'$ . and north lat.  $50^{\circ} 55'$ .

**GRAMPOUND**, a borough-town of Cornwall, thirty-eight miles south-west of Launceston: west lon.  $5^{\circ} 25'$ , and north lat.  $50^{\circ} 20'$ .

It sends two members to parliament.

**GRAMPUS**, in ichthyology, the english name of a fish of the dolphin-kind, with the snout turning upwards, and broad serrated teeth. See **DELPHINUS**.

**GRAN**, a city of lower Hungary, situated on the Danube: east lon.  $18^{\circ} 40'$ , north lat.  $48^{\circ}$ .

**GRANA REGIA** and **TIGLIA**, in the materia medica, names by which the purging grains or seeds of ricinus are called. They are violent and dangerous purgatives, prescribed in the Indies in rheumatisms and dropsies; but whilst safer and equally efficacious medicines may be had, there is no necessity to have recourse to these.

**GRANADA**, a province of Spain, bounded by Andalusia on the north, by Murcia and the Mediterranean on the east, by the same sea on the south, and by Andalusia on the west.

**GRANADA**, the capital city of the province of Granada, in Spain, situated two hundred miles south of Madrid: west lon.  $3^{\circ} 40'$ , and north lat.  $37^{\circ} 15'$ .

**GRANADA**, a province of terra firma, in south America, bounded on the north by the provinces of Carthagena and St. Martha, on the east by Venezuela, by Popoyan on the south, and by Darien on the west.

**GRANADA**, a city of Mexico, in north America, situated on the side of the lake Nicaragua: west lon.  $89^{\circ}$ , and north lat.  $11^{\circ} 8'$ .

**GRANADA** is also the most southerly of the Caribbee-islands, situated one hundred and fifty miles south-west of Barbadoes: west lon.  $61^{\circ} 30'$ , and north lat.  $12^{\circ} 15'$ .

**GRANADIER**, a soldier armed with a sword, a firelock, a bayonet, and a pouch full of hand-granaadoes. They wear high caps, are generally the tallest and briskest fellows, and are always the first upon all attacks.

Every battalion of foot has generally a company of granadiers belonging to it, or else four or five granadiers belong to each company of the battalion; which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

**Horse-GRENADIERS**, called by the French *grenadiers volans*, or flying-grenadiers, are such as are mounted on horseback, and fight on foot: their exercise is the same with the other grenadiers.

**GRANADILLA**, **PASSION-FLOWER**, a plant called by Linnæus *passiflora*. See the article **PASSIFLORA**.

**GRANADILLOS**, some of the Caribbee-islands, situated between the island of St. Vincent and Granada; but so inconsiderable that no nation has thought them worth possessing.

**GRANADO**, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter; which being filled with fine powder, is set on fire by means of a small fusee fastened to the touch-hole, made of the same composition as that of a bomb: as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near. See the article **BOMB**.

Thuanus observes, that the first time granadoes were used, was at the siege of Wachtendonck, a town near Gueldres: and that the inventor was an inhabitant of Venlo, who, in making an experiment thereof, occasioned two thirds of that city to be burnt, the fire being kindled by the fall of a granado.

**GRANARY**, a building to lay or store corn in, especially that designed to be kept a considerable time.

Sir Henry Wotton advises to make it look towards the north, as much as may be, because that quarter is the coolest and most temperate. Mr. Worlidge observes that the best granaries are built of brick, with quarters of timber wrought in the inside, to which the boards may be nailed, with which the inside of the granary must be lined so close to the bricks, that there

there may not be any room left for vermine to shelter themselves. There may be many stories one above another, which should be near the one to the other; because the shallower the corn lies, it is the better, and more easily turned.

Some have two granaries, one above the other, and fill the upper with wheat, or other corn; the upper one having a small hole in the floor, by which the corn falls down into the lower one, like the sand in an hour-glass; which, when it is all come down into the lower granary, is carried up again into the upper one; and by this means, is kept continually in motion, which is a good preservative for the corn. A large granary, full of square wooden pipes, may likewise serve to keep corn from heating.

In Kent, when corn is first brought into granaries, they lay it about half a foot thick, turn it twice a week, and once in that time screen it, for the first two months; after which they lay it a foot thick for two months more, turning it once or twice a week, and screening it proportionably according as the weather is moist or dry. After five or six months more, they lay it two feet thick, and turn it once a fortnight, screening it once a month, as occasion requires. After a year, they lay it two feet and a half, or three feet thick, and turn it once in three weeks or a month, screening it proportionably. When it has lain two years or more, they turn it once in two months, and screen it once a quarter. And in this manner they proceed, turning and screening it at greater or smaller intervals, according as they find it in brightness, hardness, and driness; for the oftener the grain is turned, the better it proves. For this purpose, an empty space, about a yard wide, is left on all sides of the room, and another at six feet distance through the whole area, into which empty spaces they turn the corn, as often as necessary. See the article CORN.

Before the corn is brought into granaries it ought to be well cleaned from impurities, and thoroughly dried; for it is observable, that such corn succeeds best.

In many parts of Africa, they preserve corn in deep pits, made in dry sandy ground, or even the solid rock: on the floor of these they lay a bed of straw, then a stratum of corn; after that another bed of straw, and then another of corn; and in this manner they proceed till the whole is filled up, taking care to place a

layer of straw between the corn and the sides of the pit.

**GRANATE**, or **GARNET**; *granatus*, in natural history. See **GARNET**.

**GRAND**, a term borrowed from the french, of the same import with *great*.

**GRAND ASSISE**, in law, a writ to determine the right of property in a real action.

**GRAND CAPE**. See **CAPE MAGNUM**.

**GRAND DAYS**, are those days in the several terms, which are solemnly kept in the inns of court and chancery, *viz.* candlemas-day, ascension-day, St. John the Baptist, and All saints-day.

**GRAND DISTRESS**, a writ that lies in two cases, either when a tenant or defendant is attached, and does not appear; or where he has appeared, if he afterwards makes default, in which case this process lies instead of a petit cape; and thereby all the goods and chattels of the defendant may be distrained within the county. See the article **DISTRESS**.

**GRAND JURY**, is the jury who find bills of indictment before justices of peace and gaol-delivery, or of oyer and terminer, &c. against any offenders that may be tried for the fact.

**GRANDE**, a branch of the river Niger, in Africa, which discharges itself into the Atlantic ocean, in 15° west lon. and 11° north lat.

**GRANDE**, is also a river of Brasil, in the province of Del Rey, in south America, which discharges itself into the Atlantic ocean, in 51° west lon. and 32° south lat.

**GRANDEE**, a designation given to a nobleman of Spain or Portugal.

The *grandees* are suffered to be covered before the king, who treats them like princes, styling them Illustrious, in his letters; and in speaking to them, or of them, they are styled Eminences.

**GRANDENTZ**, or **GRAUDENTZ**, a city of Poland, forty-two miles south of Dantzick: east longit. 19°, and north lat. 53° 30'.

**GRANDPRE**, a town of Champaign, in France, thirty miles east of Rheims: east lon. 4° 56', and north lat. 49° 18'.

**GRANGE**, a house or farm, not only furnished with necessary places for all manner of husbandry, as stables for horses, stalls for cattle, &c. but where there are granaries and barns for corn, hay-lofts, &c. And by the grant of a grange, such places will pass, without being particularly mentioned.

**GRANICUS**, a little river near the Hellespont, in the lesser Asia, where Alexander

ander fought the first battle with the forces of Darius.

**GRANIFEROUS** PODS, among herbalists, those that bear small seeds like grain.

**GRANITE**, *granita*, in natural history, a distinct genus of stones, composed of separate and very large concretions rudely compacted together, of great hardness, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire.

Of this genus there are three species :

1. The hard white granite, with black spots, commonly called moor-stone: this is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among, or running into one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass: it is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required.

2. The hard red granite, variegated with black and white, and common in Egypt and Arabia. 3. The pale whitish granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

**GRANIVOROUS**, an appellation given to animals which feed on corn or seeds. These are principally of the bird-kind.

**GRANT**, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, advowsons in gross, tithes, &c.

The person making such a conveyance is called the grantor, and he to whom the grant is made, the grantee.

A grant has usually the words *give and grant*, &c. which in a deed of what lies in grant, will amount either to a gift, grant, feoffment, or release, &c. and accordingly may be pleaded: though to every good grant it is requisite that there be a grantor, or person able to give; a grantee, capable of the thing granted; something granted, as grantable; that it be done in the manner the law requires; and that there be an agreement to, and an acceptance of the grant by him to whom made, &c.

When persons *non sane memorie* make grants, they may be good as to themselves, though voidable by their heirs, &c. and notwithstanding infants and

feme coverts are prohibited by law to be grantors, yet they may be grantees: however, an infant, when at his full age, may disavow to his grant, and the husband to that made to his wife. All grants are expounded according to the substance of the deed in a reasonable sense, and agreeable to the intent of the parties. In case a person grants a rent-charge out of land, and he has then nothing in the same, admitting he afterwards purchases the land, nevertheless the grant is void. And the law does not allow of grants of titles only, or imperfect interest, or of things that are merely future. Likewise grants may be void on account of uncertainty, impossibility, being against the law, &c.

**GRANT** of the king is good for himself and his successors, though they are not named therein: but the king may not grant away an estate-tail in the crown.

A grant tending to a monopoly cannot be made by the king, to the detriment of the interest and liberty of the subject; neither can the king make a grant non obstante any statute, made or to be made; for if he does, any subsequent statute prohibiting what is granted will be a revocation of the grant: yet there may be a non obstante to a former grant made by the king, where he has been deceived in such grant, as where it contains more than what was intended to be granted, or there is any deceit in the consideration, &c. by which the first grant becomes void.

**GRANT**, an ancient name for the river Cam. See the article CAM.

**GRANTHAM**, a borough-town of Lincolnshire, twenty-two miles south of Lincoln.

It sends two members to parliament.

**GRANVILLE**, a port-town of Normandy, from whence the noble family of Carteret take the title of earl.

**GRANULATED**, something that has undergone granulation. See the next article.

**GRANULATION**, according to Cramer, is the reducing metals to small particles, in order to promote their fusion and mixture with other bodies.

This is more coarsely done in the wet way, by means of running them into water through a new broom, or rolling them about in a hollow cylinder contrived on purpose: but the nicer and finer is the dry method, by means of a wooden box chalked within. Lead is very nicely granulated this way, and is to be done in the following manner.

Fig. 1. GNOMON.

Fig. 2. GRAPHOMETER.

Fig. 3. GRAVITATION.

Fig. 4. GRINDING OPTIC GLASSES.

Put a quantity of lead into an iron-ladle, and melt it slowly over a gentle fire; so soon as it is perfectly liquid, pour it into a round wooden box, with a wooden cover nicely fitted to it; and let both that and the cavity of the box be well rubbed over with chalk: shut the box immediately when the melted lead is in, and shake it violently, so that the metal within may be agitated forcibly against all parts of the box. Continue this agitation till the metal is cold, and on opening the box, you may find the greatest part of it finely granulated, or comminuted into very small porous grains. Let the chalk that adheres to these grains be rubbed off, and then sift them, to make them of an equal size.

Lead, tin, and brass are the most proper metals for this process, since these, when ready to melt, are always extremely brittle, somewhat like wetted sand. This sort of granulation, therefore, cannot be obtained from such metals as are the more tenacious the nearer they come to fusion, as gold, silver, &c. for which reason these can only be granulated the other and coarser way, by means of water.

**GRANULOSE ROOTS**, those composed of small knobs, like grains of corn.

**GRANUM**, in the materia medica. See the article *GRANA*, *supra*.

**GRAPE**, the fruit of the vine, *vitis*. See the article *VINE*.

Those kind of grapes which are thin-skinned, grow sooner ripe than others, and will thrive in a temperate climate, where the others will not. If it happen that grapes are struck with hail at the time that they are large and near ripening, they never become ripe at all, but harden, and so remain. See *WINE*.

The best sort of grapes are the white and sweet grapes with a tender skin, and without stones. It is said, that this fruit, when ripe, is of an hot and moist nature, very fattening, refreshing an inflamed liver, provoking urine, and good for the stomach; yet being windy, they disturb the entrails, so that they are best eaten before meals, or else with pomegranates, and other sharp fruit: but if for a few days they are hung up, they will lose their windiness, and become better. See the article *RAISIN*.

The juice of the agrestæ, or unripe wild grapes, is the omphacinum of the antients, as their oleum omphacinum was the expressed oil from the unripe olives. See the article *AGRESTÆ*.

They used to expose the grapes to the sun for some days, and then press out their juice into large vats: and in the time of Dioscorides, they used to let it stand open in them, exposed to the sun, till most of the humidity was exhale, and the remainder inspissated into a rob, a form much used among the antients. This is reckoned a cooler, but has no place in our present pharmacy.

**GRAPHOMETER**, a mathematical instrument, otherwise called a semi-circle, the use of which is to observe any angle, whose vertex is at the center of the instrument in any plane (though it is most commonly horizontal, or nearly so) and to find how many degrees it contains.

The graphometer is a graduated semi-circle ABC, made of wood, brass, or the like, and so fixed on a fulcrum GH, by means of a brass-ball and socket, that it easily turns about, and retains any situation. It has two sights-fixed on its diameter AC, and at the center there is commonly a magnetical needle and compass in a box. There is likewise a moveable ruler, or index ED, with two sights P, P; which turns round the center, and retains any situation given it. See plate CXIX. fig. 2. n<sup>o</sup> 1. and 2.

To measure by this instrument any angle ACB (*ibid.* n<sup>o</sup> 3.) in any plane, and comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its fulcrum; and let the immoveable sights on the diameter of the instrument DE, be directed towards the point A; and likewise while the instrument remains immoveable, let the sights of the ruler FG, which is moveable about the center C, be directed to the point B. Now it is evident, that the moveable ruler cuts off an arch DH, which is the measure of the angle ACB, sought. Moreover, by the same method, the inclination of DE, or of FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and moveable about the center of the instrument.

**GRAPTOLITHUS**, in natural history, a name given by Linnæus to a kind of stone, resembling a geographical map, found in Scandinavia.

**GRAPNELS**, a sort of anchors with four flooks, serving for boats to ride by.

There is also a kind called fire and chain-grapnels, made with four barbed claws

instead of flocks, and used to catch hold of the enemies rigging, or any other part, in order for boarding them. See plate CXXI. fig. 1.

**GRASS**, *gramen*, in botany, &c. a name given to several distinct plants, as the agrostis or couch-grass, the briza or quacking-grass, &c. Under the term grass are also comprehended all manner of herbaceous plants serving for the food of cattle, as clover, rye-grass, &c. The best season for sowing grass-seed is the latter end of August and the beginning of September, that the grass may be well rooted before the frost sets in, which is apt to turn the plants out of the ground when not well rooted. This seed should be sown in moist weather, or when there is a prospect of showers; but where this cannot be performed in autumn, the seeds may be sown in the spring, about the latter end of March, if the season proves favourable.

Some people mix clover and rye-grass seeds together, allowing ten pounds of clover and one bushel of rye-grass to an acre; but this is only to be done where the land is designed to remain but three or four years in pasture, because neither of these kinds are of long duration; so that where the land is designed to be laid down for many years, it will be proper to sow with the grass-seeds some white trefoil, or dutch clover, which is an abiding plant, and spreads close to the surface of the ground, sending forth roots at every joint, and makes the closest sward of any, and is the sweetest food for cattle: six or eight pounds of this seed should always be sown upon each acre.

The land on which grass-seed is intended to be sown, should be well plowed, and cleared from the roots of noxious weeds, such as couch-grass, fern, rushes, heath, gorse, broom, rest-harrow, &c. which if left in the ground, will soon get the better of the grass, and over-run the land. Therefore, where any of these weeds abound, it will be a good method to plow up the surface in April, and let it lie some time to dry; then lay it in small heaps, and burn it: the ashes so produced will be a good manure for it. But where couch-grass, fern, or rest-harrow grow thick, and their roots run far underground, the land should be plowed two or three times pretty deep in dry weather, and the roots carefully harrowed off after each plowing, which is the most certain method of destroying them.

Before the seed is sown, the surface of the ground should be made level and fine, otherwise the seed will be buried unequally. The quantity of grass-seed for an acre of land is usually three bushels, if the seed be clean; otherwise a much greater quantity must be allowed: when the seed is sown it must be gently harrowed in, and the ground rolled with a wooden roller, which will make the surface even, and prevent the seeds being blown in patches. If, when the grass comes up, there should be any bare spots where the seed has not grown, they may be sown again, and the ground rolled, which will fix the seeds, and the first kindly showers will bring up the grass.

If any thistles, ragwort, or such other troublesome weeds in the following spring come up among the grass, they should be carefully cut up with a spaddle before they grow too large; and this should be repeated two or three times in the summer, which will effectually destroy them.

As to grass-plats and green walks, they are made, for the most part, not by sowing grass-seed, but by laying turfs: and indeed the turfs from a fine common or down, are much preferable to sown grass: but if walks or plats are to be made by sowing, the best way is to procure the seed from those pastures where the grass is naturally fine and clear, or else the trouble of keeping it from spiry or benty grass will be very great, and it will scarce ever look handsome.

In order to sow grass-walks, the ground must be first dug; and when it has been first dressed and laid even, it must be very carefully raked over, and all the clods and stones taken off, and then covered over an inch thick with good mould. This being done, the seed is to be sown pretty thick, that it may come up close and short; it must then be raked over again, to cover the seed, that if the weather should happen to be windy, it may not be blown away. It ought also to be observed, that where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil or dutch clover sown with it; for this will make a fine turf much sooner than any other sown grass, and will continue a better verdure than any other of the grass-tribe.

In order to keep grass-plats or walks handsome, and in good order, you may sow in autumn fresh seed over any places that

that are not well filled, or where the grafs is dead: but nothing improves grafs fo much, as mowing and confant rolling.

When turf is laid in gardens, it is a general practice to cover the furface of the ground under the turf, either with fand or very poor earth: the defign of this is to keep the grafs fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not fo for fuch land as is but middling, or poor; for when this is praftised in fuch places, the grafs will foon wear out and decay in patches.

When turf is taken from a common or down, fuch ought to be chofen as is free from weeds: and when it is defigned to remain for years without renewing, a drefling fould be laid upon it every other year, either of very rotten dung, afhes, or, where it can be eafily procured, very rotten tan; but thefe dreflings fould be laid on early in the winter, that the rain may wafh them into the ground, otherwife they will occafion the grafs to burn, when the warmth of the fummer begins.

Where grafs is fo drefled, and kept well rolled and mowed, it may be kept very beautiful for many years; but where it is not drefled, or fed with fheep, it will rarely continue handfome more than eight or ten years.

**GRASSHOPPER**, in zoology, a fpecies of gryllus, frequent in paftures. See the article **GRYLLUS**.

Thefe infests fometimes infest particular places in prodigious fwarms, and eat up the whole fruits of the earth, like the devouring locufis. See the article **LOCUST**.

**GRATIAS A DIOS**, a cape or promontory of the province of Honduras, in Mexico: weft lon.  $84^{\circ}$ , north lat.  $14^{\circ} 30'$ .

**GRATINGS**, in a fhip, a kind of lettuce-work formed of ledges and battins, the fquare holes of which being three or four inches wide, are for the current footing of men over hatch-ways, to give air below, and vent for the fmoke in an engagement.

**GRATIOLA**, **HEDGE-HYSSOP**, in botany, a genus of the *diandria-monogynia* clafs of plants, the flower of which is monopetalous and ringent; its tube is longer than the cup, and of an angular figure, and the limb is fmall, and divided into four parts: the fruit is an oval pointed capfule, compofed of two valves, and containing two cells; in which are

included numerous fmall feeds. Some erroneoufly confound it with the digitalis, or fox-glove. See **DIGITALIS**.

It is good in dropfies, jaundices, and other chronic complaints, taken in infufion; and though a rough and violent medicine, operating both by vomit and ftool, is reckoned a very powerful one.

**GRATIOSA**, one of the Azores-iflands: weft lon.  $29^{\circ}$ , and north lat.  $39^{\circ}$ .

**GRATZ**, a city of Germany, and capital of the dutchy of Stiria, fixty-five miles fouth of Vienna: eaft lon.  $15^{\circ} 55'$ , and north lat.  $47^{\circ} 20'$ .

**GRAVE**, in mufic, is applied to a found, which is of a low or deep tune. See the article **TUNE**.

The thicker the cord or ftring, the more grave is the note or tone; and the fmall, the more acute. The gravity of founds depends on the fownefs of the vibratory motions of the chord; and their acutenefs, on its quick vibrations.

**GRAVE**, in the italian mufic, denotes a very grave and flow motion, fomewhat fafter than adagio, and flower than largo.

**GRAVE ACCENT**, in grammar, fhews that the voice is to be lowered: its mark is wrong printed in the article **ACCENT**, and fould ftand thus.

**GRAVE** alfo denotes a tomb, or fepulchre, wherein the dead are buried. See the articles **BURIAL**, **TOMB**, and **SEPULCHRE**.

**GRAVE**, in geography, a ftrong city of the Netherlands, in the province of dutch Brabant, eight miles fouth of Nimeguen: eaft lon.  $5^{\circ} 45'$ , and north lat.  $51^{\circ} 50'$ .

**GRAVEDO**, in medicine, a heavinefs and pain in the head, which always accompanies a catarrh. See **CATARRH**.

**GRAVEL**, in natural hiftory and gardening, a congeries of pebbles, which, mixed with a fuff loam, makes lafting and elegant gravel-walks; an ornament peculiar to our gardens, and which gives them the advantage over thofe of other nations.

There are many different opinions about the choice of gravel; fome are for having it as white as poffible, and in order to make the walks more fo, caufe them to be rolled with ftone-rollers, which are often hewn by the mafons fo as to add a whitenefs to the walks; but this renders them troublefome to the eyes by their reflecting too ftrongly the rays of light; this therefore fould be avoided, and fuch gravel as will lie fmoother, and reflect the leaft,

least, should be preferred. Again, some screen the gravel too fine, but this is an error; for if it be cast into a round heap, and the great stones only are raked off, it will be the better. There are many kinds of gravel which do not bind, and by this means cause a continual trouble of rolling, to little or no purpose; as for such, if the gravel be loose or sandy, you should take one load of strong loam and two of gravel, and so cast them well together.

The month of March is the properest time for laying gravel; for it is not prudent to do it sooner, or to lay walks in any of the winter-months before that time. In making these walks, great regard must be had to the level of the ground, so as to lay the walks with easy descents toward the low parts of the ground, that the wet may be easily drained off: but when the ground is level, it will be proper to have sink-stones laid by the sides of the walk, and at convenient distances, to let off the wet; and when the ground is naturally dry, the drains from the sink-stones may be contrived so as to convey the water into fesspools, from which the water will soak away in a short time: but in wet lands there should be under ground drains, to convey the water off, either into ponds, ditches, or the nearest place proper to receive it.

Some are apt to lay gravel walks too round; but this is an error, because they are not so good to walk upon; and besides, it makes them look narrow; one inch is enough in a crown of five feet; and it will be sufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each side: if fifteen feet, three inches; if twenty feet, four inches; and so in proportion.

For the depth of gravel-walks, six or eight inches may do well enough; and a foot in thickness will be sufficient for any; but then there should always be a depth of rubbish laid under the gravel, especially if the ground be wet.

Some turn up gravel walks into ridges in December, in order to kill the weeds: but this is very wrong, since it never answers the end, and therefore if constantly rolling them after rain and frost will not effectually kill the weeds and moss, you should turn the walks in March, and lay them down at the same time.

In order to destroy worms that spoil

the beauty of gravel or grass-walks, some recommend the watering them by water made very bitter by walnut-tree leaves being steeped in it: but if in the first laying of the walks there be a good bed of lime-rubbish laid in the bottom, it will be the most effectual method to keep out the worms, for they do not care to harbour near lime.

GRAVEL, in medicine, a terrible distemper arising from a gritty matter concreting into small stones in the bladder. See the article **STONE**.

GRAVELIN, a port-town of the french Netherlands, twelve miles south-west of Dunkirk.

GRAVELLING, a misfortune that happens to a horse by travelling, occasioned by gravel-stones getting between the hoof and the shoe, which settling at the quick, there fester and fret. It is cured by taking off the shoe, picking out all the gravel, and afterwards washing and cleansing the part affected; which done. sheep's tallow and bay salt melted together, are to be poured hot upon it, and the shoe set on again; and at two or three dressings it will be healed.

GRAVELLY LAND, or soil, that abounding with gravel and sand, which easily admits of heat and moisture; and the more stony they are, the more barren they prove.

The best produce of these lands in corn, is rye, white-oats, brank-turneps, &c. The natural produce in weeds is quick-grass, sorrel, broom, furze, brakes, heath, &c. The best manure is marl, or any sort of clay that will dissolve with the frost, cow-dung, chalk, mud, and half-rotten straw from dunghills.

GRAVENE, a town of Swabia, in Germany, thirty miles west of Ulm.

GRAVER, in the art of engraving, a tool by which all the lines, scratches, and shades are cut in copper, &c.

Gravers are of three sorts, round-pointed, square-pointed, and lozenge. The round are the best for scratching withal; the square-pointed are for cutting the largest strokes; and the lozenge-pointed ones for the most fine and delicate strokes: but a graver of a middle form, between the square and lozenge-pointed, will make the strokes or hatches appear with more life and vigour.

The manner of making the gravers is as follows: provide some cross-bow steel, and procure it to be beaten out into small rods, and softened, and then, with a good

good file, shape them as you please. This being done, heat them red-hot, and then immediately dip them in soap, which will render them very hard. In doing this observe, that if you turn your hand never so little awry in dipping them into the soap, the graver will be crooked. If the graver prove too hard, lay the end of it upon red-hot charcoal, till it begin to grow yellowish, and afterwards dip it in tallow (or, as some say, in water) and it will toughen it. Then having sharpened the graver upon an oil-stone, strike the point of it into a piece of hard box-wood, to take off the roughness about the points, which was caused by whetting it upon the stone. In the last place, touch the edge of the graver with a file; if it cuts, it is too soft, and will not work; but if it will not touch it, it is fit for the work. If the point of the graver breaks, it is a sign that it is tempered too hard; but it will frequently, after a little use by whetting, come to be well conditioned.

**GRAVESEND**, a port town of Kent, situated on the southern shore of the river Thames, twenty miles east of London.

**GRAVINA**, a city and bishop's see of the kingdom of Naples, twenty-seven miles south-west of Barri: east lon.  $17^{\circ}$ , and north lat.  $41^{\circ}$ .

**GRAVING**, or **ENGRAVING**. See the article **ENGRAVING**.

**GRAVING**, in the sea-language, is bringing a ship a-ground, and then burning off with furze, reed, or broom, all the filth and foulness that sticks to her bottom without-board, in order to pay her a new.

**GRAVITATION**, in physiology, a species of attraction, of the tendency of one body towards another, in consequence of its gravity. See **ATTRACTION** and **GRAVITY**.

*Cause of GRAVITATION.* This indeed is so difficult to be accounted for, that sir Isaac Newton himself is cautious how he does it. At the close of his *Principia* he tells us, that he has not hitherto assigned the cause of gravity, which is a power, however, that proceeds from a cause reaching even to the centers of the sun and planets, without losing its virtue, and that acts, not according to the particles of the surface, like a mechanical cause, but according to the quantity of solid matter in bodies; its action being every way extended to immense distances, and always decreasing in a duplicate proportion of them. The gravity of bodies towards the sun,

he further says, is composed of their gravity towards all its particles; and in going from the sun, decreases exactly in a duplicate proportion of the distance to the orbit of saturn; and even the farthest aphelia of the comets, if those aphelia are at rest. But the reason of these properties of gravity, I could never hitherto, says sir Isaac, deduce from phenomena; and am unwilling to frame hypotheses about them: for whatever is not deduced from phenomena, ought to be called an hypothesis; and no sort of hypotheses are allowable in experimental philosophy, wherein propositions are deduced from phenomena, and made general by induction. Thus the impenetrability, the mobility, the momentum of bodies, the laws of motion and gravity, were discovered; and it is enough that gravity has a real existence, and acts according to such laws as we have delivered, and that it suffices to produce all the motions of the celestial bodies, and of our sea. See the articles **PLANET**, **MOON**, &c.

*Laws of GRAVITATION* are as follows:

1. It is common to all bodies, and mutual between them.
  2. It is proportional to the quantity of matter in bodies.
  3. It is exerted every way from the center of the attracting body in right-lined directions.
  4. It decreases as the squares of the distances increase: thus, if a body at A (plate CXIX. fig. 3.) on the earth's surface, distant one semidiameter from the center C, weighs 36.00 pounds, it will, at the distance of 2, 3, 4, 5, 6, semidiameters, weigh 9.00, 4.00, 2.25, 1.45, 1.00 pounds, which numbers decrease as the squares of the distances increase. The truth of this proposition is not to be had from experiments; the utmost distance we convey bodies to, from the surface of the earth, bearing no proportion to their distance from its center, but is sufficiently clear from the motions observed by the heavenly bodies. See the articles **CENTRAL FORCES**, **COPERNICAN SYSTEM**, &c.
- Hence we learn, that all bodies have gravity, or are heavy, and that there is no such thing as absolute levity in nature: and by the second law, the gravitation of all bodies is proportional to the quantity of matter they contain: and hence, since bodies of equal bulk are found to have unequal quantities of matter, it evidently follows, that a vacuum, or solid void of matter, must necessarily exist, and

and that an absolute plenum is a doctrine unphilosophical, and equally false and absurd. See VACUUM and DENSITY.

Also from the third law it follows, that all bodies descending freely by their gravity, tend towards the earth in right lines perpendicular to its surface, and with equal velocities, abating for the resistance of the air ; as is evident from the second law above. See the article DESCENT.

Again, since the gravitation is always as the quantity of matter, and inversely as the square of the distance, it follows that were the internal parts of the earth a perfect void, or hollow concavity, a body placed any where therein, would be absolutely light, or void of gravity ; but supposing the earth a solid body throughout, the gravitation from the surface to the center will decrease with the distance, or it will be directly proportional to the distance from the center.

Gravitation being found by many experiments and observations to affect all the matter of bodies equally, we have hence more reason, says Mr. Maclaurin, to conclude its universality, since it appears to be a power that acts not only at the surfaces of bodies, and on such bodies as are removed at a distance from them, but to penetrate into their substances, and into that of all other bodies, even to their centers, to affect their internal parts with the same force as the external, to be obstructed in its action by no intervening body or obstacle, and to admit of no kind of variation in the same matter, but from its different distances only from that to which it gravitates.

This action of gravity on bodies arises from its action on their parts, and is the aggregate of these actions ; so the gravitation of bodies must arise from the gravity of all their particles towards each other. The weight of a body towards the earth, arises from the gravity of the parts of that body : the gravity of a mountain towards the earth, arises from the gravitation of all the parts of the mountain towards it ; the gravitation of the northern hemisphere towards the southern, arises from the gravitation of all its parts towards it ; and if we suppose the earth divided into two unequal segments, the gravitation of the greater towards the lesser, arises from the gravitation of all the parts of the greater towards the lesser. In the same manner the gravity of the whole earth, one particle being excepted, toward that particle must arise from the

quantity of gravitation of all the other particles of the earth towards that particle. Every particle, therefore, of the earth gravitates towards every other particle : and for the same reason every particle in the solar system gravitates towards every other particle in it.

*Center of GRAVITATION.* See CENTER.

*Line of GRAVITATION.* See LINE.

*Plane of GRAVITATION.* See PLANE.

**GRAVITY**, in physiology, the natural tendency of bodies towards a center. See the article GRAVITATION.

From the two following observations we not only learn that gravity is universal and inseparable from all matter ; but that it is an active principle, and the most general for conserving and recruiting motion.

Gravity, says Dr. Desaguliers, may be looked upon as a property of matter, which, though not essential, is yet universal, and in one sense inseparable from it ; that is, all parcels of matter, however modified, or all bodies, have a gravitation or attraction towards one another, as well in respect of the heavenly as of the terrestrial bodies. The tendency of heavy bodies towards the center of the earth, being owing to the same cause that makes the sun and planets tend towards one another.

The *vis inertia*, says sir Isaac Newton, is a passive principle by which most bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. By this principle alone there never could have been any motion in the world ; some other principle was necessary for putting bodies into motion ; for, from the various compositions of two motions, it is certain that there is not always the same quantity of motion in the world. But by reason of the tenacity of fluids, the attrition of their parts, and the weakness of elasticity in solids, motion is much more apt to be lost than got, and is always upon the decay. There is therefore a necessity of conserving and recruiting it, by active principles ; and such is the cause of gravity, by which the planets and comets keep their motion in their orbs, and bodies acquire great motion in falling, &c.

The same philosopher observes, that bodies immersed in fluids have two kinds of gravity, the one absolute, and the other relative.

Absolute gravity is the whole force where-with a body tends downwards ; for the laws

laws of which, see ACCELERATION, DESCENT, and GRAVITATION.

Relative gravity is the excess of gravity whereby a body tends downwards more than the fluid which surrounds it.

By the former kind of these gravities, says the last mentioned philosopher, the parts of fluids and of all bodies gravitate in their proper places, and by their joint weights compose the weight of the whole. For every whole has weight, as is evident in vessels filled with liquids; and the weight of the whole being equal to the weight of all the parts, must of necessity be composed of them. But bodies, by the latter kind of gravity, do not gravitate in their own places; that is, do not, when compared with one another, pregravitate; but mutually hindering each others endeavour to descend, they remain in their places as if they had no weight. Bodies in the air, which do not pregravitate, are thought by the vulgar not to be heavy, but those which pregravitate they judge to be heavy, so far as the air does not support them; so that the weight of bodies among the vulgar is only the excess of their real weight above that of the air. And therefore they call those things light which, being less heavy than the air, and yielding to its greater gravity, mount upwards. But these bodies are only comparatively light, not really so: for they will descend in vacuo. Thus bodies, which by reason of their greater or less gravity descend or ascend in water, are but comparatively and apparently heavy or light, and their comparative and apparent levity is the excess or defect whereby their real gravity either exceeds or falls short of the gravity of water. But whatever bodies neither descend by pregravitating, nor ascend by yielding to one that pregravitates, though they still by their real weights increase the weight of the whole, yet comparatively, and in a popular sense, they do not weigh in water. Hence,

*Specific GRAVITY*, called also relative, comparative, and apparent gravity, is that by which one body is said to be heavier or lighter than another of a different kind: thus lead is said to be specifically heavier than cork, because, supposing an equal bulk of each, the one would be heavier than the other. From hence it follows, that a body specifically heavier than another, is also more dense; that is, contains a greater

quantity of matter under the same bulk, because bodies weigh in proportion to the quantity of matter they contain.

If a solid be immersed in a fluid of the same specific gravity with itself, it will remain suspended therein in whatever part of the fluid it is put; but if the body is specifically heavier than the fluid, it will subside to the bottom. On the contrary, if the body is specifically lighter than the fluid, it will rise to the top.

A body being laid on the surface of a fluid specifically heavier than itself sinks in it, till the immersed part takes up the quantity of fluid, whose weight is equal to that of the whole body; and a body suspended in a fluid specifically lighter than itself, loses a part of its weight equal to that of a quantity of the fluid of the same bulk. See the article FLUID. For the method of finding the various comparative or specific gravities of fluids and solid bodies to the last degree of accuracy, see the articles HYDROSTATICAL BALANCE, and HYDROMETER. We shall here subjoin a table of the specific gravities of metals, minerals, ores, stones, fossils, animal substances, vegetable substances, miscellaneous substances, and fluids, considering rain-water as 1,000.

#### A Table of Specific GRAVITIES.

##### 1. Of Metals.

Fine, or pure gold	—	19,640
Gold of a guinea of George II.	—	17,150
Gold of a moidore	—	17,140
Silver fine or pure	—	11,091
Silver of a shilling of George II.	—	10,000
Lead	—	11,325
Copper	—	9,000
Brass cast	—	7,850
wrought	—	8,000
Steel tempered	—	7,704
Iron	—	7,645
Tin	—	7,550

##### 2. Of mineral Ores, &c.

Copper ore	—	3,775
Lead ore	—	6,800
Bismuth	—	9,700
Turbith mineral	—	8,325
Antimony from Germany	—	4,000
from Hungary	—	4,700
Speltar	—	7,065

##### 3. Of Stones, Fossils, &c.

Adamant or diamond	—	3,500
A pseudo-topaz	—	2,672
hyacinth	—	2,631
jasper	—	2,666
A bohemian granate,	—	4,360

A swedish granate	—	3,978	Ditto	—	1,240
Onyx stone	—	2,510	Ditto	—	1,433
A cornelian	—	3,290	Ditto	—	1,660
An english agate	—	2,512	Oyster-shell	—	2,892
A turcois stone	—	2,508	Murex-shell	—	2,590
Sardachates	—	3,595	A cockle-shell	—	2,520
A golden marcasite	—	4,589	Mother of pearl	—	2,480
Rock crystal	—	2,659	A piece of hard fish-skin	—	1,621
Iceland crystal	—	2,720	A piece of dried flesh of fish	—	1,129
Lapis nephriticus	—	2,894	The quill part of a feather	—	1,330
lazuli	—	3,054	5. Of Vegetable Substances.		
hæmatites	—	4,360	Dry box-wood	—	1,030
calaminaris	—	5,000	oak	—	0,925
judaicus	—	2,500	elm	—	0,600
manati	—	2,270	Ash, sappy	—	0,734
amianthus or asbestos, from			Ditto more dry about the heart	—	0,845
Wales	—	2,913	Dry mapple	—	0,755
Ditto from Italy	—	2,360	fir	—	0,546
Glass of the common sort	—	2,666	cedar	—	0,600
Flint	—	2,542	walnut-tree	—	0,631
Black italian marble	—	2,704	yew	—	0,760
White italian ditto	—	2,707	Beech, meanly dried	—	0,854
A fine marble	—	2,700	Crab-tree, meanly dried	—	0,765
Another ditto from Italy	—	2,718	Lignum vitæ	—	1,327
A pellucid pebble	—	2,641	nephriticum	—	1,200
A selenitis	—	2,322	aloes	—	1,177
Mundic, or gold spar	—	4,430	brazilicum	—	1,030
Kidney stone	—	3,600	rhodium	—	1,125
Blue stone	—	2,740	asphaltum	—	1,179
Star stone	—	3,450	guaiaacum	—	1,337
Hard paving stone	—	2,460	Saffraas wood	—	0,482
Burford stone	—	2,049	Red wood	—	1,031
Alabaster	—	1,875	santalum wood	—	1,128
Rag stone	—	2,470	White ditto	—	1,041
Rotten stone	—	1,980	Citrine ditto	—	0,809
Copperas stone	—	4,300	Speckled wood of Virginia	—	1,313
Chalk	—	2,370	Maltic wood	—	0,849
Slate	—	2,740	Ebony	—	1,177
Oil-stone	—	2,380	Good wheat of the last year	—	0,757
A hone	—	2,388	Cork	—	0,240
China	—	2,270	White oats	—	0,472
Piece of brown stone bottle	—	1,777	Blue pease	—	0,795
Piece of white stone mug	—	2,250	White pease very dry	—	0,807
Talc	—	2,657	Barley of the last year	—	0,658
of Venice	—	2,780	Malt made of the same	—	0,485
of Jamaica	—	3,000	Field beans very dry	—	0,807
Armenian hole or earth	—	2,727	Wheaten meal unsifted	—	0,495
Common sea coal	—	1,300	Rye meal unsifted	—	0,454
Magnet, or load-stone of Penfylv-			Wood ashes	—	0,930
vania	—	4,585	6. Of Miscellaneous Substances.		
Piece of stonehenge very hard	—	2,618	Amber	—	1,040
Ditto of a softer sort	—	2,500	Jet	—	1,238
Bristol-stone	—	2,510	Bezoar oriental	—	1,530
4. Of Animal Substances.			occidental	—	1,500
Bone of an ox	—	1,656	Sulphur common	—	1,800
Ivory	—	1,826	vivum	—	2,000
The tip of a rhinoceros's horn	—	1,242	Wood petrified	—	2,341
of an ox-horn	—	1,689	Borax	—	1,720
of a stag's horn	—	1,875	Coral, red	—	2,689
Calculus humanus	—	1,700	white	—	2,500
					Coral-

Corallachates	—	--	2,605
Cinnabar natural	—		7,300
artificial	—		8,200
of antimony	—		6,044
The reputed silver ore of Wales			7,464
The metal thence extracted			11,087
Ceruse	—	--	3,156
Tartar crude	—		1,849
emetic	—		2,246
vitrioli	—		2,298
Cream of tartar	--		1,900
Camphire	—	--	0,996
Mercury crude	—		13,593
distilled once	—		13,570
sublimed 511 times	—		14,110
Glass of antimony	—		5,280
Vitriol of Dantzick	—		1,715
English	—		1,880
white	—		1,900
Sal gemmæ	—		2,143
prunellæ	—		2,148
polychrestum	—		2,141
ammoniacum	—		1,453
Mirabile Glauberi	—		2,246
Salt of hartshorn	—		1,496
Salt of vitriol	—		1,900
Alum	--		1,714
Nitre	---		1,900
Gum arabic	—		1,375
tragacanth	—		1,333
Myrrh	—	--	1,250
Verdigrease	—		1,714
Opium	---		1,363
Litharge of gold	—		6,000
of silver	—		6,044

Milk of goats	-		1,009
Cow's milk	-		1,030
Urine	-		1,030

Since all bodies are subject to expand with heat, and be condensed with cold, it will follow, that the specific gravities of bodies cannot be precisely the same in summer and winter. This was first observed in experiments by M. Homberg, and after him, by M. Eifenschmid, who found the absolute weight of a cubic inch of several sorts of bodies in summer and winter, as in the table below.

	Summer.			Winter.		
	oz.	dr.	gr.	oz.	dr.	gr.
Brandy	0	4	32	0	4	42
Distilled water	0	5	8	0	5	11
Spring-water	0	5	11	0	5	14
River-water	0	5	10	0	5	13
Spirit of nitre	0	6	24	0	6	44
sea-salt	0	5	49	0	5	55
vitriol	0	5	33	0	5	38
Oil of vitriol	0	7	59	0	7	71
Milk	0	5	20	0	5	25
Mercury	7	1	66	7	2	14
Vinegar	0	5	15	0	5	21
Ditto distilled	0	5	11	0	5	15

**GRAVITY**, in music, an affection of sound, whereby it is denominated deep or low. See the article **SOUND**.

Gravity stands in opposition to acuteness, or that affection of sound whereby it is denominated acute or shrill. See the article **ACUTE**.

The relation of gravity and acuteness is the principal thing concerned in music; the distinctness and determinateness of which relation gives the sound the denomination of harmonical and musical.

The degrees of gravity, &c. depend on the nature of the sonorous body itself, and the particular figure and quantity thereof. Though in some cases on the part of the body where it is struck.

Thus, *e. g.* the sounds of two bells of different metals, of the same shape and dimensions, being struck in the same place, will differ; and two bells of the same metal will differ in sound, if they differ in shape and magnitude, or be struck in different places: so in chords, all other things being equal, if they differ in tension, matter, or dimension, they will always differ in gravity. Thus again, the sound of a piece of gold is much graver than that of a piece of silver of the same shape and dimensions; and in this case the tones are, *cæteris paribus*, proportional to the specific gravities: so a solid sphere of brass, two feet diameter, will sound graver than another of one foot diameter; and here the sounds are proportional to the quantities of the matter, or absolute weights. But it must be observed, that acuteness and gravity, as also loudness and slowness, are but relative things. We commonly call a sound acute, or loud, in respect of another which is grave or low in respect of the former: so that the same sound may be acute and grave, as also loud and low, in different comparisons.

The degrees of acuteness and gravity make the different tones of a voice or sound; so we may say one sound is in tune with another, when they are in the same degree of gravity.

The immediate cause or means of this diversity lies deep. The modern musicians fix it on the different velocities of the vibrations of the sonorous bodies. If two or more sounds are compared in relation of gravity, they are either equal or unequal in the degrees of tune: such as are equal are called unisons, and the unequal constitute what we call an in-

terval in music. See the articles **UNISON**, and **INTERVAL**.

**GRAVY**, in cookery, the juice of dressed meat, whether roasted, fried or boiled. Gravy is obtained from beef, mutton, veal, poultry, and even fish. The gravy of partridges, pullets, and other fowls, may be gotten by pressing them when about half roasted. The gravy of veal, beef, mutton, &c. is thus obtained: cut them in pieces, and putting them into an earthen pot, stop it close by passing the cover that no steam may get out; then set it on a gentle fire, for two hours, and the gravy will be made.

A fish gravy for soup may be made of tench or eels, cleaned, and put into a kettle with water, salt, a bunch of sweet herbs, and an onion stuck with cloves: let these boil for an hour and half; and straining off the liquor, thro' a clean linnen cloth, add to it the peelings of mushrooms, or mushrooms themselves cut small: boil these together, and strain the liquor into a stew-pan, upon fried flour, and a little lemon-juice. This may serve for a foundation to all fish-soups, and will keep good for some time.

**GRAY**, or **GREY**, in the manege, &c. See the article **GREY**.

**GRAY**, in zoology, an animal known among authors, by the name meles. See the article **MELES**.

**GRAY**, in ornithology, a species of duck, called also gadwal. See the articles **DUCK** and **GADWAL**.

**GRAY**, in geography, a city of Franche Compté, in France, twenty-two miles north-west of Besançon: east long.  $5^{\circ} 32'$ , north lat.  $47^{\circ} 30'$ .

**GRAYLING**, in ichthyology, a species of coregonus, with the upper jaw longest, and with twenty-three bones in the back-fin. See the article **COREGONUS**.

**GREASE**, a swelling and gourdiness of the legs of a horse.

If the horse be full of flesh, the cure is to be begun by evacuation, such as bleeding, purging, &c. and keeping his heels as clean as possible, by washing them with warm water and soap; for nothing promotes the grease more than negligence and nastiness. In general, turning out in the day-time, moderate exercise, a large and convenient stall, with good dressing, are the best remedies; but if the grease be got to a great height, and there is a nauseous discharge, after cutting off the hair, and washing the heels with soap and water, bathe them with the follow-

following wound-water, pretty warm, twice a day, for three days. Take rock alum, and white vitriol, of each two ounces; powder them together, and burn them in a clean fire-shovel, till they become a white calx: then take powdered camphire, one ounce; bole armenic in powder, two ounces; river or rain-water, two quarts. Make the water hot, and stir the other things into it. When you use it, it should be shaken up, and a little of it warmed in a pot, and the sores washed with a piece of sponge or rag.

**GREASE, MOLTEN**, a distemper incident to horses, in which the fat is melted by over hard riding or labour. It may be known by the horse's panting at the breast and girding-place, and heaving at the flank, which will be easily seen the night you bring him in, or the next morning.

For the cure, bleed him in the neck vein, to a good proportion; give him dried bran, and if he empties himself, a restraining glyster; but forbear giving him any hot drugs.

**GREASE**, with hunters, the fat of a boar, or hare; but the former has commonly the word bevy added to it, and is called bevy-grease.

**GREAT**, a term of comparison applied to things of extraordinary quantity or quality: thus, we say, a great city, a great genius, &c.

**GREAT CIRCLES** of the sphere. See the article **CIRCLE**.

**GREAT-CIRCLE SAILING**, the manner of conducting a ship in, or rather pretty near the arch of a great circle, that passes thro' the zenith of the two places, *viz.* from whence she came, and to which she is bound. See the article **SAILING**.

**GREAT MEN**, in law books, signify the lords of parliament, or other persons of note and distinction.

**GREAT SEAL**. See the article **SEAL**.

**GREE**, in a legal sense, is used for satisfaction.

**GREECE**, the present Rumelia, and the antient Hellas, is situated between 20° and 26° east long. and between 36° and 44° north lat.

It reaches from the Adriatic Sea, eastward, to the Archipelago, and is generally a healthy and fruitful country.

**GREEK, or GRECIAN**, any thing belonging to antient Greece.

The greek language, as preserved in the writings of the celebrated authors of an-

tiquity, as Homer, Hesiod, Demosthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expressions, suitable to the genius and occasions of a polite and learned people, who had a taste for arts and sciences. In it, proper names are significative; which is the reason that the modern languages borrow so many terms from it. When any new invention, instrument, machine, or the like, is discovered, recourse is generally had to the greek for a name to it; the facility wherewith words are there compounded, affording such as will be expressive of its use: such are barometer, hygrometer, microscope, telescope, thermometer, &c. But of all sciences, medicine most abounds with such terms, as diaphoretic, diagnosis, diarrhoea, hæmorrhage, hydrophobia, phthisis, atrophy, &c. Besides the copiousness and significance of the Greek, wherein it excels most, if not all, other languages, it has also three numbers, *viz.* a singular, dual, and plural; also abundance of tenses in its verbs, which makes a variety in discourse, prevents a certain driness that always accompanies too great a uniformity, and renders that language peculiarly proper for all kinds of verse. The use of the participles of the aorist and preterit, together with the compound words already mentioned, give it a peculiar force and brevity without taking any thing from its perspicuity.

It is no easy matter to assign the precise difference between the modern and antient Greek; which consists in the terminations of the nouns, pronouns, verbs, &c. not unlike what obtains between some of the dialects of the Italian or Spanish. There are also in the modern Greek many new words, not to be met with in the antient. We may therefore distinguish three ages of the greek tongue, the first of which ends at the time when Constantinople became the capital of the roman empire; the second lasted from that period to the taking of Constantinople by the Turks; and the third, from that time to this.

**GREEK BIBLE**. See the article **BIBLE**.

**GREEK CHURCH**. See **CHURCH**.

**GREEK MONKS and NUNS**, of whatever order, consider St. Basil as their founder and common father, and esteem it the highest crime to deviate in the least from his constitutions. There are several beautiful convents with churches, in which the monks perform divine service

day

day and night. Some of the monks are cœnobites, or live together, wear the same habit, eat at the same table, and pursue the same exercises and employments: These are of two sorts; the one of the grand and angelical habit, being such as profess to live more righteously than the rest; the other of the lesser habit, who do not pretend to lead such sanctified lives. Other monks again are anachorets. See the article ANACHORET.

**GREEN**, one of the original colours, excited by the rays of light. See COLOUR. Artificial greens, however, are rarely simple colours, but produced by the mixture of yellow and blue: thus, two powders, one blue and the other yellow, appear perfectly green when mixed; tho' if viewed with a microscope, the mixture will be seen chequered yellow and blue. See YELLOW and BLUE.

The dyers make divers shades, or degrees, of green; all which are first dyed in blue, and then taken down with woad, verdigrease, &c. and afterwards greened with the weed, there being no one ingredient that will dye green alone. See the article DYEING.

**GREEN**, among painters. Gamboge will give five or six sorts of green with verdigrease. But the yellow, which some prefer before all others, is made of french berries; which is either deeper or fainter, according as the liquor is more or less stained by them. In like manner, a yellow, drawn from the roots of the barberry or mulberry, will answer the same purpose, being mixed with transparent verdigrease. As to verdigrease itself, it produces a fine bluish green, flows readily in the pencil, and may even serve as an ink to write with; but is subject to decay. Mountain-green is used for a grass-colour. Verditer is a light green, seldom used but to colour landscapes that seem afar off. Sap-green is dark and dirty, and therefore never used but to shadow other greens in the darkest places. Copper-green is an excellent transparent and shining grass-green, if thickened in the sun-shine, or over a gentle fire. It is the most used of any green in washing of prints or maps.

**GREEN-CLOTH**, a board, or court of justice, held in the compting-house of the king's household, composed of the lord steward, and officers under him, who sit daily. To this court is committed the charge and oversight of the king's household in matters of justice and govern-

ment, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court royal; which is every way about two hundred yards from the last gate of the palace where his majesty resides.

It takes its name, board of green-cloth, from a green cloth spread over the board where they sit.

Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

*Clerks of the GREEN-CLOTH*, are two officers of the board of green-cloth who appoint the diet of the king and his household, and keep all records, ledgers and papers relating thereto; make up bills, parcels and debentures for salaries, and provisions and necessaries for the officers of the pantry, buttery, cellar, &c.

They also wait upon foreign princes when entertained by his majesty.

**GREEN-FINCH**, in ornithology, the english name of the greenish fringilla, with the wings and tail variegated with yellow. See the article FRINGILLA.

This bird is very frequent with us, and is a little larger than the chaffinch. See Plate CXVIII. fig. 1.

There is also a very beautiful green-finch brought from Surinam, with a red-head, and a roundish yellow spot near the joint of the wing. See *ibid.* fig. 2. where it is figured nearly of the bigness of life.

**GREEN-HOUSE**, or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful. See plate CXX.

The length of these houses, says Mr. Miller, must be proportioned to the number of plants they are to contain; but their depth should never be greater than their height in the clear; which in small or middling houses may be sixteen or eighteen feet, and in large ones from twenty to twenty-four. The windows in front should extend from about one foot and a half above the pavement, to within the same distance of the ceiling, which will admit of a corniche round the building, over the heads of the windows. In a small green-house, the sashes should not be less than four or five feet broad, and in a large one, they ought not to exceed

*Fig. 1.* The *GREEN GOLD-FINCH*.

*Fig. 2.* The *RED-HEADED GREEN-FINCH*.

*Fig. 3.* *GLYCYRRHIZA Liquorice.*

exceed seven and a half, the shutters of which ought to fall back close to the piers on the inside, that when open, they may not prevent any of the rays of light from reaching the plants. The piers between these windows, which support the building, should be as narrow as possible, for which reason they should either be of stone or of well-burnt brick. If they are of stone, they ought not to exceed two feet and a half in front, and should be sloped off backward to about eighteen inches broad, by which means the rays of the sun will not be obstructed by the corners of the piers; which they would be, if they were square: but if they are built with brick, it will be proper to make them near three feet in front, otherwise, they will be too weak to support the building: these ought also to be sloped off in the manner directed for those of stone.

Over the green-house there may be rooms for drying and preserving seeds, roots, &c. and behind it, there may be erected a house for tools and other purposes; which will prevent the frost from entering that way; so that the wall between them need not be more than two bricks and a half in thickness.

The floor of the green-house, which should be laid either with marble, common stone, or broad tiles, must be raised two feet above the surface of the ground on which the house is placed: or if the situation be moist, at least three feet; and if the whole be arched with low brick arches under the floor, it will be of great service in preventing the damps rising in winter. Under the floor, about three feet from the front, it will be advisable to make a flue of about ten inches in width, and two feet deep, to be carried the whole length of the house, which may be returned along the back part, and the smoke be carried up into funnels adjoining to the tool-house. The fire-place may be contrived at one end of the house; and the door at which the fuel is put in, as also the ash-grate, may be contrived to enter into the tool-house, and the fuel being laid in the same place, the whole will be out of sight. Fires, however, must be very sparingly used in this place: not one winter in three or four will require them to be lighted, since this ought never to be done but when the frost cannot well be kept out any other way, and when this is the case, this expedient may save a whole house of plants. Indeed

the coldest weather cannot make it necessary for the green-house to be shut up close for a long time together, which would be attended with very ill consequences; for as it frequently happens, that in continued frosts, we have an hour or two of sun-shine in the middle of the day, it will be of great service to the plants if they are allowed to enjoy its rays thro' the glasses; but the window-shutters should be closed again as soon as it is clouded. The inside of the house should either be white-washed, or painted white; for this colour reflects the rays of light in a greater quantity than any other.

In this green-house, there should be trussels, upon which rows of planks should be fixed, in order to hold the pots or tubs of plants, the foremost of which should be placed four feet from the window, and the rows behind should rise gradually from the first, in such a manner, that the heads of the second row be entirely advanced above the first, the stems only being hid by it: and at the backside, there should be allowed at least a space of five feet, for the convenience of watering the plants, and admitting a current of air around them: care should also be taken not to place the plants too close to each other, nor ever to place euphorbiums, sedums, torch-thistles, and other tender succulent plants, amongst oranges, myrtles, and other ever-greens.

To avoid the inconvenience of placing plants of very different natures in the same house, it will be very proper to have two wings added to the main green-house, which, if placed in the manner of the annexed plan, will greatly add to the beauty of the building, and also collect a greater share of heat. In this plan the green-house is supposed exactly to front the south, one of the wings to face the south-east, and the other the south-west: so that from the time of the sun's first appearance upon any part of the building, until it goes off at night, it will be constantly reflected from one part to the other, and the cold winds will be also kept off from the front of the main green-house. In the area may be placed many of the tender exotic plants, that will bear to be exposed in the summer season: and in the spring, before the weather will permit the plants to be set out, the beds and borders of this area may be full of anemonies, ranunculuses, tulips, &c.

In the annexed plate A, is the ground plan of the green-house; BB the ground plan of the two stoves. CCC the sheds behind the green-house and stoves. DD the passage of communication between the green-house and stoves, where the stairs are placed which lead to the rooms over the green-house. EE the section of the flues in the back of the stoves, and F is the upright of the green-house and stoves.

In the center of this area may be contrived a small basin for water, which will be very convenient for watering the plants; and the two wings of the building should be so contrived as to maintain plants of different degrees of hardiness, which should be effected by the situation and extent of the fire-place, and the manner of conducting the flues. These wings being, in the draught annexed, allowed sixty feet in length, may be divided in the middle by partitions of glass, with glass-doors, and to each of these there should be a fire-place, with flues carried up against the back-wall. The sloping glasses of these houses should be made to slide and take off, so that they may be drawn down more or less in warm weather, to admit air to the plants; and the upright glasses in front may be so contrived, as that every other may open as doors upon hinges, and the alternate glasses may be divided into two, the upper part of each to be drawn down like sashes, to let in the air.

If there are not sheds running behind the whole length of these wings, the walls should not be less than two bricks thick, and the back part having sloping roofs covered with tiles or slates, should be lined with reeds, &c. under the covering, in order to keep out the cold.

**GREENLAND**, or *West Greenland*, extends from the meridian of London to  $50^{\circ}$  west long. and from  $60^{\circ}$  to  $80^{\circ}$  north lat.

The Danes have some colonies here, and pretend to the property of the whole. However, the Dutch make very free with the fishery on this coast, notwithstanding the representations, and even menaces of the Danes on that head.

*East Greenland*, or *GROENLAND*. See the article *GROENLAND*.

**GREENLAND FISHERY**. See the article *FISHERY*.

**GREENWICH**, a town of Kent, situated on the southern shore of the Thames, five miles east of London; remark-

able for its royal and magnificent hospital, erected for decayed or disabled seamen, who have served their country; and for its palace, and most delightful park. See the article *HOSPITAL*.

On the top of a steep hill in the park, stands the royal observatory, built by Charles II. and furnished with all manner of instruments for astronomical observations, and a deep dry well for observing the stars by day.

**GREGARIOUS**, among zoologists, a term applied to such animals as do not live solitary, but in herds, flocks, or coveys.

**GREGORIAN CALENDAR**, that which shews the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epacts, disposed thro' the several months of the gregorian year. See *CALENDAR* and *EPACT*.

**GREGORIAN CHANT**. See *CHANT*.

**GREGORIAN EPOCH**, the epocha, or time whence the gregorian calendar or computation took place. The year 1754 is the 172 year of that epocha.

**GREGORIAN YEAR**, the Julian year corrected, or modelled, in such a manner as that three secular years, which in the Julian account are bissextile, are here common years, and only every fourth secular year is made a bissextile year. See the articles *BISSEXTILE* and *YEAR*.

The Julian computation is more than the solar year by eleven minutes, which in one hundred and thirty-one years amounts to a whole day. By this calculation, the vernal equinox was anticipated ten days from the time of the general council of Nice, held in the year 325 of the Christian æra, to the time of pope Gregory XIII. who therefore caused ten days to be taken out of the month of October, in 1582, to make the equinox fall on the twenty-first of March, as it did at the time of that council, and to prevent the like variation for the future he ordered that three days should be abated in every four hundred years by reducing the leap year at the close of each century for three successive centuries to common years, and retaining the leap year at the close of each fourth century only. See *JULIAN* and *EQUINOX*.

This was at that time esteemed as exactly conformable to the true solar year, but it is found not to be strictly just, because that in four hundred years it gets one hour and twenty minutes, and consequently in 7200 years, a whole day.

The

A Plan and Elevation of the  
GREEN-HOUSE, &c.

T. Jefferys Sculp.

The greatest part of Europe have long used the gregorian style : but Great Britain retained the julian till the year 1752, when by act of parliament this style was adjusted to the gregorian ; since which time Sweden, Denmark, and other european states, who computed time by the julian account, have followed this example.

**GRENADIER** and **GRENADO**. See the articles **GRANADIER** and **GRANADO**.

**GRENOBLE**, a city of France, capital of Dauphiny, forty-five miles south-east of Lyons, and thirty-six miles south-west of Chamberry : east long.  $5^{\circ} 28'$ , north lat.  $45^{\circ} 12'$ .

**GRENOCK**, or **GREENOCK**, a port-town of Scotland, near the mouth of the river Clyde ; being the principal station for the herring fishery.

**GRESHAM-COLLEGE**. See **COLLEGE**.

**GREVE**, in our antient writers, a denomination of power and authority, signifying as much as *comes*, and *vice comes*, a sheriff ; and according to Lambert, it is the same with *reve*. See the articles **COUNT** and **REVE**.

**GREWIA**, in botany, a genus of the *gynandria-polyandria* class of plants, the corolla whereof consists of five petals, of the form of the cup, but less, and emarginated at the base : the fruit is a quadrangular berry, containing four cells : the seeds are few, and of a globose figure.

**GREWT**, among miners, signifies earth of a different colour from the rest, found on the banks of rivers as they are searching for mines.

**GREY**, or **GRAY**, a mixed colour partaking of the two extremes, black and white. See **COLOUR**.

*To dye a silver GREY*. Take water a sufficient quantity ; of galls bruised small, two ounces ; tartar bruised, three ounces ; boil them, and enter twenty yards of stuff or cloth, &c. handle and boil an hour and a half ; cool it ; then put in copperas a sufficient quantity ; enter your cloth again at a boiling heat ; handle it, boil a quarter of an hour, and so cool ; if you would have it sadder, put in more copperas. See **COLOUR** and **DYEING**.

*To dye a light GREY colour*. Take water a sufficient quantity ; nut-galls bruised small, four ounces ; white tartar bruised small, four ounces ; make them boil, then enter twenty yards of broad-cloth, and handle it ; boiling an hour and half, cool your cloth, and put in copperas an ounce and half ; enter your cloth again,

and handle it ; boil it a quarter of an hour, and cool it ; if you would have it sadder, put in more copperas.

*To dye a dark GREY*. For every pound of woollen ware, use a quarter of a pound of copperas, and a quarter of a pound of brown wood, or walnut-tree wood. To finish it, take two ounces of brown wood, and half an ounce of copperas.

*To dye stuff, &c. a lavender GREY*. Heat a proper quantity of clean rain-water in a kettle, and for every pound of stuff, take an ounce of blue lac, beaten small ; and half an ounce of pounded galls, and the same quantity of vitriol : boil them together, and put in the stuffs ; and boil them for half an hour. This dye is proper for slight ware, as stockings and coarse stuffs, but not for the better sort.

*To dye silk a good GREY*. This you may do as in the tawney dye, and after you have wrung out, rinsed, and beaten it, if it be browned, it becomes a good grey. In the manege, they have several sorts of greys, as the branded-grey, which has spots quite black dispersed here and there ; they have also the dapple-grey, the silver-grey, the iron-grey, &c.

**GREY-FLY**, an insect called by authors oestrum. See the article **OESTRUM**.

**GREY-HOUND**. See the article **HOUND**.

**GRICE**, a term denoting a young wild boar. See the articles **BOAR** and **HOG**.

**GRIFFON**, in heraldry, an imaginary animal, feigned by the antients to be half eagle and half lion ; by this form they intended to give an idea of strength and swiftness joined together, with an extraordinary vigilance in guarding the things intrusted to its care. Thus the heathen naturalists persuaded the ignorant, that gold mines were guarded by these creatures with incredible watchfulness and resolution.

**GRIG**, a name given to the lesser ammodytæ, or sand-eels. See **AMMODYTÆ**.

**GRILLADE**, in cookery, meat broiled on a gridiron.

**GRIMBERG**, a town of the austrian Netherlands, in the province of Brabant, five miles north of Brussels : east long.  $4^{\circ} 15'$ , north lat.  $50^{\circ} 55'$ .

**GRIMPERG**, a city of Germany, in the circle of the lower Rhine, and earldom of Triers : east long.  $6^{\circ} 35'$ , north lat.  $49^{\circ} 40'$ .

**GRIMSBY**, a borough and port-town of Lincolnshire, situated at the mouth of the Humber : east long.  $4'$ , north lat.  $53^{\circ} 34'$ . It sends two members to parliament.

**GRINDERS**, *dentes molares*, in anatomy, &c. See **TEETH** and **MOLARES**.

**GRINDING**, *trituration*, the reducing hard substances to fine powders, either by the mortar, or by way of levigation upon a marble.

Grinding has a great share in some instances of raising or depressing the efficacy of what comes under its management: for in grinding, all those bodies whose efficacy consists in the peculiar shape and points of their component particles, the more and the finer they are broke, the less will they operate. Thus may calomel be rendered much gentler, and made capable of being given in much larger quantities, only by long rubbing in a glass mortar; for the continual triture has the same effect upon it, as repeated sublimation, which is only breaking the saline spicula more and more, until it become almost plain mercury. But in resinous substances, particularly purgative ones, as jalap, scammony, &c. the finer the powder they are reduced to, the greater is likely to be their efficacy: for as the sense which the stomach and bowels have of them is in proportion to their contacts, therefore the more the quantity is divided, the farther will it diffuse itself, and vellicate the fibres; that is, it will work the more.

**GRINDING** is also the rubbing or the wearing off the irregular or otherwise redundant parts of the surface of a body, and reducing it to the destined figure, whether that be flat, concave, or the like.

*Method of GRINDING optic glasses.* Mr. Huygens directs, in general, to make the breadth of the concave tool, plate, dish, or form, in which an object-glass must be ground, almost three times the breadth of the glass. Though in another place he speaks of grinding a glass whose focal distance was 200 feet, and breadth  $8\frac{1}{4}$  inches, in a plate only fifteen inches broad. But for eye-glasses, and others of lesser spheres, the tools must be broader in proportion to the breadth of these glasses, to afford room enough for the motion of the hand in polishing. Mr. Huygens made his tools of copper, or of cast brass, which, for fear they should change their figure by bending, can hardly be cast too thick: however, he found by experience, that a tool fourteen inches broad, and half an inch thick, was strong enough for the forming glasses to a sphere of thirty-six feet diameter; when the tool was strongly cemented

upon a cylindrical stone an inch thick, with hard cement made of pitch and ashes.

In order to make moulds for casting such tools as are pretty much concave, he directs, that wooden patterns should be turned in a lathe, a little thicker and broader than the tools themselves; but for tools that belong to spheres above twenty or thirty feet diameter, he says it is sufficient to make use of flat boards turned circular to the breadth and thickness required. When the plates are cast, they must be turned in a lathe exactly to the concavity required; and for this purpose it is requisite to make a couple of brass-gages in the manner following, according to the directions of Mr. Molyneux.

Take a wooden pole, a little longer than the radius of the spherical surface of the glass to be formed; and through the ends of it strike two small steel points, at a distance from each other equal to the radius of the sphere intended; and by one of the points hang up the pole against a wall, so that this upper point may have a circular motion in a hole or socket made of brass or iron, fixed firmly to the wall. Then take two equal plates of brass or copper, well hammered and smoothed, whose length is somewhat more than the breadth of the tool of cast brass, whose thickness may be about a tenth or a twelfth of an inch, and whose breadth may be two or three inches. Then having fastened these plates flat against the wall in a horizontal position, with the moveable point in the pole, strike a true arch upon each of them. Then file away the brass on one side exactly to the arch struck, so as to make one of the brass edges convex, and the other concave; and to make the arches correspond more exactly, fix one of the plates flat upon a table, and grind the other against it with emery. These are the gages to be made use of in turning the brass tools exactly to the sphere required.

But if the radius of the sphere be very great, Mr. Huygens directs the gages to be made as follows. Imagine the line AE, (plate CXIX. fig. 4. n<sup>o</sup> 1.) drawn upon the brass plate to be the tangent of the required arch AFB, whose radius, for example, is 36 feet, and diameter 72. From A set off the parts AE, EE, &c. severally equal to an inch, and let them be continued a little beyond half the  
breadth

breadth of the tool required: then as 72 feet, or 864 inches is to 1 inch, so let 1 inch be to a fourth number: this will be the number of decimal parts of an inch in the first line EF, reckoning from A. Multiply this fourth number successively by 4, 9, 16, 25, &c. the squares of 2, 3, 4, 5, &c. and the several products will be the number of parts contained in the 2d, 3d, 4th, 5th, EF respectively. But because these numbers of parts are too small to be taken from a scale by a pair of compasses, subtract them severally from one inch, represented by the lines EG, and the remainders being taken from a scale of an inch divided into decimal parts, and transferred by the compasses from G to F, will determine the points F, F, &c. of the arch required. And the same being done on the other side of the line AD, the brass plates must be filed away exactly to the points of this arch, and polished as before.

Mr. Huygens would have his plates or tools first formed in a turning lathe, and then ground together with emery; that is to say, the concave and convex tool of the same sphere together: but the tools of very large spheres, he would have ground at first quite plane, by a stone-cutter; and then ground hollow with a round flat stone and emery, to the desired gage.

The tools thus ground must be polished by an incrustation of pitch and emery, and perfected with blue hones. See the article POLISHING.

The glass being planed to an equal thickness, and polished a little by a glass grinder, and rounded by a grind-stone, take away the plate with several steel cavities, and with some sifted emery, made into a cement, fix on a smaller round piece of brass, or rather steel, truly flat, and turned, about the bigness of a farthing, but thicker, having first made in the center thereof, with a triangular steel punch, a hole about the bigness of a goose-quill, and about the depth of  $\frac{1}{12}$  of an inch; and at the very bottom of this triangular hole, a little round hole must be punched somewhat deeper, with a very small steel punch. A small steel point, of about an inch long, must be truly shaped and fitted to this triangular hole, and at the very apex to the small round deep impression. Nevertheless it must not be fitted so exactly, but that it may have the liberty to move a little to

and fro; and the apex always continuing to press upon the surface of the round hole below. This steel triangular point must be fixed to the end of a pole; to the other end of which another round iron point must be fixed, of about five or six inches long, to play freely up and down in a round hole in a piece of brass let into a board fixed against the ceiling for that purpose, perpendicularly over the bench and over the center of the tool, which must be strongly and truly fixed horizontally thereon, as represented in plate CXIX. fig. 4. n<sup>o</sup> 2.

Having these things prepared, with some pots of emery of various finenesses, take of your roughest sort a small half pugil, wetting the same, and daubing it pretty equably on the tool; then lay on your glass, and fix up your pole, and continue to grind for a quarter of an hour; not pressing upon the pole, but barely carrying the glass round thereby: then take a little quantity of some finer emery, and work another quarter of an hour therewith: then take the like quantity of emery still finer, and work for the same time: last of all take a less quantity of some of the very finest you have, which will be sufficient for a glass of five inches diameter, and work therewith for an hour and a half; taking away by little and little some of the emery with a wet sponge. Do not keep it too wet nor too dry, but about the consistence of paper for much depends on this. If it be too dry, your emery will stick, clog, and incorporate, and cut little or none at all, besides it will scratch and cut your glass irregularly; and if it is too wet, and too much diluted, it will, from the irregular separation of its parts, cut in some places more than others, as in the other case.

But Mr. Huygens tells us, that this method of using various sorts of fresh emery is not good; finding by experience, that the surfaces of large glasses are often scratched. And therefore he says, that it is best to take a large quantity of the first and second emery, and so work with the same from the first to the last, taking away, by little and little, every half hour, or quarter of an hour, more and more of the emery with a wet sponge, by which means he could bring the glass extremely smooth and fine, so as to see pretty distinctly a candle or the sash-windows well defined through it, which is a mark when it is ground enough to receive a polish.

When you first begin to grind, and the  
9 F 2 emery

emery begins to be smooth, the glass will stick a little to the tool, and run stiff; then fresh emery is to be added. The method hitherto described of grinding with emery, is what is recommended by Mr. Huygens. Le Pere Cherubin prescribes another material, which is the grit of a hard grind-stone, well beaten into a fine powder, and sifted pretty fine: and here in England the same thing was used to be performed by Mr. Cox with common clean white sand, taking away by little and little the said grit and sand, as it is ground finer and finer; but it seems this method is now quite disused.

*The method of GRINDING plate-glass.* See the article GLASS.

**GRINDSTEAD**, or *East GRINSTEAD*, a borough-town of Suffex, twenty-four miles directly south of London, which sends two members to parliament.

**GRIPE**, or **GRIPEs**, in medicine, a sort of colic, or painful disorder of the belly. See the article COLIC.

**GRIPE**, or **GRIP**, in husbandry, a small ditch cut across a meadow, or plowed land, in order to drain it.

**GRIPE**, in the sea-language, is a piece of timber fayed against the lower piece of the stern, from the fore-mast end of the keel, joining with the knee of the head: its use is to defend the lower part of the stern from any injury; but it is often made the larger, to make the ship keep a good wind.

Gripe of a ship, is also the compass or sharpness of the stern under water, chiefly towards the bottom of it.

Gripe is also a sea-term, for a ship's turning her head more to the wind than she should; this is caused either by overloading her a-head, the weight of which presses her down, so that the will not readily fall off from the wind; or by staying or setting her masts too much aft: which is always a fault in short ships that draw much water, since it causes them to be continually running into the wind: though in floating ships, if the masts be not stayed very far aft, they will never keep a good wind.

**GRIPSWALD**, a town of Germany, in the circle of Upper Saxony, and province of Swedish Pomerania, situated on a bay of the Baltic sea: east long.  $13^{\circ} 40'$ , north lat.  $54^{\circ} 15'$ .

**GRISLAGINE**, in ichthyology, a species of cyprinus, with whitish fins, and eleven rays in that beside the anus.

**GRISLEA**, in botany, a genus of the *oëandria-monogynia* class of plants, the flower of which consists of four extremely minute petals, of an oval figure, arising from the denticulations of the cup, and scarce larger than they. It is an american tree, sufficiently distinguished by its flower alone.

**GRISONS**, allies of Switzerland; their country is almost of a circular form, about sixty miles over every way, and is bounded on the north by Tyrol and part of Switzerland; on the east, by Tyrol and Trent; on the south, by Italy; and by the Swiss cantons on the west.

**GRIST**, in country-affairs, denotes corn ground; or ready for grinding. See the articles CORN and MILL.

**GRITH**, a faxon word signifying peace; from whence grithbreche is used in law-books for the breach of the peace.

**GROANING**, or **HOOTING**, among sportsmen, the cry or noise of a buck in rutting time.

**GROAT**, an english money of account, equal to four-pence.

**GROATS**, in country-affairs, oats after the hulls are off, or great oat-meal.

**GROCERS**, antiently were such persons as engrossed all merchandize that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

**GRODNO**, a great city of Poland, in the province of Lithuania: east long.  $24^{\circ}$ , north lat.  $51^{\circ} 40'$ .

**GROENDALE**, a town of Brabant, six miles south-east of Brussels.

**GROENLAND**, or **SPITZBERGEN**, a cold miserable country without inhabitants, and with very few animals or vegetables, situated between  $10^{\circ}$  and  $30^{\circ}$  east long: and between  $77^{\circ}$  and  $82^{\circ}$  north lat.

**GROGRAM**, a kind of stuff, made of silk and mohair. Turkey programs pay on

importation  $8\frac{66\frac{1}{2}}{100}$  d. the yard; and draw

back, on being exported,  $7\frac{50\frac{3}{4}}{100}$  d. Lisle

programs, if narrow, pay 11 s.  $6\frac{60}{100}$  d. each piece, not exceeding 15 yards, and draw back 10 s.  $1\frac{1}{2}$  d. but if broad they pay 17 s.  $3\frac{90}{100}$  d. and draw back 15 s.  $2\frac{25}{100}$  d. each piece, not exceeding 15 yards.

**GROIN**, *pubes*, in anatomy. See the article PUBES.

**GROLL**, a town of Guilderland, twenty-one miles east of Zutphen.

**GROMETS**,

**GROMETS**, in the sea-language, small rings formerly fastened with staples to the yards, to make fast the gaskets, but now never used.

**GRONINGEN**, the capital of a province of the same name, which makes one of the seven united provinces: east long.  $6^{\circ} 40'$ , north lat.  $53^{\circ} 20'$ .

**GRONOVIA**, in botany, a genus of the *pentandria-monogynia* class of plants, the flower of which consists of five extremely small petals, of a roundish figure: the fruit is a roundish, coloured capsule, with only one cell, in which is contained a single, large, and roundish seed.

**GROOM**, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole. See the articles **STOLE** and **WARDROBE**.

**GROOM-PORTER**, an officer of the king's household, who provides chairs, stools, and firing for the king's lodging, and also furnishes cards, dice, &c. and decides the disputes which arise at play.

**GROOM** is more particularly used for a servant appointed to attend on horses in the stable. It is his business to feed and water them, to curry and rub them down, and to keep a watchful eye over them, that they may have no inward or outward disorder, without his discovering it, and using his endeavours to remove it.

**GROOVE**, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

**GROOVE**, among joiners, the channel made by their plough in the edge of a moulding, style, or rail, to put their pannels in, in wainscoting.

**GROOVE** also denotes a gardener's tool for transplanting plants.

**GROSS**, in law-books, signifies absolute or independent on another: thus, an advowson in gross, is one distinct and separate from the manor.

**GROSS** also denotes the quantity of twelve dozen, of things sold by tale.

**GROSS-BEAK**, in ornithology, the english name of a bird called by authors *loxia*. See the article **LOXIA**.

**GROSS-WEIGHT**, the whole weight of merchandizes, with their dust and dross; as also the bag or chest wherein they are contained. An allowance is usually made out of the gross-weight for tare and tret. See the article **TARE**.

**GROSSE-BOIS**, in our old law-books, signifies wood of such a growth as to be accounted timber. See **TIMBER**.

**GROSSETTA**, a city of Tuscany, in Italy, fifty-five miles south of Florence: east long.  $12^{\circ}$ , north lat.  $42^{\circ} 40'$ .

**GROSSULARIA**, the **GOOSEBERRY** and **CURRENT-BUSHES**, the same with the *ribes* of Linnaeus. See the articles **RIBES**, **GOOSEBERRY**, &c.

**GROTESQUE**, or **GROTESK**, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprise and ridicule.

Grotesque work is the same with what is sometimes called antique. The name is said to have taken its rise from the figures of this kind much used in adorning the grottos which in antient times were the tombs of eminent persons or families; such as that of Ovid, whose grotto was discovered near Rome about eighty years ago.

**GROTESQUES**, or **GROTESKS**, are particularly used to signify those fanciful ornaments of animals interspersed among foliages, fruit, &c. as those painted by Raphael Urbin in the Vatican, and those carved by Michael Angelo, in the ceiling of the portico of the capitol. These kind of compartments are called by Vitruvius, *harpagenituli*.

**GROTSKA**, a city of Silesia, and capital of a dutchy of the same name, thirty miles south of Breslaw: east long.  $17^{\circ}$ , north lat.  $50^{\circ} 40'$ .

**GROTSKA** is also a town of Servia, in european Turkey, twenty miles south-east of Belgrade: east long.  $21^{\circ}$ , north lat.  $45^{\circ}$ .

**GROTTO**, in the natural history of the earth, a large deep cavern or den in a mountain or rock.

Of these we find several remarkable ones in different parts of the world. The most celebrated one of our own country, is that called Oookley-hole, on the south side of Mendip-hills. Its length is about two hundred yards, and its height various; being in some places very low, and in others eight fathoms. There is another at Puzzoli, about four leagues from Naples, called the dog's grotto; because a dog thrown into it is immediately killed, by a destructive vapour equally fatal to all animals within its reach. The milky grotto, *crypta lactea*, about a mile from the antient village of Bethlehem, is said to have been thus called from the holy virgin's letting fall some drops of her milk in it; on which  
account

account the earth of this cavern has been supposed to possess the virtue of restoring womens milk.

**GROTTO** is also used for a small artificial edifice made in a garden, in imitation of a natural grotto.

The outsidcs of these grottos are usually adorned with rustic architecture, and their inside with shell-work, coral, &c. and also furnished with various fountains, and other ornaments.

The following is recommended as a good cement for grotto-work. Take two parts of white rosin, melt it clear, add to it four parts of bees-wax; when melted together, add some flower of the stone you design to cement, two or three parts, or so much as will give the cement the colour of the stone; to this add one part of the flower of sulphur: first incorporate all together over a gentle fire, and afterwards knead it with your hands in warm water. With this fasten the stones, shells, &c. after they are well dried, and warmed before the fire.

**GROVE**, in gardening, a small wood impervious to the rays of the sun.

Groves are not only great ornaments to gardens, but are also the greatest relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the garden are useless; so that every garden is defective which has not shade. See the article **GARDEN**.

Groves are of two sorts, *viz*, either open or close. Open groves are such as have large shady trees which stand at such distances, as that their branches approach so near to each other, as to prevent the rays of the sun from penetrating through them.

Most of the groves that have been planted either in England or in the celebrated gardens of France, are only a few regular lines of trees; many of which are avenues to the habitation, or lead to some building or other object: but these do not appear so grand, as those that have been made in woods, where the trees have grown at irregular distances: where they have large spreading heads, and are left so far asunder, as to permit the grass to grow under them, they then afford the greatest pleasure; for nothing is more noble than fine spreading trees, with large stems, growing through grass, especially if the grass is well kept, and has a good verdure; besides, most of those

planted groves have a gravel walk, made in a straight line between them, which greatly offends the sight of persons who have a true taste: therefore whenever a gravel-walk is absolutely necessary to be carried through these groves, it will be much better to twist it about, according as the trees naturally stand, than to attempt regularity: but dry walks, under large trees, are not so useful as in open places; because after rain, the dropping of the trees will, for a considerable time, render the walks useless.

In planting groves, it is much the best way to dispose the trees irregularly, which will give them a more magnificent and noble appearance, and also form a shade sooner than when the trees are planted in lines.

When, in planting a garden, full grown trees are found upon the spot, they should, if possible, remain inviolate; for it will be better to put up with many inconveniences, than to destroy what will require an age to retrieve; so that nothing but offending the habitation, by being so near as to occasion great damps, should tempt us to cut them down.

Close groves have frequently large trees standing in them; but the ground under these are filled with shrubs or underwood; so that the walks which are in them are private, and screened from winds; by which means they are rendered agreeable for walking, at such times when the air is either too hot or too cold for walking in the more exposed parts of the garden. These are often contrived so as to bound the open groves, and frequently to hide the walls or other inclosures of the garden; and when they are properly laid out, with dry walks winding through them, and on the sides of these sweet-smelling shrubs and flowers irregularly planted, they have a charming effect: for here a person may walk in private, sheltered from the inclemency of cold or violent winds, and enjoy the sweets of the vegetable kingdom: therefore, when it can be admitted, if they are continued round the whole inclosure of the garden, there will be a much greater extent of walk; and these shrubs will appear the best boundary, where there are not fine prospects to be gained.

**GROUND**, in agriculture, is much the same with earth or soil. See the articles **EARTH** and **SOIL**.

**GROUND**,

**GROUND**, in painting, the surface upon which the figures and other objects are represented.

The ground is properly understood of such parts of the piece, as have nothing painted on them, but retain the original colours upon which the other colours are applied to make the representations.

A building is said to serve as a ground to a figure, when the figure is painted on the building.

The ground behind a picture in miniature, is commonly blue or crimson, imitating a curtain of sattin or velvet; if it be to be blue, it should be laid on as follows: wash bice till it is very pure and clear, and temper a quantity in a shell sufficient for your ground, letting it be thoroughly moist and well bound with gum. Then with a small pencil lay on the same colour about the profile, that is, the ambient superficies of the picture; having done this, take a large pencil, and wash over the whole ground you design to cover with a blue, somewhat thin and waterish, and then with a pretty large pencil, full of colour and flowing, lay over with a thick and substantial colour what you had before only washed over; in the doing of this you must be very quick, keeping the colour you have laid on moist, and not suffering any part to dry till you have covered the whole.

If you would have your ground a crimson like sattin, then trace out where and in what places you will have those strong and hard lights and reflections to fall, which are seen in sattin or velvet, with indian lake; there lay your lights with a lake that is thin and waterish, and while it is yet wet, lay the deepening and hard strong shadows with a stronger and darker colour of lake thick ground, close by the other lights. The best way for imitation, is to have a piece of sattin before you to imitate.

**GROUND**, in etching, denotes a gumous composition smeared over the surface of the metal to be etched, to prevent the aquafortis from eating, except in such places where this ground is cut through with the point of a needle. See the article **ETCHING**.

**GROUND of a shield**, the same with field. See the article **FIELD**.

**GROUND-ANGLING**, fishing under water without a float, only with a plumb of lead or a bullet, which is better, because it will roll on the ground; this method

of fishing is most proper in cold weather, when the fish swim very low.

The bullet is to be placed about nine inches from the baited hook. A person in fishing in this manner, ought not to strike as soon as he feels the fish bite, but slack his line, that the fish may the better swallow the bait and hook. As for the tackle, it should be fine and slender; for strong and thick lines only serve to fright the fish.

The morning and evening are the chief seasons for the ground-line in fishing for trout; but if the day prove cloudy, or the water muddy, you may fish at ground all day.

**GROUND-PLUMBING**, is to find out the depth of the water in fishing; which is done by a musket-bullet with an hole through it, tied to a strong twist and hung on the hook.

**GROUND-IVY**, *hedera terrestris*, in botany. See the article **GLECHOMA**.

Ground-ivy is attenuant and dissolvent, and famous both internally and externally as a vulnerary. It is much used with us in an infusion in form of tea, for disorders of the breast and lungs, and is sometimes an ingredient in pectoral decoctions. A conserve made of the plant when in flower, retains its virtues in an agreeable form, but is seldom kept in the shops. It is esteemed a specific in crosions and exulcerations of the viscera, and particularly of the kidneys and lungs. It is also recommended in consumptions, bruises from falls, head-achs, and other the like disorders.

**GROUND-PINE**, in botany, a plant called by authors *chamæpitys*, or *teucrium*. See the article **TEUCRIUM**.

*Stinking* **GROUND-PINE**, in botany. See the article **POLYCNEMUM**.

**GROUND-TACKLE**, is a ship's anchors, cables, &c. and, in general, whatever is necessary to make her ride safe at anchor.

**GROUND-TIMBERS**, are those timbers in the ship which lie on her keel, and are fastened to it with bolts thro' the keelson. They are so called from the ship's resting upon them when she is aground.

**GROUND-TOWS**, are what comes from the hemp when dressed at the hatchel for the spinners, and out of which ham-burgh or cabin-lines, marlin, and white ocham are made.

**GROUND-WORK**, in a building, the same with foundation. See **FOUNDATION**.

**GROUND-**

**GROUNDAGE**, a custom or tribute paid for the ground on which a ship stands in port.

**GROUNDING**, is bringing a ship on ground to be cleaned, trimmed, or to have a leak stopped.

**GROUNDLING**, in ichthyology, the smooth, spotted cobitis, with the body of a cylindrical figure, and otherwise called the loach. See **COBITIS**.

**GROUNDSEL**, *erigeron*, in botany, &c. See the article **ERIGERON**.

**GROUP**, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other.

It is necessary in a good piece of painting, that all the figures be divided into groups: this has somewhat in it of the nature of symphony or concert of voices; for as in the one the voices must sustain each other, in order to fill the ear with an agreeable harmony from the whole; so in groups, if the parts or figures be not well disposed, something will be found disagreeable.

There are two kinds of groups, or two manners of considering them, with respect to the design, and to the clair-obscur. The first of these is common both to works of painting and sculpture; but the latter is peculiar to painting.

Groups, with respect to the design, are combinations of several figures, which bear a relation to each other, either upon account of the action, or of their proximity, or of the effect they produce. These we conceive as representing so many different subjects, or at least so many distinct parts or members of one great subject. Thus, in architecture, we say a group of columns, when we speak of three or four columns standing together on the same pedestal.

Groups, with respect to the clair-obscur, are assemblages of figures, where the lights and shadows are diffused in such a manner, that they strike the eye together, and naturally lead it to consider them in one view.

**GROUP**, in music, one of the kinds of diminutions of long notes, which, in working, form a sort of group, knot, or bush. It usually consists of four or more crotchets, quavers, &c. tied together at the discretion of the composer.

**GROUPADE**, or **CROUPADE**, in the manege. See the article **CROUPADE**.

**GROUPED COLUMN**. See **COLUMN**.

**GROUSE**, or **GROUSE**, a species of the tetrao, is a valuable bird of the size of a well-grown fowl; the head is large; the eyes bright and piercing; the ears are patulous, the beak is three quarters of an inch long, and of a pale colour, somewhat hooked, and pointed at the extremity: it has a scarlet protuberance over the eyes, which is very bright and beautiful; its wings are variegated, and its tail forked. The male, excepting the little variegations of white in his wings, is totally black, and there is a fine changeable tinge of a deep blue on his neck; but the female is brown and mottled, and in colour resembles the woodcock.

This a native of England, but is not very frequent; it lives on large mountainous heaths.

**GROWAN**, among the miners of Cornwall, a coarse gritty stone, of a greyish colour, which they are often obliged to dig through, before they can reach the ore.

**GROWTH**, the increase of a thing, or its advancing towards maturity.

**GROWTH-HALF-PENNY**, a rate paid in some places for the tithes of every fat beast, or other unfruitful cattle.

**GROYNE**, or **CORUNNA**, a port of Spain. See the article **CORUNNA**.

**GRUARI**, in law-books, in general, signifies the principle officers of a forest.

**GRUB**, in zoology, the english name of the hexapode worms, produced from the eggs of beetles, and which at length are transformed into winged insects of the same species with their parents. See the article **SCARABÆUS**.

**GRUBS**, in medicine, certain unctuous pimples arising in different parts of the face, but chiefly in the alæ of the nose. The cure of these ought only to be attempted by evacuations and cleansers of the blood.

**GRUBBING**, in agriculture, the digging or pulling up the stubs and roots of trees.

When the roots are large, this is a very troublesome and laborious task; but Mr. Mortimer has shewn how it may be accomplished so as to save great expence by a very simple and easy method. He proposes a strong iron-hook to be made, about two feet four inches long, with a large iron-ring fastened to the upper part of it. See plate CXXI. fig 2. This hook must be put into a hole on the side of the root, to which it must be fastened, and a lever being put into the ring, two or three

three men, by means of this lever, may wring out the root, and twist the sap-roots asunder. Stubs of trees may also be taken up with the same hook, in which work it will save a great deal of labour, though not so much as in the other, because the stubs must be first cleft with wedges before the hook can enter the sides of them, to wrench them out by pieces.

**GRUBBING a cock**, with cock-fighters, a term used for cutting off the feathers under his wings.

This is a thing not allowed by cockpit-law, nor is any one permitted to cut off the feathers in any handling place.

**GRUBENHAGEN**, a town and castle of lower Saxony and dutchy of Brunfwic, remarkable for its mines of silver, copper, iron, and lead: east lon.  $9^{\circ} 36'$ , and north lat.  $51^{\circ} 45'$ .

**GRUINALIS**, in botany, the same with geranium. See the article **GERANIUM**.

**GRUME**, *grumus*, in medicine, denotes a concreted clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscosity, and stagnating in the capillary vessels, produces several disorders.

**GRUMOSE ROOTS**, among herbalists, such as are knotty, and fastened to one head, like those of celandine and anemones. See the article **ROOT**.

**GRUNDULUS**, the **GROUNDLING**. See the article **GROUNDLING**.

**GRUS**, the **CRANE**, in ichthyology, a bird of the ardea or heron-kind. See the article **ARDEA**.

The common crane, or ardea with the top of the head papillose, is a large, stately, and beautiful bird, with a very long neck. The indian crane, with the whole upper part of the head papillose, is smaller than the european or common kind, but otherwise very like it. See the article **CRANE**.

**GRUS**, in antiquity, a kind of dance which the young Athenians performed every year at Delphos, about the altar of Apollo, on the day of Delia.

The steps and figures of this dance, which were intricate and running one into another, were designed to express the turnings and windings of the labyrinth in which Theseus killed the minotaur.

**GRY**, a measure containing one tenth of a line. See the article **LINE**.

**GRYGALLUS**, in ornithology, a name given to the urogallus, or tetrao. See the article **TETRAO**.

**GRYLLO-TALPA**, the **MOLE-CRICKET**, a species of gryllus, with the anterior feet palmated. See the next article.

This is the largest of all the european winged insects, being two inches and a half in length, and three quarters of an inch in diameter. Its colour is a dusky-brown, and there grow from the extremity of the tail, on each side, two hairy bodies resembling in some degree the tail of a mouse. See plate **CXXI**. fig. 4.

**GRYLLUS**, in zoology, the name of the cricket and locust-kind, which, together with the grasshoppers, make only one genus of insects, the characters of which are these: the antennæ are setaceous; the exterior wings are membranaceous, narrow, and have much of the appearance of the wings of some of the fly-kind; the thorax is compressed and angulated; and the legs are formed for leaping. See the articles **LOCUST** and **GRYLLO-TALPA**.

**GRYLLUS**, in ichthyology, a name given to two distinct fishes, the conger-eel and ophidion. See the articles **CONGER** and **OPHIDION**.

**GRYPHITES**, in natural history, in english **CROW'S STONE**, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward.

They are frequently found in our gravel or clay-pits, in many counties. There are three or four distinct species of them; some are extremely rounded and convex on the back, others less so; and the plates of which they are composed, are in some smaller and thinner, in others thicker and larger, in specimens of the same bigness. See plate **CXXIV**. fig 2.

**GRYPHUS**, a kind of ænigma. See the article **ÆNIGMA**.

**GUADALAJARA**, a city of Mexico, in north America, and the capital of Guadalajara, or New Galicia: west lon.  $108^{\circ}$ , and north lat.  $20^{\circ} 45'$ .

**GUADALAVIAR**, a river of Spain, which rises in the province of Arragon, and runs south-east through the province of Valencia, falling into the Mediterranean a little below the city of Valencia.

**GUADALAXARA**, a city of Spain, in the province of New Castile, twenty-eight miles north-west of Madrid: west long.  $3^{\circ} 50'$ , and north lat.  $40^{\circ} 40'$ .

**GUADALUPE**, one of the largest of the Caribbee-islands, eighty miles north of

Martinico, subject to France : west lon. 61°, and north lat. 16° 30'.

**GUADARAMA**, a town of New Castile, in Spain, twenty-three miles north-west of Madrid : west lon. 4° 45', and north lat. 40° 45'.

**GUADIANA**, a river of Spain, which rises in the middle of New Castile, and running through Estremadura, enters Portugal; where passing through the provinces of Alentejo and Algarva, it discharges itself into the Atlantic ocean.

**GUADILBARBAR**, a river of Africa, which rises in the mountains of Atlas, runs through the kingdom of Tunis, and falls into the Mediterranean sea near Bona.

**GUADILQUIVIR**, a river of Spain, which rises in the mountains of Segura, in New Castile, runs the whole length of Andalusia, and passing by Cordova and Seville, falls into the Atlantic ocean at St. Lucar.

**GUADIX**, a city of Spain, in the province of Granada : west long. 3°, and north lat. 37° 15'.

**GUADUM**, in botany, a name sometimes given to isatis or woad. See **ISATIS**. The same term is also used for the genistella tinctoria, or dyer's weed.

**GUAJAC**, *guajacum*, in botany and medicine. See the article **GUAJACUM**.

**GUAJACANA**, in botany, a plant otherwise called diospyros.

**GUAJACUJA**, the same with the lophius. See the article **LOPHIUS**.

**GUAJACUM**, or **GUAIACUM**, in botany, a genus of the *decandria-monogynia* class of plants, the flower of which consists of five ovato-oblong patent petals, whereof the superior ones are least; the fruit is a roundish obliquely acuminate drupe, furrowed on one side; and the seeds are oval nuts, covered with pulp. The wood of guajacum is extremely hard and solid, of a dense, compact texture, and remarkably heavy; it consists of two parts, a central matter, or heart, and an exterior one, or blea : the central part is extremely hard and ponderous, and is of a greenish colour, or else it is variegated with a pale or whitish colour, a dusky green, and a brownish with the black : the external part is of the colour of box-wood; but when we see the fragments of the branches of the tree entire, it is covered with a thin strong bark. The wood is of a fragrant smell, and of an aromatic and pungent, but somewhat bitterish taste.

Guaiacum is attenuant and aperient : it promotes the discharges by sweat and urine, and strengthens the stomach and the other viscera. It is an excellent medicine in obstructions of the liver and spleen, in the jaundice, dropsy, and many other chronic cases, and gives relief in the rheumatism, and even in the gout.

The bark is a more powerful attenuant than the wood, but it is less proper for people of a feverish disposition. Neither of them are given much in substance, the usual way being in decoction with saffras, and other medicines of the same intention.

Besides the wood and the bark, we have a resin of it, under the improper name of gum-guaiacum. This is a solid but very friable substance, much resembling common resin, except in colour, it being of a dusky greenish hue, and sometimes, though less frequently, of a reddish colour. It is very acrid and pungent to the taste, and when burnt, smells like guaiacum wood. It is given in the same cases with the wood, and the famous balsamum polychrestum is made of it.

**GUAJAVA**, in botany, the name by which Tournefort calls the psidium of Linnæus. See the article **PSIDIUM**.

**GUAINUMBI**, the HUMMING-BIRD. See the article **HUMMING-BIRD**.

**GALEOR**, a city of the hither India, and the capital of the province of Galeor, situated forty miles south of Agra : east lon. 79°, and north lat. 26°.

**GUAM**, the chief of the Ladrone-islands, in the Pacific ocean : east lon. 140°, and north lat. 14°.

**GUAN**, or **QUAN**, an american bird, a little bigger than the common hen. In shape it somewhat resembles a turkey, to which Mr. Edwards takes it to be near of kin. The top of the head is covered with black feathers, which it can erect into a crest : the upper part of the body is of a dark colour, and the neck, breast, and belly are of the same colour, only spotted with white. See plate CX. fig. 3.

**GUANABANUS**, in botany, the name by which Plumier calls the anona. See the article **ANONA**.

**GUANIHANI**, or **ST. SALVADOR**, now called Catt-island, one of the Bahama-islands in the Atlantic ocean, in north America : west lon. 76°, north lat. 24°.

**GUANUCO**, a town of Peru, in south America, one hundred and eighty miles north east

north-east of Lima: west lon.  $75^{\circ} 15'$ . and south lat.  $10^{\circ}$ .

**GUAPERVA**, in ichthyology, a name given to several species of balistes. See the article **BALISTES**.

**GUARANTY**, in matters of polity, the engagement of mediatorial or neutral states, whereby they plight their faith, that certain treaties shall be inviolably observed, or that they will make war against the aggressor.

**GUARANTY**, or **WARRANTY**, in law. See the article **WARRANTY**.

**GUARD**, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprize; or the care, precaution, and attention we make use of, to prevent any thing happening contrary to our intention or inclinations.

**GUARD**, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy.

In a garrison the guards are relieved every day, and it comes to every soldier's turn once in three days, so that they have two nights in bed, and one upon guard. To be upon guard, to mount the guard, to dismount the guard, to relieve the guard, to change the guard, the officer of the guard, or the serjeant of the guard, are words often used, and well understood.

**Advanced GUARD**, is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger.

When an army is upon the march, the grand-guards which should mount that day, serve as an advanced-guard to the army: in small parties, six or eight horse are sufficient, and these are not to go above four or five hundred yards before the party.

An advanced-guard is also a small body of twelve or sixteen horse, under a corporal, or quarter-master, posted before the grand-guard of a camp.

**Artillery-GUARD**, is a detachment from the army, to secure the artillery: their corps de garde is in the front, and their centries round the park. This is a forty-eight hours guard: and upon a march, they go in the front and rear of the artillery, and must be sure to leave nothing behind; if a gun or waggon break down, the captain is to leave a part of his guard to assist the gunners and matrosses in getting it up again.

**Corps de GARDE**, are soldiers entrusted with the guard of a post, under the command of one or more officers.

**Counter-GUARD**, in fortification. See the article **COUNTER-GUARD**.

**Forrage-GUARD**, a detachment sent out to secure the forragers, which are posted at all places, where either the enemy's party may come to disturb the forragers; or where they may be spread too near the enemy, so as to be in danger of being taken. They consist both of horse and foot, and must stay at their posts till the forragers all come off the ground.

**Grand-GUARD**, three or four squadrons of horse, commanded by a field-officer, posted at about a mile and a half from the camp, on the right and left wings, towards the enemy, for the security of the camp.

**Main-GUARD**, that from whence all the other guards are detached.

Those who are to mount the guard, meet at their respective captain's quarters, and go from thence to the parade; where, after the whole guard is drawn up, the final guards are detached for the posts and magazines; and then the subaltern officers throw lots for their guards, and are commanded by the captain of the main-guard.

**Picquet-GUARD**, a good number of horse and foot always in readiness in case of an alarm: the horse are all the time saddled, and the riders booted. The foot draw up at the head of the battalion, at the beating of the tattoo; but afterwards return to their tents, where they hold themselves in readiness to march, upon any sudden alarm. This guard is to make resistance, in case of an attack, till the army can get ready.

**Quarter-GUARD**, a small guard, commanded by a subaltern officer, posted by each battalion, about an hundred yards before the front of the regiment.

**Rear-GUARD**, that part of the army which brings up the rear, which is generally the old grand-guards of the camp. The rear-guard of a party is six or eight horse, that march about four or five hundred paces behind the party. The advanced-guard of a party on its going out, make the rear guard on its return.

**Standard-GUARD**, a small guard, under a corporal, out of each regiment of horse, and placed on foot, in the front of each regiment.

**Van-GUARD**, that part of the army which marches in the front.

**GUARD** is more particularly understood of a soldier detached from a company or corps, to protect, detain, or secure any person, &c.

**GUARDS** are also troops kept to guard the king's person, called also royal-guards, life-guards, gardes du corps, &c. These are distinguished into horse, foot, grenadiers, and yeomen.

The english horse-guards are distinguished by troops, and the foot-guards by regiments.

*Yeomen of the GUARDS.* See YEOMAN.

*The french GUARDS* are divided into those within, and those without the palace; the first consists of the gardes du corps, or body-guard, which consists of four companies of horse, the first of which companies was antiently Scotch, and still retains the name, though it now consists wholly of Frenchmen. The guards without, are the gens d'armes, light-horse, musketeers, and two other regiments, the one of which is French and the other Swiss. See GENDARMES.

**GUARD**, in fencing, is a posture proper to defend the body from an enemy's sword.

There are four general guards of the sword; to form a perfect idea of which, we must suppose a circle drawn on a wall, and divided into four cardinal points, viz. top and bottom, right and left. When the point of the sword is directed to the bottom of the circle, with the hilt opposite to its top, the body inclining very forward, this is called the prime or first guard. The second guard, by many improperly called the tierce, is when the point is directed to the right or second point of the same circle, with the hilt of the sword turned to the left, and the body proportionably raised. The tierce, or third guard, is when the point of the sword is raised to the uppermost part of the same circle; in which case the body, the arm, and the sword, are in their natural position, and in the mean of the extremes of their motion. The quart, or fourth guard, is when the point of the sword is directed to the fourth point of the circle, descending to the right as far as one fourth of the tierce, with the outward part of the arm and the flat of the sword turned towards the ground, and the body out of the line to the right, and the hilt of the sword towards the line to the left. There is also a quint, or fifth guard, which is only the return of the point of the sword to the right, after tra-

versing the circle to the point of the prime, from whence it had departed, with a different disposition of the body, arm, and sword. The common center of all those motions ought to be in the shoulder.

In all these kinds of guards, there are the high-advanced, high-retired, and high-intermediate guard, when disposed before the upper part of the body, either with the arm quite extended, quite withdrawn, or in a mean state. The mean-advanced guard, or simply mean guard, is when the sword is placed before the middle part of the body. The low-advanced, retired or intermediate guards, are those where the arm and sword are advanced, withdrawn, or between the two extremes, before the lower part of the body.

**GUARDANT**, or **GARDANT**, in heraldry. See the article **GARDANT**.

**GUARDIAN**, in law, a person who has the charge of any thing; but more commonly it signifies one who has the custody and education of such persons as have not sufficient discretion to take care of themselves and their own affairs, as children and idiots.

There are several sorts of these guardians at common law, viz. guardians by nature, who are the father and mother; guardians in socage, being the next of blood; and guardians by reason of nurture, which is when the father by will appoints a person to be the guardian of his child. The statute ordains, that a father, by deed in his life-time, or by his will, may dispose of the custody of his child, under twenty-one years of age and not married, during the child's minority, to any persons who are not popish recusants, as he shall think fit; which guardians may bring actions of trespass, &c. against any unlawful takers away of such child or children, and take possession of their lands, &c. If the father appoints no guardians to his child, the ordinary, or spiritual court have power to order one for the goods and personal estate only, until the infant is of the age of fourteen; but as to his lands, there shall be a guardian in socage, &c. This guardianship in socage continues till the minor is fourteen years of age, at which time he may choose his guardian before a judge, at his chambers, or in court, or chancery: likewise after the infant comes to that age, he may sue his guardian in socage, to account as bailiff.

The business of guardians is to take the profits of the minor's lands to his use, and

and to account for the same : they ought to sell all moveables within a reasonable time, and to convert them into land or money, except the minor is near of age, and may want such things himself ; and they are to pay interest for the money in their hands, that might have been so placed out ; in which case it will be presumed that the guardians made use of it themselves. They are to sustain the land of the heir, without making destruction of any thing thereon, and to keep it safely for him : if they commit waste on the lands, it is a forfeiture of the guardianship. 3 Edw. I. And where persons, as guardians, hold over any land, without the consent of the person who is next intitled, they shall be adjudged trespassers, and shall be accountable. 6 Annæ, cap. xviii.

**GUARDIANS D'EGLISE**, are churchwardens or officers chosen in every parish, to have the care and custody of the goods of the church.

**GUARDIANS of the peace**, are those who have the keeping of the peace.

**GUARDIAN, or WARDEN of the cinqueports**, is an officer who has the jurisdiction of the cinqueports, with all the power which the admiral of England has in other places.

**GUARDIAN of the spiritualities**, the person to whom the spiritual jurisdiction of any diocese is committed, during the time the see is vacant.

A guardian of the spiritualities may likewise be either such in law, as the archbishop is of any diocese within his province ; or by delegation, as he whom the archbishop, or vicar-general for the time, appoints. Any such guardian has power to hold courts, grant licences, dispensations, probates of wills, &c.

**GUAPERVA**, in ichthyology, a species of chætodon. See **CHÆTODON**.

**GUAZUMA**, in botany, the same with the cacao or theobroma. See the article **THEOBROMA**.

**GUBEN**, a town of Germany, in the circle of upper Saxony : east lon. 15°, and north lat. 51° 50'.

**GUDGEON, gobius**, in ichthyology. See the article **GOBIVUS**.

**GUDGEONS**, in a ship, are the eyes drove into the stern-post, into which the pintles of the rudder go, to hang it. See plate

[ CXXI. fig. 3.

The stems of the gudgeons are barred, to prevent their being drawn out.

**GUELPHS and GIBELINS**. See the article **GIBELINS**.

**GUENGA**, a great river of the hither India, which rising in the mountains of Balagate, runs north-east, and falls into the west branch of the river Ganges, in Bengal.

**GUERET**, a town of France, in the province of Lioinois : east lon. 2°, and north lat. 46° 5'.

**GUERITE**, a small tower of wood or stone, generally placed on the point of a bastion, or on the angles of the shoulder, to hold a centinel, who is to take care of the foss, and to watch, in order to prevent a surprize.

**GUERNSEY, or GARNSEY**, an island in the english channel, on the coast of Normandy, fifty-eight miles south of Portland, in Dorsetshire, and twenty-two west of cape la Hogue, in Normandy ; about ten miles long and as many broad, containing ten parishes. The natives, who speak french, are still governed by the norman laws, but are subject to England.

**GUIAQUIL**, a city and port-town of Peru, situated near the Pacific ocean : west lon. 80°, and south lat. 3°.

**GUIARA**, a port-town on the Caracooa-coast, in terra firma, in south America : west longitude 66°, and north latitude 10° 35'.

**GUIDON**, a sort of flag or standard, borne by the king's life-guards ; being broad at one extreme, and almost pointed at the other, and slit or divided into two.

**GUIDON** also denotes the officer who bears the guidon. He is the same in the horse-guards that the ensign is in the foot. The guidon of a troop of horse takes place next below a cornet.

**GUIDONIA**, in botany, the name given by Plumier to the famyda of Linnæus.

**GUIENNE**, a province of France, bounded by the Orleansois on the north, by Gascony, from which it is separated by the river Garonne, on the south, by Languedoc on the east, and by the bay of Biscay on the west.

**GUILANDINA, BONDUCH**, in botany, a genus of the *decandria-monogynia* class of plants, the flower of which consists of five lanceolate and sessile petals : the fruit is a rhomboidal pod, containing only one cell, in which are included numerous osseous seeds, of a globose-compressed figure. For the virtue of these seeds, see the article **BONDUCH**.

**GUILD**,

**GUILD**, or **GILD**, a fraternity or company. As to the original of these guilds or companies, it was a law among the Saxons that every freeman of fourteen years of age, should find sureties to keep the peace, or be committed; upon which the neighbours entered into an association, and became bound for each other, either to produce him who committed any offence, or to make satisfaction to the injured party; in order to which they raised a sum among themselves, which they put into a common stock; out of which they, upon occasion, made a pecuniary compensation according to the quality of the offence committed. These guilds are now companies, joined together with laws and orders made by themselves, by the licence of the prince.

**GUILD**, **GILD**, or **GELD**, is also used among our antient writers for a compensation, or mulct, for a fault committed.

**GUILD-HALL**, the chief hall of the city of London, for holding of courts, and for the meeting of the lord-mayor and commonalty, in order to make laws and ordinances for the welfare and regulation of the city.

**GUILD-RENTS**, are rents paid to the crown by any guild or fraternity: or those that formerly belonged to religious houses, and came to the crown at the general dissolution of monasteries.

**GUILDFORD**, or **GULDEFORD**, a borough-town of Surry, situated on the river Wye, thirty miles south-west of London.

It sends two members to parliament.

**GUILLESTRE**, a city of France, in the province of Dauphiny: east lon.  $6^{\circ} 20'$ , and north lat.  $44^{\circ} 45'$ .

**GUINEA**, a large country of Africa, situated between  $15^{\circ}$  east and  $15^{\circ}$  west longitude, and between  $4^{\circ}$  and  $10^{\circ}$  north latitude.

The British, Dutch, French, and other nations, have forts and factories on this coast.

**GUINEA** is also the name of a british gold-coin. See the article **COIN**.

**GUINEA-PIG**, in zoology, a quadruped of the mouse or rat-kind, with a variegated body, resembling, in some measure, a young pig, whence the name. It is considerably larger than the rat, but less than the rabbit. See plate CXXI. fig. 5.

**GUINEA-WORM**, *dracunculus*, in zoology and medicine. See **DRACUNCULI**.

**GUIPUSCOA**, the north-east division of the province of Biscay, in Spain, situ-

ated on the confines of Navarre in France.

**GUIRA**, or **GUARA GUAINUMBI**, in ornithology, the brasilian name of the green iipida, with a crested head and very long tail.

**GUISE**, a town of France, in the province of Picardy, situated on the river Oyse: east lon.  $3^{\circ} 36'$  and north lat.  $49^{\circ} 55'$ .

**GUITAR**, or **GUITARRA**, a musical instrument of the string-kind, with five double rows of strings, of which those that are bass, are in the middle, unless it be for the burden, an octave lower than the fourth.

This instrument was first used in Spain, and by the Italians. It has the particular denomination of *spagnuola* given it; and is found in Italy and other countries, but more frequently in Spain.

**GULA**, in anatomy, the same with the oesophagus. See **OESOPHAGUS**.

**GULA**, or **GOLA**, in architecture, a wavy member, the contour of which resembles the letter S, which the Greeks call *cymatium*, and our architects an *ogee*. See the article **CYMATIUM** and **OGE**. This member is of two kinds, *recta* and *inversa*. The first and principal has its cavities or hollows above, and convexities below. This always makes the top of the corona of the cornice, jetting over the drip of the cornice, like a wave ready to fall. It is sometimes absolutely the entablature, as being the first or uppermost member of it.

The second, being also called *gula inversa*, as the first is called *gula recta*, is exactly the reverse of the former, the cavity or hollowness of it being at the bottom, so that with respect to the former it appears inverted. This is used in the architrave, and sometimes in the cornice along with the former, only separated by a *reglet*.

**GULES**, in heraldry, signifies the colour red, which is expressed in engraving by perpendicular lines falling from the top of the escutcheon to the bottom. See plate CXXI. fig. 6.

It is the first of all colours in armory, and was formerly prohibited to be worn by any person in his coat-armour, unless he were a prince, or had a permission from him. This colour is a symbol of charity, valour, generosity, and represents blood-colour, and true scarlet.

The Romans, according to Spelman, painted the bodies of their gods, and generals that triumphed, with vermilion;

*Fig. 1.*

GUSSET.

*Fig. 8. GERANIUM CRANE'S BILL.*

and under the consuls, their soldiers were clad in red, hence called *ruffati*. And we are told that the Lacedemonians wore scarlet, to prevent seeing the blood issue from their wounds. Those who bear this colour, are obliged to relieve such as are in danger of being oppressed by injustice.

**GULICK**, the same with *Juliers*. See the article *JULIERS*.

**GULL**, the english name of a genus of birds, called by authors *larus*. See the article *LARUS*.

**GULLET**, in anatomy, the english name of the *oesophagus*. See *OESOPHAGUS*.

**GULPH**, or *GULF*, in geography, a part of the sea, almost surrounded by land, as the gulph of Mexico, gulph of Venice, of Lyons, &c.

A gulph is strictly distinguished from a sea, in that the latter is larger. See the article *SEA*.

It differs from a bay, in being greater than it. See the article *BAY*.

Some will have it essential to a gulph, to run into the land through a streight or narrow passage. It is observed that the sea is always most dangerous near gulphs, by reason of the currents being penned up by the shores.

**GUM**, in pharmacy, a concreted vegetable juice, which transudes through the bark of certain trees, and hardens upon the surface.

The chemists allow only those to be properly gums, which are dissolvable in water; those which are only dissolvable in spirits, they call resins; and those of a middle nature, gum-resins. Geoffroy says, that gums are something between acid and oil; being an acid salt so fixed in earth, as that the greatest part of it is changed to an alkali, the other into oil; so that the mixture arising from thence is an oily salt resembling the saponaceous concretes of the chemists, made of oil of olives, and a lixivium of tartar; or the mucilaginous bodies formed of spirit of wine, and the volatile spirit of urine. The bodies of this class, Dr. Hill observes, if we were to allow all to be so which are generally received as such, and called by the name gum, would appear very numerous: but, on a strict enquiry, the far greater part of them appear to be properly either of the gum-resin, or of the absolute resin-class, when all that are thus improperly called gums are separated and placed in their proper classes. See the article *RESIN*,

The bodies truly belonging to this, are, by that author, reduced to so small a number as four; these are, 1. Gum arabic. 2. Gum seneca. 3. Gum tragacanth. 4. Manna.

**GUM ARABIC**. See *Gum ARABIC*.

**GUM SENECA**, or *SENEGA*, as it is commonly written, is a gum extremely resembling gum arabic. It it brought to us from the country through which the river Senega runs, in loose or single drops, but these are much larger than those of the gum arabic usually are; sometimes it is of the bigness of an egg, and sometimes much larger: the surface is very rough, or wrinkled, and appears much less bright than the inner substance, where the masses are broken. It has no smell, and scarce any taste. We are not acquainted with the tree which produces it. The virtues of it are the same with the gum arabic; but it is rarely used in medicine, unless as mixed with the gum arabic: the dyers and other artificers consume the great quantities of it that are annually imported here. The negroes dissolve it in milk, and in that state make it a principal ingredient in many of their dishes; and often feed on it thus alone.

**GUM TRAGACANTH**. See the article *TRAGACANTH*.

**GUM MANNA**. See the article *MANNA*. Other substances known by the name of gums, are as follow.

**GUM ALOES**, a preparation of aloes, as set down in the London Dispensatory. See the article *ALOES*.

It is made thus: Take of succotrine aloes, four ounces; of water, a quart: boil the aloes till it is dissolved as much as may be; and set all by for a night: the resin will be precipitated to the bottom of the vessel; the liquor, poured off or strained, being evaporated, will leave the gum. The intention of this separation of the resin, is to procure, in the gum, a medicine less purgative, but more agreeable to the stomach, than the crude aloes.

**GUM AMMONIAC**. See the article *Gum AMMONIAC*.

**GUM ANIME**. See *Gum ANIME*.

**GUM ELEMI**. See the article *ELEMI*.

**GUM GUAIACUM**. See *GUAIACUM*.

**GUM LACCA**. See the article *LACCA*.

It may be observed in general, that gums and inspissated juices are the better, the freer they are from mixture and dross; but that they are seldom fit for use before straining,

**GUM**, among gardeners, a kind of gangrene incident to fruit-trees of the stone-kind, arising from a corruption of the sap, which, by its viscosity, not being able to make its way through the fibres of the tree, is, by the protrusion of other juice, made to extravasate and ouze out upon the bark.

When the distemper surrounds the branch, it admits of no remedy, but when only on one part of a bough, it should be taken off to the quick, and some cow-dung clapped on the wound, covered over with a linnen-cloth, and tied down. M. Quintinie directs to cut off the morbid branch two or three inches below the part affected.

**GUMS**, *gingiva*, in anatomy. See the article GINGIVÆ.

**GUN**, a fire-arm, or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, through a cylindrical barrel, by means of gun-powder. See the article GUN-POWDER.

Gun is a general name, under which are included divers or even most species of fire-arms. They may be divided into great and small.

Great guns, called also by the general name cannons, make what we also call ordnance, or artillery; under which come the several sorts of cannons, as cannon-royal, demi-cannon, &c. Culverins, demi-culverins, fakers, minions, falcons, &c. See CANNON, CULVERIN, &c. as also ORDNANCE and ARTILLERY.

Small guns include musquets, muskettoons, carabines, blunderbusses, fowling-pieces, &c. See MUSQUET, &c.

Pistols and mortars are almost the only sort of regular weapons, charged with gun-powder, that are excepted from the denomination of guns. See the articles PISTOL and MORTAR.

We have given the proportions and uses of these fire-arms, under their respective articles; but that their parts may be the more distinctly comprehended, there is delineated in the Plate of Gunnery (CXXII) fig. 1. a view of the outside of a piece of ordnance, with the names of its parts; fig. 2. *ibid.* shews the chase or bore, and the thickness of the metal; fig. 4. is a cannon mounted on its carriage; and fig. 3. is a mortar mounted on its carriage.

The advantage of large guns, or cannons, over those of a smaller bore, is generally acknowledged. Robins observes that this advantage arises from several circumstances, particularly in distant can-

nonading. The distance to which larger bullets fly with the same proportion of powder, exceeds the flight of the smaller ones, almost in proportion to their diameters; so that a thirty-two pound shot, for instance, being somewhat more than six inches in diameter, and a nine-pound shot but four inches, the thirty-two pound shot will fly near half as far again as that of nine pound, if both pieces are so elevated as to range to the farthest distance possible. Another and more important advantage of heavy bullets is, that with the same velocity they break holes in all solid bodies, in a greater proportion than their weight. Finally, large cannons, by carrying the weight of their bullet in grape or lead-shot, may annoy the enemy more effectually than could be done by ten times the number of small pieces. See the article GUNNERY.

The author here quoted, has proposed to change the fabric of all the pieces employed in the british navy, from the twenty-four pounders downwards, so that they may have the same or less weight, but a larger bore. He thinks the thirty-two pounders in present use would be proper models for this purpose. These being of fifty-two or fifty-three hundred weight, have somewhat less than a hundred and two thirds for each pound of bullet. And that this proportion would answer in smaller pieces, in point of strength, seems clear from these considerations: 1. That the strength of iron, or any other metal, is in proportion to its substance. 2. That the lesser quantity of powder fired in a space it fills, has proportionably less force than a larger quantity; so that if two pieces, a large and a small one, be made in the same proportion to their respective bullets, and fired with a proportionable quantity of powder, the larger piece will be more strained, will heat more, and recoil more than the smaller.

On this scheme our present twenty-four pounders will be eased of six or eight hundred weight of useless metal; and some pieces of a less calibre, as nine and six pounders, would be sometimes eased by fourteen hundred: hence much larger guns, of the same weight, might be borne. Thus, instead of six, nine, twelve, and eighteen pounders, our ships might carry twelve, eighteen, and twenty-four pounders: guns would be kept cooler and quieter, and would be of more service, in many respects, if their usual charge of powder were diminished.

**GUN** is also a name given to an instrument used by miners in cleaving rocks with gun-powder. It is an iron cylinder of an inch and a half thick, and about six inches long; and having a flat side to receive the side of a wedge; and a hole drilled through it to communicate with the inside of the hole in the rock: this hole is made about eight inches deep, and in the bottom of it is put about two or three ounces of gun-powder: then this gun is driven forcibly in, so as to fill up the hole, and the wedge is driven in on its flat side to secure it.

The priming at the hole is then fired by a train, and the orifice being so well stopped by this gun, the force of the powder is determined to the circumadjacent parts of the rock, which it splits.

See the article **MINING**.

**GUN-ROOM**, in a ship, the apartment under the great cabin, where the master-gunner and his crew rendezvous, get ready their cartridges, &c. and do all things belonging to their business.

**GUNELLUS**, in ichthyology, a species of blennius, called also the butter-fish, with about ten black spots beside the back-fin.

**GUNNER**, an officer appointed for the service of the cannon; or one skilled to fire the guns.

In the Tower of London, and other garrisons, as well as in the field, this officer carries a field staff, and a large powder horn in a string over his left shoulder: he marches by the guns, and when there is any apprehension of danger, his field staff is armed with match: his business is to lay the gun to pass, and to help to load and traverse her.

**GUNNER** of a ship, or master gunner, has the charge of all the ordnance the ship carries, to see that they be serviceably mounted, and sufficiently supplied with sponges, ladles, and rammers; that in foul weather they be traversed within board, especially those of the lower tire, and that the parts be shut, and caulked up; and that at all times they may be well lashed, and made fast, lest any of them break loose, to the imminent danger of foundering the ship. In the time of an engagement, the gunner is to see that every piece be sufficiently manned: he is answerable to give an account of all his charge upon demand. He has a mate and quarter-gunners for his assistance.

**Master-GUNNER**, a patent-officer of the ordnance, who is appointed to teach all

such as learn the art of gunnery, and to certify to the master-general the ability of any person recommended to be one of the king's gunners. To every scholar he administers an oath, not to serve, without leave, any other prince or state; or teach any one the art of gunnery, but such as have taken the said oath.

**GUNNER'S LEVEL**. See the article **LEVEL**.

**GUNNER'S TACKLE**. See **TACKLE**.

**GUNNERY**, is the art of determining the the course and directing the motion of bodies shot from artillery, or other war-like engines.

The great importance of this art is the reason it is distinguished from the doctrine of projectiles in general: for it is no more than an application of those laws which all bodies observe when cast into the air, to such as are put in motion by the explosion of guns or other engines of that sort. And it is the same thing whether it is treated in the manner of projectiles in general, or of such only as belong to gunnery; for from the moment the force is impressed, all distinction with regard to the power which put the body first in motion is lost, and it can only be considered as a simple projectile. See the article **PROJECTILES**.

**Prob. I.** The impetus of a ball, and the horizontal distance of an object aimed at, with its perpendicular height or depression, if thrown on ascents or descents, being given, to determine the direction of that ball.

From the point of projection A (plate CXXII. fig. 5, 6, 7, 8) draw Am representing the horizontal distance, and Bm the perpendicular height of the object aimed at: Bisect Am in H, and AH in f; on H and f erect HT, fF perpendicular to the horizon, and bisecting AB the oblique distance or inclined plane in D, and AD in F. On A raise the impetus AM at right angles with the horizon, and bisect it perpendicularly in c, with the line GG. Let the line AC be normal to the plane of projection AB, and cutting GG in C; from C as center, with the radius CA, describe the circle AGM cutting if possible the line FS in S, s, points equally distant from G; lines drawn from A through S, s will be the tangents or directions required.

Continue A S, A s to T, t; bisect DT, Dt, in V, v; and draw lines from M to S, s; then the  $\angle ASF = \angle MAS = \angle AMs = \angle sAF$ ; and for the same reason  $\angle A s F = \angle MAs = \angle AMS =$

$\angle SAF$ ; wherefore the triangles  $MAS$ ,  $SAF$ ,  $FAF$  are similar, and  $AM : AS :: AS : sF = tv$ ; consequently  $AT$  is a tangent of the curve passing through the points  $A$ ,  $v$ , and  $B$ ; because  $tv = vD$ ,  $AD$  is an ordinate to the diameter  $TH$ , and where produced must meet the curve in  $B$ .

In horizontal cases (fig. 7.)  $v$  is the highest point of the curve, because the diameter  $TVH$  is perpendicular to the horizon.

When the mark can be hit with two directions (the triangles  $SAM$ ,  $sAF$  being similar) the angle which the lowest direction makes with the plane of projection is equal to that which the highest makes with the perpendicular  $AM$ , or  $\angle sAF = \angle SAM$ . And the angle  $SA s$ , comprehended between the lines of direction, is equal to the angle  $SCG$ , and is measured by the arch  $SG$ .

When the points  $S$ ,  $s$  coincide with  $G$ , or when the directions  $AS$ ,  $As$  become  $AG$ ; (fig. 8.)  $AB$  will be the greatest distance that can be reached with the same impetus on that plane; because  $SF$  coinciding with  $Gg$  the tangent of the circle at  $G$ , will cut off  $Ag$  a fourth part of the greatest amplitude on the plane  $AB$ . The rectangular triangles  $mAB$ ,  $cAC$  are similar, because the angle of obliquity  $mAB = cAC$ ; wherefore  $mA : mB :: \frac{1}{2} \text{ impetus} : cC$ , and  $mA : AB :: AC : AC$ .

*Horizontal projections (ibid. fig. 7, 8.)*

When the impetus is greater than half the amplitude, there are two directions,  $TAH$ , and  $tAH$  for that amplitude; when equal to it, only one; and when less, none at all; and conversely. For in the first case the line  $FS$  cuts the circle in two points  $S$ ,  $s$ , in the second case it only touches it, and in the last it meets not with it at all; and conversely. When there is but one direction for the amplitude  $Am$ , the angle of elevation is  $45^\circ$ ; and when the angle of elevation is of  $45^\circ$   $Am$  is the greatest amplitude for that impetus, and equal to twice the impetus. The impetus remaining the same, the amplitudes are in proportion to one another as the sines of double the angles of elevation, and conversely. For drawing  $sN$  (fig. 7.) parallel and equal to  $AF$  a fourth part of the amplitude, and supposing lines drawn from  $s$  to the points  $C$  and  $M$ , the angle  $ACs = 2 \angle AMs = 2 \angle sAF$ ; therefore  $Ns$ , the sine of  $ACs$ ,

is the sine of twice the angle  $sAF$ ; half the impetus being radius.

Whence, at the directions of  $45^\circ$  or  $75^\circ$ , the amplitude is equal to the impetus: for from what has been said, half the impetus being radius, a fourth part of the amplitude is the sine of twice the angle of elevation; but the sine of twice  $45^\circ$ , that is, the sine of  $90^\circ$  is always equal to half the radius; or in this case a fourth part of the impetus is equal to a fourth part of the amplitude. From this and the preceding prop. there are two easy practical methods for finding the impetus of any piece of ordnance. The fourth part of the amplitude is a mean proportional between the impetus at the curve's principal vertex and its altitude. For  $MN : Ns :: Ns : NA = sF = vD$ .

The altitudes are as the versed sines of double the angles of elevation, the impetus remaining the same. For making half the impetus radius,  $AN$  the altitude is the versed sine of the angle  $ACs =$  twice  $\angle sAF$ . And also, radius : tangent  $\angle$  elevation ::  $\frac{1}{2}$  amplitude : altitude. that is,  $R : \text{tangent } \angle sAf :: Af : fs = Dv$ .

*Proj. on ascents and descents, fig. 5, 6.*

If the mark can be hit only with one direction  $AG$ , the impetus in ascents will be equal to the sum of half the inclined plane and half the perpendicular height, and in descents it will be equal to their difference; but if the mark can be reached with two directions, the impetus will be greater than that sum or difference. For when  $AG$  is the line of direction, the  $\angle gGA$  being  $= MAG = GAg$ ;  $Gg = Ag$ , and  $gz$  added to or subtracted from both makes  $Gz$  half the impetus equal to the sum or difference of  $Ag$  a fourth part of the inclined plane, and  $gz$  a fourth part of the perpendicular height. In any other direction  $FP$  is greater than  $Fo = AF$ ; and  $Ff$  added to or subtracted from both, makes  $fP$  half the impetus greater than the sum or difference of  $AF$  a fourth part of the inclined plane, and  $Ff$  a fourth part of the perpendicular height. Whence if in ascents the impetus be equal to the sum of half the inclined plane and half the perpendicular height, or if in descents it be equal to their difference, the mark can be reached only with one direction; if the impetus is greater than that sum or difference, it may be hit with two directions;

rections ; and if the impetus is less, the mark can be hit with none at all.

Prob. II. The angles of elevation, the horizontal distance, and perpendicular height being given, to find the impetus.

Fig. 5, 6.

From these data you have the angle of obliquity, and length of the inclined plane ; then as

$As : AM :: S. LAMs : S. LAsM$   
 $:: S. LsAF : S. LMAF$ , and  
 $AF : As :: S. LMA s : S. LMAF$  ;  
 whence by the ratio of equality,  $AF : AM :: S. LsAF \times S. LMA s : S. LMAF \times S. LMAF$ , which gives this rule.

Add the log. of  $AF$  to twice the logarithmic sine of the angle  $MAF$  ; from their sum subtract the logarithmic sines of the angles  $sAF$  and  $MA s$  ; and the remainder will give the logarithm of  $AM$  the impetus.

When the impetus and angles of elevation are given, and the length of the inclined plane is required, this is the rule. Add the log. of  $AM$  to the log. sines of the angles  $sAF$  and  $MA s$  ; from their sum subtract twice the log. sine of  $MAF$ , and the remainder will give the log. of  $AF$  the fourth part of the length of the inclined plane.

If the angle of elevation  $tAH$  and its amplitude  $AB$  (fig. 8.) and any other angle of elevation  $tAH$  is given ; to find the amplitude  $Ab$  for that other angle, the impetus  $AM$  and angle of obliquity  $DAH$  remaining the same.

Describe the circle  $AGM$  take  $AF$  a fourth part of  $AB$ , and  $As$  a fourth part of  $Ab$  : From the points  $F, s$ , draw the lines  $Fs$  and  $fs$  parallel to  $AM$ , and cutting the circle in the points  $s, p$  ; then  
 $AF : AM :: S. LsAF \times S. LMA s : S. LMAF \times S. LMAF$  ; and  $AM : As :: S. LMAF \times S. LMAF : S. LpAs \times S. LpAM$  ; whence by the ratio of equality,

$AF : As :: S. LsAF \times S. LMA s : S. LpAs \times S. LpAM$ , which gives this Rule.

Add the log. of  $AF$  to the log. sines of the angles  $pAs, pAM$  ; from their sum subtract the log. sines of the angles  $sAF, sAM$ , and the remainder will give the log. of  $As$ , a fourth part of the amplitude required.

Prob. III. To find the force or velocity of a ball or projectile at any point of the

curve, having the perpendicular height of that point, and the impetus at the point of projection given. From these two data find out the impetus at that point ; then  $2 \times 16$  feet 1 inch is the velocity acquired by the descent of a body in a second of time ; the square of which ( $4 \times \square 16$  feet 1 inch) is to the square of the velocity required, as 16 feet 1 inch is to the impetus at the point given ; wherefore multiplying that impetus by four times the square of 16 feet 1 inch, and dividing the product by 16 feet 1 inch, the quotient will be the square of the required velocity ; whence this rule. Multiply the impetus by four times 16 feet 1 inch, or 64 feet  $\frac{1}{2}$ , and the square root of the product is the velocity.

Thus suppose the impetus at the point of projection to be 3000, and the perpendicular height of the other point 100 ; the impetus at that point will be 3500. Then 2900 feet multiplied by 64  $\frac{1}{2}$  feet gives 186566 feet, the square of 432 nearly, the space which a body would run through in one second, if it moved uniformly.

And to determine the impetus or height, from which a body must descend, so as at the end of the descent it may acquire a given velocity, this is the rule :

Divide the square of the given velocity (expressed in feet run through in a second) by 64  $\frac{1}{2}$  feet, and the quotient will be the impetus.

11. The duration of a projection made perpendicularly upwards, is to that of a projection in any other direction whose impetus is the same, as the sine complement of the inclination of the plane of projection (which in horizontal projections is radius) is to the sine of the angle contained between the line of direction and that plane.

Draw out  $A t$  (fig. 5.) till it meets  $mB$  continued in  $E$ , the body will reach the mark  $B$  in the same time it would have moved uniformly through the line  $AE$  ; but the time of its fall through  $MA$  the impetus, is to the time of its uniform motion thro'  $AE$ , as twice the impetus is to  $AE$ . And therefore the duration of the perpendicular projection, being double the time of its fall, will be to the time of its uniform motion through  $AE$ , as four times the impetus is to  $AE$  ; or as  $AE$  is to  $EB$  ; that is, as  $A t$  is to  $tD$  ; which is as the sine of the angle  $tDA$  (or  $MAB$  its complement to a semicircle) is to the sine of the angle  $tAD$ .

Hence the time a projection will take to arrive at any point in the curve, may be found from the following data, *viz.* the impetus, the angle of direction, and the inclination of the plane of projection, which in this case is the angle the horizon makes with a line drawn from the point of projection to that point.

Hence also in horizontal cases, the durations of projections in different directions with the same impetus, are as the sines of the angles of elevation. But in ascents or descents their durations are as the sines of the angles which the lines of direction make with the inclined plane. Thus, suppose the impetus of any projection were 4500 feet; then 16 feet  $\frac{1}{2}$  inch : 1" :: 4500 feet : 275" the square of the time a body will take to fall per-

pendicularly thro' 4500 feet, the square root of, which is 16" nearly, and that doubled gives 32" the duration of the projection made perpendicularly upwards. Then to find the duration of a horizontal projection at any elevation, as  $20^{\circ}$ ; say  $R : S. L. 20^{\circ} :: 32'' : \text{Duration}$  of a projection at that elevation with the impetus 4500. Or if with the same impetus a body at the direction of  $35^{\circ}$  was projected on a plane inclined to the horizon  $17^{\circ}$ , say as sine  $73^{\circ} : \text{sine } 18^{\circ} :: 32'' : \text{duration required}$ .

The two following tables, at one view, give all the necessary cases as well for shooting at objects on the plane of the horizon, with proportions for their solutions, as for shooting on ascents and descents.

T A B L E I. For Horizontal Projections. Fig. 7.

	Given.	Required.	Proportions.
1	AM, $A_m$	$tAH$ $Hv$	$2AM : A_m :: R : S. 2L tAH$ $R : T. L tAH :: \frac{A_m}{4} : Hv$
2	AM, $tAH$	$A_m$	$R : S. 2L tAH :: 2AM : A_m$

**GUN-POWDER**, a composition of saltpetre, sulphur, and charcoal, mixed together, and usually granulated; which easily takes fire, and, when fired, rarifies, or expands, with great vehemence, by means of its elastic force.

It is to this powder we owe all the action and effect of guns, ordnance, &c. so that the modern military art, fortification, &c. in great measure depend thereon.

*Method of making GUN-POWDER.* Dr. Shaw's recipe for this purpose is as follows. Take four ounces of refined saltpetre, an ounce of brimstone, and six drams of small coal: reduce these to a fine powder, and continue beating them for some time in a stone mortar, with a wooden pebble, wetting the mixture between whiles with water, so as to form the whole into an uniform paste, which is reduced to grains, by passing it thro' a wire-sieve fit for the purpose; and in this form being carefully dried, it becomes the common gun-powder.

For greater quantities, mills are usually provided, by means of which more work may be performed in one day, than a man can do in a hundred. See *MILL*.

The nitre or saltpetre is refined thus: dissolve four pounds of rough nitre as it

comes to us from the Indies, by boiling it in as much water as will commodiously suffice for that purpose: then let it shoot for two or three days in a covered vessel of earth, with sticks laid across for the crystals to adhere to. These crystals being taken out, are drained and dried in the open air.

In order to reduce this salt to powder, they dissolve a large quantity of it in as small a proportion of water as possible; then keep it constantly stirring over the fire, till the water exhales, and a white, dry powder is left behind. See *NITRE*. In order to purify the brimstone employed, they dissolve it with a very gentle heat; then scum and pass it through a double strainer. If the brimstone should happen to take fire in the melting, they have an iron cover that fits on close to the melting vessel, and damps the flame. The brimstone is judged to be sufficiently refined if it melts without yielding any fetid odour between two hot iron plates into a kind of red substance.

The coal for the making of gun-powder is either that of willow, or hazel, well charred in the usual manner, and reduced to powder. And thus the ingredients are prepared for making this commodity:

modity: but as these ingredients require to be intimately mixed and as there would be danger of their firing if beat in a dry form, the method is to keep them continually moist, either with water, urine, or a solution of sal ammoniac: they continue thus stamping them together for twenty-four hours, after which the mass is fit for coming and drying in the sun, or otherwise, so as sedulously to prevent its firing.

*Rationale of GUN-POWDER.* The explosive force of gun-powder is now a thing commonly known, but the physical reason thereof may not perhaps be hitherto sufficiently understood. In order to explain it, Dr. Shaw proposes the following observations, 1. That salt-petre of itself is not inflammable, and though it melts in the fire, and grows red hot, yet does not explode, unless it comes in contact with the coals. 2. That brimstone easily melts at the fire, and easily catches flame. 3. That powdered charcoal readily takes fire, even from the sparks yielded by a flint and steel. 4. That if nitre be mixed with powdered charcoal, and brought in contact with the fire, it burns and flames. 5. That if sulphur be mixed with powdered charcoal, and applied to the fire, part of the sulphur burns slowly away, but not much of the charcoal; and, 6. That if a lighted coal be applied to a mixture of nitre and sulphur, the sulphur presently takes fire with some degree of explosion; leaving part of the nitre behind, as we see in making the sal prunellæ, and sal polychrestum.

These experiments duly considered, adds the doctor, may give us the chemical cause of the strange explosive force of gun-powder. For each grain of this powder consisting of a certain proportion of sulphur, nitre, and coal, the coal presently takes fire, upon contact of the smallest spark: at which time both the sulphur and the nitre immediately melt, and by means of the coal interposed between them, burst into flame; which, spreading from grain to grain, propagates the same effect almost instantaneously: whence the whole mass of powder comes to be fired; and as nitre contains both a large proportion of air and water, which are now violently rarified by the heat, a kind of fiery explosive blast is thus produced, wherein the nitre stems, by its aqueous and aerial parts, to act as bellows to the other inflammable

bodies, sulphur and coal, to blow them into a flame, and carry off their whole substance in smoke and vapour.

*Different kinds of GUN-POWDER.* The three ingredients of gunpowder are mixed in various proportions according as the powder is intended for musquets, great guns, or mortars; though these proportions seem not to be perfectly adjusted, or settled by competent experience.

Semenowitz for mortars, directs 100 lb of salt-petre, 25 lb of sulphur, and as many of charcoal; for great guns, 100 lb of salt-petre, 15 lb of sulphur, and 18 lb of charcoal; for musquets and pistols 100 lb of salt-petre, 8 lb of sulphur, and 10 lb of charcoal. Miethius extols the proportion of 1 lb of salt-petre to three ounces of charcoal, and two, or two and a quarter of sulphur; than which, he affirms, no gun-powder can possibly be stronger. He adds, that the usual practice of making the gunpowder weaker for mortars than guns, is without any foundation, and renders the expence needlessly much greater: for whereas to load a large mortar, 24 lb of common powder is required, and consequently to load it ten times 240 lb he shews by calculation, that the same effect would be had by 150 lb of the strong powder.

To increase the strength of powder, Dr. Shaw thinks it proper to make the grains considerably large, and to have it well sifted from the small dust. We see that gun-powder, reduced to dust, has little explosive force; but when the grains are large, the flame of one grain has a ready passage to another, so that the whole parcel may thus take fire nearly at the same time, otherwise much force may be lost, or many of the grains go away as shot unfired.

It should also seem that there are other ways of increasing the strength of powder, particularly by the mixture of salt of tartar; but perhaps, adds the last-mentioned author, it were improper to divulge any thing of this kind, as gun-powder seems already sufficiently destructive.

*Method of trying and examining GUN-POWDER.* There are two general methods of examining gun-powder; one with regard to its purity, the other with regard to its strength. Its purity is known by laying two or three little heaps near each other upon white paper, and firing one of them: for if this takes fire readily

readily, and the smoke rises upright, without leaving any dross, or feculent matter behind, and without burning the paper, or firing the other heaps, it is esteemed a sign that the sulphur and nitre were well purified, that the coal was good, and that the three ingredients were thoroughly incorporated together: but if the other heaps also take fire at the same time, 'tis presumed that either common salt was mixed with the nitre, or that the coal was not well ground, or the whole mass not well beat, and mixed together; and if either the nitre or sulphur be not well purified, the paper will be black or spotted.

In order to try the strength of gun-powder, there are two kinds of instruments in use; but neither of them appear more exact than the common method of trying to what distance a certain weight of powder will throw a ball from a musquet.

There has been much talk of a white powder which, if it answered the character given it, might be a dangerous composition: for they pretend that this white powder will throw a ball as far as the black, yet without making a report; but none of the white powder we have seen, says Dr. Shaw, answers to this character; being, as we apprehend, commonly made either with touchwood or camphor, instead of coal.

*Observations on the force of GUN-POWDER.*

Gun-powder fired either in vacuum, or in air, produces by its explosion a permanent elastic fluid. For if a red-hot iron be included in a receiver, after being exhausted, and gun-powder be let fall on the iron, the powder will take fire, and the mercurial gage will suddenly descend upon the explosion; and though it immediately ascends again, yet it will never rise to the height it first stood at, but will continue depressed by a space proportioned to the quantity of gun-powder which was let fall on the iron.

The same production likewise takes place, when gun-powder is fired in the air: for if a small quantity of powder be placed in the upper part of a glass tube, and the lower part of the tube be immersed in water, and the water be made to rise so near the top, that only a small portion of air is left in that part where the gun-powder is placed; if in this situation the communication of the upper part of the tube with the external air be closed, and the powder be fired, which will easily be

done by a burning-glass, the water will in this experiment descend upon the explosion as the quicksilver did in the last; and will always continue depressed below the place at which it stood before the explosion; and the quantity of this depression will be greater, if the quantity of powder be increased, or the diameter of the tube be diminished. From whence it is proved, that as well in air as in a vacuum, the explosion of fired powder produces a permanent elastic fluid. It also appears from experiment, that the elasticity or pressure of the fluid produced by the firing of gun-powder, is, *cæteris paribus*, directly as its density. This follows from hence, that if in the same receiver a double quantity of powder be let fall, the mercury will subside twice as much as in the firing of a single quantity. To determine the elasticity and quantity of this elastic fluid, produced from the explosion of a given quantity of gun-powder, Mr. Robins premises, that the elasticity of this fluid increases by heat, and diminishes by cold in the same manner as that of the air; and that the density of this fluid, and consequently its weight, is the same with the weight of an equal bulk of air having the same elasticity, and the same temperature. From these principles, and from his experiments, for a detail of which we must refer the reader to his *New Principles of Gunnery*, in Scholium, to prop. II. he concludes, that the fluid produced by the firing of gun-powder will be  $\frac{3}{5}$  of the weight of the gun-powder, and the ratio of the respective bulks of the powder, and the fluid produced from it, will be in round numbers 1 to 244. Hence we are certain, that any quantity of powder fired in any confined space, which it adequately fills, exerts, at the instant of its explosion, against the sides of the vessel containing it, and the bodies it impels before it, a force at least 244 times greater than the elasticity of common air; or which is the same thing, than the pressure of the atmosphere; and this without considering the great addition which this force will receive from the violent degree of heat with which it is endued at that time, the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elasticity of the air is augmented when heated to the extreme heat of red hot iron, in the proportion of 796 to 194  $\frac{1}{2}$ , and supposing that the flame of

fired

fired gun-powder is not less hot than red hot iron, and the elasticity of the air, and consequently of the fluid, generated by the explosion, being augmented by the extremity of this heat in the ratio of 796 to 194  $\frac{1}{2}$ , it follows that if 244 be augmented in this ratio, the resulting number which is 999  $\frac{1}{3}$  will determine how many times the elasticity of the flame of fired powder exceeds the elasticity of common air, supposing it to be confined in the same space, which the powder filled before it was fired.

Hence then the absolute quantity of the pressure exerted by gun-powder, at the moment of its explosion may be assigned: for since the fluid then generated has an elasticity of 999  $\frac{1}{3}$ , or in round numbers 1000 times greater than common air; and since common air by its elasticity exerts a pressure on any given surface equal to the weight of the incumbent atmosphere, with which it is in equilibrio, the pressure exerted by fired powder, before it has dilated itself, is 1000 times greater than the pressure of the atmosphere; and consequently the quantity of this force on a surface of an inch square, amounts to above six tun weight, which force however diminishes as the fluid dilates itself. The variations of the density of the atmosphere does not any way alter the action of powder by any experiment that can be made. But the moisture of the air has a very great influence on the force of it: for that quantity which in a dry season would communicate to a bullet a velocity of 1700 feet in one second, will not in damp weather communicate a velocity of more than 12 or 1300 feet in a second, or even less, if the powder be bad and negligently kept.

The velocity of expansion of the flame of gun-powder when fired in a piece of artillery, without either bullet, or any other body before it, is prodigious. By the experiments of Mr. Robins, it seems this velocity cannot be much less than 7000 feet in a second. This, however, must be understood of the most active part of the flame. For as was observed before, the elastic fluid in which the activity of gun-powder consists, is only  $\frac{1}{10}$  of the substance of the powder, the remaining  $\frac{9}{10}$  will in the explosion be mixed with the elastic part, and will by its weight retard the activity of the explosion; and yet they will be so com-

pletely united as to move with uncommon motion; but the unelastic part will be less accelerated than the rest, and some of it will not even be carried out of the barrel, as appears by the considerable quantity of unctuous matter, which adheres to the inside of all fire-arms, after they have been used. These inequalities in the expansive motion of the flame render it impracticable to determine its velocity, otherwise than from experiments.

*To recover damaged GUN-POWDER.* The method of the powder-merchants is this; they put part of the powder on a sail-cloth, to which they add an equal weight of what is really good, and with a shovel mingle it well together; dry it in the sun, and barrel it up, keeping it in a dry and proper place. Others again, if it be very bad, restore it by moistening it with vinegar, water, urine, or brandy: then they beat it fine, searce it, and to every pound of powder add an ounce, an ounce and a half, or two ounces, according as it is decayed, of melted saltpetre. Afterwards, these ingredients are to be moistened and mixed well, so that nothing can be discerned in the composition, which may be known by cutting the mass; and then they granulate it as aforesaid. In case the powder be in a manner quite spoiled, the only way is to extract the salt-petre with water, according to the usual manner, by boiling, filtrating, evaporating, and crystallizing; and then with fresh sulphur and charcoal to make it up a-new again. In regard to the medical virtues of gun-powder, Boerhaave informs us, that the flame of it affords a very healthy fume in the height of the plague: because the explosive acid vapour of nitre and sulphur corrects the air; and that the same vapour, if received in a small close pent up place, kills insects.

It is enacted by 5 and 11 of Geo. I. and 5 Geo. II. c. 20, that gun-powder be carried to any place in covered carriages; the barrels being close jointed; or in cases, and bags of leather, &c. And persons keeping more than 200 pounds weight of gun-powder, at one time, within the cities of London and Westminster, or the suburbs, &c. are liable to forfeitures if it be not removed; and justices of peace may issue warrants to search for, seize, and remove the same.

The invention of gun-powder is ascribed by Polydore Virgil to a chemist, who having accidentally put some of the ingredients

redients in this composition in a mortar, and covered it over with a stone, it happened to take fire, and blew up the stone. Thetvet says, the person here spoken of was a monk of Edinburgh, named Constantine Anelzen; but Belleforest and others hold it to be Bartholdus Schwartz, or the black; at least it is affirmed, that he first taught the use of it to the Venetians, in the year 1380, during the war with the Genoese. But what contradicts this account, and shews gun-powder to be of an older date, is, that Pet. Mexia, in his *Variae Lectiones*, relates, that Alphonsus XI. king of Castile used mortars against the Moors in a siege in 1343. Ducange adds, that there is mention made of this powder in the registers of the chambers of accounts in France, as early as the year 1338, and Frier Bacon, our country-man, mentions the composition in express terms, in his treatise *De nullitate magia*, published at Oxford, in the year 1216.

**GUN-SHOT-WOUNDS**, are attended with much worse consequences than wounds made by sharp instruments; for the parts are more shattered and torn, especially when the shot falls upon the joints, bones, or any considerable part.

In treating these wounds, the following rules must be observed; to extract all foreign bodies, to stop the hæmorrhage, to promote suppuration, to encourage new flesh, and to make an even cicatrix. The extraction of foreign bodies should, if possible, be performed with the hand; or if that cannot be done, with the forceps or a hook. They are easiest removed at first; for, after some delay, the tumour and inflammation of the parts, render it difficult and painful. Sometimes the orifice of the wound is so narrow, that it will be impossible to come at the body you have a desire to extract, without making a larger opening; which should be done on the most convenient side, always observing that no nerve, blood-vessel, tendon, or ligament lies in the way. And as two balls are frequently concealed in the same wound, after the removal of one, the surgeon should diligently search for another, or for any other extraneous body that may be forced in with it, which might protract the cure of the wound. When an attempt is made to extract the ball, or any other extraneous body, the patient should be laid in the same situation he was in at the time of receiving the wound; for, by

frequent changes of situation, the ball will easily bury itself and get out of your reach. Whenever a ball has penetrated so deep, that you can easily feel it with your finger on the side opposite to the wound, you should examine nicely whether it is safest to bring it back by the way it came in, or to make an opening upon it, and draw it out at the opposite side. If the wound cannot safely be enlarged, nor the balls extracted without great pain and danger, they must be left in the wound, either till the pain is abated, or the passage rendered so easy by suppuration, that they work themselves out. On the other hand, extraneous bodies are instantly to be removed, where there is danger of bringing on convulsions, pain, and an inflammation, by being left behind. If a ball has passed into any of the cavities of the body, where the extraction of it cannot be attempted with safety, it is best to leave it where it has lodged, and to heal the wound: for there have been variety of instances, where persons have carried balls within them for many years, without suffering any inconvenience. Balls lodged in the bones, are to be extracted with restrained forceps, observing the same rules and directions we have already laid down. When this cannot be done, they may be laid hold of with a sort of trepan necessary to extract balls that are lodged in bones, and that are covered with a large quantity of flesh, as in the thigh bone; but if the ball is so strongly fixed in the bone, as to resist all these methods, it must be left there till the parts suppurate, and set it at liberty. Balls that are thrown into the joints are to be removed with all expedition, for delays are here extremely dangerous; but it is scarce possible to prevent violent pains, inflammations, and caries of the bones, which generally require amputation of the limb. In wounds from large guns, the joint or bone is frequently grievously shattered, or carried off; in this case, it is far better to take off the limb at once, than to spend a great deal of time in fruitless attempts to cure it; for the natural figure of the shattered joint can never be restored, and the branches of nerves that were sent to the bone, and the insertion of the tendons and ligaments being torn from it in many places, cannot but bring on violent inflammations and a gangrene; but where the bones are not violently shattered and broken, the surgeon should be

careful in time to remove the splinters, and all extraneous bodies, and to treat the wound according to the rules prescribed above : lastly, if any large artery is wounded, either in the arms or legs, which will appear by the loss of blood, the tourniquet should be applied, and the blood being stopped, you must endeavour to take up the vessel, by the assistance of the crooked needle ; but if this cannot be done, or if the condition of the wound will allow no hopes of success from the future dressings, it will be proper to take off the limb a little above the wound.

The wound being cleaned, and the blood stopped, the first intention is to use our utmost endeavours to prevent or assuage the tumour and inflammation. The wound should be dressed up with lint dipped in spirits of wine warmed, covering it up with compresses wet with the same liquor, or with camphorated spirit of wine, either alone, or diluted with aqua calcis. Having done this, the next intention is to forward the suppuration of the bruised and torn parts, and then to fill up the wound with new flesh, neatly cicatrized ; for the method of doing which, see the articles SUPPURATION and WOUND.

In gun-shot wounds, several grains of powder frequently penetrate the skin of the face, and occasion deformity, if they are not taken out : which may be done with a pin, or an instrument like an ear-picker : but if they are got in too deep to be picked out in this manner, the skin must be laid open with a fine small lancet, in order to get at them with the instruments we have described. Great care should be taken not to break the grains in taking them out ; for that will occasion very foul spots.

**GUNSTBERG**, a town of Germany, in the circle of Swabia, situated on the east side of the Danube : east long.  $10^{\circ} 15'$ , north lat.  $48^{\circ} 35'$ .

**GUNTER'S LINE**, a logarithmic line, usually graduated upon scales, sectors, &c. See SCALE and SECTOR.

It is also called the line of lines, and line of numbers ; being only the logarithms graduated upon a ruler, which therefore serves to solve problems instrumentally in the same manner as logarithms do arithmetically. It is usually divided into an hundred parts, every tenth whereof is numbered, beginning with 1, and ending with 10 ; so that if the first great di-

vision, marked 1, stand for one tenth of any integer, the next division, marked 2, will stand for two tenths ; 3, three tenths, and so on ; and the intermediate divisions will, in like manner, represent 100th parts of the same integer. If each of the great divisions represent 10 integers, then will the lesser divisions stand for integers ; and if the great divisions be supposed each 100, the sub-divisions will be each 10.

*Use of GUNTER'S LINE.* 1. *To find the product of two numbers.* From 1 extend the compasses to the multiplier ; and the same extent, applied the same way from the multiplicand, will reach to the product. Thus if the product of 4 and 8 be required, extend the compasses from 1 to 4, and that extent laid from 8 the same way, will reach to 32, their product. 2. *To divide one number by another.* The extent from the divisor to unity, will reach from the dividend to the quotient : thus to divide 36 by 4, extend the compasses from 4 to 1, and the same extent will reach from 36 to 9, the quotient sought. 3. *To three given numbers, to find a fourth proportional.* Suppose the numbers 6, 8, 9 ; extend the compasses from 6 to 8, and this extent, laid from 9 the same way, will reach to 12, the fourth proportional required. 4. *To find a mean proportional between any two given numbers.* Suppose 8 and 32 : extend the compasses from 8 in the left-hand part of the line, to 32 in the right ; then bisecting this distance, its half will reach from 8 forward, or from 32 backward, to 16, the mean proportional sought. 5. *To extract the square root of any number.* Suppose 25 : bisect the distance between 1 on the scale and the point representing 25 ; then the half of this distance, set off from 1, will give the point representing the root 5. In the same manner the cube root, or that of any higher power, may be found by dividing the distance on the line, between 1 and the given number, into as many equal parts as the index of the power expresses ; then one of those parts, set from 1, will find the point representing the root required.

**GUNTER'S QUADRANT**, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere, on the plane of the equinoctial ; the eye being supposed placed in one of the poles. Besides the use of this quadrant in finding heights and distances, it serves also

*Fig. 1. G O B I U S. N<sup>o</sup> 1.*

*N<sup>o</sup> 2.*

*N<sup>o</sup> 3.*

*Fig. 2. The Red G U R N A R D.*

to find the hour of the day, the sun's azimuth, and other problems of the globe. See the article **QUADRANT**.

**GUNTER'S SCALE**, called by navigators simply the **gunter**, is a large plain scale, generally two feet long, and about an inch and a half broad, with artificial lines delineated on it, of great use in solving questions in trigonometry, navigation, &c. See the article **SCALE**.

**GUN-WALE**, or **GUNNEL**, is the uppermost wale of a ship, or that piece of timber which reaches on either side from the quarter-deck to the forecabin, being the uppermost bend which finishes the upper works of the hull, in that part in which are put the stanchions which support the waste-trees.

**GURIEL**, a subdivision of Georgia, in Asia, situated on the eastern coast of the Euxine-sea.

**GURK**, a city of Carinthia, in Germany: east long.  $14^{\circ}$ , north lat.  $47^{\circ} 20'$ .

**GURNARD**, in ichthyology, the english name of two species of trigla. See the article **TRIGLA**.

These fishes, from their different colours, are called the grey and red gurnard. The grey gurnard has a bifid and spinose snout, with two spines at each eye. The red kind has likewise the rostrum bifid, and the coverings of the gills striated, and each of them armed with three spines. This last is a very remarkable spinose fish, which seldom exceeds a foot in length. See plate **CXXIII**. fig. 2.

Both these fishes make a singular noise, when out of the water, not unlike the grunting of a hog; whence their english name.

**GUSSET**, in heraldry, is formed by a line drawn from the dexter or sinister chief points, and falling down perpendicularly to the extreme base. See plate **CXXI**. fig. 7.

The gusset is an abatement of honour, denoting an effeminate person. See the article **ABATEMENT**.

**GUSTROW**, a town of Germany, in the dutchy of Mecklenburg: east long.  $12^{\circ} 15'$ , north lat.  $54^{\circ}$ .

**GUTS**, or **INTESTINES**, in anatomy. See the article **INTESTINES**.

**GUTSKROW**, a city of Germany, in the circle of Upper Saxony, and province of Swedish Pomerania: east long.  $13^{\circ} 40'$ , north lat.  $54^{\circ}$ .

**GUTTA**, a town of Hungary, situated on the east side of the Danube: east long.  $18^{\circ}$ , north lat.  $48^{\circ} 20'$ .

**GUTTÆ ANGLICANÆ**, volatile english drops. See the article **DROPS**.

**GUTTÆ**, in architecture, are ornaments in the form of little cones, used in the plafond of the doric cornice, or on the architrave underneath the triglyphs, representing a sort of drops or bells. They are usually six in number. See the article **DORIC**.

**GUTTA SERENA**, a disease in which the patient, without any apparent fault in the eye, is entirely deprived of sight.

Its cause is ascribed to an obstruction of the optic nerve, which may proceed from a palsy in the nerve, from a suppression of usual hæmorrhages, from ulcers healed too soon, or from an epilepsy.

Heister affirms, that it is to be cured by aromatics, carminatives, and attenuants; chiefly eye-bright, veronica, hyssop, rose-mary-flowers, sage, fennel and anniseeds, valerian-root, saffra, cinnamon and wood-lice, either in infusion, or in powder. The juice of wood-lice newly expressed, and taken for some weeks, increasing the dose, is of excellent use; as likewise mercurials, and sometimes a salivation. If it arises from a suppression of usual hæmorrhages, they are to be restored; but if this cannot be done, artificial bleeding is to be substituted. Coward recommends volatiles, antiscorbutics, chalybeats, mercurials, cephalics, and nervine medicines.

Externally, issues, setons, and clysters, are said to be good, especially in the phlegmatic; but if the patient is plethoric, cupping and bleeding, particularly cauteries, or issues on the coronal suture, or in the neck, are proper: and the eyes may be washed with fennel, valerian, eye-bright, or rose-water: or an infusion of fennel-roots in wine, with bags of strengthening herbs and fennel-seeds, may be put upon them. Sneezing powders may likewise be proper, especially florentine orris, or horse-chestnuts. An old gutta serena, however, is generally incurable.

**GUTTE**, or **GUTTY**. See **GUTTY**.

**GUTTERS**, in architecture, a kind of canals in the roofs of houses, serving to receive and carry off the rain.

Gutters, with respect to their position, are of two kinds: such as come something near a parallelism with the horizon; and such as incline towards a vertical position to the horizon.

**GUTTER-TILES**, those intended for gutters. See the article **TILE**.

**GUTTURAL**, a term applied to letters or sounds pronounced or formed as it were in the throat. There are four guttural letters in the hebrew, viz. ע פ ת כ; which, for memory's sake, are termed *ahachah*. See the article **LETTER**.

**GUTTY**, *gutté*, in heraldry, a term used when any thing is charged or sprinkled with drops.

In blazoning, the colour of the drops is to be named, as gutty of sable, of gules, &c.

**GUY**, in a ship, is any rope used for keeping off things from bearing or falling against the ship's sides when they are hoisting in.

That rope which at one end is made fast to the fore-mast, and seized to a single block at the pendant of the garnet, is called the guy of the garnet.

**GUY'S HOSPITAL**. See **HOSPITAL**.

**GUZES**, in heraldry, roundles of a sanguine or murrey colour. These, from their bloody hue, are by some supposed to represent wounds.

**GUZURAT**, the same with Cambaya. See the article **CAMBAYA**.

**GYMNASIARCH**, *γυμνασιάρχης*, in antiquity, the director of the gymnasium. He had two deputies under him; the one called *xytarch*, who presided over the *athletæ*, and had the oversight of the wrestling; the other, *gymnastes*, who had the direction of all the other exercises.

**GYMNASIUM**, *γυμνασιον*, in grecian antiquity, a place fitted for performing exercises.

Gymnasia, according to Potter, were first used at Lacedæmon, but were afterwards very common in all the parts of Greece, and imitated, very much augmented, and improved at Rome. They were not single edifices, but a knot of buildings united, being so capacious as to hold many thousands of people at once, and having room enough for philosophers, rhetoricians, and the professors of all other sciences, to read their lectures; and wrestlers, dancers, and all others that would, to exercise at the same time without the least disturbance or interruption. They consisted of a great many parts, the chief of which were the *porticos*, *elæothesium*, *palæstia*, *conistrium*, &c. See the articles **PORTICO**, **ELÆOTHESIUM**, &c.

Athens had several gymnasia, of which the lyceum, academia, and cynosarges, were those of most note.

The lyceum was situated upon the banks of the river Ilissus, and received its name

from Apollo *λυκίστονος*, or *λυκισ*, to whom it was dedicated.

The lyceum was the place where Aristotle taught philosophy, walking there every day till the hour of anointing; whence he and his followers got the name of peripatetics, from *περιπατεῖν*, to walk. The academy was part of the ceramicus without the city, where Plato lectured. See the article **ACADEMY**.

The cynosarges was a place in the suburbs, near the lyceum, so called from a white or swift dog, *κυν αργος*. Here Antisthenes instituted a sect of philosophers called cynics, from the name of the place.

**GYMNASTICS**, the art of performing the several bodily exercises, as wrestling, running, fencing, dancing, &c. See the article **WRESTLING**, &c.

That part of medicine which regulates the exercises of the body, whether for preserving or restoring health, is also termed gymnastic.

**GYMNIC**, something belonging to the athletic exercises; for an account of which, see the articles **PENTATHLON**, **OLYMPIC**, **ISTHMIAN**, &c.

**GYMNOPÆDIA**, a dance used by the antient Lacedæmonians, and performed during their sacrifices by young persons naked, who at the same time sung a song in honour of Apollo.

**GYMNOPYRIS**, in natural history, a name given by Dr. Hill to the pyritæ of a simple internal structure, and not covered with a crust.

Of these there are only two species. 1. A green variously shaped kind. 2. A botryoide kind. See **PYRITÆ**.

The first species is the most common of all the pyritæ, and appears under a great diversity of shapes. It is very hard and heavy, very readily gives fire with steel, but will not at all ferment with aquafortis. The second species is very elegant and beautiful, and its usual colour is a very agreeable pale green; but what most distinguishes it from all other pyritæ is, that its surface is always beautifully elevated into tubercles of various sizes, resembling a cluster of grapes. See plate **CXXIV**. fig. 3.

**GYMNOSOPHISTS**, a sect of philosophers who clothed themselves no farther than modesty required. There was some of these sages in Africa; but the most celebrated clan of them was in India. The african gymnosophists dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either

of

*Fig. 1.* G L O S S O P E T R Æ.

*Fig. 2.* G R Y P H I T Æ.

*Fig. 3.* G Y M N O P Y R I S.

of house or cell. They did not form themselves into societies like those of India, but each had his private retirement, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They observed an extraordinary frugality, and lived only upon the fruits of the earth. Lucan ascribes to these gymnosophists, several new discoveries in astronomy.

As to the indian gymnosophists, they dwelt in the woods, where they lived upon the wild products of the earth, and never drank wine, nor married. Some of them practised physic, and travelled from one place to another: these were particularly famous for their remedies against barrenness. Some of them, likewise, pretended to practise magic, and to foretell future events.

In general, the gymnosophists were wise and learned men: their maxims and discourses, recorded by historians, do not in the least savour of a barbarous education, but are plainly the result of great sense, and deep thought. They kept up the dignity of their character to so high a degree, that it was never their custom to wait upon any body, not even upon princes themselves; for which reason Alexander, who would not condescend to visit them in person, sent some of his courtiers to them in order to satisfy his curiosity. Their way of educating their disciples, is very remarkable. Every day, at dinner, they examined them how they had spent the morning; and every one was obliged to shew, that he had discharged some good office, practised some virtue, or improved in some part of learning: if nothing of this appeared, he was sent back without his dinner. They held a transmigration of souls; and it is probable that Pythagoras borrowed his doctrine from them.

**GYMNOSPERMIA**, in botany, a series or sub-division of the *didynamia* class of plants; comprehending all those with labiated flowers, without any pericarpium or capsule surrounding their seeds, which are only lodged in the base of the cup; whence the name gymnospermia. See the article **DIDYNAMIA**.

**GYMNOTUS**, in ichthyology, a genus of malacopterygious fishes, without any back or belly-fins, and with only five bones in the membrane of the gills.

There is only one known species of this genus, the carapo of Marcgrave.

**GYNÆCEUM**, among the ancients, the apartment of the women, a separate room in the inner part of the house, where they employed themselves in spinning, weaving, and needle-work.

**GYNÆOCRACY**, *γυναικραπεία*, denotes the government of women, or a state where women are capable of the supreme command. Such are Britain and Spain. **GYNANDRIA**, in botany, the name of one of Linnæus's classes of plants, the twentieth in order; comprehending all the plants whose stamina are placed either on the style or on the receptacle, elongated into the form of a style, and carrying on it both the pistil and stamina. See the article **BOTANY**.

Of the several genera of this class, some have two stamina to each flower; some, again, have three; and others, four, five, six, ten, or more. And hence they are naturally arranged into several distinct orders, under the appellations of gynandria-diandria, gynandria-triandria, &c.

**GYNGLIMUS**, or **GINGLYMUS**, in anatomy. See the article **GINGLYMUS**.

**GYPSUM**, or **PLASTER-STONE**, in natural history, a genus of fossils naturally and essentially simple, not inflammable nor soluble in water, and composed of small flat particles; which form bright, glossy, and in some degree transparent masses, not flexible or elastic, not giving fire with steel, nor fermenting with or being soluble in acid menstrua, and very easily calcining in the fire.

Of these gypsums, some are harder, others softer; and are of several colours, as white, grey, red, green, &c. sometimes distinct, and sometimes variously blended together.

The texture of all the gypsums being ultimately the same, it may be sufficient to observe, that their origin is plainly from particles of a determinate nature and substance, and of a certain and invariable figure, an oblong, flat, and irregularly angular one. These we sometimes see, as indeed is most natural to them, disposed without order or regularity, into loose, complex, friable masses; at others, they are getting out of their native order, and emulating the structure of other classes of bodies, of which they are indeed properly the basis, and appearing somewhat in the figure of the fibrariæ; and at other times, of the foliaceous composite flakes of the selenitæ:

the

The species which have these structures, are truly varying from the gypsums into those bodies they emulate; for the fibrariæ are only a peculiar arrangement of these very particles, and the selenitæ only more broad flakes of the same, like those of the foliaceous talcs.

The gypsums are much used in plaster, for stuccoing rooms, and casting busts and statues.

**GYP SUM STRIATUM**, *striated plaster-stone*,

the whitish, less glossy tricheria, with short thick filaments. See **TRICHERIA**.

**GYRFALCON**, or **GERFALCON**. See the article **GERFALCON**.

**GYRLE**, or **GIRLE**, among sportsmen. See the article **GIRLE**.

**GYSHORN**, a town of Germany, in the dutchy of Lunenburg, situated on the river Aller, forty-five miles north-east of Hanover: east long. 10° 45', north lat. 52° 50'.

## H.

**H**, or *h*, the eighth letter, and sixth consonant in our alphabet; tho' some grammarians will have it to be only an aspiration, or breathing. But nothing can be more ridiculous than to dispute its being a distinct sound, and formed in a particular manner by the organs of speech, at least in our language: witness the words *eat* and *beat*, *arm* and *harm*, *ear* and *bear*, *at* and *bat*, &c. as pronounced with or without the *h*.

It is pronounced by a strong expiration of the breath between the lips, closing, as it were, by a gentle motion of the lower jaw to the upper, and the tongue nearly approaching the palate.

There seems to be no doubt, but that our *h*, which is the same with that of the Romans, derived its figure from that of the hebrew ה. And, indeed, the Phœnicians, most antient Greeks and Romans, used the same figure with our *H*, which in the series of all these alphabets keeps its primitive place, being the eighth letter.

**H**, used as a numeral, denotes 200; and with a dash over it, **H̄**, 200,000.

As an abbreviation, *H* was used by the antients to denote *homo*, *hæres*, *hora*, &c. Thus *H. B.* stood for *hæres bonorum*; and *H. S.* corruptly for *L. L. S.* a letter; and *H. A.* for *Hadrianus*.

**HAAG**, a town of Germany, and circle of Bavaria, thirty-two miles north-west of Munich.

**HAAK**, or **HAKE**, in ichthyology. See the article **HAKE**.

**HABAT**, the north-west province of the

empire of Morocco, situated on the freights of Gibraltar.

**HABBAKUK**, or the prophecy of *Hab-bakuk*, a canonical book of the Old Testament.

There is no mention made in scripture, either of the time when this prophet lived, or of the parents from whom he was descended; but according to the authors of the lives of the prophets, he was of the tribe of Simeon, and a native of Beth-zacar. As he foresaw the taking of Jerusalem by Nebuchadnezzar, he fled to Ostracin in Arabia, where he lived for some time; but after the Chaldæans had made themselves masters of Jerusalem, and were on their return home, he returned into Judæa, where he employed himself in agriculture; but as he was carrying the reapers their dinner, he is said to have been transported by an angel to Babylon, with what he had provided for his people in the field; which he set before Daniel, who was shut up in the lion's den, and was transported back again to Judæa, where he died, before the end of the captivity.

He is reported to have been the author of several prophecies which are not extant: but those that are indisputably his, are contained in three chapters. In these the prophet complains very pathetically of the disorders which he observed in the kingdom of Judæa. God reveals to him, that he would shortly punish them in a very terrible manner by the arms of the Chaldæans. He foretels the conquests of Nebuchadnezzar, his metamorphosis, and death. He foretels, that the vast

designs of Jehoiakim would be frustrated. He speaks against a prince (probably the king of Tyre) who built with blood and iniquity; and he accuses another king (perhaps the king of Egypt) of having intoxicated his friend, in order to discover his nakedness. The third chapter is a song or prayer to God, whose majesty he describes with the utmost grandeur and sublimity of expression.

**HABDALA**, a ceremony of the Jews, observed on the sabbath in the evening, when every one of the family is come home. At that time, they light a taper, or lamp, with two wicks at least: the master of the family then takes a cup with some wine, mixed with fragrant spices; and, after having repeated a passage or two of scripture, as, for example, "I will take the cup of salvation, &c." Psal. cxvi. and, "The Jews had light and gladness, &c." Esth. viii. he blesses the wine and spices. Afterwards he blesses the light of the fire, and then casts his eyes on his hands and nails, as remembering that he is going to work. The whole is intended to signify that the sabbath is over, and is from that moment divided from the day of labour which follows. For this reason the ceremony is called habdala, which signifies distinction.

**HABEAS CORPORA**, in law, a writ issued for bringing in a jury, or such of them as refuse to appear upon the venire facias, for the trial of a cause brought to issue.

It commands the sheriff to have the jurors before the judges on such a day, &c. and is of the same nature in the common pleas, as the *distingas juratores* in the court of king's bench.

**HABEAS CORPUS**, in law, is a writ of two kinds, the one being the great writ of the english liberty, which lies where a person is indicted for any crime or trespass before justices of the peace, or in a court of any franchise, and on being imprisoned, has offered sufficient bail, which has been refused, though the case be bailable; in which case he may have this writ out of the king's bench, in order to remove himself thither, to answer the cause at the bar of that court.

The practice in this case, is first to procure a *certiorari* out of the court of chancery, directed to all the justices for removing the indictment into the king's bench; and upon that to obtain this writ, directed to the sheriff, for causing the

body of the party to be brought at a certain day.

The other kind of habeas corpus is used for bringing the body of a person into court, who is committed to any goal or prison, either in criminal or civil causes; which writ will remove the person and cause from one court and prison to another.

No habeas corpus, or other writ, to remove a cause from out of an inferior court, can be allowed, if the same be not delivered to the judge of the court, before the jury who are to try the cause have appeared, and before any of them are sworn, 43 Eliz. c. 5.

The habeas corpus act, 31 Car. II. c. 2. has ordained, that a person may have a habeas corpus from any judge, on complaint made and view of the warrant of commitment, (except such person is committed for treason or felony expressed in the warrant, or some other offence that is not bailable) which habeas corpus must be made returnable immediately; and on producing a certificate of the cause of commitment, the prisoner is to be discharged on bail given to appear in the court of king's bench the next term, or next assizes, &c. Persons committed for either treason or felony, expressly mentioned in the warrant, upon a motion made in open court, in the first week of the term, or day of sessions, &c. after commitment, are to be brought to trial; and if they are not indicted the next term or sessions after commitment, on a motion made the last day of that term, they shall be let out upon bail, except it appear on oath that the king's witnesses are not ready; and in case they are not indicted or tried the second term after commitment, they shall be discharged.

Judges denying a habeas corpus, shall forfeit 500*l.* and if an officer refuse to obey it, or to deliver a true copy of the commitment-warrant, he forfeits 100*l.* for the first offence.

**HABEAS CORPUS AD PROSEQUENDUM**, a writ for the removal of a person in order to prosecution and trial in the proper county.

**HABEAS CORPUS AD FACIENDUM ET RECEPIENDUM**, a writ issued out of the court of common pleas, on behalf of defendants sued in inferior courts, to remove their cause into the said court.

**HABEAS CORPUS AD RESPONDENDUM**, a writ that lies where a person is imprisoned at another's suit in any prison except that of the king's bench; and a third person would

would sue the prisoner there, in which case this writ will remove such prisoner from the prison where he is, into the king's bench, to answer the action in that court.

**HABEAS CORPUS AD SATISFACIENDUM**, a writ that lies against a person in the fleet-prison, &c. to charge him in execution. The delivery of this writ to the warden, is sufficient.

**HABENDUM**, in law, a term signifying to have and to hold.

A deed or conveyance has two principal parts; the premises and the habendum. The office of the first is to express the names of the grantor, the grantee, and the things granted: that of the habendum, to shew what estate or interest the grantee is to have in what is granted. According to lord Coke, the habendum is to limit the estate, so that the general implication, which by construction of law passes in the premises, is by the habendum controlled and qualified. Thus in a lease to two persons, to have and to hold to the one for life, alters the implication of the joint tenancy in the freehold, which would pass by the premises, were it not for the habendum.

**HABERDASHER**, in commerce, a seller of hats, or of small wares.

The master and wardens of the company of haberdashers in London, calling to their assistance one of the company of cappers, and another of the hat-makers, and mayors, &c. of towns, may search the wares of all hatters that work hats with foreign wool, and have not been apprentices to the trade, or who dye them with any thing but copperas and galls, or woad and madder; in which case they are liable to penalties, by stat. 8 Eliz. c. 7. and 3 Geo. II. c. 22.

**HABERE FACIAS POSSESSIONEM**, a writ that lies where one has recovered a term for years in an action of ejectment, in order to put him into possession again.

The sheriff is obliged to execute this writ, and may raise the posse comitatus to assist him, in case he be opposed. He may also break open a house into which entrance is denied, to deliver possession to the person recovering by law. But an action of the case lies against him, if he deliver possession of more than is contained in the writ.

**HABERE FACIAS SEISINAM**, a writ which lies where a person has recovered land in the king's court; directed to the sheriff,

commanding him to give seisin of the land recovered.

This writ sometimes issues out of the records of a fine, and requires the sheriff to give the cognisee, or his heirs, seisin of the land in which the fine is levied.

There is likewise a writ called, *habere facias seisinam*, ubi rex habuit annum, diem & vastum, that lies for the delivery of lands to the lord of the fee, after the king has had his year, day and waste, in the lands of one convicted of felony.

**HABERE FACIAS VISUM**, is a writ that lies in divers cases, as in dower, foreclosure, &c. where it is necessary to take a view of the lands or tenements in question.

**HABERGION**, a small coat of mail, or only sleeves and gorget of mail, formed of little iron rings, or masses linked into each other. See the article *GORGET*.

**HABILIMENTS of war**, in our antient statutes, signify armour, harness, utensils, or other provisions for war, without which there is supposed no ability to maintain war.

**HABIT**, in philosophy, an aptitude or disposition either of mind or body, acquired by a frequent repetition of the same act.

This habit is by some of the schoolmen termed *habitus qualitativus*, a qualitative habit, and defined a quality adventitious to a thing, fitting and disposing it either to act or suffer. Others again define habit an affection of the mind or body, persisting by long use and continuance. Hence habits may be distinguished into those of the mind and of the body: thus virtue is called an habit of the mind; strength, an habit of the body. All natural habits, whether of body or mind, are no other than the body and mind themselves considered as either acting or suffering; or they are modes of the body or mind wherein either perseveres, till effaced by some contrary mode.

Custom, says Mr. Locke; settles habits of thinking in the understanding, as well as of determining in the will, and of motions in the body, all which seem to be but trains of motion in the animal spirit, which once set agoing, continue on in the same steps they have been used to, which by often treading are worn into a smooth path, and the motion in it becomes easy as well as natural. See *ASSOCIATION*. The archbishop of Cambray defines habits in general to be the certain impressions left in the mind, by means whereof we find a greater ease, readiness, and incli-

inclination to do any thing formerly done, by having the idea ready at hand to direct us how it was done before. Thus, for example, we form the habit of sobriety, by having always before us the inconveniencies of excess; the reflections whereof being often repeated, render the exercise of that virtue continually more and more easy.

Malebranche gives a more mechanical theory of habits. His principle is, that they consist in a facility which the spirits acquire of passing easily from one part of the body into another. He argues thus: if the mind act on, and move the body, it is in all probability by means of a stock of animal spirits lodged in the brain, ready to be sent at the motion of the will, by means of the nerves which open or terminate in the brain; into the muscles of the body.

Now an influx of spirits into a muscle occasions a swelling, and of course a shortening of the muscle, and consequently a motion of that part to which the muscle is fastened. Further, the spirits do not always find all the roads open and free through which they are to pass: whence that difficulty we perceive of moving the fingers with that quickness necessary to play on a musical instrument, or of moving the muscles necessary to pronounce the words of a foreign language. But by degrees the spirits, by their continual flux, smooth the way so, that at length they meet with no resistance at all. Now it is in this facility the spirits find of passing, when directed into the members of the body, that habits consist.

**HABIT**, in medicine, denotes the settled constitution of the body, or the habitude of any thing else, as the structure or composition of a body, or the parts thereof.

**HABIT** is also used for a dress or garb, or the composition of garments, wherewith a person is covered; in which sense we say, the habit of an ecclesiastic, of a religious, &c. a military habit, &c.

The different habits and cloths that the generality of the world wear, are, through inadvertency and inattention, very frequently the cause of very unhappy maladies. The antients have observed the inconveniencies of many parts of dress; and daily observations confirm to us the many mischiefs the ladies suffer from the stiff whale-bone stays they wear, and the disorders of the viscera of the lower belly to which these are subject who lace them-

selves too tightly; and this is not only of dangerous consequence to themselves, but frequently is the death of children in breeding women. The tight binding of the neck by the mens neck-cloths, stocks, or the too tight collars of their shirts, &c. has been very frequently the occasion of very terrible disorders of the head, the eyes, and the breast; deafness, vertiges, faintings, and bleedings at the nose, are the frequent consequences of this practice. Mr. Winslow has observed, that the different motions of the bones of the foot, which are very free in their natural state, as is very plainly seen in young children, are usually wholly lost to us as we grow up, by means of the improper pressure of our shoes. The high-heeled shoes the women wear, entirely changes the natural conformation of the bones of the whole foot.

**HABITATION**, or **COHABITATION**, in law. See the article **COHABITATION**.

**HABITUAL**, something grown to a habit by long use. See the article **HABIT**.

**HABITUAL GRACE**, among divines. See the article **GRACE**.

**HABITUDE**, among schoolmen, the respect or relation one thing bears to another. See **RELATION**.

Some of the more precise schoolmen consider habitude as a genus, and sub-divide it into two species; where it is considered as quiescent, they call it respect; where as moved, relation: to which some add a third species, considered in respect of figure, which they call mode. See the article **RELATION**, &c.

**HABITUDE** is also used by philosophers for what we commonly call habit, or a certain disposition or habitude for the performing or suffering certain things, acquired by repeated acts of the same kind.

**HACHA**, a town of Terra firma, in South America, situated on the north sea, at the mouth of the river Hacha, in west long. 72°, north lat. 11° 30'.

**HACKNEY**, a village on the north-east side of London, with a handsome church, three meeting-houses, and seventeen almshouses.

**HACKNEY-COACH**. See **COACH**.

**HADDINGTON**, a parliament-town of Scotland, about eighteen miles east of Edinburgh.

**HADDOCK**, the english name of a well known fish of the gadus-kind, with a bearded mouth, and three fins on the

**back**: its body is whitish; the upper jaw longest, and the tail a little forked.

See the article **GADUS**.

**HADÉ**, among miners, signifies the steep descent of a shaft, or the like passage.

**HADEMAR**, a town of Germany, in the circle of the upper Rhine, and county of Nassau in the Weteraw, situated in 7° 45' east long. and 50° 26' north lat.

**HADERSLEBAN**, a town of Sleswick, or south Jutland, situated near the sea called the little Belt, in east long. 10°, north lat. 55° 15'.

**HADLEY**, a market-town of Suffolk, situated seventeen miles south-east of Bury.

**HADRAMUT**, a city of Arabia Fælix, the capital of the province of Hadramut, situated in east long. 50° 30', north lat. 16°, three hundred and sixty miles north-east of Mocho.

**HÆMACHATES**, in natural history, the variegated, blood-coloured agat of the antients. See the article **AGAT**.

**HÆMAGOGOS**, among physicians, a compound medicine, consisting of fetid and aromatic simples, mixed with black hellebore; and prescribed in order to promote the menstrual and hæmorrhoidal fluxes, as also to bring away the lochia. See the article **MENSES**, &c.

**HÆMANTHUS**, **GUINEA-ORCHIS**, in botany, a genus of the *hexandria-monogynia* class of plants, the corolla whereof consists of a single petal, erect, and divided into six erect linear segments; the tube is very short, and angular: the fruit is a roundish berry, containing three cells; the seeds are single and triquetrous; the involucre has sometimes six leaves.

The flowers stand at the top in a kind of little umbel, and are of a very beautifully stellated appearance.

**HÆMATITES**, **BLOOD-STONE**, in natural history, an extremely rich and fine iron-ore. See **IRON**.

It is very ponderous, and is either of a pale red, a deeper red, or a bluish colour; usually of a very glossy surface; and when broken, of a fine and regularly striated texture: the striæ converging toward the center of the body; and the masses thereof naturally breaking into fragments of a broad base and pointed end; appearing sometimes pyramidal. The hæmatites is various in its degrees of purity and hardness, as well as in its figure: the finest and most pure is of a botryoid surface; the whole superficies rising into larger or smaller roundish tu-

bercles: sometimes the hæmatites is of a coarse texture, and a laxer structure, in which state it is known to many by the name schistus.

The hæmatites, besides its value as an ore, has its uses in medicine: the highest coloured and most like cinnabar that can be had, being esteemed astringent and delicate. It is given in powder from ten grains to five and twenty for a dose, in hæmorrhages; and is also used in distemperatures of the eyes.

**HÆMATOPUS**, the **SEA-PYE**, in ornithology, a distinct genus of birds of the order of the scolopaces, with a compressed beak, terminating in a wedge-like point. The hæmatopus is of the bigneis of the common magpye, and is so called from the colour of its legs, which are of a bright scarlet.

**HÆMATOSIS**, among physicians, the same with sanguification. See the article **SANGUINIFICATION**.

**HÆMATOXYLUM**, **CAMPECHE-WOOD** in botany, a genus of the *decandria-monogynia* class of plants, the flower of which consists of five equal and ovated petals; the fruit is a lanceolated, obtuse and unilocular, bivalve capsule, containing a few compressed, oblong seeds. See the article **CAMPECHE**.

**HÆMOPTOSIS**, **HÆMPTYSIS**, or **HÆMOPTOE**, in medicine, a spitting of blood.

An hæmptysis is either accidental or habitual, and is stopped by astringents, as bole-armenic, dragon's blood, and the lapis hæmatites, and best and most safely cured by the peruvian bark. In this disorder purging is to be avoided, but bleeding is convenient; diuretics and diaphoretics are of use, but opiates are excellent; in particular semen hyosciami is a noble specific, commended both by the antients and moderns, yet it is to be given with great precaution, in small quantities, and often repeated; for when given in too large a dose, it occasions a delirium: hederæ terrestris, or ground-ivy, produces marvelous effects.

In a desperate accidental hæmptysis, other things being tried in vain, (as in all other hæmorrhages) the expectation of the physician is seldom frustrated, if he makes use of the following remedy. Take plantain water and red wine, of each half a pound; syrup of poppies, half an ounce; to these add a very small quantity of the oil of vitriol, and make the whole up into a julep.

In cases of extremity, the fumes of quick lime and vinegar, are said to be very good.

**HÆMORRHAGE**, in medicine, a flux of blood from any part of the body.

Hæmorrhages are divided by medical writers into natural and preternatural.

Natural hæmorrhages comprehend bleeding at the nose, spitting of blood, the fluxes of the hæmorrhoids and menses, the lochia in lying-in women, vomiting of blood, and voiding of blood by urine.

The preternatural hæmorrhages are such as derive their origin from external accidents, as falls, blows, and wounds: some also comprehend under this term the artificial evacuations by bleeding, cupping, and the like.

Hæmorrhages differ much according to the age and state of the patient, and other accidents: hæmorrhages from the nose, are most frequent in young persons; those of the hæmorrhoids, in persons of a middle age, or later in life; the spitting of blood, to persons in a middle age; and voiding of blood by urine, usually to older people.

Some hæmorrhages are periodical, and others vague or uncertain. The first observe some stated periods of time for their return upon people: the last are wholly uncertain in that particular. Some are also termed critical; these are such as happen in the crisis of fevers. There are usually violent pains about those parts whence natural hæmorrhages are to proceed; but these always go off as soon as the bleeding comes on in due quantity. Young persons of a healthy and florid constitution, are most subject to hæmorrhages: people of plethoric habits, are also much subject to them; and especially such whose blood is sound and fluxile, not subject to any dyscrasy; those who drink much wine, or eat high seasoned food; and chiefly those persons who are subject to violent passions, especially anger: hence it is that brutes are rarely afflicted with them. The principal causes therefore of hæmorrhages are a plethora, violent commotions of the body, hot foods and liquors, a heat of the season, a sudden cooling of the body after violent heat, and passion.

As to the prognostics of hæmorrhages, it may in general be observed, that those proceeding from the lungs, vomiting, and voiding blood by urine, are all very dangerous. The others, when re-

gulated, and in due proportion, are salutary, and often prevent diseases. But the common custom of stopping them by astringents, or otherwise, is often productive of stagnations, inflammations, and violent fevers.

Natural hæmorrhages are more particularly,

**HÆMORRHAGE**, or **BLEEDING at the nose**, is owing to the more plentiful appulse of blood to the nostrils, by a stronger motion of the heart, whereby the small arteries in the pituitary coat become turgid, and too much distended, till at length they gape, and the blood gushes out. A bleeding at the nose may be promoted when persons of sedentary lives, that indulge their appetites, and so become plethoric, put their blood into extraordinary agitation, by any of the causes already mentioned, or by volatile medicines, hot baths, or suddenly chilling their feet, &c. This hæmorrhage differs much as to the quantity: some lose only a few drops, some several ounces, and some five or six pounds. No hæmorrhage is more apt to return; which it does to some in a few days, to others in a few hours. To the plethoric it is generally salutary; and there are many instances of a vertigo, scotomia, dull, heavy pains of the head, a phrensy, and even an epilepsy, being carried off by it. On the contrary, from its suppression there have arisen vertiges, apoplexies, epilepsies, convulsions, noise in the ears, hardness of hearing, and even a gutta serena.

But enormous and long continued bleedings at the nose, when they arise from spasms of the internal parts, and are preceded with coldness of the extreme parts, and fainting fits, generally occasion death: it is also dangerous in spotted and malignant fevers, and in chronical diseases. If the bleeding is very inordinate, it will be proper to use cooling emulsions, gentle or stronger opiates, to moderate the spastic strictures, as occasion shall require. Camphor mixed with nitre and calx of antimony, will be highly necessary, if the matter of exanthemata or cutaneous eruptions is the cause of the hæmorrhage, as is often the case. A revulsion may be made from the head by bleeding in the lower parts; then by temperate pediluvia, and putting the hands into warm water. After a revulsion by bleeding, there is nothing equal to nitre, to appease the orgasm of the blood; next to these are vegetable acids,

such as the juice of seville-oranges, barberries, the water and juice of wood sorrel; but more especially the diluted spirit of vitriol, tincture of roses, &c.

Externally refrigerants may be mixed with discutients, and applied to the forehead, nose, and neck. In persons of a bilious constitution, cold water alone drank freely, has a good effect.

**HÆMORRHAGE** of the *hæmorrhoids*, or of the *piles*. See **HÆMORRHOIDS**.

**HÆMORRHAGE** of the *lochia*, in lying-in women. See the articles **LOCHIA** and **DELIVERY**.

**HÆMORRHAGE** of the *menfes*. See the article **MENSES**.

**HÆMORRHAGE** of the *lungs*. See the articles **BLOOD** and **HÆMOPTOSIS**.

**HÆMORRHAGE** of the *urinary passages*, a disorder commonly called *pissing of blood*, being an emission of blood, with or without urine, from the vessels of the kidneys or bladder, which may be either enlarged, broken, or eroded; and is more or less dangerous, according to the different circumstances that attend it. If pure blood is voided suddenly, without interruption, and without pain, we conclude, says Hoffman, it proceeds from the kidneys. It likewise comes from the kidneys if the urine is coffee-coloured, or more florid, and generally precedes a fit of the gravel: it sometimes accompanies the passage of a stone through the ureter: but if the blood is of a dark colour, with or without purulent matter, emitted with heat and pain in the pubes, and in a small quantity, it certainly proceeds from the bladder. It may be occasioned by a stoppage of the hæmorrhoidal flux; from a violent motion of the body, especially riding; from a stone concealed in the kidney; from an erosion and ulcers of the bladder; from external violence; from gripping pains caused by violent purges; from sharp diuretics, especially cantharides.

All bloody urine has some degree of danger, but it is most so when mixt with purulent matter.

If the patient is plethoric, or it proceeds from a sanguineous evacuation, bleeding is necessary, as also cooling nitrous draughts, and purified nitre mixed with absorbents, with whey for a vehicle, or barley-broth, or small-beer acidulated with drops of the spirit of vitriol. The body must be kept open with laxatives, as rhubarb, with currants; or with cream of tartar; also emollient clysters. The

relaxed vessels must be agglutinated with decoctions of vulnerary herbs, such as agrimony, ground-ivy, yarrow, golden-rod, and the roots of comfrey dulcified with virgin-honey, to which milk may be occasionally added.

If there is an ulcer in the kidneys or bladder, medicines must be given that sheath the acrimony, such as syrup of marsh-mallows, also infusions of the vulnerary herbs above-mentioned, likewise of the barks of acacia, cherry-tree, and gum.

When grumous blood plugs up the passage of the ureter into the bladder, or the sphincter of the bladder, and occasions a difficulty or stoppage of urine, warm water drank plentifully, and baths of the same, are useful: likewise warm water should be injected into the bladder with a syringe, that the sharp humour may be diluted, and the grumes dissolved: but if the urine should be quite stopped with a spasm, then give emulsions of the four cold seeds, with crabs-eyes, and calx of antimony. Externally apply a bladder filled with a decoction of emollient flowers in milk to the abdomen, and keep the body open with manna, or an emollient oily clyster. Milk and whey are likewise excellent in these disorders, if a dram of bole armenic is taken in every draught.

It is an error of fatal consequence to give astringents in these disorders, which stop the flux too suddenly.

For such preternatural hæmorrhages as derive their origin from external accidents, as falls, blows, and wounds, see the articles **CONTUSION**, **WOUND**, **FISURE**, **CONTRAFFISURE**, &c.

For artificial hæmorrhages by bleeding, cupping, and the like, see the articles **PHLEBOTOMY**, **CUPPING**, &c.

For the critical hæmorrhages in fevers, &c. See the article **FEVER**, &c.

**HÆMORRHOIDAL**, an appellation given by anatomists to the arteries and veins going to the intestinum rectum. The internal hæmorrhoidal artery is a branch of the inferior mesenteric; and the external one, a branch of the iliac. The hæmorrhoidal veins are branches of the hypogastrics.

**HÆMORRHOIDS**, or **PILES**, in medicine, an hæmorrhage, or flux of blood from the hæmorrhoidal vessels. See **HÆMORRHAGE**, and **HÆMORRHOIDAL**. When the hæmorrhoidal vessels only swell, and discharge no blood, but are exceeding

exceeding painful, this is termed the blind piles.

All copious fluxes of the blood from the anus, are not to be reckoned of the morbus kind. For the habit of body, strength, age, and temperament, of the patient are to be considered. That which is enormous and excessive to one person, may be moderate and salutary to another. That only is to be esteemed pernicious, which continues too long, and enfeebles the patient, whereby the digestion, nutrition, and other functions are hurt, and there is reason to fear the production of dangerous chronic diseases. An extensive hæmorrhoidal flux is generally preceded by a heavy pressing pain of the back and loins: sometimes a numbness of the legs and thighs; a constriction of the external parts, with a slight shivering, and a subsidence of the vessels therein; a hard contracted pulse; a dryness of the mouth and fauces; the urine diminished in quantity, and most commonly pale; a sense of weight about the anus extending to the perinæum; a weakness of the stomach; a flatulency in the lower belly; a frequent desire to make water, and to go to stool; with sometimes an exclusion of a white bilious mucus; the old and weak have a *pro-cidentia ani*.

In this case the blood is generally at first black, and very grumous, and sometimes comes away in large clots from the varicous vessels; afterwards it becomes red, and at last serous: sometimes it is pituitous, or like the white of an egg. There are instances of voiding a pint or a quart of blood daily. It often continues long, from twenty to thirty, or even forty days.

The external or blind piles seldom bleed, but turn to painful varices, which being opened, weep a little, but will not yield much blood. But the internal piles, which are the off-spring of the splenic branch, and are extended to the inner substance of the rectum, and as far as the sphincter of the anus, together with the small arteries derived from the lower meseraic, not only bleed plentifully, but when the flux is suppressed create diseases of the liver, spleen, pancreas, mesentery and intestines.

The persons subject to this disease, are those of a loose, spongy texture, of a bulky size, who live high, and lead a sedentary life, or to whom it is hereditary: sharp purges, aloetics, high-seasoned

food, free drinking of sweet wines, neglect of customary bleeding, anger, sadness, hard riding, and the like, will usher in this disorder.

This hæmorrhage is dangerous, because it decays the strength, wastes the body, and produces a sense of weight in the thighs. The sleep is laborious, and the precordia oppressed, there is a rumbling in the belly, and a weak pulse. When it continues long, the ancles swell, and the countenance is ghastly. There is a straitness of breathing; and last of all, it terminates in a cachexy, dropsy, or a slow and hectic fever.

If the patient is plethoric, bleed, and let his drink be cold water of the chalybeate kind; or whey turned with orange juice, or juleps, made with tincture of roses, cooling waters, and syrup of roses; likewise nitre, in powder, with absorbents; and to appease the spasm, opiates of the mildest kind.

If it continues long, and the blood begins to grow serous, then give rhubarb with currants, and tamarinds, or which is much the same, with cream of tartar. Then gentle diaphoretics may be compounded of burnt hartshorn, calx of antimony, wine-vinegar, mixt with crabs-eyes, water of elder flowers, simple alexitereal water, and diascordium, or hot decoctions of yarrow, veronica, &c. may be taken in bed in order to sweat; also half a grain of camphor mixt with nitrous and bezoardic powders. The camphor may seem an inconsiderable dose, yet its efficacy is very great in disorders of this kind.

In the blind piles there is a most intense pain at the time of going to stool, and the excrements are tinged with blood: sometimes tumours like warts lie hid under the sphincter, or appear on the verge of the anus. Sydenham orders to take away ten ounces of blood from the arm; then to dissolve two drams of litharge, in four ounces of spring water, with which mix one scruple of thebaic extract. Dip a hot cloth in a little of this mixture, and apply it to the part; or if the tumour is within, inject a few spoonfuls of it with a syringe; the patient must abstain from flesh, drink barley water, and take diacodium every night.

Sometimes the veins in the blind piles are so much dilated with blood, as to be very painful, and raise tubercles as large as pease, grapes, or eggs: they appear livid and black from the stagnation of a thick

thick blood, and when pressed with the fingers, feel like a bladder filled with liquor. Some are soft and indulent, others hard, inflamed, and painful, rendering the patient unable to walk, sit, or stand, and produce such a spasm in the anus, as not to admit a clyster: sometimes they bleed, or turn to troublesome itching ulcers, and occasion an abscess, or a fistula.

According to Heister, linnen dipt in warm spirit of wine, and emollients, are of infinite service. Leeches may be also applied to exhaust the blood; if they are not at hand, and the parts are inflamed, the lancet must be used; then dressings must be made with lint, with compresses, and the T bandage. The tubercles, which are full and large, may be removed by a ligature, unless inflamed. Sometimes they are high in the rectum, and then a speculum ani must be used, in which case they must be either scarified with a lancet, or divided with scissars, that the thick noxious blood may be discharged, and the pains relieved.

**HÆMUS**, now called **RHODOPE**, a mountain that divides Bulgaria from Thrace, or Romania, in European Turkey.

**HÆREDE ABDUCTO**, an antient writ that lay for the lord, who having the wardship of his tenant while under age, could not come by his body, it being carried away by another person.

**HÆREDE DELIBERANDO**, &c. a writ directed to the sheriff, to require one who had the ward of another, to deliver him to the person whose ward he was, on account of his land.

**HÆREDE RAPTO**, or ravishment de gard. See the article **RAVISHMENT**.

**HÆRESY**, the crime of heretics. See the article **HERETIC**.

**HÆRETICO COMBURENDO**, a writ which formerly lay against one convicted of heresy by his bishop, and having abjured, afterwards fell into it again, or at least into some other, upon which he was committed into the hands of the secular power; and by virtue of this writ, upon a certificate of his conviction, he was burnt.

This writ was taken away by statute 29 Car. II. c. 9.

**HAERLEM**, a populous city of the United Provinces, in the province of Holland, situated near the lake which from this town is called Haerlem-Meer; four miles east of the ocean, and twelve west of

Amsterdam: east long. 4° 20', north lat. 52° 30'.

**HAGAI**, a canonical book of the Old Testament, so called from the prophet of that name, who, in all probability was born at Babylon, from whence he returned with Zerubbabel.

This prophet, by the command of God, exhorted the Jews, after their return from the captivity, to finish the rebuilding of the temple, which they had intermitted for fourteen years. His remonstrances had the desired effect; and to encourage them to proceed in the work, he assured them from God, that the glory of this latter house, should be greater than the glory of the former: which was accordingly fulfilled, when Christ honoured it with his presence; for, with respect to the building, this latter temple was nothing in comparison of the former.

**HAGENAU**, a fortified town of Germany, in the Landgraviate of Alsace: east long. 7° 40', north lat. 48° 45'.

**HAGGARD FALCON**, the greenish legged falcon, with a livid back. It is a large species, equal to a full grown hen in size. See the article **FALCON**.

**HAGIAZ**, a province of Arabia, whereof Mecca is the capital.

**HAGIOGRAPHIA**, or holy writings, a name given to a particular division of the Old Testament, as containing hymns to God, and moral precepts for the conduct of life. The books distinguished by this term were the Psalms, Proverbs, Ecclesiastes, and the Song of Solomon.

**HAGIOSIDERON**, in the greek church, a name given to an instrument made of iron, used by the Greeks, under the dominion of the Turks, to supply the place of bells, the use of which is prohibited. It is a plate of iron about three inches broad, and sixteen long, fastened by the middle to a chain or cord, and hung at the church door; on this they strike with an iron-hammer, with a kind of measure or cadence that is not disagreeable.

This is used to call the people to church; and it is also carried before the priest, in a procession of the sacrament to a sick person, when it is beat upon from time to time, to advertise the people to adore it, just as the romish church do with a bell.

**HAGUE**, a town of the United Provinces, in the province of Holland, situated two miles

miles east of the sea, and fourteen north-west of Rotterdam. This is one of the finest towns in Europe; but tho' it enjoys all the privileges of a city of Holland, except that of sending representatives to the states, yet as it has no walls, it is only esteemed a village. Here every city of the United Provinces has a house for their respective deputies, and here the states of the province of Holland assemble, and all public affairs are transacted.

**HAIL**, *grando*, in physiology, an aqueous concretion, in form of white or pellucid spherules, descending out of the atmosphere.

Hail is evidently no other than drops of rain congealed into ice. This happens when in their passage thro' the inferior air, they meet with nitrous particles, which are known to contribute greatly to freezing. Their magnitude is owing to a fresh accession of matter as they pass along. Hence we see the reason why hail is so frequent in summer, because at that time greater quantities of nitre are exhaled from the earth, and float up and down the air. See the articles **RAIN** and **FROST**.

**HAILBRON**, a city of Germany, in the Circle of Swabia, and duchy of Wirtemberg: east long. 9° north lat. 49° 10'.

**HAINAN**, or **AYNAN**, an island of an oval form, and about 300 miles in circumference, about fifty miles south of the continent of China, and subject to that emperor. It is situated between 107 and 120° of east long. and between 18 and 20° of north latitude.

**HAINAULT**. See **HAYNAULT**.

**HAINBURG**, a town of Germany, in the circle and archduchy of Austria, situated on the Danube, thirty-five miles east of Vienna: east long. 17° 8' north lat. 48° 20'.

**HAINES**, a river of the Austrian Netherlands, which runs from east to west thro' the province of Hainault, and falls into the Scheld at Conde.

**HAIR**, in physiology, slender, oblong, and flexible filaments, growing out of the pores of animals, and serving most of them as a covering.

When these filaments, in human subjects, grow on the body, they are denominated *pili*; when on the head, *capilli*. These last are most proper for examination: that part of them, which is without the skin, appears cylindric to the naked eye; but, when examined by the

help of glasses, it is found to be unequal and irregular, and often knotty. It is pellucid, but is not hollow; but the extremities of them are often split into several parts, so as to resemble a pencil. The part of the hair that is within the skin, is called the root of it; and, from its roundish figure, the bulb. This part is hollow and vasculous, in the manner of the bases of the young feathers on birds: this vasculous part is inclosed in a follicle, or case, and is most conveniently to be examined in the large hairs of a cat's whiskers, or in the beards of other animals.

The origin of the hair is in the cutis, and in the fat that lies underneath it; and probably from nerves, as an acute pain is felt in pulling them off. The nutritious matter of the hair is probably the same with that of the other parts of the body; not merely excrementitious, as the old authors have supposed. It is a common assertion, that the hair grows after a person is dead; but unquestionable experiments prove this to be of the number of vulgar errors, not at all the more true for being universally received as truth.

The colour of the hair is very different in different people of the same country; but there are also general differences of it, peculiar, in a manner, to the climates. In the hottest countries it is very black; in the colder, it is yellowish, redish, or brown; but in all places it grows grey or white with age; and in the labourers in copper mines, and others, who are continually receiving the effluvia of that metal, it becomes greenish. The length of the hair is, in the individual, very different. It is always much longer on the head than elsewhere. In general, it is short and curled under the torrid zone, and gradually longer in the more temperate climates. Its consistence to the touch, also, varies greatly, 1. In regard to the different climates and subjects. In general, it is harsher in the *Æthiopian* than in the *European*; and harder and drier in adults than in infants, whose habit abounds more with humidities. 2. In regard to the parts of the body on which it grows; it is very harsh and hard under the arm-pits, and about the pudenda: on the head it is much softer; and on all the other parts of the body it is greatly softer than there, and very short.

As to the time of the origination of the hair, that of some parts of the body is of the same date with the parts it grows on; such is that of the head, the eye-lashes, and eye-brows. That of others begins to grow only at a certain time; such is that of the beard, of the arm-pits, and of the pudenda: and in the same manner some of the hair continues always increasing in length, while other parts of it never grow after the birth of the infant.

The use of the hair of the head is to keep that part warm, as well as to be an ornament to it: that of the rest of the hair, except only that of the eye-brows and eye-lashes, is not so easily determined.

*Human-HAIR*, in commerce, makes a considerable article of trade, the goodness of which consists in its being neither too coarse, nor too slender.

Hair that does not curl or buckle naturally, is made to do so by first boiling, and then baking it. Having sorted it, they next roll it carefully upon pipes, hollowed in the middle; these they put into a pot or cauldron, and let them boil about two hours; then taking them out, they are dried and covered with papers; and, lastly, sent to the pastry-cook, who bakes them in an oven, till the crust with which they are covered is about three fourths baked.

The hair of several other animals, as the beaver, hare, coney, &c. is also used in commerce, and especially in the manufacture of hats. See the article *HAT*. As to the duties upon hair, that of camels pays, upon importation  $6\frac{93}{100}$ d. each pound; and draws back, upon exportation,  $6\frac{72\frac{1}{2}}{100}$ d. Cow or ox-hair,

pays  $7s. 2\frac{17\frac{1}{2}}{100}$ d. the 112 pounds; and draws back, upon exportation,  $6s. 5\frac{62\frac{1}{2}}{100}$ d. Elks-hair for saddles, the hundred weight, pays  $2s. 4\frac{87\frac{1}{2}}{100}$ d. and draws back, upon exportation,  $2s. 13\frac{11}{100}$ d. Ordinary goats-hair pays  $4\frac{57}{100}$ d. the pound; and draws back, upon exportation,  $4\frac{23\frac{3}{4}}{100}$ d. Goats-hair, otherwise called carmenia-wool, pays  $6\frac{44\frac{1}{2}}{100}$ d.

the pound; and draws back, upon exportation,  $6\frac{11\frac{1}{2}}{100}$ d. Horse-hair pays  $7\frac{18\frac{1}{2}}{100}$ d. the pound; and draws back, upon exportation,  $6\frac{46\frac{7}{8}}{100}$ d. Human hair

for perukes, pays  $1s. 7\frac{15}{100}$ d. the pound; and draws back, upon exportation,  $1s. 5\frac{25}{100}$ d.

*HAIR*, among farriers, is generally called the coat; and, with regard to horses, deserves particular consideration.

The hair growing on the fetlock, serves as a defence to the prominent part of it, in travelling in stony ways, or in frosty weather: if the hair of a horse's neck, and the parts most uncovered, be close, smooth and sleek, it is an indication of his being in health and good case. In order to make the hair of an horse soft and sleek, he must be kept warm at heart, for the least inward cold will cause the hair to stare; also sweat him often, for that will loosen, and raise the dust and filth that renders his coat foul; and when he is in the heat of a sweat, scrape off all the white foam, sweat and filth that is raised up, with an old sword blade; and also when he is blooded, if you rub him all over with his own blood, repeating it two or three days, and curry and dress him well, it will make his coat shine as if covered with a fine varnish.

Hair falling from the main or tail, is caused either by his having taken some heat, which has engendered a dry mange; or from some surfeit which causes the evil humours to resort to those parts. To cure this, anoint the horse's mane and crest with black soap; make a strong lee of ashes, and wash it all over with it. But if a canker should grow on a horse's tail, which will eat away both flesh and bone; then put some oil of vitriol to it, and it will consume it: and if you find that the vitriol corrodes too much, you need only to wet it with cold water, and it will put a stop to it.

If you would take away hair from any part of a horse's body; boil half a pound of lime in a quart of water, till a fourth part is consumed, to which add an ounce of orpiment; make this into a plaster, and lay it on.

*HAIR'S-BREADTH*, a measure of length, being the forty-eighth part of an inch.

*HAKÉ*, in ichthyology, the english name of the gadus, with two fins on the back, and

and the under jaw longest. It grows to two feet or more in length, but is the slenderest of all the gadi. See *GADUS*.

**HALABAS**, a city of the higher India, and capital of the province of Halabas, situated at the conflux of the rivers Ganges and Jemna: east long.  $85^{\circ}$  north lat.  $26^{\circ} 35'$ .

**HALBARD**, or **HALBERT**, in the art of war, a well-known weapon, carried by the serjeants of foot and dragoons.

It is a sort of spear, the shaft of which is about five feet long, and made of ash, or other wood. Its head is armed with a steel point, edged on both sides, not unlike the point of a two-edged sword. But besides this sharp point, which is in a line with the shaft, there is a cross piece of steel, flat and pointed at both ends; but generally with a cutting edge at one extremity, and a bent sharp point at the other; so that it serves equally to cut down, or push withal. It is also useful in determining the ground betwixt the ranks, and in adjusting the files of a battalion.

**HALBERSTAT**, a city of Germany, in the circle of Upper Saxony, the capital of the dutchy of the same name; subject to the king of Prussia, east long.  $11^{\circ} 6'$ , north lat.  $51^{\circ} 55'$ .

**HALBERT**, among farriers, is a small piece of iron an inch broad, and three or four inches long, soldered to the toe of a horse's shoe, to hinder a lame horse from treading on his toe.

These halbert-shoes necessarily constrain a lame horse, when he goes at a moderate pace, to tread or rest on his heel, which lengthens and draws out the back sinew, that was before in some measure shrunk.

**HALCRYPTIUM**, a name given by Dr. Hill, to the salt suspended in a fluid form, and in very small quantities, in mineral waters, scarce discernible by the taste, and with much difficulty separable from them; but, by proper management, may be procured in form of a dry powder; which, being carefully prepared by solution and evaporation, affords extremely minute, oblong, quadrangular crystals. The halcryptium, thus obtained, has all the properties of the common alkaline salts. See the article *ALKALI*.

All the chalybeate waters afford it; but none in such large quantities as that of Pyrmont. See the article *PYRMONT*.

**HALCYON**, in ornithology, a name given by the antients to the *lipida*, or king-fisher. See the article *KING-FISHER*.

**HALCYON DAYS**, *dies halcyonii*, in antiquity, a name given to seven days before and as many after the winter-solstice; by reason the halcyon, invited by the calmness of the weather, laid its eggs in nests built on the rocks, close by the brink of the sea, at this season.

**HALE**, in the sea-language, signifies pull; as to hale up, is to pull up; to hale in or out, is to pull in or out. To over-hale a rope, is to hale it too stiff, or to hale it the contrary way.

*Keel-HALE*. See the article *DUCKING*.

**HALEM**, a town of the Austrian Netherlands, in the province of Brabant, twenty-five miles west of Maestricht: east long.  $5^{\circ} 5'$  north lat.  $51^{\circ} 5'$ .

**HALESWORTH**, a market-town of Suffolk, thirty-five miles east of Bury: east long.  $1^{\circ} 40'$ , north lat.  $52^{\circ} 30'$ .

**HALF-BLOOD**, in law, is where a man marries a second wife, the first being dead, and by the first venter has a son, and by his second venter has likewise a son, the two brothers in this case are but of half-blood; they being issue by different venters; and on that account, lands in fee cannot descend from the one to the other; except in case of crown-lands, dignities, or estates-tail. But half-blood is no impediment to an administration, which may be granted to that as well as to the whole blood, of the effects of an intestate; and the half-blood shall come in for a share of his personal estate, equally with the whole blood, as the brothers by different venters are next of kin in equal degree. 22 Car. II. c. 10.

**HALF-MARK**, a noble or 6s. 8d.

**HALF-MOON**, in fortification, an outwork composed of two faces, forming a salient angle, whose gorge is in form of a crescent, or half-moon; whence the name.

We owe the invention of half-moons to the Dutch, who placed them before the points of bastions, which are now much better defended by counter-guards; the half-moons being placed before the curtains, which they defend to admiration.

There are two sorts of half-moons, one with, and the other without flanks. Those without flanks, which are most common, may be thus constructed: From F, (plate CXXV. fig. 1.) the angle of the flank, describe an arch, M A, with the radius FM, four or five toises longer than the part of the line of defence EF. The point A, where this arch intersects the line C A, which divides the curtain in

two equal parts, shall be the flanked angle of the half-moon; then the points, *b, b*, where the line of the counterscarpe intersects the line *A M*, will determine the length of its faces, *A b, A b*. Those with flanks are constructed much in the same manner; only that *D b*, from four to ten toises, is cut off of each demigorge, and the flanks *D G, E F*, are raised perpendicular to the curtain:

**HALL-SEAL**, that used in the court of chancery for sealing commissions to delegates, upon any appeal, in ecclesiastical or marine causes.

**HALL-TANGENTS**. See the articles **TANGENT** and **SCALE**.

**HALF-TONGUE**, *medietas linguæ*, among lawyers. See the article **MEDIETAS**.

**HALLÆTUS**, in ornithology, a name used by some for the bald buzzard. It is of the size of a large cock, and its head is white, whence it has got the epithet bald, because at a distance it appears as if there were no feathers on it.

**HALIOTIS**, the **EAR-SHELL**, in conchyliology, a simple shell without any hinge, and formed all of one piece, of a depressed figure, very patent at the mouth, having an approach to the spiral form at the summit, and having several perforations on the lateral part of the disk. It has got the name ear-shell from its figure. See **EAR** and **AURIS**.

**HALL**, in architecture, a large room at the entrance of a fine house and palace. Vitruvius mentions three kinds of halls; the tetrastyle, with four columns, supporting the platform, or ceiling; the corinthian, with columns all round let into the wall, and vaulted over; and the egyptian, which had a peristyle of isolated corinthian columns, bearing a second order with a ceiling.

The hall is properly the finest as well as first member of an apartment; and in the houses of ministers of state, magistrates, &c. is the place where they dispatch business, and give audience. In very magnificent buildings, where the hall is larger and loftier than ordinary, and placed in the middle of the house, it is called a saloon. See **APARTMENT**.

**HALL**, in old writers, is also used for a mansion-house; and to this day, in many parts of the kingdom, gentlemen's seats are called halls.

**HALL** is also a public building, or court of justice, as Westminster-hall, Guild-hall, a company's hall, &c.

In Westminster-hall are held the courts of King's bench, Common-pleas, Chancery, and exchequer. See the articles **KING'S BENCH**, **COMMON-PLEAS**, &c.

**HALL**, in geography, a town of Germany, in the circle of Austria, and county of Tyrol, situated six miles north-east of Inspruck: east long.  $11^{\circ} 28'$  north lat.  $47^{\circ} 15'$ .

**HALL** is also a town of the Austrian Netherlands in the province of Brabant, seven miles south of Brussels: east long.  $4^{\circ} 10'$ , north lat.  $50^{\circ} 50'$ .

**HALL** is also a city of Germany, in the circle of Upper Saxony, the capital of a dutchy situated on the river Sala, subject to the king of Prussia: east long.  $12^{\circ} 5'$  north lat.  $51^{\circ} 35'$ .

**HALL** is also a town of Germany, in the circle of Swabia, twenty miles east of Hailbron; being an imperial city, or sovereign state: east long.  $9^{\circ} 45'$ , north lat.  $49^{\circ} 20'$ .

**HALLAGE**, a fee or toll paid for cloth brought to be sold in Blackwell-hall, London.

**HALLAMAS**, the same with all-saints. See the article **ALL-SAINTS**.

**HALLATON**, a market-town, ten miles south-east of Leicester.

**HALLAND**, a subdivision of Gothland, in Sweden, at the entrance of the Baltic.

**HALLEIN**, a town of Bavaria, eight miles south of Salzburg.

**HALLELUJA**, a word signifying, praise the Lord.

The singing halleluja was a sort of invitational, or call to each other, to praise the Lord.

St. Austin says, that in some churches, it was sung only on Easter-day, and the fifty days of Pentecost; but that even in those churches where it was most in use, it was never used in the time of Lent. The fourth council of Toledo forbids the singing it, not only during Lent, but on all other days of fasting; and by the same council it is appointed to be sung after the reading of the gospel. It was also sung at funerals, as St. Jerom informs us in his epitaph of Fabiola, where he speaks of the whole multitude singing psalms together, and making the golden roof of the church shake with echoing hallelujas.

**HALLEN**, a town of the austrian Netherlands, in the province of Brabant: east long.  $5^{\circ}$ , north lat.  $50^{\circ} 55'$ .

**HALLEIN**, a town of Germany, in the archbishopric

Fig. 1. H A L F M O O N.

Fig. 2. H A L O.

archbishopric of Saltzburg: east long.

$13^{\circ} 6'$ , north lat.  $47^{\circ} 36'$ .

**HALLER**, a town in the Netherlands, in the province of Brabant: east long.  $5^{\circ}$ , north lat.  $50^{\circ} 40'$ .

**HALLERIA**, in botany, a genus of the *didymia-angiospermia* class of plants, the flower of which is monopetalous and ringent, with a quadrifid limb: the fruit is a berry, containing two cells, with a solitary seed.

**HALLIFAX**, a large market-town in the west riding of Yorkshire, thirty four miles south-west of York: west long.  $1^{\circ} 40'$ , north lat.  $53^{\circ} 45'$ .

**HALMSTAT**, a port-town of Gothland in Sweden, eighty miles south of Gottenberg: east longitude  $13^{\circ} 5'$ , north lat.  $56^{\circ} 45'$ .

**HALO**, in physiology, a meteor in the form of a luminous ring or circle, of various colours, appearing round the bodies of the sun, moon, or stars. See the articles **COLOUR**, **SUN**, &c.

Concerning the production of halos, Sir Isaac Newton intimates, that they are formed by the light which comes through the drops of rain, by two refractions, *viz.* at N and F (plate CXXV. fig. 2. n<sup>o</sup> 1.) without any reflection; but how this may be, is not easy to conceive.

A rainbow, or deeply coloured ring, as will be shewn under rainbow, might have been expected at the distance of about thirty-eight degrees from the sun; and also why it cannot happen. See **RAINBOW**.

For the same reason we should also not expect an halo to be formed by the same refracted rays, *viz.* on account of their not being refracted parallel to the eye, and consequently not entering it dense enough to render that part of the heaven more luminous than the rest; or to produce the lucid ring we call by this name. Again, Sir Isaac says, it ought to appear strongest at the distance of about twenty-six degrees from the sun, *viz.* when the angle  $IMG = 26^{\circ}$ , and to decay gradually both ways. But though that philosopher did not undoubtedly assert any thing without very great reason, yet this does not appear to us. For that the angle  $IMG$  may be twenty-six degrees, the angle of incidence  $BCN$  must be about forty-six; and then the angle of refraction  $CNF$  will be near thirty-three degrees: but why such an incidence and refraction should cause the rays to be refracted in greater plenty to the eye than any other, does not appear to me, says

Martin, nor can I find it by any experiment. On the contrary, as the angle  $IMG$  increases with the angle of incidence, and consequently with the angle of refraction, it is evident that with respect to heterogeneous light, the greater the angle  $IMG$  is, the more will it be refracted and scattered; and consequently the farther the drops are situated from the sun, the less dense will be the light transmitted by refraction to the eye, which therefore ought to decrease, as the distance of the sun increases. See **REFRACTION**.

As Sir Isaac Newton has said but little, so his expositors Dr. 'S Gravesande and Dr. Pemberton have thought fit to be absolutely silent on this head. Mr. Huygens has advanced an hypothesis by which the phenomenon may be solved, if we grant him the following postulatam, *viz.*

That there are certain globules in the atmosphere, consisting of a coat or shell of transparent ice or water, containing an opaque nucleus or kernel within; and that these are made from particles of snow, which is in itself opaque, attracting the aqueous particles in the vapour or exhalation by which it is sustained, which gathering together, form the semipellucid shell of water, or are frozen into a crystalline shell of ice; and this, he thinks, is proved to be matter of fact by the hailstones which fall to the earth: for these, says he, when broken, discover some snow at the center.

These things premised, he addresses himself to the solution, as follows. Let  $ABCD$  (*ibid.* n<sup>o</sup> 2.) represent such a globule with the opaque nucleus  $EF$  in the middle of it; and let us suppose the rays coming from  $G, H$ , to fall on the side  $AD$ . It is manifest they will be refracted inwards, from the surface  $AD$ ; from whence it follows that a great number of them must strike upon the kernel  $EF$ . Let  $GA$ , and  $HD$ , be the rays which, after refraction, touch the sides of the kernel  $EF$ , and let them be refracted again at  $B$  and  $C$ , emerging in the lines  $BK$ , and  $CK$ , crossing each other in the point  $K$ , whose distance from the globule is somewhat less than its semidiameter.

Wherefore, if  $EK$  and  $DK$  be produced towards  $M$  and  $L$ , it follows that no light coming from the sun through the globule, can proceed to the eye any where placed within the angle  $LKM$ , or rather in the cone which that represents; supposing that the obliquity of the incident rays  $HD$  and  $GA$  is such as shall

make the arch QC, and QB, the greatest possible: for then all the rays exterior to HD and GA, will be refracted nearer to Q, and after emergence cross each other in a point *k*, nearer the globule than the former; and therefore cannot come at the eye placed within the said cone LKM. Suppose now the eye placed at N, (*ibid.* n° 3.) and let NR, NQ, be drawn parallel to LK, and MK; then it is plain none of the globules, the same as ABCD, within the cone RNQ, can come to the eye at N. Thus the globules at O and P have their refracted rays *akb* and *ckd*, including the eye in the cone of obscurity. But other globules which lie without the cone QNR, as S and T, do not involve the eye N by their shadow-cones *lkc*, and *fmk*; and therefore some of those rays which are more refracted than *kc*, or *kf*, will fall upon the eye, and produce a luminous circular ring or corona, including a dark area within, and whose light outwardly decreases as it is more remote from the center.

**HALSFANG**, or **HEALSFANG**, in old writers, the same with pillory. See the article **PILLORY**.

Sometimes it signifies a mulct, paid to be exempted from that punishment.

**HALSTEAD**, a market-town of Essex, sixteen miles north of Chelmsford.

**HALTER**, in the manege, a headstall of hungary leather, mounted with one and sometimes two straps, with a second throat-band, if the horse is apt to unhalter himself.

**HALTER-CAST**, among farriers, an excoiation of the pastern occasioned by a horse's endeavouring to scrub the itching part of his body near the head and neck, when one of his hinder feet entangling in the halter, he sometimes receives very dangerous hurts in the hollow of his pastern by his struggling to disengage himself.

For the cure of this, take linseed-oil and brandy, of each an equal quantity; shake them together in a bottle till they are well mixt, and anoint the place morning and evening; having first clipt away the hair; but take care to keep the foot very clean.

**HALTERISTS**, *halteriste*, in antiquity, a sort of players at discus, so called from the greek *αλτηρ*; which is supposed to have been a leaden weight or ball, carried in each hand with a view to poise their bodies.

**HALTING**, among farriers, a limping or

going lame, an irregularity in the motion of an horse, arising from a lameness in the shoulder, leg, or foot, which makes him spare the part, or use it timorously.

Halting happens sometimes before, and sometimes behind; if it be before, the ailment must necessarily be either in the shoulder, knee, flank, pastern, or foot. If it be in the shoulder, it must be towards the withers, or in the pitch of the shoulder; and it may be known by his drawing one of his legs after him, and not fling it so nimbly as the other. If he cast it more outward than the other, it is a sign of lameness, and that the grief lies in the shoulder; and if you turn him short, on either hand, you will find that he will either favour that leg, or trip in turning. His lameness may also be seen by his standing in the stable, where he will hold the same leg more out than the other. If when you are upon his back, he complains more than he usually does, the grief certainly lies in the withers; so that on gripping him hard, you will perceive him to shrink, or perhaps offer to bite. If he treads thick and short before, then the grief is upon the pitch of the shoulder, close to the breast, which may be discovered by pressing the thumb hard against the place, on which he will shrink, and put back his leg, foot, and body. If the grief be in the elbow, it may be known by pinching him with the forefingers and the thumb, and then he will hold up his leg and offer to bite; but if the grief be in the knee, it may be discovered by the stiffness of his going; for he will not bend it so nimbly as he does the other. If it be in the flank or shinbone, the same may be seen or felt, it being a back sinew, splenter, strain, or the like. If it be in the bend of the knee, it is a malander, which is also easily discovered. Further, when the pastern or joint is affected, it may be known by his not bending it so well as the other, and by its being very hot. If it be in the foot, it must be either in the coronet or sole: if in the coronet, it probably came by some strain or wrench; if in the hoof, by some over-reach or distemper in or about the frush: if in the sole, from some prick, acclay, nail, &c.

**HALTWESEL**, a market-town of Northumberland, thirty-two miles west of Newcastle: west long. 2°, north lat. 55°.

**HALYMOTE**, in old law-books, signifies a holy or ecclesiastical court. See the article **COURT**.

**HALY**

**HALYWERC FOLK**, in old writers, were persons who enjoyed land, by the pious service of repairing some church, or defending a sepulchre.

This word also signified such persons in the diocese of Durham, as held their lands to defend the corps of St. Cuthbert, who from thence claimed the privilege of not being forced to go out of the bishopric.

**HAM**, in anatomy, the part behind the knee. See **KNEE** and **LEG**.

**HAM**, in old writers, a saxon word used for a home or dwelling-place, for a borough and a village, and also for a little narrow slip of meadow.

**HAMA**, in geography, a city of Germany, in the circle of Westphalia, and the capital of the county of Mark, subject to Prussia: east long.  $7^{\circ} 15'$ , north lat.  $51^{\circ} 35'$ .

**HAM**, in cookery, the leg and thigh of a hog seasoned and dried.

To salt a ham in imitation of those of Westphalia: let the ham be of young pork, sprinkle it with salt for one day, that it may fetch out the blood; then wipe it dry, and rub it with the following mixture: take a pound of brown sugar, a quarter of a pound of saltpetre, half a pint of bay-salt, and three pints of common salt; stir these together in an iron pan over the fire, till they are pretty hot, and then rub the leg of pork with it; let it lie three weeks in this salting, frequently turning it, and then dry it in a chimney.

**HAMA**, or **APAMEA**. See **APAMEA**.

**HAMADAN**, a city of Persia, in the province of Eyrac Agem, 200 miles north-west of Ispahan: east long.  $47^{\circ} 35'$ , north lat.  $35^{\circ}$ .

**HAMADRYADS**, in heathen theology, certain rural deities; being nymphs of the woods, whose fate depended on certain trees, together with which they were supposed both to be born and to die.

It was principally with oaks that these deities were thus united; and these nymphs were supposed to shew extraordinary gratitude to those who preserved them from death. As for those who destroyed the trees on which their life depended, they were sure to be punished for it in an exemplary manner.

It was easy for the Gentiles to fall into the opinion of these sort of divinities; for as they entertained a kind of religious veneration for such trees as were very old, and of an uncommon size, it was an easy transition to the belief, that they

were the abode and residence of some deity.

**HAMAMELIS**, in botany, a genus of the *tetrandria-digynia* class of plants, the corolla of which consists of four linear, equal, and very long petals: the fruit is a bivalve capsule, containing two cells: the seed is a single nucleus, of an oblong oval figure, and smooth surface.

**HAMAXOBIANS**, *hamaxobii*, an antient people of european Sarmatia, so called from their living together in chariots or waggons, for the convenience of shifting the place of their abode at pleasure.

**HAMBLING**, or **HAMELLING**, in the forest-law, is the ham-stringing of dogs, or cutting the great tendon called the ham-string.

**HAMBURG**, a large city and well fortified port-town of Germany, in the circle of lower Saxony, and dutchy of Holstein, situated on the north side of the river Elbe, partly on islands, and partly on the continent. It is an imperial city, or sovereign state, governed by its own magistrates, and subject only to the general laws of the empire. Merchants from all parts of Europe resort to it, from whence their goods are sent into the heart of the empire: east long.  $9^{\circ} 40'$ , north lat.  $54^{\circ}$ .

**HAMBURG-COMPANY** of merchants. See the article **COMPANY**.

**HAMCHEU**, the capital of the province of Chekiam, in China, situated on the river Cienton, 160 miles south-east of Nanking: east long.  $120^{\circ}$ , north lat.  $30^{\circ}$ .

**HAMELIN**, a town of Germany, in the circle of lower Saxony, and dutchy of Brunswick, subject to the elector of Hanover: east long.  $9^{\circ} 12'$ , north lat.  $52^{\circ} 15'$ .

**HAMELLING**, or **HAMBLING**. See the article **HAMELLING**.

**HAMIA**, or **AMIA**, in ichthyology. See the article **AMIA**.

**HAMILTON**, a town of Scotland, in the county of Clydesdale, situated on the river Clyde, eleven miles south-east of Glasgow: west long.  $3^{\circ} 50'$ , north lat.  $55^{\circ} 40'$ .

**HAMLE**, the name of the eleventh month of the ethiopian year, beginning on the 25th of June, old style.

**HAMLET**, **HAMEL**, or **HAMPEL**, is a small village, or part of a parish.

**HAMMER**, a well known tool used by mechanics, consisting of an iron-head, fixed cross-wise upon a handle of wood. There are several sorts of hammers used by black-smiths; as, 1. The hand-ham-

mer,

mer, which is of such weight that it may be wielded or governed with one hand at the anvil. 2. The up-hand sledge, used with both hands, and seldom lifted above the head. 3. The about-sledge, which is the biggest hammer of all, and held by both hands at the farthest end of the handle, and being swung at arms-length over the head, is made to fall upon the work with as heavy a blow as possible. There is also another hammer used by smiths, called a rivetting-hammer, which is the smallest of all, and is seldom used at the forge, unless upon small work. See Plate of Smithery.

Carpenters and joiners have likewise hammers accommodated to their several purposes. See Plate of Joinery.

**HAMMER**, *malleus*, in anatomy. See the articles **EAR** and **MALLEUS**.

**HAMMER** of a clock. See **CLOCK**.

*Coining with the HAMMER*. See the article **COINING**.

**HAMMOCK**, in a ship, a piece of canvas hung up fast by the four corners between decks, for seamen to sleep in.

**HAMMONT**, a town of Germany, in the circle of Westphalia, and bishopric of Liege, situated near the confines of Brabant: east long.  $5^{\circ} 32'$ , north latitude  $51^{\circ} 20'$ .

**HAMPER**, or **HANPER**, in chancery. See the article **HANPER**.

**HAMPSHIRE**, an english county, bounded by Berkshire, on the north; by Surrey and Sussex, on the east; by the english channel, on the south; and by Wiltshire and Dorsetshire, on the west. It comprehends the isle of Wight. Its chief towns are Winchester, Southampton, and Portsmouth.

*New* **HAMPSHIRE**, a province of New England, in north America, bounded by Nova Scotia, on the north; by the Atlantic ocean, on the east; by the province of Massachusetts-bay, on the south; and by New York, on the west: subject to Great Britain.

**HAMPSTEAD**, a pleasant village in Middlesex, four miles north of London.

**HAMSOKEN**, in old law-books, signifies the liberty or privilege a man enjoys in his own house. It is also said to signify a franchise granted to lords of manors, by which they hold pleas, and take cognisance of the breach of that immunity. In Scotland it is used for the crime of him that violently, and contrary to the peace, assaults a person in his own house.

**HAMPTON**, a market-town of Gloucestershire, twelve miles south of Gloucester: west long.  $2^{\circ} 15'$ , north lat.  $51^{\circ} 38'$ .

**HAMPTON**, is also a port-town of New Hampshire, forty miles north of Boston: west long.  $70^{\circ}$ , north lat.  $42^{\circ} 35'$ .

**HAMPTON-COURT**, a town in Middlesex, situated on the north side of the Thames, twelve miles west of London, and two west of Kingston; in which is the finest palace belonging to the king of England.

**HANAPER**, or **HANPER**, in chancery. See the article **HANPER**.

**HANAU**, the capital of a county of the same name in Germany, is pleasantly situated on the river Kunts, thirteen miles east of Francfort, and twelve north-west of Aschaffenburg: east long.  $8^{\circ} 45'$ , north lat.  $50^{\circ} 12'$ .

**HANCES**, in a ship, are falls or descents of the sife rails, which are placed from the stern down to the gang-ways.

**HAND**, *manus*, in anatomy, the extreme part of the arm. See the article **ARM**.

The bones of the hand are those of the carpus, metacarpus, and fingers, with the ossa sesamoidea. See **CARPUS**, &c.

The gibbous or convex part of the two first of these bones, constitutes the back of the hand; and the hollow part, the palm. Their bodies are placed distant from each other, and the interstices between them are filled up with the muscles called *musculi interossei*, serving to move the fingers.

As for the muscles of the hands, see the articles **FINGER**, **WRIST**, **METACARPUS**, &c.

The mechanism of the hand, is admirably contrived to answer the manifold uses and occasions wherein it is employed, being made up not only of nerves, muscles, &c. but a great number of little bones, all curiously jointed into each other; whence its extraordinary flexibility, which enables it to lay hold of adjacent bodies.

*Luxation of the HAND*, in surgery. The hand is said to be luxated forwards, or inwards, when it recedes from the muscles that bend the fingers; the luxation is said to be backward, when it departs from the muscles which extend the fingers; and when the carpus makes a tumour near the thumb, and a cavity near the little finger, the luxation is said to be outward.

To reduce luxations of the hand, it must be sufficiently extended by two assistants; one

one of whom is to lay hold of the hand, and the other of the humerus, pulling in opposite directions; then the part of the hand where the sinus is, must be placed on a flat table, that whatever sticks out may be depressed by the surgeon, and the hand reduced into its natural state.

**HAND**, in the manege, a measure of four inches, or of a clinched fist, by which the height of a horse is computed. Thus, a horse of war should be sixteen hands high.

Hand is also used for the division of a horse, into the fore and hind parts. The parts of the fore-hand, are the head, neck, and fore-quarters; and those of the hind-hand, include all the other parts of his body.

Hand is also used for the horseman's hand. Thus spear-hand, or sword-hand, is the horseman's right hand; and bridle-hand, is his left hand. And as the bridle hand gives motion to the bit, and serves to guide the horse more than the other helps, there are several expressions which relate to it. As, this horseman has no hand, that is, he makes use of the bridle unseasonably, and does not know how to give the helps of the hand with due nicety. To keep a horse upon the hand, is to feel him in the stay upon the hand, and to be prepared to avoid any surprisal or disappointment from the horse. A horse is said to lie or to rest upon the hand, that never refuses, but always obeys the hand. A good horseman ought to have a light hand; that is, he ought to feel the horse upon his hand, only that he may resist him when he attempts to slip from it; and instead of cleaving to the bridle, he should lower it, as soon as he has made his resistance: thus if a horse, through his eagerness to go forward, presses too much upon the hand, the rider ought, at certain times, to slack his hand, and at other times to keep a hard hand, that he may disappoint the horse, and prevent his pressing continually upon the bit; and this facility of slackening and stiffening the hand, is what is called a good hand. A horse is said to force the hand, when he does not fear the bridle, but runs away in spite of the horseman. To make a horse part from the hand, or to suffer him to slip from the hand, is to put on at full speed. To work a horse upon the hand, is to manage him by the effects of the bridle, without any other helps, except, upon occasion, those of the calves of the legs.

To make a horse right upon the hand, and free in the stay, he must be taught, by degrees, and by gentle methods, to know the hand; the horseman must turn him, or change hands, stop him, or manage with dexterity the pressure of his mouth, so as to make him suffer cheerfully and freely the effect of the bit, without resisting or resting heavy upon the hand.

**HAND-BARROW**, a wheel-barrow, which is of great use in fortification, for carrying earth from one place to another, and in a siege, for carrying bombs or cannon-balls along the trenches.

**HAND-BOROW**, in law-books, a surety, or manual pledge, of an inferior rank; as head-borow signifies a chief or superior.

**HAND-BREADTH**, a measure of three inches.

**HAND-CUFFS**, an instrument formed of two circular pieces of iron, each fixed on a hinge at the ends of a very short iron bar, which being locked over the wrists of a malefactor, prevents his using his hands.

**HAND-HABEND**, in law-books, a thief caught with the stolen goods about him.

**HAND-HOOK**, an instrument used by smiths to twist square iron.

**HAND-SCREW**, an instrument more usually called a jack. See the article **JACK**.

**HAND-SPIKES**, wooden levers used at sea to traverse the ordnance, or to turn the windlafs in weighing up the anchor, &c. They are more commodious than iron crows, because their length allows a better poize.

**Harmonical HAND**, in music, a name given to the antient diagram. See **DIAGRAM**. The reason of this appellation was, that Guido Aretine, upon inventing the notes *ut, re, mi, fa, sol, la*, disposed them on fingers, of the figure of a hand stretched out. See the article **NOTE**.

He thus changed the letters of the alphabet, which till that time used to express the notes, for these six syllables, taken out of the first strophe of the hymn of St. John the baptist, composed by Paulus Diaconus.

*Ut queant laxis re-sonare fibris  
Mi-ra gestorum fa-muli tuorum,  
Sol-ve polluti la-bii rectum,*

*Sancte Johannes.*

**Imposition of HANDS**, the ceremony of laying the hands on the head of a person to be ordained. See **ORDINATION**.

**HANDS**, in heraldry, are borne in coat-armour dexter and sinister, that is, right and

and left, expanded or open. These are the most necessary parts of the human body, as they serve to express all sorts of actions, and even our very thoughts and designs; thus joining of hands is an universal token of friendship, and clapping of hands a general mark of applause.

**HANDLING**, among cock-fighters, signifies the measuring the girth of a cock's body, by the hands.

**HANGINGS**, the linings of rooms, whether made of paper, arras, or the like.

**HANKWITE**, or **HANGWITE**, a fine imposed for hanging a felon or thief, without due course of law, or for suffering him to escape out of legal custody. Thus to be quit of hangwite, denotes a freedom from the penalty above-mentioned.

**HANOVER**, a city of Germany, in the circle of Lower Saxony, and dukedom of Brunswick, situated on the river Leina, thirty-six miles west of Brunswick: it is the capital of his britannic majesty's german dominions, situated in east long.  $9^{\circ} 45'$ , north lat.  $52^{\circ} 32'$ .

**HANPER**, **HANAPER**, or **HAMPER**, an office of the chancery, answering to the *fiscus* of the Romans.

*Clerk of the HANPER*, or **HAMPER**. See the article **CLERK**.

**HANSE**, or **HANS**, a company of merchants united for the promotion and advantage of trade.

**HANSE-TOWNS**, port-towns of Germany, of which Lubec and Hamburg were the chief. They were formerly all of them imperial cities, confederated for their mutual defence, and the protection of their trade.

**HAP**, in a legal sense, signifies to catch the rent, where partition is made between two parceners, and more land is allowed to one than the other, and she who has most of the land charges it to the other, who haps the rent, &c.

\* **HAPPINESS**, among philosophers, consists in the enjoyment not only of the goods of the body, as health, strength, neatness, decency, &c. but also of the more refined goods of the mind, as knowledge, memory, taste, and especially the moral virtues, magnanimity, fortitude, benevolence, &c.

Human happiness, in the present state of things, consists of many separate and little rivulets, which must often be left dry in the perpetual flux and reflux of human affairs; yet the main stream, with which these lesser ones generally communicate,

flows from within, from the heart of man; and, if this be sound and clear, happiness will roll on through life with a strong and equal current. Many of the inferior goods that enter the account of happiness, as health, fame, fortune, and the like, are often even after our utmost care unattainable, or at least precarious; it is therefore of the utmost consequence to be prepared against the want or loss of them, by having our desires moderated, and our passions under due command. And, let it be remembered, that it is not only of great importance to our ease and security against ill, but one of the highest improvements of virtue, to condemn what is thus unattainable and precarious, to condemn those things the contempt of which is truly great and heroic, and to place our happiness chiefly in those virtuous exercises and affections which arise from a pure and well disposed mind, an happiness which no condition in life can exclude, no change of fortune interrupt or destroy. This will arm and fortify the mind against those pains, which result to the generality of mankind, from the contrary evils.

Hence it is evident, 1. That the happiness of such a creature as man, can never be at a stand, or continue a fixed invariable thing. His finite nature, let it rise ever so high, admits still higher degrees in improvements and perfection. And his progression in improvement, or virtue, always makes way for a progression in happiness, so that no possible point can be assigned in any period of his existence in which he is perfectly happy; that is, so happy as to exclude higher degrees of happiness. All his perfection is only comparative. 2. It appears that many things must conspire to complete the happiness of so variable a creature as man, subject to so many wants, and susceptible of such different pleasures. 3. As his capacities of pleasure cannot be all gratified at the same time, and must often interfere with each other in such a precarious and fleeting state as human life, or be frequently disappointed, perfect happiness, *i. e.* the undisturbed enjoyment of the several pleasures of which we are capable, is unattainable in our present state. 4. That state is mostly to be sought after, in which the fewest competitions and disappointments can happen, which least of all impairs any sense of pleasure, and opens an unexhausted source of the most refined and lasting

lasting enjoyments. 5. That state which is attended with all those advantages, is a state or course of virtue. 6. Therefore, a state of virtue, in which the moral goods of the mind are attained, is the happiest state.

**HAQUEBUS**, the same with **harquebuss**. See the article **HARQUEBUSS**.

**HAQUENY**, or **HACKENY**. See the article **HACKENY**.

**HARANGUE**, a speech made by an orator in public.

It is frequently used for a too pompous and prolix declamation.

**HARBINGER**, an officer of the king's household, having four yeomen under him, who ride a day's journey before the court, when it travels, to provide lodgings, &c.

**HARBOROUGH**, a town of Leicester-shire, thirteen miles south-east of Leicester: west long.  $1^{\circ}$ , north lat.  $52^{\circ} 26'$ .

**HARBOUR**, a place where ships may ride safe at anchor, chiefly used in speaking of those secured by a boom and chain, and furnished with a mole. See the articles **BOOM**, **CHAIN**, and **MOLE**.

By many acts of parliament, persons casting and unlading ballast, rubbish, or the like, in any harbour or haven, forfeit  $5l$ .

**HARBOURING**, among sportsmen, is said of a hart that goes to rest: hence to unharm a deer, is to dislodge him.

**HARBURGH**, a port-town of Germany, in the circle of Lower Saxony, and dutchy of Lunenburg, situated on the river Elbe, opposite to Hamburg: east long.  $9^{\circ} 30'$ , north lat.  $53^{\circ} 57'$ .

**HARCOURT**, a town of France, in the province of Normandy, twenty-three miles south-west of Rouen.

**HARDENING**, the giving a greater degree of hardness to bodies than they had before. See the article **HARDNESS**.

There are several ways of hardening iron and steel, as by hammering them, quenching them, when hot, in cold water, case-hardening, &c.

To harden english and swedish steel, being heated pretty hot, it is suddenly plunged in water; but spanish and venice steel requires only a blood-red heat, before it is quenched in the water: sometimes the steel is rubbed with a woollen rag, dipt in a mixture of powdered indigo and fallad-oil, while it is heating, and afterwards let cool of itself.

**Case-HARDENING** is performed after the following manner: take cow-horn or

hoof, dry it well in an oven; pound it to powder; put as much bay-salt as o this powder into stale urine, or white-wine vinegar, and mix them well together; then cover the iron or steel with this mixture, and wrap it up in loam or plate-iron, so that the mixture may touch every part of the work; then put it into the fire, and blow the coals till the whole lump has a blood-red heat, but no higher, and then take it out and quench it.

**HARDERWICK**, a town of Guelderland, in the United Netherlands, twenty-three miles north-west of Zutphen: east long.  $5^{\circ} 30'$ , north lat.  $52^{\circ} 35'$ .

**HARDNESS**, in physiology, that quality in bodies whereby their parts cohere firmly together, so as not to give way to any external impulse, nor yield inwards, without breaking.

In this sense hardness coincides with what on other occasions we call firmness, in opposition to softness and fluidity. See **SOFTNESS** and **FLUIDS**.

From that species of attraction called cohesion, it is easy to account for the different degrees of hardness in bodies: those whose constituent particles are flat or square, and so situated as to touch in many points, will be hard; those particles which are more round, and touch in fewer points, will constitute a softer body; those which are spherical, or nearly of that figure, will form a fluid. See the articles **ATTRACTION** and **COHESION**. But nothing can conduce more to explain the nature of this doctrine, than the following passage of Sir Isaac Newton.

“ The parts of all homogeneous bodies, says he, which fully touch one another, stick together very strongly. And for explaining how this may be, some have invented hooked atoms, which is begging the question; and others tell us, that bodies are glued together by rest, that is by an occult quality, or rather by nothing; and others, that they stick together by conspiring motions, that is, by relative rest among themselves. I had rather infer from their cohesion, that their particles attract one another by some force, which, in immediate contact, is exceeding strong; at small distances, performs many chemical operations, and reaches not far from the particles with any sensible effect. All bodies seem to be composed of hard particles: even the rays of light seem to be hard bodies; and therefore hardness may be reckoned the property of all uncompounded matter:

for all bodies, so far as experience reaches, are either hard, or may be hardened. Now if compound bodies are so hard, as we find some of them to be, and yet are very porous, and consist of parts which are only laid together, the simple particles which are void of pores, and were never yet divided, must be much harder. For such hard particles being heaped up together, can scarce ever touch one another in more than a few points, and therefore must be separable by a much less force than is requisite to break a solid particle where parts touch in all the space between them, without any pores or interstices to weaken their cohesion. And how such very hard particles, which are only laid together, and touch only in a few points, can stick together, and that so firmly as they do, without the assistance of something which causes them, to be attracted, or pressed towards one another, is very difficult to conceive."

There are several ways, says Mr. Boyle, whereby a body may be put into a texture proper to make it hard, though for the most part one of them is not employed apart, but two or more in conjunction. The first and chiefest of these seem to be the fitness and shapes of the component particles to fasten them to each other, as if some were figured like the handles of buckets, and others like the hooks employed to draw them; some like buttons, others like loops; some like male, others like female screws; or as if many together were so variously branched, that their parts may be interwoven one with another, and not prove easily separable; thus only, by twisting threads together, they are so well fastened to one another as to constitute a cable, which is not to be broken without a vast force. See the article *ATOM*.

And so numerous may be the correspondent figures fit to fasten bodies to one another, that it is very possible for two fluids, upon their conjunction, to intangle their parts, and thereby acquire such a new texture, that they cannot dissociate themselves, nor flow after the manner of liquors, but remain connected and unactive, as to become one intire hard body. See the article *FREEZING*.

**HARDS**, or **HURDS**, the coarser part of hemp or flax, separated from the fine. See the articles *HEMP* and *FLAX*.

**HARDY-SHREW**, in zoology. See the article *SHREW*.

**HARDY-SHRUBS**, among gardeners. See the article *SHRUB*.

**HARE**, in zoology, an animal of the *lepus*-kind, distinguished by its abrupt tail, and black eyes. It greatly resembles the rabbit, but is larger, and somewhat longer, in proportion to its thickness; and its ears are remarkably long, being always in a position to receive the least sound, and moveable with surprising ease. See plate *CXXVII*. fig. 1.

The hare is a beast of venery, or of the forest, but peculiarly so termed in the second year of her age. There are reckoned four sorts of them, from the place of their abode: some live in the mountains, some in the fields, some in marshes, and some wander about every where. The mountain-hares are the swiftest, the field-hares are not so nimble, and those of the marshes are the slowest; but the wandering hares are the most dangerous to follow, for they are cunning in the ways and mazes of the fields, and knowing the nearest ways, run up the hills and rocks, to the confusion of the dogs, and the discouragement of the hunters. See the article *HUNTING*.

**HARE-LIP**, *labium leporinum*, in surgery. See the article *LIP*.

**HARE'S EARS**, *bupleurum*, in botany. See the article *BUPLEURUM*.

**HARE'S LETTUCE**, a name sometimes given to the sonchus, or sow-thistle.

**HARE-STRONG**, the same with *peucedanum*, or hog's fennel.

**HARENGUS**, the herring. See the article *HERRING*.

**HARFLEUR**, a port-town of France, in the province of Normandy, situated near the mouth of the Seyne, four miles west of Havre de Grace: east long. 15°, north lat. 49° 36'.

**HARIOT**, or **HERIOT**, in law, a due belonging to a lord at the death of his tenant, consisting of the best beast, either horse, ox, or cow, which he had at the time of his death; and in some manors, the best goods, piece of plate, &c. are called harlots.

There is both hariot-service, and hariot-custom: when a tenant holds by service to pay a hariot at his decease, which is expressly reserved in the deed of feoffment, this is hariot-service; and where harlots have been customarily paid time out of mind, after the death of a tenant for life, this is termed hariot-custom. For hariot-service, the lord may distrain any beast belonging to the tenant, that is on the land. For hariot-custom, the lord is to seize and not distrain; but he may seize the

the best beast that belonged to the tenant, tho' it be out of the manor, or in the king's highway, because he claims it as his proper goods by the death of his tenant. Nevertheless, where a woman marries and dies, the lord shall have no harriot-custum, because a feme-covert has no goods to pay as a harriot.

**HARLE**, in ornithology, the name by which the merganser is called in several parts of the kingdom. See **MERGANSER**.

**HARLEBECK**, a town of the austrian Netherlands, in the province of Flanders, situated on the river Lys six miles north-east of Courtray : east long.  $3^{\circ} 15'$ , north lat.  $50^{\circ} 50'$ .

**HARLEQUIN**, a buffoon or merry-andrew; but is now used for a person of extraordinary agility, dressed in party-coloured cloaths, the principal character in a pantomime entertainment. See the article **PANTOMIME**.

**HARLESTON**, a market-town of Norfolk, situated on the river Waveney, fourteen miles south of Norwich : east long.  $1^{\circ} 25'$ , north lat.  $52^{\circ} 35'$ .

**HARLINGEN**, a port town of the United Netherlands, in the province of west Friesland, situated on the German sea : east long.  $5^{\circ} 20'$ , north lat.  $53^{\circ} 15'$ .

**HARLOT**, a whore, or one that prostitutes her body for hire. These are liable to be committed to prison, and kept to hard labour. For the punishment of those who keep and entertain them, see the article **BAWDY-HOUSE**.

**HARLOW**, a market-town of Essex, situated fifteen miles west of Chelmsford : east long.  $6'$ , north lat.  $51^{\circ} 45'$ .

**HARMALA**, in botany, a plant otherwise called peganum. See **PEGANUM**.

**HARMONIA**, **HARMONY**, in music. See the article **HARMONY**.

**HARMONIA**, in anatomy, a species of articulation, being a kind of symphysis intended for absolute rest. See the article **ARTICULATION**.

**HARMONICA**, **HARMONICS**, among musicians. See the article **HARMONICS**.

**HARMONICAL**, something belonging to harmony. See the article **HARMONY**.

**HARMONICAL ARITHMETIC**, that part of arithmetic which considers musical intervals, expressed by numbers, in order to our finding their mutual relations, compositions, and resolutions.

**HARMONICAL COMPOSITION**, in a general sense, includes both harmony and melody, *i. e.* of music or songs, both in a single part, and in several parts.

In its more proper and limited sense, harmonical composition is restrained to that of harmony; and may be defined the art of disposing and concerting several single parts together, so as to make one agreeable whole. See **HARMONY**, **COMPOSITION**, and **COUNTER-POINT**.

**HARMONICAL DIVISION**, in music. See the article **DIVISION**.

**HARMONICAL INTERVAL**, in music, denotes the difference of two sounds, which is agreeable to the ear, whether a consonance or succession; and are, therefore, the same with concord. See the articles **CONCORD** and **INTERVAL**.

**HARMONICAL PROPORTION**. See the article **PROPORTION**.

**HARMONICAL SERIES**, a series of many numbers in continual harmonical proportion. Thus if there are four or more numbers, of which every three immediate terms are harmonical, the whole will make an harmonical series: such is  $30 : 20 : 15 : 12 : 10$ . Or, if every four terms immediately next each other are harmonical, it is also a continual harmonical series, but of another species, as  $3, 4, 6, 9, 18, 36, \&c.$

**HARMONICAL SOUNDS**, an appellation given, by Mr. Sauveur, to such sounds as always make a determinate number of vibrations, in the time that one of the fundamentals, to which they are referred, makes one vibration.

Harmonical sounds are produced by the parts of chords, *&c.* which vibrate a certain number of times, while the whole chord vibrates once.

The relations of sounds had only been considered in the series of numbers,  $1 : 2, 2 : 3, 3 : 4, 4 : 5, \&c.$  which produced the intervals called octave, fifth, fourth, third, *&c.* Mr. Sauveur first considered them in the natural series,  $1, 2, 3, 4, 5, \&c.$  and examined the relations of sounds arising therefrom. The result is, that the first interval,  $1 : 2$ , is an octave; the second,  $1 : 3$ , a twelfth; the third,  $1 : 4$ , a fifteenth, or double octave; the fourth,  $1 : 5$ , a seventeenth; the fifth,  $1 : 6$ , a nineteenth, *&c.*

This new consideration of the relations of sounds, is more natural than the old one; and is, in effect, all the music that nature makes without the assistance of art. See the articles **CHORD**, **VIBRATION**, **ORGAN**, *&c.*

**HARMONICS**, *harmonica*, that part of music which considered the differences and proportions of sounds, with respect to

acute and grave; in contradistinction to rhythmica and metrica.

The harmonics is the only part of the ancient music whereof we have any tolerable account. According to Mr. Malcolm, the doctrine of harmonics was reduced into seven parts, *viz.* of sounds, of intervals, of systems, of the genera, of the tones or modes, of mutation, and of the melopoia. See the articles SOUND, INTERVAL, &c.

**HARMONY**, *ἁρμονία*, in music, the agreeable result, or union, of several musical sounds, heard at one and the same time; or the mixture of divers sounds, which together have an effect agreeable to the ear. See the article SOUND.

As a continued succession of musical sounds produces melody, so does a continued combination of these produce harmony. See the article MELODY.

Among the antients, however, as also sometimes among the moderns, harmony is used in the strict sense of consonance, and is equivalent to symphony; and concord and harmony do in reality signify the same thing, though custom has made a little difference between them. See the articles SYMPHONY, &c.

The antients, says Mr. Malcolm, seem to have been entirely unacquainted with harmony, the soul of modern music: in all their explications of the melopoia, they say not a word of concert, or the harmony of parts. We have instances, indeed, continues that author, of their joining several voices or instruments in consonance; but then these voices and instruments are not so joined as that each had a distinct and proper melody, and so made a succession of various concords; but were either unisons or octaves in every note; and so all performed the same individual melody, and so constituted one song. See the article SYNAULIA.

When the parts differ not in the tension of the whole, but in the different relations of the successive notes, it is this that constitutes the modern art of harmony. See MUSIC and MELOPOIA.

To understand the nature, and determine the number and preference of harmonies, it is to be considered, that in every compound sound, where there are not more than three simple ones, there are three kinds of relations, *viz.* primary relation of every simple sound to the fundamental or gravest, whereby they make different degrees of concord with it; the mutual relations of the acute sounds each

with the other, whereby they mix concord or discord into the compound; and the secondary relation of the whole, whereby all the terms unite their vibrations, and coincide more or less frequently.

Suppose four sounds A, B, C, D, whereof A is the gravest, B the next, then C, and D the acutest. Here A is the fundamental, and the relations of B, C, and D are primary relations: so if B be a third greater above A, that primary relation is 4 to 5; and if C be a fifth to A, that primary relation is 2 to 3; and if D be an octave to A, that is 1 to 2. For the mutual relations of the acute terms B, C, D, they are had by taking their primary relations to the fundamental, and subtracting each lesser from each greater: thus B to C is 5 to 6, a third lesser; B to D, 5 to 8, a sixth lesser, &c. Lastly, to find the secondary relation of the whole, seek the least common dividend to all the lesser terms or numbers of the primary relations, *i. e.* the least number that will be divided by each of them exactly, this is the thing sought, and shews that all the simple sounds coincide after so many vibrations of the fundamental as the number expresses.

So in the preceding example, the lesser terms of the three primary relations are 4, 2, 1, whose least common dividend is 4, consequently at every fourth vibration of the fundamental, the whole will coincide.

The proper ingredients of harmony are concords; and all discords, at least in the primary and mutual relations, are absolutely forbidden. It is true, discords are used in music, but not of themselves simply, but only to set off the concords by their contrast and opposition. Hence, any number of concords being proposed to stand in primary relations with a common fundamental, we discover whether or no they constitute perfect harmony, by finding their mutual relations: thus, suppose the following concords or primary relations, *viz.* the greater third, fifth, and octave given, their mutual relations are all concord, and therefore may stand in harmony; for the greater third and fifth are to one another as 5 to 6, a lesser third; the greater third and octave, as 5 to 8, a lesser sixth; and the fifth and octave, as 3 to 4, a fourth. But if fourth, fifth, and octave be proposed, it is evident they cannot stand in harmony, by reason between the fourth and fifth there is a discord, *viz.* the ratio 8 to 9.

Again,

Again, supposing any number of sounds which are concord each to the next, from the lowest to the highest; to know if they can stand in harmony, we must find the primary and all the mutual relations, which must be all concord: thus the following ones cannot, *viz.* 4, 6, 9, by reason 4 to 9 is a discord.

The perfection of harmonies depends on all the three relations, it is not the best primary relation that makes the best harmony; for then a fourth and a fifth must be better than a fourth and a sixth; whereas the first two cannot stand together, because of the discord of the mutual relation. Nor does the best secondary relation carry it; for then would a fourth and a fifth, whose secondary relation, with one common fundamental, is 6, be better than a third and fifth, whose secondary relation is 10: but here also the preference is due to the better mutual relations. Indeed, the mutual relations depend on the primary, though not so as that the best primary shall always produce the best mutual relations. However, the primary rela-

tions are of the most importance; and, together with the secondary, afford us the following rule for determining the preference of harmonies, *viz.* comparing two harmonies together that have an equal number of terms, that which has the best primary and secondary relations, is the most perfect. But in cases where the advantage lies in the primary relation of the one, and in the secondary of the other, we have no certain rule; the primary are certainly the most considerable, but how the advantage in these ought to be proportioned to the disadvantage of the other, or *vice versa*, we know not; so that a well-tuned ear must be the last resort in these cases.

Harmony is divided into simple and compound.

*Simple HARMONY* is that in which there is no concord to the fundamental above an octave. The ingredients of simple harmony are the seven original simple concords, of which there can be but eighteen different combinations that are harmony, which are given in the following table from Mr. Malcolm.

T A B L E of SIMPLE HARMONIES.

Secondary Relations.				Secondary Relations.			
Fifth	octave	2	third greater	fifth	4	third greater	fifth
Fourth	octave	3	third less	fifth	10	third less	fifth
Sixth greater	octave	3	fourth	sixth greater	3	fourth	sixth greater
Third greater	octave	4	third greater	sixth greater	12	third greater	sixth greater
Third less	octave	5	third less	sixth less	5	third less	sixth less
Sixth less	octave	5	fourth	sixth less	15	fourth	sixth less

These are all the possible combinations of the concords, that are harmony; for the octave is compounded of a fifth and a fourth, or a sixth and a third, which have the variety of greater and lesser: out of these are the first six harmonies composed. Then the fifth being composed of a greater and a lesser third, and the sixth of a fourth and third; from these proceed the next six harmonies of the table: then an octave joined to each of these six, make the last six of the table.

The perfection of the first twelve is, according to the order of the table; of the first six each has an octave; and their preference is according to the perfection of that other lesser concord joined to the octave. For the next six, the preference is given to the two combinations with the fifth, whereof that which has the third greater is the best. For the last six, they are not placed last, because the least perfect,

but because they are the most complex, and are the mixtures of the other twelve with each other: in point of perfection, they are plainly preferable to the preceding six, as having the same ingredients with an octave more.

*Compound HARMONY* is that which to the harmony of one octave, adds that of another. For the compound harmonies, their varieties are easily found out of the combinations of the simple harmonies of several octaves.

Harmony may also be divided into that of concords and that of discords. The first is that which we have hitherto considered, wherein nothing but concords are admitted: the second is that wherein discords are used, and mixed with concords. See the articles CONCORD and DISCORD.

*Composition of HARMONY.* See the article COMPOSITION.

HARMONY

**HARMONY** is also sometimes used to denote an agreement, suitableness, union; conformity, &c. thus, in music, we sometimes apply it to a single voice, when sonorous, clear, and soft; to a single instrument, when it yields a very agreeable sound: in matters of literature, we use it for a certain agreement between the several parts of the discourse: in architecture, harmony denotes an agreeable relation between the parts of a building: in painting, they speak of an harmony both in the ordonnance and composition, and in the colours of a picture; in the ordonnance it signifies the union or connection between the figures, with respect to the subject of the piece; in the colours, it denotes the union or agreeable mixture of different colours. See **SYMMETRY**, **COLOURING**, &c.

**HARMONY** of the *spheres*, or *Celestial HARMONY*, a sort of music much talked of by many of the antient philosophers and fathers, supposed to be produced by the sweetly tuned motions of the stars and planets. This harmony they attributed to the various proportionate impressions of the heavenly globes upon one another, acting at proper intervals. It is impossible, according to them, that such prodigious large bodies, moving with so much rapidity, should be silent; on the contrary, the atmosphere continually impelled by them, must yield a set of sounds proportionate to the impression it receives; consequently as they do not all run the same circuit, nor with one and the same velocity, the different tones arising from the diversity of motions, directed by the hand of the Almighty, must form an admirable symphony, or concert.

They therefore supposed, that the moon, as being the lowest of the planets, corresponded to *mi*; mercury, to *fa*; venus, to *sol*; the sun, to *la*; mars, to *si*; jupiter, to *ut*; saturn, to *re*; and the orb of the fixed stars, as being the highest of all, to *mi*, or the octave.

*Pre-established HARMONY*, a celebrated system of M. Leibnitz, by means whereof he accounts for the union or communication between soul and body. The philosophers had universally held, that the soul and the body act physically on each other. Des Cartes first shewed that the heterogeneity of their natures did not allow of such real union; and that they could only have an apparent one, whereof God is the mediator. Mr. Leibnitz, unsatisfied with either of these hypotheses, establishes a third: a

soul or spirit, he observes, is to have a certain series of thoughts, desires, and wills; a body, which is only a machine, is to have a certain series of motions, to be determined by the combination of its mechanical disposition, with the impressions of external objects.

If now there be found a soul and a body so framed, that the whole series of wills of the soul, and the whole series of motions of the body, exactly correspond; and at the same time, for instance, when the soul desires to go to any place, the two feet move mechanically that way; this soul and body will have a relation to one another; not by any actual union between them, but by the constant and perpetual correspondence of the several actions of both. Now God puts together this soul and body, which had such a correspondence antecedent to their union. And the same is to be understood of all the other souls and bodies, that have been or ever will be joined.

In effect the laws of motion in the body, succeeding in the order of efficient causes, do all agree and correspond with the ideas of the soul; so that the body is determined to act at the time when the soul wills. The same principle he extends further, and makes a pre-established harmony between the kingdoms of nature and grace, to account for the apparent communication between them, and makes physical and moral evil correspond. For a farther account of his manner of reasoning upon this doctrine, we refer the reader to his *Essais de Theodicée*.

**HARMOSTES**, in grecian antiquity, an appellation given to several magistrates among the Spartans, whose business was to look to the building of citadels, the reparation of forts and fortifications, and the like.

**HARNESS**, the furniture put upon a horse to draw in a coach, or other wheel-carriage.

**HARNESS-GALLS**, swellings or soreness on the breasts of coach-horses, occasioned by the galling of the harness, especially in rainy weather.

To cure this, first shave off the hair about the sore very close, and rub the whole breast with a lather of water and black-soap; then wash that part of the breast which is usually covered with the petrel, with salt-water, suffering it to dry of itself. If the hardness of any part of the harness occasions the galling, take it away, or cover it with little bolsters.

**HARO**,

**HARO**, or **HAROL**, *clamor de haro*, in our old customs, an out-cry after felons, the original of which came from the Normans. See the article **HUE** and **CRY**.

**HARP**, a musical instrument of the string-kind, of a triangular figure, held upright between the legs of the person who plays upon it.

There is some diversity in the structure of harps. That called the triple harp, has three rows of strings or chords, which in all make seventy-eight, or four octaves; the second row makes the half-turn, and the third is unison with the first. There are two rows of pins on the right side, called buttons, that serve to keep the strings tight in their holes, which is fastened at the other end to three rows of pins on the upper side, called the keys. This instrument is struck with the fingers and thumbs of both hands: its music is like that of the spinet, all its strings going by semi-tones; whence some have called it the inverted spinet. There are among us two sorts of this instrument, *viz.* the Irish harp, which is strung with wire; and the Welch harp, strung with gut.

King David is usually painted with a harp in his hands; but we have no testimony in all antiquity, that the Hebrew harp was any thing like ours: on a Jewish medal of Simon Macchabæus, we see two sorts of musical instruments, but they are both of them different from our harp, having only three or four strings. The harp in use among the ancient Jews, is supposed to be more like a lute, or a guitar, than the instrument above described, which it is thought was invented either by the Cimbri, or the Anglo-faxons.

**Bell-HARP**, a musical instrument of the string-kind, thus called from the common players upon it, swinging it about as a bell on its bias.

It is about three feet long; its strings, which are of no determinate number, are of brass or steel-wire, fixed at one end, and stretched a-cross the sound-board, by screws fixed at the other end. It takes in four octaves, according to the number of the strings, which are struck only with the thumbs, the right hand playing the treble, and the left the base; and in order to draw the sound the clearer, the thumbs are armed with a little wire-pin. This may perhaps be the *lyra* or *cythara* of the ancients; but we find no mention of it under the name it now

bears, which must be allowed to be modern.

**HARPEGGIATO**, or **HARPEGGIO**, in music, is to cause the several sounds of one accord to be heard distinctly one after the other, beginning with either at pleasure, but commonly with the lowest.

**HARPIES**, *harpyiæ*, *ἀρπυιαι*, among the ancient poets, fabulous impure monsters, said to be the daughters of Neptune and Earth. Virgil mentions three of them, Aello, Ocypete, and Celeno; they are described to be fowls with the face of a virgin, bear's ears, their bodies like vultures, and hands like their crooked talons. Virg. *Æn.* III.

**HARPINEER**, or **HARPONEER**, the person who manages the harping-iron. See the next article.

**HARPING-IRON**, or **HARPOON**, a large spear or javelin, made of forged iron, and five or six feet long; it is fastened to a line, and used in the whale-fishery. See the article **FISHERY**.

**HARPINGS**, in a ship, properly denote her breadth at the bow. Some also give the same name to the ends of the bends that are fastened into the stern.

**HARPSICHORD**, the most harmonious of all the musical instruments of the string-kind. It is played on after the manner of the organ, and is furnished with a set and sometimes with two sets of keys; the touching or striking of these keys, move a kind of little jacks, which also move a double row of chords or strings, of brass or iron, stretched over four bridges on the table of the instrument.

**HARQUEBUSS**, a piece of fire arms, of the length of a musket, usually cocked with a wheel. It carried a ball that weighed one ounce seven eighths.

There was also a larger sort, called the great harquebuss, used for the defence of strong places, which carried a ball of about three ounces and a half; but they are now but little used, except in some old castles, and by the French in some of their garriçons.

**HARRIER**, a kind of hound, endowed with an admirable gift of smelling, and very bold in the pursuit of his game. There are several kinds of harriers; some being for the hare, the fox, the wolf, hart, weasel, badger, &c.

**HARROW**, in agriculture, an instrument used by husbandmen, to break the clods of earth, and to draw the ground over the seed when sown. It is a sort of wooden drag, made in form of a square, with large

large iron-teeth, or tines, not unlike those of a herse. See HERSE.

**HART**, a stag, or male deer, in the sixth year. See STAG and CERVUS.

**HART-ROYAL**, one that has been hunted by the king or queen, and escaped with life; in which case proclamation is usually made, that none kill or offend him, as being a hart-royal proclaimed.

**HART-HUNTING**. See HUNTING.

**HART'S HORNS**, *cornua cervi*, in pharmacy, the whole horns of the common male deer, as separated from the head, without farther preparation.

The chemical analysis of hart's horn is sufficiently known: it yields a water highly impregnated with a volatile salt, which is called spirit of hart's horn, with a fetid oil, and a volatile salt by the common distillation in a retort. The remainder in the bottom of the retort, after the distillation is finished, is black; but on being calcined in an open fire, it becomes white and friable, and is what is kept in the shops under the name of burnt hart's horn. Beside these preparations, we use the thin shavings of the horns, which, on long boiling in water, become a jelly: this jelly is nutritive and strengthening; it is sometimes given in diarrhoeas; but a decoction of burnt hart's horn in water, is more frequently used for this purpose, and is what is called hart's horn drink.

The salt of hart's horn is a great sudorific, and is given in fevers of many kinds with great success; the spirit has the same and all the other virtues of volatile alkalis, and is used to bring people out of faintings by its pungency, on holding it under their nose, and at the same time pouring some drops of it in water down the person's throat.

**HART'S HORN**, in botany, a name given by some writers to coronopus. See the article CORONOPUS.

**HART-WORT**, *tordyllum*, in botany. See the article TORDYLLIUM.

**Ethiopian HART-WORT**, a plant more usually called peucedanum, or hog's fennel.

**HARTFORD**, the capital of Hartfordshire, situated twenty-one miles north of London: west longit. 7°, and north lat. 51° 45'.

**HARTFORD** is also a town of New England, in the province of Connecticut, situated fifty miles west of Boston: west lon. 71° 15', and north lat. 42°.

**HARTLAND**, a market-town of Devon,

situated near the Bristol-channel; it gives name to a cape, called Hartland-point, at the entrance of the Bristol-channel: west lon. 4° 45', and north lat. 51° 9'.

**HARTLEPOOL**, a port-town of the county of Durham, situated on the German ocean, fourteen miles south-east of Durham: west longit. 55', and north lat. 54° 40'.

**HARVEST**, the time or season that the corn is ripe, and fit to be reaped and taken into barns.

**HARVEST-FLY**, in zoology, a large four-winged fly, of the cicada-kind, very common in Italy, and erroneously supposed to be a grasshopper. See the article CICADA.

**HARUSPEX**, or **ARUSPEX**, in roman antiquity. See ARUSPICES.

**HARWICH**, a borough and port-town of Essex, sixty-two miles north-east of London: east lon. 1° 25', north lat. 52° 5'. It sends two members to parliament.

**HASEL**, or **HAZLE**. See HAZLE.

**HASLEM**, an island of Denmark, in the Categate-sea, north of the island of Zealand.

**HASLEMERE**, a borough-town of Surry, thirty-eight miles south-west of London, and ten miles south-west of Guildford.

It sends two members to parliament.

**HASELT**, a town of Westphalia, in Germany, fifteen miles north-west of Maafricht.

**HASSIDEANS**, or **ASSIDEANS**, an appellation given to those Jews who resorted to Mattathias, to fight for the law of God, and the liberties of their country.

**HASSOCK**, a bask made of rushes, to kneel or rest the feet upon in churches.

**HASTA**, among medallists, a kind of javelin, not shod or headed with iron; or rather an antient sort of scepter, longer than ordinary, occasionally given to all the gods.

**HASTATED LEAF**, among botanists, one resembling the head of an halbert. See plate CXXVII. fig. 4.

**HASTINGS**, a borough-town of Suffex, situated on the coast of the English channel, fifty miles south-east of London: east lon. 36', and north lat. 50° 50'.

**HAT**, a covering for the head, worn by the men in most parts of Europe. Those most in esteem are made of the pure hair of the castor or beaver; for they are also made of the hair or wool of divers other animals, and that by much the same process.

*Method of making HATS.* To make the beaver-hats, they tear off the long and short hair from the skin, with knives suitable to the occasion. After which they proportion the quantity of the several sorts of beaver-hair, by mixing one third of the dry castor to two thirds of old-coat, which is a term for a skin that has been worn some time by the Indians of America, who catch and sell them to the Europeans. The hair, so mixed, is carded and weighed out into parcels, according to the size and thickness of the hat intended. The stuff is now laid on the hurdle, with an instrument called a bow, resembling that of a violin, but larger; whose string being worked with a small bow-stick, and made to play on the furs, they fly, and mix themselves together, the dust and filth at the same time passing through the chinks. Instead of a bow, some hat-makers use a sence of hair, through which they pass the stuff. Thus hats are formed of an oval figure, ending with an acute angle at the top: with what stuff remains they strengthen them where slenderest, yet designedly make them thicker in the brim near the crown, than towards the circumference, or in the crown itself. They next harden the stuff, so managed, into more compact flakes, by pressing down a hardened leather upon it. This done, they are carried to the bason, upon which laying one of the hardened hats they sprinkle it over with water, and mould it; and the heat of the fire, with the water and pressing, imbody the stuff into a slight hairy sort of felt; after which, turning up the edges all round over the mould, they lay it by, and proceed with another, which being in like manner reduced to the same consistence and form, they are both joined together, so as to make them meet in an angle at top, making only one conical cap. The next process is to remove the hat to a trough, resembling a mill-hopper, which is a copper-kettle filled with water and grounds, kept hot for the purpose; and, after being dipped in the kettle, the hat is laid on the sloping side, called the plank. Here they proceed to work it, by rolling and unrolling it again and again, one part after another, first with the hand, and afterwards with a small wooden roller, taking care to dip it from time to time, till at length, by thus fulling and thickening it four or five hours, it is brought to the dimensions intended. In this violent labour,

the workmen usually guard their hands with thick leather, which they call gloves. The hat thus wrought into the form of a conical cap, is reduced into proper shape on a block of the size of the intended crown, by tying it round with a string, called a commander; after which, with a bent iron, called a stamper, they gradually beat down the commander all round, till it has reached the bottom of the block, and what remains at the bottom below the string forms the brim. In this station it is set to dry, and afterwards singed, by holding it over the blaze of a fire, made of straw, or shavings: it is then rubbed with pumice-stone, to take off the coarser nap; then rubbed over with seal-skin, to lay the nap still finer; and lastly, carded with a fine card, to raise the fine cotton, with which the hat is to appear when finished: then fitting it to the block, they tie it, cut round the edges, and deliver it to the dyers. (See the article DYEING.) The dye being completed, the hat is dried by being hung in the roof of a stove heated with a charcoal-fire; and, when dry, it is stiffened with melted glue, or rather gum-senega, which is smeared over the hat with a brush, and rubbed in with the hand. Then, having spread a cloth over the steaming bason, which is a little fireplace raised about three feet high, with an iron-plate laid over it, exactly covering the fire, the hat is laid upon the cloth, with the brim downwards, the cloth being first sprinkled with water, to raise a strong steam, to force in the stiffening. When it is moderately hot, the workman strikes gently on the brim, with the flat of his hand, to make the joinings incorporate and bind so as not to appear, turning it from time to time, and at last setting it on the crown. And when it has been sufficiently steamed and dried, it is put again on the block, brushed, ironed, well smoothed, and fitted for lining.

Hats make a considerable article in commerce: England supplies Spain, Portugal, Italy, and Germany, with extraordinary quantities of them; and as our manufacturers have the reputation of making the best hats in Europe, their importation is prohibited.

HATS are also made for women's wear, of chips, straw, or cane, by plating, and sewing the plats together; beginning with the center of the crown, and working round till the whole is finished. Hats

for the same purpose are also wove and made of horse-hair, silk, &c. Straw-hats knotted, pay on importation 1s.  $3\frac{4}{10}$  d. the dozen, and draw back 1s.  $1\frac{5}{10}$  d.

Straw-hats plain, pay  $3\frac{46\frac{1}{2}}{100}$  d. the dozen, and draw back  $3\frac{3\frac{1}{2}}{100}$  d.

**HAT-BAND**, a band to tie or buckle round the crown of a hat, in order to let it out, or draw it closer to the head. These are of several sorts. They pay on importation 19s. 3d. the gross, and draw back 16s.  $10\frac{5}{10}$  d.

**HATCHEL**, or **HITCHEL**, a tool with which flax and hemp are combed into fine hairs. It consists of long iron-pins, or teeth, regularly set in a piece of board. See plate CXXVII. fig. 2.

There are several sorts of hatchels, each finer than the other, with which flax and hemp are prepared for spinning. See the articles **FLAX** and **HEMP**.

**HATCHES**, in a ship, a kind of trap-doors between the main-mast and fore-mast, through which all goods of bulk are let down into the hold.

*Coamings of the HATCHES*, are the pieces of timber, or planks, which raise up the hatches, when they are made higher than the rest of the deck.

**HATCH-WAY**, the place where the hatches are. Thus, to lay a thing in the hatch-way, is to put it so, that the hatches cannot be come at, or opened.

**HATCHES** also denote flood-gates set in a river, &c. to stop the current of the water, particularly certain dams or mounds made of rubbish, clay, or earth, to prevent the water that issues from the stream-works and tin-washes in Cornwall, from running into the fresh rivers.

**HATCHET**, a small light sort of an ax, with a basil-edge on its left side, and a short handle, as being to be used with one hand.

Hatchets are used by various artificers, and more particularly in hewing of wood.

Hatchets and axes pay on importation 1s.  $3\frac{4}{10}$  d. the dozen, and draw back 1s.  $1\frac{5}{10}$  d. And for every 112 lb. of iron 4s.  $8\frac{2\frac{1}{2}}{100}$  d. which is repaid on exportation.

**HATCHING**, the maturing fecundated eggs, whether by the incubation and warmth of the parent bird, or by artificial heat, so as to produce young chickens alive.

The art of hatching chickens by means of ovens has long been practised in Egypt; but it is there only known to the inhabitants of a single village named Berme, and to those that live at a small distance from it. Towards the beginning of autumn they scatter themselves all over the country, where each person among them is ready to undertake the management of an oven, each of which is of a different size, but in general they are capable of containing from forty to fourscore thousand eggs. The number of these ovens placed up and down the country is about three hundred and eighty-six, and they usually keep them working for about six months: as therefore each brood takes up in an oven, as under a hen, only twenty-one days, it is easy in every one of them to hatch eight different broods of chickens. Every Bermean is under the obligation of delivering to the person who intrusts him with an oven, only two thirds of as many chickens as there have been eggs put under his care; and he is a gainer by this bargain, as more than two thirds of the eggs usually produce chickens. In order to make a calculation of the number of chickens yearly so hatched in Egypt, it has been supposed that only two thirds of the eggs are hatched; and that each brood consists of at least thirty thousand chickens; and thus it would appear that the ovens of Egypt give life yearly to at least ninety-two millions six hundred and forty-thousand of these animals.

This useful and advantageous method of hatching eggs has been lately discovered in France, by the ingenious Mr. Reaumur, who, by a number of experiments, has reduced the art to certain principles. He found by experience that the heat necessary for this purpose is nearly the same with that marked 32 on his thermometer, or that marked 96 on Fahrenheit's. This degree of heat is nearly that of the skin of the hen, and what is remarkable of the skin of all other domestic fowls, and probably of all other kinds of birds. The degree of heat which brings about the developement of the cygnet, the gosling, and the turkey-pout, is the same as that which fits for hatching the canary-songster, and, in all probability, the smallest humming-bird: the difference is only in the time during which this heat ought to be communicated to the eggs of different birds: it will bring the canary bird to perfection in eleven or twelve days, while the

turkey-

turkey-pout will require twenty-seven or twenty-eight.

After many experiments, Mr. Reaumur found that stoves heated by means of a baker's oven, succeeded better than those made hot by layers of dung: and the furnaces of glass-houses and those of the melters of metals, by means of pipes, to convey heat into a room, might, no doubt, be made to answer the same purpose. As to the form of the stoves, no great nicety is required: a chamber over an oven will do very well; nothing more will be necessary but to ascertain the degree of heat, which may be done by melting a lump of butter, of the size of a walnut, with half as much tallow, and putting it into a phial; this will serve to indicate the heat with sufficient exactness, for when it is too great, this mixture will become as liquid as oil, and when the heat is too small, it will remain fixed in a lump; but it will flow like a thick syrup, upon inclining the bottle, if the stove be of a right temper: great attention therefore should be given to keep the heat always at this degree, by letting in fresh air, if it be too great, or shutting the stove more close, if it be too small; and that all the eggs in the stove may equally share the irregularities of the heat, it will be necessary to shift them from the sides to the center; thereby imitating the hens, who are frequently seen to make use of their bills, to push to the outer parts those eggs that were nearest to the middle of their nests, and to bring into the middle such as lay nearest the sides.

Mr. Reaumur has invented a sort of low boxes, without bottoms, and lined with furs. These, which he calls artificial-parents, not only shelter the chickens from the injuries of the air, but afford a kindly warmth, so that they presently take the benefit of their shelter as readily as they would have done under the wings of a hen. After hatching, it will be necessary to keep the chickens, for some time, in a room artfully heated and furnished with these boxes; but afterwards they may be safely exposed to the air in the court-yard, in which it may not be amiss to place one of these artificial-parents to shelter them if there should be occasion for it.

As to the manner of feeding the young brood, they are generally a whole day after being hatched, before they take any food at all; and then a few crumbs of

bread may be given them for a day or two, after which they will begin to pick up insects and grubs for themselves.

But to save the trouble of attending them, capons may be taught to watch them in the same manner as hens do. Mr. Reaumur assures us that he has seen above two hundred chickens at once, all led about and defended only by three or four such capons. Nay, cocks may be taught to perform the same office, which they, as well as the capons, will continue to do all their lives after.

**HATCHING**, or **HACHING**, in designing, &c. the making of lines with a pen, pencil, graver, or the like; and the intersecting or going across those lines with others drawn a contrary way, is called counter-hatching. The depths and shadows of draughts are usually formed by hatching.

Hatching is of singular use in heraldry, to distinguish the several colours of a shield, without being illumined: thus, gules or red is hatched by lines drawn from the top to the bottom; azure, by lines drawn across the shield; and so of other colours. See the article **GULES**, **AZURE**, &c.

**HATCHMENT**, in heraldry, a name sometimes used for an achievement, or escutcheon over a gate, door, or on the side of an house.

**HATCHMENT** also signifies the marshalling of several coats of arms in an escutcheon. See the article **MARSHALLING**.

**HATESBURY**, or **HEYTSBURY**. See the article **HEYTSBURY**.

**HATFIELD**, a market-town of Hertfordshire, situated twenty miles north-west of London.

**HATFIELD-BROADOAK**, or **KING'S HATFIELD**, a market-town of Essex, twelve miles from Chelmsford, and twenty-eight from London.

**HATHERLY**, a market-town of Devonshire, twenty miles north-west of Exeter.

**HATTEM**, a town of Gelderland, one of the United Provinces: east long. 6°, north lat. 52° 36'.

**HATTOCK**, a flock of corn containing twelve sheaves: others make it only three sheaves laid together.

**HATUAN**, a town of upper Hungary, fifteen miles north-east of Buda: east lon. 19° 35'. and north lat. 47° 48'.

**HAVANNA**, a port-town of the island of Cuba, in America, situated at the entrance of the gulph of Mexico; sub-

ject to Spain: west lon.  $84^{\circ}$ , and north lat.  $23^{\circ}$ .

**HAVANT**, a market-town of Hampshire, six miles north-east of Portsmouth.

**HAVEL**, a river of Brandenburg, in Germany, which receives the river Spree, near Berlin, and discharges itself into the Elbe, a little below Havelburg.

**HAVELBURG**, a town of Germany, in the circle of upper Saxony, and marquisate of Brandenburg, subject to the king of Prussia: east long.  $12^{\circ} 44'$ , and north lat.  $53^{\circ}$ .

**HAVEN**, a sea-port or harbour. See the article **HARBOUR**.

**HAVER**, a term used by country-people for oats.

**HAVERFORD-WEST**, a borough-town of Pembrokeshire, in south Wales, situated twelve miles south-east of St. David's. It sends only one member to parliament.

**HAVERIL**, a market-town of Essex, twenty-four miles north of Chelmsford.

**HAUGH**, or **HAW**. See the article **HAW**.

**HAUNCH**, or **HANCH**, the hip, or that part of the body between the last ribs and the thigh. See the article **HIP**.

The haunches of a horse are too long, if, when standing in the stable, he limps with his hind legs farther back than he ought; and when the top or onset of his tail is not in a perpendicular line to the tip of his hocks, as it always does in horses whose haunches are of a just length. There are some horses, which, though they have too long haunches, yet commonly walk well: such are good to climb hills, but are not at all sure upon a descent, for they cannot ply their hams, and never gallop slowly, but always nearly upon a full speed.

The art of riding the great-horse has not a more necessary lesson than that of putting a horse upon his haunches, which in other words is called coupling him well, or putting him well together, or compact. A horse that cannot bend or lower his haunches, throws himself too much upon his shoulder, and lies heavy upon the bridle.

**HAUNT**, among sportsmen, the place to which game are accustomed to resort: among hunters, it is the walk of a deer, or the place of his ordinary passage.

All kinds of large fowl that divide the foot, have their haunts by the sides of shallow rivers, brooks, and plasies of water; they delight in boggy places and the dry parts or fens over-grown with rushes, reeds, and sedges, in half drown-

ed moors, and the hollow vales of downs and heaths, where there is shelter for them to lurk in obscurity. These do not appear in flocks, but they are the best flight for hawks that can be imagined.

The lesser fowl, which are web-footed, continually haunt drowned fens, the main stream of rivers where the current is swiftest, and all places where there is plenty of water, in which they may swim undisturbed by man or beast; the wild-geese and barnacle excepted, who like no water above their sounding, and seek none but shallow places. These last are inconceivably delighted with green winter corn, and may always be found where it is sown, especially if the ends of the lands have much water about them.

The smaller fowl frequent small brooks, rivers, ponds, drowned meadows, loughs or lakes, especially if stored with unfrequented islands well furnished with shrubs, rushes, reeds, &c.

**HAVRE**, in geography, a french term signifying haven. Hence,

**HAVRE DE GRACE** is a port-town of France, in the province of Normandy, situated on the English channel, at the mouth of the river Seyne: east longit.  $10'$ , and north lat.  $49^{\circ} 30'$ .

**HAUTBOY**, a musical instrument of the wind-kind, shaped much like the flute, only that it spreads and widens towards the bottom, and is sounded through a reed. The treble is two feet long; the tenor goes a fifth lower, when blown open: it has only eight holes; but the bass, which is five feet long, has eleven.

**HAW**, in botany, &c. a sort of berry, the fruit of several species of *meipilus*, thence denominated haw-thorns. See the article **MESPILUS**.

**HAW**, among farriers, an excrescence resembling a gristle, growing under the nether eye-lid and eye of a horse, which, if not timely removed, will put it quite out. It proceeds from grofs, tough, and phlegmatic humours, which falling from the head, and there uniting together, grow to this infirmity; the signs of which are the watering of the eye, and the involuntary opening of the under eye-lid.

Every farrier can cut it out; but ordinarily the horse must be held fast by the head, and a needle with a strong double thread run through the middle of his upper eye-lid, which must be held open by the thread's being tied to his head: a needle and thread should then be run through the haw, when cutting the skin round

round with a sharp pen-knife, the hawk may be plucked out. Then take the blood out of his eye, wash it with beer or ale, and put in a good deal of salt; afterwards wash it again, and stroking it down with your own hand, let him go. Sheep are cured of this malady by dropping into the eye the juice of chamomile or crows-foot.

**HAW-FINCH**, in ornithology, the english name of a bird, known among authors by the name *coccothraustes*.

**HAWK**, a synonymous term with *falcon*, though, by some, restrained to the lesser sort of falcons. See the articles *FALCON* and *FALCONRY*.

Others distinguish hawks into the long-winged and short-winged kinds: of the first kind are the gentle-falcon, *gerfalcon*, *lanner*, *faker*, *hobby*, &c. See the articles *FALCON*, *GERFALCON*, &c.

And of the short-winged kind are the *goshawk*, *sparrow-hawk*, *stanyel*, &c. See the articles *GOSHAWK*, *SPARROW-HAWK*, &c.

Here it is to be observed, that the female hawks, as well as of all other birds of prey, being larger and more robust than the males, are likewise more hardy, bold, and serviceable.

**HAWKER**, in commerce, a pedlar, or person that goes about the country selling wares: this name is said to arise from their uncertain wandering, like persons who with hawks seek their game where they may find it.

Every hawker, &c. must take a licence, for which he must pay 4*l.* and if with horse, ass, or mule, for every one of them 4*l.* a-piece: if he travels without, or contrary to his licence, he forfeits for every offence, to the informer and the poor of the parish where discovered, 12*l.* If he travels with a forged licence, he forfeits 50*l.* and if he refuses to shew his licence 5*l.*

The acts relating to hawkers do not extend to the makers of goods or their agents; to those who sell goods in fairs or markets; to the sellers of fish, fruit, or other victuals; nor to the vendors of acts of parliament, proclamations, forms of prayer, almanacs, books, and newspapers.

**HAWKING**, the exercise of taking wild-fowl by means of hawks.

The method of reclaiming, manning, and bring up a hawk to this exercise, is called *falconry*. See *FALCONRY*.

As for the exercise itself, though at present much disused, it furnishes a great variety of terms still retained in our language, as *gleam*, *leash*, *pannel*, *quarry*, *train*, *feeling*, &c.

When your hawk comes readily to the lure, a large pair of luring-bells are to be put upon her; and the more giddy-headed, and apt to rake out, your hawk is, the larger must the bells be. Having done this, and she being sharp-set, ride out in a fair morning, into some large field unencumbered with trees or wood, with your hawk on your fist; then having loosened her hood, whistle softly, to provoke her to fly, unhood her, and let her fly with her head into the wind, for by that means she will be the better able to get upon the wing, and will naturally climb upwards, flying a circle. After she has flown three or four turns, then lure her with your voice, casting the lure about your head, having first tied a pullet to it; and if your falcon come in, and approach near you, cast out the lure into the wind, and if she stoop to it, reward her.

You will often find, that when she flies from the fist, she will take stand on the ground: this is a fault, which is very common with *soar-falcons*. To remedy this, fright her up with your wand; and when you have forced her to take a turn or two, take her down to the lure, and feed her. But if this does not do, then you must have in readiness a duck sealed, so that she may see no way but backwards, and that will make her mount the higher. Hold this duck in your hand, by one of the wings near the body; then lure with the voice, to make the falcon turn her head, and when she is at a reasonable pitch, cast your duck up just under her, when, if she strike, stoop, or trust the duck, permit her to kill it, and reward her by giving her a reasonable gorge. After you have practised this two or three times, your hawk will leave the stand, and delighted to be on the wing, will be very obedient.

It is not convenient, for the first or second time, to shew your hawk large fowl; for it frequently happens, that they escape from the hawk, and she not recovering them, rakes after them: this gives the falconer trouble, and frequently occasions the loss of the hawk. But if she happens to pursue a fowl, and being unable to recover it, gives it over, and comes

comes in again directly, then cast out a sealed duck, and if she stoop and truſt it a-croſs the wings, permit her to take her pleaſure, rewarding her alſo with the heart, brains, tongue, and liver. But if you have not a quick duck, take her down with the dry lure, and let her plume a pullet and feed upon it. By this means a hawk will learn to give over a fowl that rakes out, and on hearing the falconer's lure, will make back again, and know the better how to hold in the head.

Some hawks have a diſdainful coynefs, proceeding from their being high fed: ſuch a hawk muſt not be rewarded, tho' ſhe ſhould kill; but you may give her leave to plume a little, and then taking a ſheep's-heart cold, or the leg of a pullet, when the hawk is buſy in pluming, let either of them be conveyed into the body of the fowl, that it may ſavour of it; and when the hawk has eaten the heart, brains, and tongue of the fowl, take out what is incloſed, call her to your fiſt, and feed her with it: afterwards give her ſome of the feathers of the fowl's neck, to ſcower her, and make her caſt.

If your hawk be a ſtately high-flying one, ſhe ought not to take more than one flight in a morning; and if ſhe be made for the river, let her not fly more than twice: when ſhe is at the higheſt, take her down with your lure; and when ſhe has plumed and broken the fowl a little, feed her, by which means you will keep her a high-flyer, and fond of the lure.

**HAWSER**, in the ſea-language, a large rope, or a kind of ſmall cable, ſerving for various uſes a-board a ſhip, as to faſten the main and fore ſhrouds, to warp a ſhip as ſhe lies at anchor, and wind her up to it by a capſtan, &c. The hawſer of a man of war may ſerve for a cable to the ſheat-anchor of a ſmall ſhip.

**HAWSES**, in a ſhip, are two large holes under the bow, through which the cables run when ſhe lies at anchor. Thus the hawſe-pieces are the large pieces of timber in which theſe holes are made. Hawſe-bags, are bags of canvas made tapering, and ſtuffed full of ocham; which are generally allowed ſmall ſhips, to prevent the ſea from waſhing in at theſe holes: and hawſe-plugs, are plugs to ſtop the hawſes, to prevent the water from waſhing into the manger.

There are alſo ſome terms in the ſea-language that have an immediate relation to the hawſes. As a *boid hawſe*, is when

the holes are high above the water. *Frefh the hawſe*, or veer out more cable, is uſed when part of the caple that lies in the hawſe is fretted or chafed, and it is ordered that more cable may be veered out, ſo that another part of it may reſt in the hawſes. *Frefh the hawſe*, that is, lay new pieces upon the cable in the hawſes, to preſerve it from fretting. *Burning in the hawſe*, is when the cables endure a violent ſtreſs. *Clearing the hawſes*, is diſentangling two cables that come thro' different hawſes. *To ride hawſe-full*, is when in ſtreſs of weather the ſhip falls with her head deep in the ſea, ſo that the water runs in at the hawſes.

**HAY**, any kind of graſs, cut and dried, for the food of cattle.

The time of mowing graſs for hay, muſt be regulated according to its growth and ripeneſs; nothing being more prejudicial to the crop than mowing it too ſoon, becauſe the ſap is not then fully come out of the root, and when made into hay, it ſhrinks away to nothing. It muſt not, however, be let ſtand too long, till it have ſhed its ſeeds. When the tops of the graſs look brown, and begin to bend down, and the red honey-ſuckle flowers begin to wither, you may conclude it ripe for mowing.

As ſoon as your graſs is mowen, if there is plenty of it, and it be thick in the ſwath, the hay-makers ſhould follow the mowers, and ſpread the ſwaths (unleſs you fear wet,) which is called tedding of them. At night, make it into cocks; and next day, as ſoon as the dew is off the ground, ſpread it again, and turn it, that it may dry on the other ſide. In this manner it is to be ſpread, turned, and made into cocks at night, till fully dry; and in caſe the weather ſeems to threaten rain, it ſhould be made into larger cocks, whereby it will be ſecured from wet, tho' let ſtand a day or two. Where thick-leaved weeds are among the graſs, it will require more drying and turning than ordinary.

Mowing of land too often is a great prejudice to it, unleſs conſtantly renewed by land-floods or manure; ſo that where theſe conveniencies cannot be had, the lands ſhould be fed once in two or three years; feeding being as neceſſary for hay-ground, as fallowing is for corn-grounds.

*Saint-foin*-HAY, is of ſeveral ſorts, which may be diſtinguiſhed by the following terms.

terms, *viz.* 1st. The virgin. 2dly. The blossomed. 3dly. The full-grown. And, 4thly. The threshed hay. The first of these is beyond comparison the best. It must be cut before the blossoms generally appear; for when it stands till it is full blown, the most spirituous and nourishing parts of its juice are spent, the sap is much impoverished, and the saint-foin can never recover that richness it had in its virgin-state. But this fine hay cannot well be had of uncultivated saint-foin, because that may not be much above an handful high when it is in a condition to be cut; it would then make a very light crop, and would be a great while before it sprang up again; but the rich will have two or three tuns to an acre, and spring again immediately for a second crop; so that little or none in quantity would be lost by so great an improvement of its quality.

The second sort is that cut in the flower, which, tho' much inferior to the virgin-hay, far exceeds any other kind as yet commonly propagated in England; and if it be a full crop, it may amount to three tuns an acre. This is that saint-foin which is commonly made, and the larger it is, the more nourishing it is for horses.

The next sort of saint-foin is the full grown, cut when the blossoms are gone, or going off: this also is good hay, tho' it falls short by many degrees of the goodness of the other two sorts: but it makes a greater crop than either of them, because it grows to its full bulk, and shrinks little in drying.

The last sort is the threshed hay, which when not damaged by wet weather, has been found more nourishing to horses than coarse water-meadow hay; and, when it is cut small by an engine, is good for cattle, and much better than the chaff of corn. The best time to cut it, is when the greatest part of the seed is well filled; the first-blown ripe, and the last-blown beginning to be full.

The goodness of the hay depends greatly upon the manner of ordering it. The best hay in all England is made of saint-foin, without ever spreading it. This method, tho' it be longer before it be finished, costs less labour than the other. If saint-foin be laid up pretty green, it will take no damage, provided it be set in small round ricks, with a large basket drawn up in the middle of each, to have a vent hole through which the super-

fluous moisture of the hay may transpire. As soon as its heating is over, these ricks ought to be thatched; and all saint-foin ricks, that are made when the hay is full dried in the cocks, ought to be thatched immediately after the making them. That which is laid up most dried, will come out of the rick of a green colour; but that which has been much heated in the rick, will be brown.

The seed affords the owner another opportunity of making a profit of his saint-foin: but this, if the hoeing husbandry were general, would not be vendible in great quantities for planting; because the ordinary crop of an acre, will produce seed enough to drill an hundred acres, which would not want planting for a long time. The other use then of this seed is for provender; and it has been affirmed by some, who have made trials of it, that three bushels of good saint-foin seed given to horses, will nourish them as much as four bushels of oats; and when well ordered, it is so sweet, that most sorts of cattle are greedy of it.

**HAY**, in geography, a market-town in Brecknockshire, south Wales, thirteen miles north-east of Brecknock.

**HAY-BOTE**, in law, a liberty to take thorns, and other wood, to make and repair hedges, gates, fences, &c. by a tenant for life or years.

**HAY-BOTE** is also taken for wood for the making of rakes and forks, used in making hay.

**HAYLESHAM**, a market-town of Suffex, situated ten miles east of Lewes.

**HAY-MARKET**, a particular place in London, or its suburbs, where hay is sold, and where all carts of hay that stand to be sold there pay 3d. per load towards paving the streets. The new hay sold in London, &c. between the first of June and the last of August, ought to weigh sixty pounds a truss; and old hay, the other part of the year, is to weigh fifty-six pounds, the seller being liable to forfeit 2s. 6d. for every truss under that weight.

**HAYN**, a town of Silesia, in the territory of Lignitz, thirty-five miles north-west of Breslaw: east long. 16° 5', north lat. 51° 17'.

**HAYNAN**. See the article **HAINAN**.

**HAYNAULT**, a province of the Netherlands, bounded by Brabant and Flanders, on the north; by Namur and Liege, on the east; by the Cambrésis, Picardy, and Champaign, on the south; and by Artois,

Artois, and another part of Flanders, on the west: the north part is subject to the house of Austria, and the south part to France. Its capital is Mons.

**HAYWARD**, the person who keeps the common herd or cattle of a town.

He is appointed by the lord's court, and his office is to see that the cattle neither break nor crop the hedges of inclosed grounds; he is also to look to the fields, and impound cattle that commit trespass therein.

**HAZARD**, a game on dice, without tables, is very properly so called; since it speedily makes a man, or undoes him.

It is played with only two dice; and as many may play at it as can stand round the largest round table.

Two things are chiefly to be observed, *viz.* main and chance; the latter belonging to the caster, and the former, or main, to the other gamblers. There can be no main thrown above nine, nor under five; so that five, six, seven, eight, and nine, are the only mains flung at hazard. Chances and nicks are from four to ten: thus four is a chance to nine, five to eight, six to seven, seven to six, eight to five; and nine and ten a chance to five, six, seven, and eight: in short, four, five, six, seven, eight, nine, and ten, are chances to any main, if any of these nick it not. Now nicks are either when the chance is the same with the main, as five and five, or the like; or six and twelve, seven and eleven, eight and twelve. Here observe, that twelve is out to nine, seven, and five; eleven is out to nine, eight, six, and five; and aces-ace and duce-ace, are out to all mains whatever.

But to illustrate this game by a few examples: suppose the main to be seven, and the caster throws five, which is his chance; he then throws again, and if five turn up, he wins all the money set him; but if seven is thrown, he must pay as much money as there is on the board: again, if seven be the main, and the caster throws eleven, or a nick, he sweeps away all the money on the table; but if he throws a chance, as in the first case, he must throw again: lastly, if seven be the main, and the caster throws aces-ace, duce-ace, or twelve, he is out; but if he throws from four to ten, he hath a chance; though they are accounted the worst chances on the dice, as seven is reputed the best and easiest main to be flung. Four and five are

bad throws (the former of which being called by the tribe of nickers, little dick-fisher) as having only two chances, *viz.* trey-ace and two duces, or trey-duce and quarter ace: whereas seven hath three chances, *viz.* cinque-duce, six-ace, and quarter-trey. Nine and ten are in the like condition with four and five; having only two chances. Six and eight have indeed the same number of chances with seven, *viz.* three; but experienced gamblers nevertheless prefer the seven, by reason of the difficulty to throw the doublets, two quaters, or two treys. It is also the opinion of most, that at the first throw, the caster hath the worst of it. On the whole, hazard is certainly one of the most bewitching and ruinous games played on the dice. Happy, therefore, the man who either never heard of it, or who has resolution enough to leave it off in time. See the articles CHANCE and GAMING.

**HAZLE**, *corylus*, in botany. See the article CORYLUS.

*Witch-HAZLE*, a name sometimes given to the elm. See the article ELM.

**HAZLE-EARTH**, or **HAZLEY-EARTH**, in agriculture, a kind of red loam, which is said to be an excellent mixture with other sorts of earth; uniting what is too loose, cooling what is too hot, and gently entertaining the moisture.

The best manure for a hazley soil is marl, chalk, and sea-coal ashes. See MARL, CHALK, and ASHES.

**HAZLE-HEN**, a bird of the size of a moderately grown pullet; it is a species of tetrao, with a grey tail, spotted and fasciated with black, frequent in many parts of Europe. See the article TETRAO.

**HEA**, a province of the empire of Morocco, situated on the ocean, south-west of Morocco proper.

**HEAD**, *caput*, in anatomy, the uppermost part of the body of an animal.

The head is the first of the five divisions into which anatomists distinguish the human body, consisting of the head, neck, thorax, abdomen, and extremities. See the article NECK, &c.

The first parts to be distinguished in the head, are the hairy part, or scalp; and the naked part, or the face; after which we are to attend to the division into the sinciput and occiput, the fore and hinder part of the head; the temples, the crown, or vertex; the bucca, the cheeks, and the philtrum, or lacuna. See the articles SCALP, FACE, &c.

The coverings of the head are, first, the hair; secondly, the skin; thirdly, the membrana cellulosa; and, fourthly, the muscles. See **HAIR**, **CUTIS**, &c.

Besides the external integuments of the head, there is an aponeurotic expansion which covers the head like a cap, and is spread round the neck, and on the shoulders, like a riding-hood; and for this reason Winslow gives it the name of coif, and calls the superior portion of it the aponeurotic cap.

The head contains in the cavity of the bones of the skull the chief organ, or primum mobile of the whole animal oeconomy; the face is the seat of several other particular organs, which are greatly compounded. The proper containing parts of the head are the frontal muscles, the pericranium, and the bones of the skull: the parts contained are the membranes of the brain, the brain itself, and the vessels. See **BRAIN**.

With regard to the bones of the head, it may be observed, that the head expresses that part of the skeleton which is placed upon the top vertebra of the neck, and in this view is divided into the cranium or skull, and maxillæ. See the articles **SKULL** and **MAXILLÆ**.

The whole head of the skeleton is spheroidal, composed as it were of two ovals a little depressed on each side: one of them is superior, the extremities pointing forward and backward; the other is anterior, the extremity being turned upwards and downwards, in such a manner as that one extremity of each oval meets, and is lost in the other, at the place particularly known by the name of the forehead.

This complex figure being viewed sideways, represents a spheroidal triangle; and we ought farther to observe, that the oval of the skull is broader behind than before, and that of the face broader above than below.

For the arteries and veins of the head, see the articles **ARTERY** and **VEIN**.

For the glands and muscles, see the articles **GLAND** and **MUSCLE**.

*Diseases of the HEAD*, are often mistaken, even by physicians, for those of other parts. Some physicians tell us, that those who are subject to disorders of the head, ought not to take any food at night.

**HEAD-ACH**, a most troublesome sensation in the nervous membranes of the head, produced by various causes, and attended

with different symptoms, according to its different degrees, and the place where it is seated.

The most common seat of this disease is the pericranium. It may likewise be in the skin that covers the skull, and in the dura mater: this last but seldom happens, but when it does it is very dangerous. There may likewise be a very acute pain in the thin membrane that covers the sinus of the os frontis.

If the head-ach be slight, and affects a particular part of the head, it is called cephalalgia; if the whole, cephalæa; if one side only, hemicrania; if there is a fixed pain on the top of the head which may be covered with the end of the thumb, it is called clavus hytericus. The general cause of the head-ach, according to Hoffman, is a hindrance of the free circulation of the blood through the vessels of the head.

When the blood rushes with impetuosity, and in too great plenty into the membranes, which may happen to the plethoric, to those whose usual bleeding at the nose is suppressed, and to young persons, there is a pain in the whole head, which becomes hot, swells, aches, and looks red; the vessels swell, and there is a strong pulsation in those of the neck and temples. The nostrils are dry and parched; there is a burning heat, and drought in the fauces.

When the vessels of the head are stuffed with a mucous serum from a stoppage of the running of the nose, then there is a heavy obtuse pressing pain chiefly in the fore part of the head, in which there seems to be such a weight, that the patient can scarce hold it up: sometimes the skin is so swelled that it will pit; sometimes it happens from the ferous, sharp, caustic matter of the french disease, which infects the pericranium, and often causes a caries in the skull: sometimes it may proceed from matter of a saline, caustic nature, driven back from the external parts, as in the gout, itch, erysipelas of the head, gutta rosacea, the small-pox and measles, before the morbid matter is expelled to the outward skin, or, which is worse, when it is driven back. In these cases where a small quantity of caustic matter causes the pain, it rather proceeds from a violent stricture of the membranes than from their distention.

There is likewise a most violent, fixed, constant, and almost intolerable head-

which brings on a debility both of body and mind, hinders sleep, disturbs digestion, destroys the appetite, causes a vertigo, dimness of sight, blindness, a noise in the ears, convulsions, and the epilepsy; and by consent of the other nervous parts of the body, produces vomiting, costiveness, coldness of the extreme parts, and the countenance of a dying person. Sometimes the head-ach is symptomatic, and attends upon continual and intermitting fevers, and especially the quartan, irregular flowing of the menses, the hypochondriac passion, and the like. A hemi-crania generally proceeds from a fault in the stomach from crudities or indigestion, and commonly appears when digestion is performed.

The curative indications are, 1. To divert the impetus of the blood and humours from the head, and to discuss them by suitable remedies. 2. To relax the spastic strictures of the membranes, the cause of which is a sharp caustic matter, that the fluids may have a more free circulation. 3. To correct the peccant matter, and evacuate it gently through the most convenient emunctories. 4. To prevent a return by strengthening the whole nervous system, by proper remedies, and especially by an accurate diet and regimen.

When the blood rushes to the head in too great quantity, bleeding is necessary, more particularly under the tongue, in the forehead, in the jugulars, or by leeches behind the ears. If the body abounds with too much blood, it will be best to bleed in the ankle first, and the next day, or a day after, in a vein about the head. But first of all cleanse the body by an emollient clyster, or by giving an infusion of rhubarb and manna, with cream of tartar.

To restrain the orgasm of the blood, it will be proper to give a diaphoretic and absorbent mixture, with diaphoretic antimony, purified nitre, burnt hart's horn, and diacodium, diluted with a sufficient quantity of suitable simple distilled waters. But if the head-ach proceeds from a copious vitiated serum stagnating in the membranes, either within or without the skull, with a dull heavy continual pain, which will neither yield to bleeding nor gentle laxatives, then more powerful remedies are required to dissolve the thick glutinous humours, and to carry them off by stool.

Take of pure gum ammoniac, sagape-

num, the best myrrh, roseated aloes, extract of black hellebore, resin of jalap, mercurius dulcis, and prepared cinnabar, each half a dram; of the extract of saffron, of the powder of castor, and of the salt of amber, each fifteen grains. Make them into a mass; out of every scruple of which make twelve pills; six of which may be taken at night, and the other six in the morning. On the day the pills are taken, let the patient take nothing but thin broths. After three days, they may be repeated again: when the vitiated serum has been sufficiently evacuated, then give strengthening remedies mixt with diuretics; at the same time the patient should use exercise to make him sweat, with strong frictions, and such aliment and liquors as tend to promote a discharge by urine. See DIURETIC. If this method fails of success, apply a blister made with an ounce of the emplastrum attrahens, and a dram of cantharides, adding a few grains of camphor. It may be of the size of a crown-piece, and applied to the nape of the neck; it should be often renewed, and continued for a long time. When the disease is evident to the sight and touch, from the serum stagnating under the skin of the head, a blister may be laid all over the head, with great advantage. See the article VESICATORY.

When there is any intense pain remaining fixed in one place lying pretty deep in the membranes, the herb ranunculus used as a vesicatory, has a wonderful efficacy: the leaves must be bruised in a marble mortar, and the part, if hairy, shaved; then a sticking plaster is to be laid on it, with a hole about the bigness of a silver-penny, and the leaves over that, just in the same manner as a caustic. See the article CAUSTIC.

If it is caused by a suppression of a coryza, a smelling-bottle of volatile salts should be held frequently to the nose, or the patient may take herb snuff, with the addition of flowers of benjamin and powder of cloves. See CATARRH.

When the head-ach arises from a corrupted mass of blood and an impure serum, as in the scurvy, and lues venerea, a decoction of the woods, with crude antimony, may be serviceable, after evacuations with the pills recommended above. Fasting a day now and then with labour and exercise, may be useful; as also a sudorific. See the articles EXERCISE and SUDORIFIC.

A hemi-

A hemicrania, especially a periodical one, is generally owing to a foulness in the stomach, and primæ viæ, for which gentle emetics will be beneficial; as also purgatives, to drive the humours from the head; afterwards stomachics. If it proceeds from profuse evacuations of the menes or hæmorrhoids, those fluxes must be reduced within bounds. See the article **FLUX**, &c.

If the head-ach is so intolerable as to endanger the patient's life, or is attended with continual watching, fainting fits, a fever, an inflammation, or a delirium, recourse must be immediately had to opiates, with native cinnabar, after a clyster has been first given. When there is an intolerable pain in the sinuses of the nose, or the boney sinuses of the head, produced by an extravasation of some fluid, the only cure is scarification of the nostrils, or causing the nose to bleed with a straw suddenly thrust therein, See the article **EXTRAVASATION**.

If there is an extravasation under the pericranium, and the humour is so sharp as to begin to render the bone carious, then recourse must be had to incision, as in a whitlow. See **WHITLOW**.

If the head-ach arises from a sudden orgasm in the blood, proceeding from heat, exercise, or labour, evacuations of any kind are not proper, but rather cooling draughts with nitre.

**HEAD-MOULD-SHOT**, a disorder affecting new-born infants, in which the edges of the bones of the cranium at the sutures, especially the coronal one, lie over one another, so that the fibres of the meninges are stretched, and torn asunder, and the brain itself compressed; whence convulsions frequently happen that carry them off.

The head-mould-shot is a disorder opposite to the horse-shoe-head. See the article **HORSE-SHOE-HEAD**.

**Ulcers and eruptions of the HEAD**. There are several ulcers or eruptions, which the hairy part of the head is subject to, and which the writers in medicine have distinguished by the several names of tineæ, favi, and achores, for the treatment and account of which, see the articles **ACHOR** and **TINEA**.

When the achor extends itself to the face, it is known by the name of crusta lactea. See **CRUSTA LACTEA**.

*For the wounds of the HEAD*. See the articles **WOUND**, **FISSURE**, **CONTRA-**

**FISSURE**, **FRACTURE**, **TREPAN**, &c. Mr. le Dran, in his observations on the wounds of the head, shews how much more dangerous the case is, when the cranium does not break by violent blows, &c. than when it is fractured, because of the greater commotions of the brain, &c. and therefore concludes it necessary to perform the operation of the trepan oftener than is commonly practised.

**HEAD** is also used for the top or extremity of any thing; thus we say the head of a tree, the head of a bone, the head of a muscle, the head of a nail, &c.

**HEAD**, in architecture, an ornament of carved work, or sculpture, frequently serving as the key of an arch, or plat-band, on other occasions.

These sort of heads usually represent some of the heathen divinities, virtues, seasons, ages, &c. with their attributes, as a thunderbolt for Jupiter, a diadem for Juno, a trident for Neptune, a crown of ears of corn for Ceres, a helmet for Mars, a caduceus for Mercury, &c.

The heads of beasts are also used in places suitable, as an horse's head for an equester; a deer's or boar's head, for a park or forest; a dog's head for a kennel; a bullock's or sheep's, for a shambles or market-house. In the metopes, friezes and other parts of certain antique doric temples, we see representations of bullocks, or rams-heads, as a symbol of the sacrifices offered there.

**HEAD**, in heraldry. The heads of men, beasts, or birds, are very frequent in armoury, and borne either full-faced, looking forward, or side-faced in profile, when only one half of the face appears, which differences ought to be mentioned in blazoning, to avoid mistakes; as a head, or heads fronting; or a head, or heads side-faced, or in profile: thus, Vert, a chevron gules, between three turks-heads couped side-faced proper, is borne by the name of Smith. And again, Or, a cross gules, between four blackmoors heads, couped at the shoulders proper, is borne by the name Juxon. As the head is the principal part of the body, so it is of course the noblest bearing.

Among medalists, the different heads on antient coins, are distinguished by the different dresses thereof. See **MEDAL**.

In the imperial medals, where the head is quite bare, it is usually a sign the person was not an emperor, but one of the children of an emperor, the presumptive

heir of the empire. The heads which are covered, are either covered with a diadem, or a crown, or a simple cask, or a veil, with some other foreign covering; whereof the diadem is the most antient. The heads of deities are distinguished by some special symbol thereof.

**HEAD**, among huntsmen, is used for the horns of a deer, as a hart, buck, &c. See **ANTLERS**, **ROYALS**, **CROCHES**, &c.

**HEAD**, in the manege. Head of a horse imports the action of his neck, and the effect of the bridle, and the wrist: this horse plants his head well, and obeys the hand; such a horse refuses to place his head; he shoots out his nose, and never rests right on the hand, &c. For the properties of the head of a horse. See **HORSE**. To give a horse head. See the articles **PARTIR** and **ECHAPER**.

**HEAD** in and likewise the hips. You must passage your horse-head and croupe in, *i. e.* work him side-ways upon two parallel lines, at step or trot, so that when the horse makes a volt, his shoulders mark a pisse, or tread at the same time, that his haunches give the tract of another, and the horse plying or bending his neck, turns his head a little within the volt, and so looks upon the ground he is to go over.

**HEAD**, in the military art. Head of a work is the front of it next the enemy, and farthest from the place, as the front of a hornwork is the distance between the flanked angles of the demibaftions; the head of a double tenaille is the salient angle in the middle; and the two other sides which form the re-entrant angles. See the article **FRONT**, &c.

**HEAD**, in painting, sculpture, &c. a representation of that part of the human body, whether in colours, draught, or creux: if taken from the life, or supposed to bear a just resemblance to the person, it is more properly called portrait. See the article **PORTRAIT**.

**HEAD-BOROW**, the person who is chief of the frank-pledge in boroughs, or who antiently had the government within his own pledge. See **FRANK-PLEDGE**.

**HEAD-BOROWS**, at this time, are a kind of constables. See **CONSTABLE**.

**HEAD-FARCIN**. See the article **FARCIN**.

**HEAD-LAND**, in husbandry, is taken to signify the upper part of land left for the turning of the plough.

**HEAD-LAND**, in the sea-language. See **LAND**, **HEAD-LINES**, in a ship, those ropes of all sorts which are next to the yards, and

by which the sails are made fast to the yard. See **SAIL** and **YARD**.

**HEAD-PENCE**, a certain sum antiently collected by the sheriff of Northumberland, of the inhabitants of that county, without any account to be given thereof to the king, which exaction was abolished by Hen. VI.

**HEAD-SEA**, is when a great wave or billow of the sea comes right a-head of the ship, as she is in her course.

**HEAD-SAILS**, in a ship, those which belong to the fore-mast, and bolt-sprit: for it is by these that the head of the ship is governed, and made to fall off and keep out of the wind; and these in quarter-winds are the chief drawing sails.

**HEAD-SILVER**, a fine paid to the lords of the leet. See the article **COMMON-FINE**.

**HEAD-STALL**, in the manege. See the article **CAVESON**.

**HEAD-STALL**, among musicians. See the article **PHORBÆA**.

**HEAD-TIN**, in metallurgy, a preparation of tin-ore toward the fitting it for working into metal. When the ore has been pounded and twice washed, that part of it which lies uppermost, or makes the surface of the mass in the tub, is called head-tin: this is separated from the rest, and after a little more washing becomes fit for the blowing-house.

**HEAD of a ship**, or other vessel, is the prow, or that part which goes foremost.

**Moor's HEAD** is understood of a horse with a black head and feet; the body being usually of a roan colour. Among engineers a moor's head is used for a kind of bomb or granado shot out of a cannon. Among chemists it is a cover, or capital, of an alembic; having a long neck to convey the vapours raised by the fire into a vessel, which serves as a refrigeratory. See **ALEMBIC**.

**Dragon's HEAD**, in astronomy, &c. is the ascending node of the moon, or other planet. See the article **NODE**.

**HEADS**, a term used by builders for that kind of tile which they use to lay at the eaves of a house; being the full breadth of a common tile, and but half a tile in length. See the article **TILE**.

**HEADFORD**, a town of Galway, in Ireland, twelve miles north of the city of Galway.

**HEADON**, or **HEYDON**. See **HEYDON**, **HEALFANG**, or **HALSFANG**. See the article **HALSFANG**.

**HEALING**, is used, by surgeons, for the curing of wounds, ulcers, and other sores.

See

See the articles **WOUND**, **ULCER**, **TUMOUR**, &c.

**HEALING**, in architecture, the covering a roof with lead, tiles, slate, or the like.

**HEALTH**, is a right disposition of the body, and of all its parts ; consisting in a due temperature, a right conformation, just connection, and ready and free exercise of the several vital functions.

Health admits of latitude, as not being the same in all subjects, who may yet be said to enjoy health.

That part of medicine, which shews the means of preserving health, is termed *hygiene*. See the article **HYGIENE**.

The Greeks and Romans deified health, representing it under the figure of a woman, whom they supposed to be the daughter of *Æsculapius*. We find the name of the goddess *Salus*, or health, on many medals of the roman emperors, with different inscriptions, as *SALUS PUBLICA*, *SALUS REIPUBLICÆ*, *SALUS AUGUSTI*, &c.

**HEAM**, in beasts, is the same with the *secundines*, or after-birth in women.

The medicines proper to expel it, are thyme, winter-savoury, and penny-royal, boiled in white wine and given inwardly ; as also common hore-hound stewed in white wine. Dittany put up in form of a pessary, drives out a dead foal, and brings away the *secundines*. Angelica produces the same effect ; so does parsley-seed, alexanders, hops, fennel, favin, and bay-berries.

**HEAN**, a town of Tonquin, in the farther India, situated on the river Domea, eighty miles north of the bay of Tonquin : east long. 107°, north lat. 22°.

**HEARING**, *auditus*, the sense whereby we perceive sounds. See **SOUND**.

The organ of hearing is the ear, and particularly the auditory nerve and membrane. See the article **EAR**.

This membrane, in the various degrees of tension and relaxation, adapts itself to the several natures and states of sonorous bodies ; becoming tense for the reception of acute sounds, and relaxed for the admission of grave sounds. In short, it is rendered tense and relaxed in a thousand different degrees, according to the various degrees of acuteness or gravity in sounds.

Sound, then, is in effect nothing but a certain modulation of the air, which being collected by the external ear, passes thro' the *meatus auditorius*, and beats upon the membrane of the *tympanum*,

which moves the bones in the *tympanum* : these move the internal air, which finally communicates the motion to the auditory nerve, in the labyrinth and cochlea ; and according as the vibrations are quick or slow, the sound is either acute or grave.

The curious structure of the labyrinth and cochlea, serves to make the weakest sounds audible ; for the whole organ of hearing being included in a small space, the impression would have been made only on a very small part of it, had the auditory nerve run in a straight line ; and the strength of the impression being, *cæteris paribus*, always as the number of parts upon which the impression is made, those sounds which are now low, could not have been heard at all. If, like the retina, the auditory nerve had been expanded into a large web, that had covered or lined some wide cavity, even in this case the impression of sounds had been much weaker than they are now : for this large cavity would have given room for the sounds to dilate, and all sounds grow weaker in proportion as they dilate : but in the present structure of the labyrinth and cochlea, both these inconveniencies are prevented ; the canals of which, by their winding, contain large portions of the auditory nerve ; upon every point of which, the smallest sound being once impressed, becomes audible ; the sounds are hindered from dilating, by their narrowness ; and the impressions that are made upon the nerves, by the first dilatation, are ever the strongest. In like manner, the strength of the impression is increased in the narrow canals, by means of the elasticity of the sides of the bony-canal ; which receiving the first and strongest impulses of the air, reverberate them the more strongly upon the auditory nerve.

It deserves observation, that though the air be the usual matter of sounds ; so that if a bell be hung in *vacuo*, it will not be heard at all ; yet most other bodies, properly disposed, will do its office, only some more faintly than others. Thus a sound may be heard through water, or even through earth, of which there are various instances.

As the sight is assisted by spectacles, or other glasses, so the hearing is enlivened and rendered quick, by means of acoustic instruments ; which are of various figures, but for the most part bear some resemblance to a trumpet, diverging and growing wider towards the external mouth,

mouth, marked B B, (plate CXXVII. fig. 3. n° 1) the slender part A being introduced into the ear. But besides this common kind, those represented *ibid.* n° 2 and 3, are highly commended; but especially the third one, which by reason of its smallness, and form, being wreathed up like a spiral shell, may be so concealed under one's hair or wig, as scarce to be observable; whilst the slender part A is introduced into the ear, and the cords B B tied round it.

However, it is to be observed, that the simple kind almost in the shape of a horn, (*ibid.* n° 1.) and made either of brass, silver, &c. is the best instrument hitherto invented for assisting the hearing.

**Dulness of HEARING.** See the articles **DEAFNESS** and **EAR**.

Some recommend the following medicine for dulness of hearing: Take essence of amber, a dram; castor and oil of chamæmyle, of each half a scruple; and oil of amber, one drop: mix them all together, and three or four times a day put a piece of cotton, wetted in the mixture, into the ear.

The drinking of mineral waters every spring in a regular manner, is also recommended as a preservative from this disorder.

**HEARSE**, among sportsmen, a hind of the second year of her age. See **HIND**.

**HEART**, *cor*, in anatomy, a muscular body, included in the pericardium, and situated nearly in the middle of the breast, between the lobes of the lungs; being the primary organ of the circulation of the blood, and consequently of life.

Its figure is nearly conic, the larger end being called its base, and the smaller end its apex. Its lower part is plane, and the upper part convex. Its situation is nearly transverse, or horizontal; so that its base is in the right, and its apex, with the greatest part of its bulk, is in the left side of the thorax; and consequently, it is there that the pulsation is felt.

The plane surface of the heart lies on the diaphragm; the convex one is turned upwards. The heart is connected, 1st, by the intervention of the pericardium with the mediastinum, and with a large part of the middle of the diaphragm: this is contrived by nature, to prevent its being displaced, inverted, or turned too rudely about, in consequence of the various motions of the body. 2. Its base is connected to its common vessels; but

its apex is free, and is received into a kind of cavity in the left lobe of the lungs.

The length of the human heart is about six fingers breadth: its breadth at the base, is about five fingers; and its circumference about thirteen. It is, both externally and internally, surrounded with a smooth membrane. There is a quantity of fat about it, which covers its base and its apex, and serves for lubricating it, and for facilitating its motions. Its blood-vessels are of two kinds, common and proper; its common or peculiar vessels being the coronary arteries and veins.

The common vessels of the heart are two veins, called the vena cava, and the vena pulmonalis; and two arteries, the pulmonary one and aorta. The nerves of the heart are small, and arise from the par vagum and intercostals. The auricles are two. See **VEIN**, **ARTERY**, &c.

There are also two cavities in the heart, called its ventricles: of these the right is thinner and weaker in its circumference, but usually much more capacious than the left: it receives the blood from the vena cava, and the right auricle, and deliver it into the pulmonary artery, to be carried to the lungs. The left ventricle is much stronger and thicker in its sides; but it is narrower and smaller than the right: it receives the blood from the pulmonary vein, and the left auricle, and extrudes it very forcibly into the aorta. The right ventricle is in the anterior part of the thorax; the left in the hinder part: so that they might be called the anterior and posterior ventricles, much more properly than the right and left. See **CIRCULATION**.

There are in the sides of both the ventricles of the heart, and of both its auricles, several columnæ carneæ, or lacertuli, with furrows between them, seeming so many small and distinct muscles; and from the concurrence of the tendinous fibres of these in the heart, there are formed peculiar membranes situated at the orifices of the auricles of the heart: and there are also other columns of this kind, which run transversely from one side of the ventricles to the other: these serve partly to assist the contraction of the heart in its systole, and partly to prevent its too great dilatation in its diastole. See the article **SYSTOLE** and **DIASTOLE**.

The valvulæ of the heart are of three kinds. 1. The tricuspidales; these are three

The H E A R T.

three in number, and are situated at the ingress of the vena cava in the right ventricle. 2. The mitrales : these are two, and are situated in the left ventricle at the ingress of the pulmonary vein : these serve to hinder the ingress of the blood from the heart into the veins again, while they are constricted. 3. The semilunar ones : these are three, and are situated at the origin of the aorta and pulmonary artery, and serve to prevent the reflux of the blood from them into the heart : these, for the sake of strength, are furnished with a number of fleshy fibres and spheroid corpuscles.

The orifices of the veins of Thebesius and Verheyen, in the hollows of the heart, are for carrying back the blood from the substance of the heart to its cavities.

The fibres of the heart are of a muscular substance, and of a most amazing fabric. They are of two kinds, 1. Straight ones in the left ventricle ; and, 2. Spiral ones, common to both ventricles, and of two orders. The exterior ones run to the left, from the base of the heart : the interior ones run to the right, and intersect the others ; and, when they act, they closely constrict the cavities of the heart, and drive out the blood from them. According to this fabric, the heart may be resolved into two muscles, each of which constitutes one of its ventricles. The use of the heart, is for the circulation of the blood. It receives the blood from the veins, running from all parts of the body ; and propels it again, by its own motion, to all those parts, through the arteries. On this depend life itself, the preservation of the frame, and the motions and actions of all its parts. See the article *CIRCULATION of the Blood*.

This motion of the heart is wonderful : it continues to the utmost period of life, day and night, without a single moment's interruption or intermission ; and is performed more than an hundred thousand times every day. Here is, indeed, something like what the mechanists want, under the name of a perpetual motion ; and the stupendous wisdom of the creator is, in nothing, expressed more gloriously.

But that the reader may have as distinct an idea as possible of this primary organ of life, we shall lay before him several views of it. That exhibited in plate CXXVIII, n° 1. represents the human heart seen in its convex part, and in its natural situation ; where B marks the branches of the coronary vein ; C, the coronary

artery ; D, the right auricle ; E, branches of veins going from the right auricle ; G, the trunk of the aorta ; H, the trunk of the pulmonary artery ; I, the ascending trunk of the vena cava ; K, the descending trunk of the vena cava ; L, L, &c. branches of the aorta, rising upwards ; M, one of the branches of the pulmonary artery ; N, N, &c. branches of the pulmonary vein. No 2. *ibid.* represents the heart opened, to shew the structure and form of its ventricles ; where A expresses the muscular septum, or partition, which divides the ventricles ; B, the right ventricle opening into the right auricle, and into the trunk of the pulmonary artery ; C, the left ventricle, opening into the left auricle, and into the great trunk of the aorta. No 3 and n° 4, *ibid.* represent the heart in different positions ; where A marks the ascending trunk of the vena cava ; B the trunk of the aorta, C branches of the pulmonary vein, D the descending trunk of the vena cava, and E part of the right auricle, cut away, to shew the different arrangement of the internal fibres and venous ducts.

*Force of the HEART.* Several ingenious persons have, from time to time, attempted to make estimates of the force of the blood in the heart and arteries ; who have as widely differed from each other, as they have from the truth, for want of a sufficient number of data to argue from. This set the truly ingenious Dr. Hales upon making proper experiments, in order to ascertain the force of the blood in the veins and arteries of several animals.

If, according to Dr. Keil's estimate, the left ventricle of a man's heart throw out in each systole an ounce, or 1. 638 cubic inch of blood, and the area of the orifice of the aorta be = 0.4187 ; then dividing the former by this, the quotient 3.9 is the length of the cylinder of blood, which is formed in passing thro' the aorta in each systole of the ventricle ; and in the seventy-five pulses of a minute, a cylinder of 292.5 inches in length will pass : this is at the rate of 1462 feet in an hour. But the systole of the heart being performed in one third of this time, the velocity of the blood in that instant will be thrice as much, *viz.* at the rate of 4386 feet in an hour, or 73 feet in a minute. And if the ventricle throws out one ounce in a pulse ; then in the seventy-five pulses of a minute,

the

the quantity of blood will be equal to 4.4 lb 11 oz. and in thirty-four minutes a quantity equal to a middle-sized man, *viz.* 158 lb. will pass through the heart. But if, with Dr. Harvey, and Dr. Lower, we suppose two ounces of blood, that is, 3.276 cubic inches to be thrown out at each systole of the ventricle, then the velocity of the blood in entering the orifice of the aorta, will be double the former, *viz.* at the rate of 146 feet in a minute, and a quantity of blood equal to the weight of a man's body will pass in half the time, *viz.* 17 minutes. If we suppose, what is probable, that the blood would rise  $7 + \frac{1}{2}$  feet high in a tube fixed to the carotide artery of a man, and that the inward area of the left ventricle of his heart, is equal to fifteen

square inches; these multiplied into  $7 + \frac{1}{2}$  feet give 1350 cubic inches of blood, which presses on that ventricle, when first it begins to contract, a weight equal to 51.5 pounds.

What the doctor thus calculates, from supposition, with regard to mankind, he actually experimented upon horses, dogs, fallow does, &c. by fixing tubes, in orifices opened in their veins and arteries; by observing the several heights, to which the blood rose in these tubes, as they lay on the ground; and by measuring the capacities of the ventricles of the heart, and orifices of the arteries. And that the reader may the more readily compare the said estimates together, he has given a table of them, ranged in the following order.

The several animals.			
		Pounds. Ounces.	Weight of each.
Man	160	On	Height of the blood in the tube from the ju- gular vein.
Horse 1st.	825	112	Feet. Inches.
2d.	529	6	Height of the blood in tubes fixed to arteries.
3d.	10	1.659	Cubic inches.
Ox	1600	1.318	Capacity of the left ventricle of the heart.
Sheep	91	5 $\frac{1}{2}$	Square inches.
Doe	9	6 $\frac{5}{8}$	Area of the orifice of the aorta.
Dogs 1st.	52	0	Feet and in- ches in a minute.
2d.	24	5	Minutes.
3d.	18	5	Quantities of blood e- qual to the wt. of the animal in what time.
4th.	12	8	Pounds.
	4		How much in a minute
			Pounds.
			Weight of the blood sustained by the left ventricle contracting.
			Nº of pulses in a minute
			Square inches.
			Area of tran/v. section of descending aorta.
			Square inches.
			Area of the transverse section of ascending aorta.

Dr. Jurin likewise deduces the force of the heart from the laws of hydraulics, in the following manner. He supposes  $p$  = to the weight of the left ventricle, or a quantity of blood equal to the same weight;  $S$  = the internal surface of the same;  $l$  = the mean length of the filaments of blood issuing from the same;  $s$  = the section of the aorta;  $q$  = the quantity of blood contained in the left ventricle;  $t$  = the time in which the blood would be expelled from the heart, taking away the resistance of the arteries, and of the blood going before;  $v$  = the variable velocity with which the blood issuing from the heart would flow thro' the aorta, abstracting from the resistance;  $x$  = the variable length of the aorta, described by the blood gushing from the heart;  $z$  = the time in which the length  $x$  is described. Hence the mean variable velocity, of the blood contiguous to the ventricle, or the mean velocity of the ventricle itself, is  $= \frac{sv}{S}$ ; the motion of

the ventricle  $= p \times \frac{sv}{S}$ ; the motion of

the issuing of the blood  $= sv \times l + x$ ; the sum of these, or the power of the

ventricle  $= sv \times \frac{p}{S} + l + x$ . But it is

$v = \frac{\dot{x}}{z}$ . Whence by Newton's inverse method of fluxions, the power of the

ventricle will be found  $\frac{sx}{z} \times \frac{p}{S} + \frac{x}{z} + l$ .

Now, since  $z = t$ , it will be  $sx = q$ . Hence the power of the ventricle  $=$

$\frac{q}{t} \times \frac{p}{S} + \frac{q}{2s} + l$ . In the same manner the power of the right ventricle will be found

$= \frac{q}{t} \times \frac{p}{S} + \frac{q}{2s} + l$ . Here the same things

are signified by the greek letters in the right ventricle, as by the italic letters in the left. Hence the whole power of the

heart  $= \frac{q}{t} \times \frac{p}{S} + \frac{q}{2s} + \frac{q}{2s} + l + \lambda$ . Q.

E. I.

If we suppose  $p$  = 8 ounces avoirdupois = 13.128 cubic inches;  $\pi$  = 4 = 6.564;  $S$  = 10 square inches;  $z$  = 10;  $l$  = 2 inches;  $\lambda$  = 1.5;  $q$  = 2 ounces avoirdupois = 3.282 cubic inches;  $s$  = 0.4185 square inches;  $\sigma$  = 0.583;  $t$  = 0.1". The power of the ventricles will be equal to the motion of the underwritten weights,

that is,

Of the left ventricle

Of the right ventricle

Of the whole heart

lb oz.

6 3

15 4

Of which weights the velocity will be such, as that a line of an inch long might be described by the same in a second.

*Weight, &c. of the HEARTS of children, compared with those of grown persons.*

Dr. Bryan Robinson has made several useful observations on this subject, which are as follow.

1. The weight of the heart with respect to the weight of the body, is greater in children than in grown persons, in proportion of 3 to 2. Hence the weight of the heart, with respect to the weight of the body, lessens continually from the birth, till the bodies come to their full growth.

2. The quantity of blood which flows through the heart or lungs in a given time, in proportion to the weight of the heart, or quantity of blood contained in the body, which quantity of blood is proportional to the weight of the heart, is greater in children than in grown bodies, in the proportion of 20 to 7; which is the proportion of their pulses in a minute. Hence, the quantity of blood that flows through the heart or lungs in a given time, in proportion to the whole quantity of blood contained in the body, lessens continually from the birth, till bodies arrive at their full growth.

3. The velocity of the blood with respect to its quantity, which quantity is as the weight of the heart, is much greater in children, than in grown persons, in the proportion of 80 to 7. Hence, tho' the blood of children moves slower than the blood of grown people; yet for its quantity, it moves much quicker, and passes much oftner thro' the lungs. On which account the blood of children, notwithstanding the slowness of its motion, may by passing oftner through the lungs, and thereby receiving more of the acid of the air, in proportion to its quantity, be more fluid, and of a brighter colour, than the blood of grown persons.

4. The quantity of blood that flows through the heart or lungs in a given time, in proportion to the weight of the body, is greater in children than in grown bodies, in the proportion of 30 to 7. Hence, though the velocity of the blood is less in children than in grown bodies, yet its motion with

respect to the weight of the body is greater.

5. The velocity of the blood with respect to the length of body, is greater in children than in grown bodies, in the proportion of 20 to 7, which is the proportion of their pulses in a minute. Hence the velocity of the blood and number of pulses in a minute, with respect to the length of the body, lessen continually in growing persons, till they arrive at their full growth.

**HEAT**, in physiology, one of the secondary qualities of bodies, produced by fire, and opposed to cold. See **COLD**.

Under the article fire, we considered the sun as the principal source of heat upon the earth's surface, and the confines of the earth and atmosphere: without this, all the bodies upon our globe would doubtless grow rigid, lifeless, and fixed. It is this that stirs within them, as the main spring of their actions. Hence vegetation and animalization are evidently promoted; and hence the ocean and the atmosphere continue in a fluid state. See **VEGETATION**.

Heat in us is properly a sensation, excited by the action of fire; or it is the effect of fire on our organs of feeling. See **FIRE**.

Hence it follows, that what we call heat is a particular idea or modification of our own mind, and not any thing existing in that form in the body that occasions it. Heat, says Mr. Locke, is no more in the fire that burns the finger, than pain is in the needle that pricks it. In effect, heat in the body that gives it, is only motion; and in the mind, only a particular idea or disposition of the soul.

Heat in the hot body, according to 'S. Gravesande, is an agitation of the parts of the body, made by means of the fire contained in it: by such an agitation a motion is produced in our bodies, which excites the idea of heat in our mind; so that heat in respect of us is nothing but that idea, and in the hot body nothing but motion. If such motion expel the fire in right lines, it gives us the idea of light; if in a various and irregular motion, only heat. See **LIGHT**.

Heat, with respect to our sensations, or the effect produced on us by a hot body, is estimated by its relation to the organ of feeling; no object appearing to be hot, unless its heat exceed that of our body. Whence the same thing to different persons, or, at different times, to the same person, shall appear both hot

and cold. The degree of heat is measured by the expansion of the air, or spirit in the thermometer. See **THERMOMETER**. Under the article fire, we considered, among the several other properties of heat, its quality of expanding and dilating bodies. It is found to expand metals considerably, as appears from an experiment of Muschenbroek; the effects of which experiment are digested in a table, which having the degrees of expansion marked in equal parts to the  $\frac{1}{12500}$  part of an inch, we have given under the article **EXPANSION**.

The ingenious Muschenbroek contrived a machine for measuring the least alteration of dimensions in metals by heat, the description of which is this: plate CXXVI. n<sup>o</sup> 1. represents the whole machine with all its parts together, as it is used. At one end of this is a brass machine, LE, &c. which for the better shewing its parts is delineated, (*ibid.* n<sup>o</sup> 2.) as seen from another side. D is a circular plate  $2\frac{1}{10}$  inches diameter, the circumference of which is divided into degrees: this plate stands upon four pillars EEEE, which join it to the lower brass plate; and between the two plates, there is a perpendicular steel-arbor or axis F, which has on its lower part a pinion of six leaves or teeth, and on its upper end a wheel of sixty teeth, marked G: there is also another axis IH, supported by a cock H, which comes down from the upper plate; serving to turn the index IK, and having at its lower end a pinion of six leaves to take the teeth of the wheel G, by one turn of which wheel the index is carried round all the divisions: L is a rack, or straight piece of metal with teeth, which take the leaves of the pinion F, while it slides along under two small cocks PP; being pressed towards the pinion F by means of two screws, M, M; or drawn from it as there is occasion: there are twenty-five teeth in each inch of this piece; and as it moves forward and backward, the pinion F is carried round, and consequently the wheel G, which carries round the pinion H; together with the index IK. Let us suppose the rack to have run the length of an inch, then F and G will have turned round  $4\frac{1}{2}$  times; and consequently, the pinion H will have gone round  $10 \times 4\frac{1}{2} = 41\frac{1}{2}$  time, because H turns round ten times for G once: so that the index IK will have moved round

A Machine  
for Measuring the Expansion  
of Metals by  
HEAT.

round  $41\frac{2}{3}$  times, or 12500 degrees; therefore, when the index goes but from one degree to another, the rack L moves but the 12500th part of an inch; and as the motion of the index over half a degree is very sensible, we may perceive when the rack has moved  $\frac{1}{25000}$  part of an inch.

N<sup>o</sup> 3, *ibid.* represents a square bar of metal, upon which the experiment is made,  $5\frac{8}{10}$  inches long, and  $\frac{3}{8}$  of an inch thick. Its end O has a small tail, that it may communicate no heat to the iron plate A, into which it is received at B (*ibid.* n<sup>o</sup> 1.) and fixed by a screw C. Its other end N has a hole in it, thro' which goes the screw Q, that makes it fast to the rack L.

The bar being thus fixed, cannot become longer without pushing forward the rack L, and thereby moving round the index IK, by means of the wheel and pinions F, G, H; so likewise when it grows shorter, they must move the contrary way.

Now in order to apply the heat of burning spirits, there is a box, R, made of brass (*ibid.* n<sup>o</sup> 4.)  $3\frac{1}{2}$  inches long,  $1\frac{2}{10}$  inch wide, and  $\frac{4}{10}$  inch deep; which is covered at top with a piece of stone, S, represented in n<sup>o</sup> 5. with the under-side uppermost, the use of which is, to prevent the spirits from taking fire. It has a long hole cut thro' the middle, into which is set a brass plate T, (*ibid.* n<sup>o</sup> 1.) with five small equidistant holes, to transmit so many wicks of fine cotton; which being lighted, one or more at a time, cause the bar to expand, and the degree whereof is shewn by the index.

N<sup>o</sup> 6. represents the lower frame with Dr. Defaguliers's alterations, where BN is the round rod of metal to be tried with the steel-plate made fast at N by the pin Q. This plate, the natural situation of which is NL, is here kept straight in the position NL, by means of the spring SL; and is directed by the grooves of the pulleys PP, so that its upper-side presses on the roller H. The dotted circles *m*gg, represents the wheel above on the axis of H; and *g*ig, the watch-chain, carrying round the last roller i, an index *nik*, as in n<sup>o</sup> 1.

It has been justly observed by some of our modern philosophers, that actual or absolute heat, is to sensible or relative heat, the same as motion is to velocity: for absolute heat is nothing but the whole

motion of all the parts of the ignited body; and sensible, or relative heat, respects only the comparative velocity of the parts. Thus, equal bulks of mercury and water set in a sand-heat, where the heat of the fire may be uniformly communicated to both, will acquire in equal times equal degrees of absolute heat: but the relative heat of the water, or that which is sensible to the finger will be near 14 times as great as that of the mercury, because the water, having 14 times a less quantity of matter, will admit of velocity so much in proportion greater.

Again, if mercury and water have the same relative or sensible heat, that is, if both are heated in such a manner as to cause an equal ascent in the thermometer, then a quantity of mercury will heat 14 times as much water as the same quantity of water will do; or it will make the same quantity of cold water 14 times hotter than the same quantity of hot water can. All which is easy to be shewn by experiment, and abundantly proves, that heat and fire are wholly owing to the velocity of the parts of the heated or ardent body: on which theory the various phenomena of heat, cold, fire, burning, &c. are rationally accounted for. For first we are to consider, that cold and heat are only comparative terms, or that the same thing may either be too hot, or too cold, according to the relative idea or standard-degree. Thus ice or snow, is said to be cold with respect to the finger, but ice or snow is warm if compared to a freezing mixture, so that if (as we commonly do) we make the hand or any part of the body the standard of heat and cold, or the term of comparison, then it is evident, 1. If the parts of any body applied to the hand have the same velocity as the parts of the hand, such a body we naturally pronounce is neither hot nor cold. 2. If the particles of the body have a greater velocity than those of the hand, we pronounce it warm, if the excess be small; but hot, if it be great. 3. If the velocity of the parts of the body applied be less than that in the hand, the sensation then is what we call cold, which also may be in various degrees. 4. Hence it is plain there can be no such thing as absolute cold, but where the particles of matter are absolutely quiescent, or at rest. 5. Hence also, there can be no such thing as absolute heat, because no degree of

velocity can be assigned but a greater is still assignable, till we come to infinity ; where we are quite lost, as having no idea of infinite velocity or heat.

From this theory of heat and cold, we may conclude, that there is no body in nature whose parts are not in motion, in some degree, since we have yet been able to discover no ultimate degree or limit of cold ; and if any such thing were to be found in nature, it is likely, that it would be as impossible to bear or endure the test, as any extreme degree of heat ; both heat and cold naturally tending to destroy the animated part, or test, in the extreme degrees : cold, by destroying the vital motion, and fixing the part rigid and inflexible ; but heat, by putting the parts into too great an agitation, causing a greater velocity of the fluids and dissipation, and a force of tension in the solids, beyond what the natural state of the body can bear ; and therefore it will inevitably destroy it.

*Kinds, degrees, directions, &c. of HEAT, in chemistry, &c.* See the article FIRE.

**HEAT**, in geography. The earth being farther removed from the sun in summer than in winter, as was shewn under the article EARTH, it may be asked, how it comes to pass, that since the sun is the fountain of heat as well as light, our winters are much colder than our summers. In answer to this, it is to be considered that the rays of the sun fall with much less obliquity upon the surface of the earth, on our side of the equator in the summer, than in the winter ; and therefore they not only act more forcibly upon it, but a greater quantity of them fall upon a given place. For it is shewn in mechanics, that a moving body, striking perpendicularly on another, acts on it with all its force, and that a body striking obliquely, acts with the less force, the more it deviates from the perpendicular. Now fire, moving in right lines, must observe the same mechanical law as other bodies ; and consequently its action must be measured by the angle of incidence ; and hence fire striking on any obstacle in a direction parallel thereto, has no sensible effect, by reason the ratio is almost infinite, *i. e.* nothing : hence the sun radiating on the earth in the morning scarce produces any warmth at all. Again, in the winter, besides that the sun is much lower in the heaven when at its meridian height, than in the sum-

mer, it's rays pass through a longer portion of the earth's atmosphere, by which great part are intercepted, and some by various refractions and reflections, turned another way. See the article ATMOSPHERE.

And lastly, in summer, the sun continues with us sixteen hours, and is absent but eight, whereas in winter it is with us but eight hours, and is absent sixteen, all which things conspire to make a considerable alteration with respect to heat and cold.

If this be so, why is not the weather hotter, when the sun is in the tropic of cancer, its rays then falling with the least obliquity, and passing the shortest way through the atmosphere, and the days being then at the longest, than it is about a month afterwards, when the sun is in the next sign ? In answer to this, it is to be remembered that bodies are not always the hottest at that very instant the greatest degree of heat is applied to them : they require time to heat, as well as to cool ; it is the length of time therefore that the heat is applied to them, as well as the degree of it, that determines the quantity of heat communicated to them. For the like reason we find it warmer about two o'clock in the afternoon, than at twelve, when the sun is in its meridian altitude, and its rays fall thickest and most forcibly upon the earth.

The diversity of the heat of climates and seasons arising chiefly from the different angles under which the sun's rays strike upon the surface of the earth, Dr. Halley gives a mathematical computation of the effect of the sun under the different seasons and climates, going upon the mechanical principle already laid down : whence the vertical ray which is of the greatest heat being put for radius, the force of the sun on the horizontal surface of the earth will be to that as the sine of the sun's altitude at any other time : but how strictly just this calculation may be, for reasons already assigned, and from the following considerations, we wholly leave to the sagacity of our readers to determine. Let it be considered, that the different degrees of heat and cold in different places depend in a very great measure upon the accidents of situation, with regard to mountains and vallies, and the soil. The first greatly helps to chill the air by the winds which come

come over them, and which blow in eddies thro' the levels beyond ; and mountains, sometimes turning a concave side to the sun, have the effects of a burning mirror upon the subject plain ; and the like effects is sometimes had from the convex parts of clouds, either by refraction or reflection. As to soils, a stony, sandy, or chalky earth, it is known, reflects most of the sun's rays into the air again, and retains but few, by which means a considerable accession of heat is derived to the air ; as, on the contrary, black, loose soils absorb most of the rays, and return few into the air, so that the ground is much the hotter.

The following table of the heat of different climates is computed for every tenth degree of latitude, to the equinoctial and tropical sun ; by which an estimate may be made of the intermediate degrees.

Lat.	Sun in ☐	Sun in ☐	Sun ☐
0	20000	18341	18341
10	19696	20290	15854
20	18797	21737	13166
30	17321	22651	10124
40	15321	23048	6944
50	12855	22991	3798
60	10000	22773	1075
70	6840	23543	000
80	3473	24673	000
90	0000	25055	000

Hence are deducible the following corollaries. 1. That the equinoctial heat, when the sun becomes vertical, is as twice the square of the radius, which may be proposed as a standard to compare with in all other cases. 2. That under the equinoctial, the heat is as the sine of the sun's declination. 3. That in the frigid zones, where the sun sets not, the heat is as the circumference of a circle into the sine of the altitude at 6 ; and consequently that in the same latitude these aggregates of warmth are as the sine of the sun's declination ; and at the same declination of the sun, they are as the sines of the latitudes into the sines of the declination. 4. That the equinoctial day's heat is every where as the cosine of the latitude. 5. In all places where the sun sets, the difference between the summer and winter-heats, when the declinations are contrary, is equal to a circle into the sine of the altitude at 6 in the summer parallel ; and consequently these differ-

ences are as the sine of the latitude into or multiplied by the sines of declination. 6. From the foregoing table, it appears that the tropical sun under the equinoctial, has of all others the least force. Under the pole, it is greater than any other day's heat whatever ; being to that of the equinoctial as 5 to 4.

From the table and these corollaries, a general idea may be conceived of the sum of all the actions of the sun in the whole year ; and thus that part of heat which ariseth simply from the presence of the sun, may be brought to a geometrical certainty. The heat of the sun for any small portion of time is always as a rect-angle contained under the sine of the angle of incidence of the rays producing heat at that time.

Heat is usually divided by the school philosophers into actual and potential ; the former of which is that hitherto treated of, and the latter that which we find in pepper, wine, and certain chemical preparations, as of oil of turpentine, brandy, quick-lime, &c.

The peripatetics account for the heat of quick-lime from an antiperistasis. The epicureans, and other corpuscularians, attribute even potential heat to atoms, or particles of fire detained and locked up in the pores of these bodies, and remaining at rest therein, which being excited to action again by the heat and moisture of the mouth, or by the effusion of cold water, or the like cause, then break their inclosures, and discover what they are.

In the memoirs of the french academy, for the year 1713, the reader may find this doctrine well illustrated by M. Lemery, the younger, in the instances of quick-lime, regulus of antimony, tin, &c. which account Mr. Boyle endeavours to set aside, and substitute a mechanical property, viz. a peculiar texture of parts in these cases in lieu of fire. See Boyle's Mechanical Origin of Heat and Cold.

HEAT, in the animal œconomy, known by the several names of natural heat, vital heat, innate heat, and animal heat, is commonly supposed to be that generated by the attrition of the parts of the blood, occasioned by its circulatory motion, especially in the arteries.

To what organs, or operations, the heat of the human body, and other animal bodies, is owing, is hitherto extremely doubtful. The opinions that at present prevail

prevail are, 1. That the heat of animal bodies is owing to the attrition betwixt the arteries and the blood. 2. That the lungs are the fountain of this heat. 3. That the attrition of the parts of the solids on one another produce it. 4. That it is owing to the mechanical attrition of the particles of our fluids. To which opinions Dr. Stevenson of Edinburgh, adds a 5, *viz.* That whole process by which our aliment and juices are constantly undergoing some alteration.

The reasonings in favour of these several opinions may be seen at large, as laid down by the above-mentioned author in an essay on the cause of animal heat, in the Medical Essays, vol. vi. The chief arguments in favour of the first opinion, are, that if an artery is tied, or cut, the part to which it goes, turns cold; and on the ceasing of the pulsation of the arteries, cold and death follow. An increase of heat attends a brisk circulation, and a languid circulation is accompanied with a small heat. One who burns in a fever, or is hot with exercise, has a full and frequent pulse. In cold faintings, chlorosis, &c. the pulse is small and slow. To these they add, that the thermometer shews the arterial blood to be a little hotter than that of the veins.

This is accounted for from the conical figure of the arteries, from their fluxes and branches into exquisitely small capillaries; whence the resistance, and consequently the attrition must be great, from the number, strength, and elasticity of their coats; from the propelling power of the heart, and their strong resistance. From all these it is inferred, that the particles of blood perpetually getting new motions, directions, and rotations, are attenuated, condensed, have their angles grinded off, and are made homogeneous: hence, it is said, follows the fluidity, red colour, and heat of the mass, which is here perfected. See the articles ARTERY, HEART, CIRCULATION, and BLOOD.

The second opinion is, that the lungs are the fountain of heat in the human body. All that has been said for the blood's being heated in the arteries, is advanced to prove this hypothesis, with considerable additions, *viz.* that in the lungs the blood vessels every where attend, divide, and subdivide, along with the ramifications of the wind-pipe, and

as these are perpetually changing their situation and form, becoming longer, or shorter, making more acute, or more obtuse angles, so must the concomitant blood-vessels every moment make new angles, and give the blood new directions; that at last it enters into an exquisitely fine net-work, spreads every where on the vastly thin air-vesicles, where these air-bladders are perpetually changing their angles, points of contact, their form, volume, interstices, and so forth. From these and the elasticity of the air, and weight of the atmosphere, the blood is said to be churned, pressed backward and forward, broken and kneaded together, dissolved and condensed, made red and hot in respiration.

The third opinion is, that the cause of the animal heat is owing to the action of the solid parts upon one another. The reason in support of this opinion, is, that the heart and arteries move most; thence that it is natural to think, that the heat should be owing to this motion.

The fourth opinion is, the mechanical attrition of the particles of the fluids upon one another. Dr. Stevenson observes, that those who support this hypothesis, must not only suppose that mechanical attrition begets heat, but begets itself without diminution; that they must not only shew what sets this attrition agoing, but what maintains it because all mechanical force perpetually decreases in a resisting medium; in short, that they must shew the possibility of a perpetuum mobile, the impossibility of which they themselves demonstrate.

The fifth opinion is, what Dr. Stevenson calls the animal process, or that process by which our aliment and fluids are perpetually undergoing some alteration. This process, according to that writer, may be one *sui generis*, somewhat of a middle nature betwixt fermentation and putrefaction; and he thinks it comes so near to the latter, that he chooses to call it by that name. In putrefaction, which is a most powerful dissolvent of bodies, the intestine action of their minute particles creates, collects, or some way or other is the cause or means of heat. The doctor thinks it probable that this process is constantly carried on in all our juices, especially where there is blood; and this is chiefly in the veins, so that the blood is both

both the fountain of heat and the first spring of motion.

The late Dr. Mortimer, in the *Philos. Trans.* n° 476. gives it as his opinion, that the heat of animals is explicable from the phosphorus and air they contain. Phosphorus exists, at least in a dormant state, in animal fluids; and it is also known, that they all contain air: it is therefore only necessary to bring the phosphoreal and aerial particles into contact, and heat must of consequence be generated.

**HEATH**, *erica*, in botany, a genus of the *ostandria-monogynia* class of plants, the flower of which consists of one erect and quadrifid petal; and its fruit is a quadrilocular capsule, containing a great number of very small seeds.

The distilled water of heath-flowers is recommended for sore eyes, as also for the colic; and fomentations of them are said to be good in the gout and paralytic cases. *Dale.*

**Berry-bearing-HEATH**, a name given to *empetrum*. See *EMPETRUM*.

**Mountain-HEATH**, the name by which some call *saxifrage*. See *SAXIFRAGE*.

**HEATH-HEN**, a name sometimes given to the grouse. See the article *GROUSE*.

**HEATH-MOSS**, *coralloides*, in botany. See the article *CORALLOIDES*.

**HEATHENS**, in matters of religion, the same with pagans. See *PAGANS*.

**HEAVING**, in the sea-language, signifies throwing any thing over-board. Also turning about the capstan, is called heaving at the capstan. Likewise, when a ship being at anchor, rises and falls by the force of the waves, she is said to heave and set.

**HEAVEN**, *cælum*, literally signifies the expanse of the firmament, surrounding our earth, and extended every way to an immense distance.

The Hebrews acknowledged three heavens: the first the aerial heaven, in which the birds fly, the winds blow, and the flowers are formed; the second, the firmament in which the stars are placed; the third, the heaven of heavens, the residence of the Almighty, and the abode of saints and angels.

Heaven is considered by christian divines and philosophers, as a place in some remote part of infinite space, in which the omnipresent Deity is said to afford a nearer and more immediate view of himself, and a more sensible manifestation of his glory, than in the other parts of the universe.

This is often called the empyrean, from that splendor with which it is supposed to be invested; and of this place the inspired writers give us the most noble and magnificent descriptions.

The pagans considered heaven as the residence only of the celestial gods, into which no mortals were admitted after death, unless they were deified. As for the souls of good men, they were consigned to the elysian fields. See the article *ELYSIAN FIELDS*.

**Crystalline HEAVENS**. See the article *CRYSTALLINE*.

**HEAVINESS**, in general, the same with weight or gravity. See *GRAVITY* and *WEIGHT*.

**HEAVINESS**, *gravedo*, in medicine. See the article *GRAVEDO*.

**HEAVY**, in the manege. A horse is said to rest heavy upon the hand, when, thro' the softness of his neck, the weakness of his back, and the weight of his fore-quarters, or through weariness, he throws himself upon the bridle, but without making any effort to escape the horseman's hand.

By stopping him, and making him frequently go back, you may make him light upon the hand; that is, if his heaviness proceeds from laziness and stiffness; but if it is occasioned by a defect in his back, there is no remedy for it.

**HEBDOMARY**, a solemnity of the ancient Greeks, in honour of Apollo, in which the Athenians sung hymns in honour of that god, and carried in their hands branches of laurel. The word signifies the seventh day, this solemnity being observed on the seventh day of every lunar month.

**HEBENSTRETIA**, in botany, a genus of the *didynamia-angiospermia* class of plants, the flower of which is monopetalous, with a cylindraceous tube shorter than the calyx, and quadrifid at the limb; the fruit is an oblong capsule, containing two oblong seeds, convex and furrowed on one side, and plane on the other.

**HEBRAISM**, an idiom or manner of speaking peculiar to the hebrew language. See the next article.

**HEBREW**, or **HEBREW LANGUAGE**, that spoken by the ancient Jews, and wherein the Old Testament is wrote.

This appears to be the most antient of all the languages in the world, at least we know of none older: and some learned men are of opinion, that this is the language in which God spoke to Adam in Paradise,

Paradise, and in which the saints will speak in heaven.

The books of the Old Testament are the only pieces to be found, in all antiquity, written in pure Hebrew; and the language of many of these is extremely sublime: it appears perfectly regular, and particularly so in its conjugations; indeed, properly speaking it has but one conjugation, but this is varied in each seven or eight different ways, which has the effect of so many different conjugations, and affords a great variety of expressions to represent by a single word the different modifications of a verb, and many ideas which in the modern, and in many of the antient and learned languages, cannot be expressed without a periphrasis.

The primitive words, which are called roots, have seldom more than three letters or two syllables.

In this language there are twenty-two letters, only five of which are usually reckoned vowels, which are the same with ours, *viz.* *a, e, i, o, u*; but then each vowel is divided into two, a long and a short, the sound of the former being somewhat grave and long, and that of the latter short and acute: it must however be remarked, that the two last vowels have sounds that differ in other respects besides quantity, and a greater or less elevation. To these ten or twelve vowels may be added others called semi-vowels, which serve to connect the consonants, and to make the easier transitions from one to another. The number of accents in this language are, indeed, prodigious: of these there are near forty, the use of some of which, notwithstanding all the enquiries of the learned, are not yet perfectly known. We know, in general, that they serve to distinguish the sentences like the points called commas, semicolons, &c. in our language; to determine the quantity of the syllables, and to mark the tone with which they are to be spoke or sung. It is no wonder then, that there are more accents in the hebrew than in other languages, since they perform the office of three different things, which in other languages are called by different names.

HEBREWS, or *Epistle to the HEBREWS*, a canonical book of the New Testament.

Though St. Paul did not prefix his name to this epistle, the concurrent testimony of the best authors, antient and modern, afford such evidence of his being the au-

thor of it, that the objections to the contrary are of little or no weight. His mentioning himself in it, as lately a prisoner in Italy, and his promise to visit the Hebrews, together with Timothy, who had been released from imprisonment, both denote the writer, and the time of his writing this epistle, that it was just after the deliverance of St. Paul from his first trial at Rome.

The Hebrews, to whom this epistle was wrote, were the believing Jews of Palestine, and its design was to convince them, and, by their means, all the jewish converts, wheresoever dispersed, of the insufficiency and abolishment of the ceremonial and ritual law. In order to which he undertakes to shew, first, the superior excellency of Christ's person above that of Moses: secondly, the superiority of Christ's priesthood above the levitical: thirdly, the mere figurative nature, and utter insufficiency of the legal ceremonies and sacrifices: and, fourthly, that to forsake the mosaical law, was not, as the Jews boldly asserted, to apostatize from God, but was their indispensible duty and obligation. These particulars are intermixed with proper inferences and exhortations, all tending to shew the jewish christians the unreasonableness, folly, and danger of relapsing into judaism.

HEBRIDES, islands on the west of Scotland, of which Sky, Mull, Isla, and Arran are some of the largest.

HECATOMB, among the antient pagans, was the sacrifice of an hundred bulls or oxen; or, in a less confined sense, an hundred animals of any sort.

Pythagoras is said to have sacrificed an hecatomb to the muses, through joy and gratitude for his having discovered the demonstration of the XLVIIth proposition in the first book of Euclid, *viz.* that, "In a rectangled triangle, the square of the hypothenuse is equal to the squares of the other two sides."

Julius Capitolinus relates, that when an hecatomb was to be sacrificed, they erected for that purpose an hundred altars of turf, on each of which they sacrificed one animal. He adds, that when the emperors offered hecatombs, they sometimes consisted of an hundred lions, an hundred eagles, or the like.

HECATOMBÆON, *ἐκατομβαιων*, in antient chronology, the first month of the athenian year, consisting of thirty days, and answering to the latter part of our

June

with ours, *viz.* *a, e, i, o, u*, but then each vowel is divided into two, a long and a short, the sound of the former being somewhat grave and long, and that of the latter short and acute: it must however be remarked, that the two last vowels have sounds that differ in other respects besides quantity, and a greater or less elevation. To these ten or twelve vowels may be added others called semi-vowels, which serve to connect the consonants, and to make the easier transitions from one to another. The number of accents in this language are, indeed, prodigious: of these there are near forty, the use of some of which, notwithstanding all the enquiries of the learned, are not yet perfectly known. We know, in general, that they serve to distinguish the sentences like the points called commas, semicolons, &c. in our language; to determine the quantity of the syllables, and to mark the tone with which they are to be spoke or sung. It is no wonder then, that there are more accents in the hebrew than in other languages, since they perform the office of three different things, which in other languages are called by different names.

**HEBREWS**, or *Epistle to the HEBREWS*, a canonical book of the New Testament.

Though St. Paul did not prefix his name to this epistle, the concurrent testimony of the best authors, antient and modern, affords such evidence of his being the author of it, that the objections to the contrary are of little or no weight. His mentioning himself in it, as lately a prisoner in Italy, and his promise to visit the Hebrews, together with Timothy, who had been released from imprisonment, both denote the writer, and the time of his writing this epistle, that it was just after the deliverance of St. Paul from his first trial at Rome.

The Hebrews, to whom this epistle was wrote, were the believing Jews of Palestine, and its design was to convince them, and, by their means, all the jewish converts, wheresoever dispersed, of the insufficiency and abolishment of the ceremonial and ritual law. In order to which he undertakes to shew, first, the superior excellency of Christ's person above that of Moses: secondly, the superiority of Christ's priesthood above the levitical: thirdly, the mere figurative nature, and utter insufficiency of the legal ceremonies and sacrifices: and, fourthly, that to forsake the mosaical law, was not,

as the Jews boldly asserted, to apostatize from God, but was their indispensable duty and obligation. These particulars are intermixed with proper inferences and exhortations, all tending to shew the jewish christians the unreasonableness, folly, and danger of relapsing into judaism.

**HEBRIDES**, islands on the west of Scotland, of which Sky, Mull, Isla, and Arran are some of the largest.

**HECATOMB**; among the antient pagans, was the sacrifice of an hundred bulls or oxen; or, in a less confined sense, an hundred animals of any sort.

Pythagoras is said to have sacrificed an hecatomb to the muses, through joy and gratitude for his having discovered the demonstration of the XLVIIth proposition in the first book of Euclid, *viz.* that, "In a rectangled triangle, the square of the hypothenuse is equal to the squares of the other two sides."

Julius Capitolinus relates, that when an hecatomb was to be sacrificed, they erected for that purpose an hundred altars of turf, on each of which they sacrificed one animal. He adds, that when the emperors offered hecatombs, they sometimes consisted of an hundred lions, an hundred eagles, or the like.

**HECATOMBÆON**, *ἑκατομβαιων*, in antient chronology, the first month of the athenian year, consisting of thirty days, and answering to the latter part of our June and beginning of July. It was so called on account of the many hecatombs sacrificed in it.

**HECK**, an engine to take fish in the river Ouse. A salmon heck is a grate for catching that sort of fish.

**HECKLE**. See the article **HATCHEL**.

**HECKLING** of *hemp* and *flax*. See the articles **HEMP** and **FLAX**.

**HECTIC**, or **HECTIC FEVER**, a kind of slow fever, occasioned by exulcerations of the lungs, and the purulent matter mixing with the blood, and disturbing its natural motion. The symptoms are an unusual heat in the palms of the hands, a redness of the cheeks, especially after eating; also a weak, but quick pulse, a languid habit of body, and loss of strength.

It is of the utmost consequence, says Dr. Mead, to attempt the cure of this dreadful disease early; and as it arises from inflammations, it requires repeated bleedings. Dr. Pringle recommends the same practice, with the use of setons and issues,

made in the side that is most affected. He observes, that he found nothing diminish the hectic fits so much as small but repeated bleedings, especially when saline draughts and a cooling diet are taken at the same time. In thirst, heat, and other symptoms, the signs of a putrid state of the humours, the ptisan is to be acidulated with the spirit of vitriol, and the aliments are to be chosen of the acefcent kind. A mixture of equal parts of barley-water and sweet milk, seasoned with sugar and nutmeg, makes a proper and an agreeable part of diet; and in case of costiveness, let the patient drink a decoction of bran with raisins and liquorice. Colliquative sweats are most safely checked by lime-water, whereof the patient may drink about a pint a day, softened with a little new milk.

A milk-course, though much recommended by physicians, as having the double advantage of being food and physic, ought to be taken with caution; not only because some people have a natural aversion to milk, but because in head-achs, acute fevers, flatulencies, bilious loosenesses, and bloody stools, it is found to be very prejudicial. The preference is generally given to asses-milk, as being most cooling and detergent; but when it can be conveniently had, whey made of cows-milk, or even of goats, may be substituted in its room, especially if the goats have been fed on fragrant herbs. In case the milk does not agree with the stomach, as frequently happens, it should be medicated in the following manner: take of red roses dried, of balauistines, pomegranate-rind, and cinnamon, each one dram; and boil them in a pint of cows-milk: when the decoction begins to boil, pour a little cold water into it, to make it subside. Repeat this process several times, and lastly strain off the liquor, sweeten it with sugar, and set it by for use. Others recommend equal quantities of milk and an infusion of male speedwell, fow-thistle, sage of Jerusalem, liverwort, colts-foot, ground-ivy, maiden-hair, flowers of St. John's wort, and roses, with a little sugar a few drops of oil of tartar per deliquium: this must be drank pretty warm, and continued for six weeks. But above all, fresh butter-milk is said to be the most efficacious specific.

Medicines that are gently corroborating are also useful: such are the solution of coral, or mother of pearl, in orange juice; cortex eleutherii, or peruvian bark, made

into an electuary with syrup of lemons. Heister affirms he has cured many of these fevers with the bark, in a few days. But above all things, riding daily must not be forgot, as being the best kind of exercise, and highly beneficial in these distempers.

Hectics attack children sometimes from voracity, and at others from refrigeration of the body; in which cases the use of the temperate baths of sweet water, continued for some time, is said to be of great service; and to remove the obstructions of the meseraic glands and vessels, the frequent but sparing use of the following saline aperient mixture will be necessary: take of salt of tartar, nitre, and arcanum duplicatum, each two drams; sal ammoniac, three drams: mix them all together, and let a little of the mixture be put into the child's drink, according to his age and strength.

HEDERA, IVY, in botany. See IVY.

HEDERA TERRESTRIS, GROUND-IVY, a genus of plants called by Linnæus glechoma. See the articles GLECHOMA and GROUND-IVY.

HEDGES, in agriculture, are either planted to make fences round inclosures, or to divide the several parts of a garden. When they are designed as outward fences, they are planted either with haw-thorn, crabs, or black-thorn; but those hedges which are planted in gardens, either to surround wilderness-quarters, or to screen the other parts of a garden from sight, are planted according to the fancy of the owner, some preferring ever-greens, in which case the holly is best; next the yew, then the laurel, laurustinus, phillyrea, &c. others prefer the beech, the hornbeam, and the elm. See the article GARDEN.

Before planting, it is proper to consider the nature of the land, and what sort of plants will thrive best in it; and also, what is the soil from whence the plants are to be taken. As for the size, the sets ought to be about the bigness of one's little finger, and cut within about four or five inches of the ground; they ought to be fresh taken up, straight, smooth, and well rooted. Those plants that are raised in the nursery, are to be preferred.

In planting outside hedges, the turf is to be laid with the grass-side downwards, on that side of the ditch the bank is designed to be made; and some of the best mould should be laid upon it to bed the quick, which is to be set upon it a foot asunder.

When

When the first row of quick is set, it must be covered with mould, and when the bank is a foot high, you may lay another row of sets against the spaces of the former, and cover them as you did the others: the bank is then to be topped with the bottom of the ditch, and a dry or dead-hedge laid, to shade and defend the under-plantation. Stakes should then be driven into the loose earth, so low as to reach the firm ground: these are to be placed at about two feet and a half distance, and in order to render the hedge yet stronger, you may edder it, that is, bind the top of the stakes with small long-poles, and when the eddering is finished, drive the stakes anew.

The quick must be kept constantly weeded, and secured from being cropped by cattle; and in February it will be proper to cut it within an inch of the ground, which will cause it strike root afresh, and help it much in the growth.

When an hedge is about eight or nine years growth, it will be proper to plash it; for the method of doing which, see the article PLASHING.

The crab is frequently planted for hedges; and if the plants are raised from the kernels of the small wild crabs, they are much to be preferred to those raised from the kernels of all sorts of apples without distinction; because the plants of the true small crab never shoot so strong as those of the apples, and may therefore be better kept within the proper compass of an hedge.

The black-thorn, or sloe, is frequently planted for hedges; and the best method of doing it, is to raise the plants from the stones of the fruit, which should be sown about the middle of January, if the weather will permit, in the place where the hedge is intended; but when they are kept long out of the ground, it will be proper to mix them with sand, and keep them in a cool place. The same fence will do for it when sown, as when it is planted.

The holly is sometimes planted for hedges; but where it is exposed, there will be great difficulty in preventing its being destroyed; otherwise, it is by far the most beautiful plant, and being an ever-green, will afford much better shelter for cattle in winter, than any other sort of hedge. The best method of raising these hedges, is to sow the stones in the place where the hedge is intended, and where this can be conveniently done,

the plants will make a much better progress than those that are transplanted; but these berries should be buried in the ground several months before they are sown. The way to do this, is to gather the berries about christmas, when they are usually ripe, and put them into large flower-pots, mixing some sand with them; then dig holes in the ground into which the pots must be sunk, covering them over with earth, about ten inches thick. In this place they must remain till the following October, when they should be taken up, and sown in the place where the hedge is intended to be made. The ground should be well trenched, and cleared from the roots of all bad weeds, bushes, trees, &c. Then two drills should be made, at about a foot-distance from each other, and about two inches deep, into which the seeds should be scattered pretty close, left some should fail. When the plants grow up, they must be carefully weeded; and if they are designed to be kept very neat, they should be cut twice a year, that is in May and in August; but if they are only designed for fences, they need only be sheered in July. The fences for these hedges while young, should admit as much free air as possible: the best sort are those made with posts and rails, or with ropes drawn through holes made in the posts; and if the ropes are painted over with a composition of melted pitch, brown spanish colour and oil, well mixed, they will last several years.

Hedges for ornament in gardens are sometimes planted with ever-greens, in which case the holly is preferable to any other. Next to this, most people prefer the yew; but the dead colour of its leaves renders those hedges less agreeable. The laurel is one of the most beautiful ever-greens, but the shoots are so luxuriant that it is difficult to keep it in any tolerable shape; and as the leaves are large, to prevent the disagreeable appearance given them by their being cut through with the sheers, it will be the best way to prune them with a knife, cutting the shoots just down to a leaf. The laurustinus is a very fine plant for this purpose; but the same objection may be made to this as to the laurel; this, therefore, ought only to be pruned with a knife in April, when the flowers are going off; but the new shoots of the same spring must by no means be shortened. The small-leaved and rough-leaved laurustinus are the best plants for  
this

this purpose. The true phillyrea is the next best plant for hedges, which may be led up to the height of ten or twelve feet, and if they are kept narrow at the top, that there may not be too much width for the (snow to lodge upon them, they will be close and thick, and make a fine appearance. The ilex or ever-green oak, is also planted for hedges, and is a fit plant for those designed to grow very tall. The deciduous plants usually planted to form hedges in gardens are, the hornbeam, which may be kept neat with less trouble than most other plants. The beech, which has the same good qualities as the hornbeam; but the gradual falling of its leaves in winter cause a continual litter. The small-leaved english elm is a proper tree for tall hedges, but these should not be planted closer than eight or ten feet. The lime-tree has also been recommended for the same purpose; but after they have stood some years they grow very thin at bottom, and their leaves frequently turn of a black disagreeable colour.

Many of the flowering shrubs have also been planted in hedges, such as roses, honeysuckles, sweet-briar, &c. but these are difficult to train; and if they are cut to bring them within compass, their flowers, which are their greatest beauty, will be entirely destroyed.

**HEDGE-HOG.** See *Hedge-HOG*.

**HEDGE-SPARROW**, the brown motacilla, white underneath, and with a grey spot behind the eyes. See *MOTACILLA*. This is of the bigness of the red-breast; the head is large and rounded; the eyes small, and their iris hazel; the beak is slender; the ears are large and patulous.

**HEDMORA**, a city of Sweden, in the province of Westmania, situated on the river Dalecarlia, fifty miles north-west of Upsal: east long.  $15^{\circ} 55'$ , and north lat.  $60^{\circ} 16'$ .

**HEDYOTIS**, in botany, a genus of the tetrandria-monogynia class of plants, the flower of which is monopetalous and infundibuliform; and its fruit is a bilocular capsule, containing a great number of seeds.

**HEDYSARUM**, the FRENCH HONEY-SUCKLE, in botany, a genus of the diadelphia-decandria class of plants, the corolla of which is papilionaceous and striated; the fruit of a bivalve articulated pod, each joint of which is roundish, compressed, and containing one kidney-shaped-seed.

This plant is deobstruent and vulnerary.

**HEEL**, in anatomy, the hind-part of the foot. See *FOOT* and *CALCANEUM*.

**HEEL of a horse**, the lower hinder part of the foot, comprehended between the quarters, and opposite to the toe.

The heel of a horse should be high and large, and one side of it should not rise higher than the other upon the pasteron. To recover the heels of a horse that is hoof-bound, you should take out his sole, and keep his heels very wide, by which they will be restored in a month.

**HEEL of a horseman.** This being the part that is armed by the spur, the word is used for the spur itself; as, this horse understands the heels well.

To ride a horse from one heel to another, is make him go sideways, sometimes to one heel, and sometimes to another.

**HEEL**, in the sea-language. If a ship leans on one side, whether she be a-ground or a-float, then it is said she heels a-starboard, or a-port; or that she heels offwards, or to the shore; that is, inclines more to one side than to another.

**HEEL of the mast**, that part of the foot of any mast, which is pared away slanting on the aftward side thereof, in order that it may be stayed aftward on. The heels of the top-masts are squares.

**HEELER**, or *Bloody HEEL-cock*, a fighting cock that strikes or wounds much with his spurs.

The masters know such a cock even while a chicken, by the striking of his two heels together in his going.

**HEGIRA**, in chronology, celebrated epocha among mahometans. See the article *EPOCHA*.

The event which gave rise to this epocha was the flight of Mahomet from Mecca, with his new proselytes, to avoid the persecution of the coraishites; who, being then most powerful in the city, could not bear that Mahomet should abolish idolatry, and establish his new religion. This flight happened in the fourteenth year after Mahomet had commenced prophet: he retired to Medina, which he made the place of his residence.

The mahometans have many fabulous traditions concerning this flight of their false prophet from Mecca to Medina: Having taken a resolution, say they, to leave the city, he went out one night, being the first of the moon, accompanied only by Abubeker, his father-in-law, and passed the night in a grotto, distant an hour's journey from Mecca. As soon

*Fig. 1. HEIGHTS & DISTANCES.*

*Fig. 3. HEXAGON.*

*Fig. 2. HELIOCENTRIC.*

as his retreat was known in the city, the coraischites, his declared enemies, went in pursuit of him, and arrived at the entrance of the grotto early the next morning: but that same night a large tree had grown up, at the mouth of the cave, in which the prophet was concealed; and what opening was left, was covered over with a spider's web; this being a plain indication, that nobody was in the cave, the coraischites went away, and Mahomet escaped the pursuit of his enemies.

HEIDELBURG, a city of Germany, in the circle of the lower Rhine, the capital of the palatinate, situated on the river Neckar: east long.  $8^{\circ} 40'$ , and north lat.  $49^{\circ} 20'$ .

HEIGHT, *altitudo*, in geometry, is a perpendicular let fall from the vertex, or top, of any right-lined figure, upon the base or side subtending it. It is likewise the perpendicular height of any object above the horizon; and is found several ways, by two staffs, a plain mirror, with the quadrant, theodolite, or some graduated instrument, &c.

The measuring of heights or distances is of two kinds: when the place or object is accessible, as when you can approach to its bottom; or inaccessible, when it cannot be approached.

Prob. I. To measure an accessible height AB, by means of two staffs. See plate CXXIX. fig. 1. n<sup>o</sup> 1.

Let there be placed perpendicularly in the ground, a longer staff DE, likewise a shorter one FG, so as the observator may see A, the top of the height to be measured, over the ends D, F, of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C: then the triangles FHD, DCA, shall be equiangular; for the angles at C and H are right ones: likewise the angle A is equal to FDH; wherefore the remaining angles are also equal. Therefore as FH, the distance of the two staffs, is to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff: and thence CA will be found by the rule of three. To which if the length DE be added, you will have the whole height of the tower BA.

Scholium. Another method may be occasionally contrived for measuring an accessible height, as by the given length of the shadow BD (*ibid.* n<sup>o</sup> 2.) I find out

the height AB: for let there be erected a staff CF, perpendicularly, producing the shadow EF: then it will be as EF, the shadow of the staff, is to EC, the staff itself; so is BD, the shadow of the tower, to BA, the height. Though the plane on which the shadow of the tower falls, be not parallel to the horizon, if the staff be erected in the same plane, the rule will be the same.

Prob. II. To measure an accessible height by means of a plain mirror.

Let AB (*ibid.* n<sup>o</sup> 3.) be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC: let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observer's eye. The triangles ABC and EDC, are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of incidence and reflection of the ray AC; wherefore the remaining angles at A and E, are also equal. Therefore it will be as CD is to DE; so is CB to BA.

Note 1. The observer will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observer may see a point of the glass exactly in a line betwixt him and the tower.

Note 2. In place of a mirror may be used the surface of water, which naturally becomes parallel to the horizon.

Prob. III. To measure an accessible height by the geometrical quadrant, theodolite, &c.

Let the angle C (*ibid.* n<sup>o</sup> 4.) be found. Then in the triangle ABC, right-angled at B (BC being supposed the horizontal distance of the observer from the tower) having the angle C, and the side BC, the required height will be found by the first case of plain trigonometry. Thus, suppose the angle C,  $37^{\circ} 24'$ , and the horizontal distance, BC 116, then the proportion will be as R: T. L C:: CB: BA, the height.

The tangent altitude $37^{\circ} 24'$	9.88341
Log. CB 116	2.06446
Added	11.94787
Radius	10.00000

Height of the object AB 88.69 1.94787

Supposing the observation made on the top of the tower, and the height of the tower to be known, to find the distance

of any object on the plane below; it is only the converse of the former case.

You may also, having the base and angles, easily find the hypotenuse  $AC$ , or how far it is from the top of the tower to the station, by the second case of right angled triangles: and it is useful in many cases. Prob. IV. To measure an inaccessible height by the geometrical quadrant, &c. at two stations.

Let the angle  $ACB$  be observed (*ibid.* n<sup>o</sup> 5.) then let the observer go from  $C$ , to the second station  $D$ , in the right line  $BCD$ ; and after measuring this distance  $CD$  take the angle  $ADC$  likewise with the quadrant. Then in the triangle  $ACD$ , which is formed by the two visual rays  $AD$ ,  $AC$ , and the distance of the two stations  $D$  and  $C$ , there is given the angle  $ADC$ , with the angle  $ACD$ , because the angle  $ACB$  was given before: therefore the remaining angle  $CAD$  is given likewise. But the distance of the stations  $C$  and  $D$  is also given; therefore by the second case of oblique-angled trigonometry, the side  $AC$  will be found. Wherefore in the right-angled triangle  $ABC$ , all the angles and hypotenuse  $AC$  are given; consequently by the third case of plain trigonometry, the height sought,  $AB$ , may be found; as also the distance of the station  $C$ , from  $AB$ , the perpendicular within the hill or inaccessible height.

Example. Suppose the angle at  $C$ ,  $43^{\circ} 30'$ , and the angle at  $D$   $32^{\circ} 12'$ , and the distance  $CD$ , betwixt the two stations,  $112$  feet; then the angle  $DAC$  will be  $11^{\circ} 18'$ , and the angle  $CAB$   $46^{\circ} 30'$ . Hence for  $CA$ , the proportion will be as  $S. \angle DAC : DC :: S. \angle D : CA$ .

The log.  $DC$   $112$  — 2.04922  
Sine  $\angle D$   $32^{\circ} 12'$  — 9.72663

Added 11.77585

$S. \angle DAC$   $11^{\circ} 18'$  — 9.29214

$CA = 304.6$  — 2.48371

Then for  $AB$ , the height of the object, it will be as  $R : S. \angle ACB :: CA : AB$ .

As radius — 10.00000

is to the sine of  $43^{\circ} 30'$  — 9.83781

so is  $CA$   $304.6$  — 2.48371

to  $AB$   $209.7$  — 2.32152

Lastly, for  $CB$ , the distance of the object from the nearest station, it will be as  $R : S. \angle CAB :: CA : CB$ .

As radius — 10.00000

is to the sine of  $CAB$   $46^{\circ} 30'$  9.86056

so is  $CA$   $304.6$  — 2.48371

to  $BC$   $221$  — 2.34427

If the height of the tower is wanted, the angle  $BCF$  (*ibid.* n<sup>o</sup> 6.) may be found with the quadrant, which being taken from the angle  $ACB$  already known, the angle  $ACF$  will remain; but the angle  $FAC$  was known before; therefore the remaining angle  $AFC$  will be known. But the side  $AC$  was supposed found by the last problem; therefore in the triangle  $AFC$ , all the angles, and one of the sides  $AC$  being known  $AF$  the height of the tower above the hill may be found by trigonometry.

Prob. V. To measure the distance of two places  $A$  and  $B$ , of which one,  $A$ , is accessible, by the theodolite, &c. *ibid.* n<sup>o</sup> 7.

Let there be erected at two points,  $A$  and  $C$  (sufficiently distant) visible signs; then let the two angles  $BAC$ ,  $BCA$ , be taken by the theodolite. Let the distance of the stations  $A$  and  $C$  be measured with a chain. Then the third angle being known, and the side  $AC$ ; therefore, by the second case of oblique trigonometry, the distance required  $AB$ , will be found.

Prob. VI. To measure, by the theodolite, &c. the distance of two places, neither of which is accessible. *ibid.* n<sup>o</sup> 8.

Let two stations  $C$  and  $D$  be chosen, from each of which the places may be seen whose distance is sought: let the angles  $ACD$ ,  $BCD$ , and likewise the angles  $BDC$ ,  $BDA$ ,  $CDA$ , be measured by the theodolite, &c. the distance of the stations  $C$  and  $D$  be measured by a chain, or, if necessary, by the last problem. Now in the triangle  $ACD$ , there are given two angles  $ACD$  and  $ADC$ ; therefore the third  $CAD$  is likewise given: moreover the side  $CD$  is given; therefore by the second case of oblique trigonometry, the side  $AD$  will be found. After the same manner, in the triangle  $BCD$ , from all the angles, and one side  $CD$  given, the side  $BD$  is found. Wherefore in the triangle  $ADB$ , from the given sides  $DA$  and  $DB$ , and the angle  $ADB$  contained by them, the side  $AB$  (the distance sought) is found to be the fourth case of oblique angled trigonometry. Note, That it is not necessary that the points  $A$ ,  $B$ ,  $C$ , and  $D$  be in one plane, and that any triangle is in one plane.

HEILA, a port-town of regal Prussia, in the kingdom of Poland, situated on the point of the peninsula in the Baltic-sea, twelve miles north of Dantzick: east long.  $19^{\circ}$ , north lat.  $54^{\circ} 30'$ .

**HEINUSE**, among hunters, a roe-buck of the fourth year.

**HEIR**, *heres*, in law, signifies the person who succeeds another by descent to lands, tenements, and hereditaments, being an estate of inheritance, or an estate in fee; because nothing passes by right of inheritance but in fee.

Where there is a grandfather, father and son, if the father die before the grandfather, who afterwards dies seised in fee, the land, in that case, shall go to the eldest grandson, and not to any other children of the grandfather. On the father's dying without issue, &c. the next eldest brother shall have the lands, &c. as heir; and for want of a brother, they descend to the father's sisters. A man has issue only a daughter, and dies leaving his wife with child of a son, who is afterwards born; here the son, after his birth, is heir; however, in the mean time, the daughter is to have the land. Yet there are some persons disqualified from being heirs, as a bastard, an alien, one attainted of treason or felony, &c. but idiots and lunatics, persons excommunicated, or that are attainted in a premonition, and out-laws in debt, &c. are capable of being heirs.

The word heir is a collective term, and extend to all heirs, under which the heirs of heirs are comprehended; as where lands are given to a person and his heirs, all his heirs are thereby totally in him. The heir is favoured by common law: for not only land, but rent not due and in arrear at the death of the ancestor, shall go to the heir; so corn sown by a tenant for years, where his term expires before his corn is ripe, and every thing fastened to the freehold, timber-trees, deeds belonging to the inheritance, deer, conies, pigeons, fish, &c. go to the heir.

Where an ancestor has bound himself and his heirs for the payment of money, or performance of some other act, the heir, tho' never so much land comes to him from such ancestor by gift in tail, or other such conveyance of the father, and not by descent, is no way chargeable; and it is likewise so in all other estates, except fee simple. If land be granted to a person and his heirs during the life of another, &c. the heir shall not be charged for this, no more than for lands entailed. The heir's body ought not to be taken in execution for the debt of his ancestor, nor any other lands but those

he received in the case of descent: and whether an heir has land by descent or not, he is triable by a jury, who are to ascertain the value of the lands descended, in order to make the heir answerable. A creditor may sue either the heir, executor, or administrator, each of whom are chargeable; as is also a collateral heir, but in that case he must be specially charged as such: but where an heir, on being sued, pays his ancestor's debts, he shall be reimbursed by the executor of such ancestor, if he has assets in his hands. The heir has this advantage, that he can force the administrator to pay debts out of the personal estate of the intestate, in order to preserve the inheritance free; and where an executor has assets, the heir may in equity compel him to redeem a mortgage.

**HEIR-APPARENT**, is a person so called in the lifetime of his ancestor, at whose death he is heir at law.

**HEIRESS**, a female heir to one who has an estate in lands, &c. Stealing an heiress, and marrying her against her will, was declared felony by 3 Hen. VII.

**HEIR-LOOME**, is a word that comprehends in it divers pieces of furniture; as the first bed, and other things, which by the custom of some places have belonged to a house for several descents. These are never inventoried after the death of the owner as chattles, and therefore do not go to the executor or administrator, but to the heir along with the house, by custom, and not by common law.

Heir-loomes are not devisable by will, for custom vests them in the heir before a devise: yet a sale thereof in the person's lifetime might make it otherwise.

**HELEGUG**, in ornithology, a name given to the arctic duck of Clavius.

**HELENA**, or *St. HELENA*, an island in the Atlantic ocean, situated 1200 miles west of the coast of Africa, and 1800 east of the coast of South America: west long. 6° 13', south lat. 16°.

It is about twenty-one miles round, and consists of one steep rock, which looks like a castle in the middle of the sea, and which is covered with about a foot of vegetable earth, that produces corn, grapes, and almost all manner of fruits and vegetables: but the corn is generally eaten up by the rats, and the country is too hot to make wine. It has but one landing place, which is defended by a platform, and a fort in which the govern-

nor resides. It is subject to the english East-India company, by whose assistance it was planted, after it was taken from the Dutch in the reign of king Charles II. **St. HELENA'S DAY**, a festival in the romish church on the 18th of August. This saint was the empress Helena, daughter of the emperor Constantine, who, it is said, discovered the cross of Christ after it had been long buried in the ground.

**HELENA**, in astronomy. See the article **CASTOR**.

**HELENIA**, or **HELENIASTRUM**, **BASTARD-ELECAMPANE**, in botany, a genus of the syngenesia-polygamia-superflua class of plants, the compound flower of which is radiated, and consists of a multitude of hermaphrodite and female ones, the former on the disk, and the latter on the verge. The hermaphrodite flowers are tubular, and quinque-dentate at the limb; whereas the female ones are linear, ligulated, and trifid at the point. The stamina are five slender and very short filaments; and the seed which is single, is contained in the cup.

**HELENUM**, **ELECAMPANE**, in botany, &c. is ranked by Linnaeus among the star-worts. See the articles **ASTER** and **ELECAMPANE**.

**HELEPOLIS**, in the antient art of war, a machine for battering down the walls of a place besieged, the invention of which is ascribed to Demetrius, the Poliorcete.

Diodorus Siculus says, that each side of the helepolis was 405 cubits broad, and 90 in height; that it had nine stages, and was carried on four strong solid wheels eight cubits in diameter; that it was armed with large battering rams, and had two roofs capable of supporting them; that in the lower stages there were different sorts of engines for casting stones; and in the middle they had large catapultas for lancing arrows, and smaller in those above, with a number of expert men for working all these machines.

**HELIACAL**, in astronomy, a term applied to the rising or setting of the stars, or, more strictly speaking, to their emergence out of and immersion into the rays and superior splendor of the sun.

A star is said to rise heliacally, when after having been in conjunction with the sun, and on that account invisible, it comes to be at such a distance from him, as to be seen in the morning before sun-rising; the sun, by his apparent motion, receding from the star towards the east;

on the contrary, the heliacal setting is when the sun approaches so near a star, as to hide it with his beams, which prevent the fainter light of the star from being perceived, so that the terms apparition and occultation would be more proper than rising and setting.

All the fixed stars in the zodiac, as also the superior planets, mars, jupiter, and saturn, rise heliacally in the morning, a little before sun-rising, and a few days after they have set cosmically. Again, they set heliacally in the evening, a little before their achronycal setting. But the moon, whose motion eastward is always quicker than the apparent motion of the sun, rises heliacally in the evening, after the new moon; and sets heliacally in the morning, when old and approaching to a conjunction with the sun.

The inferior planets, venus and mercury, which sometimes seem to go westward from the sun, and sometimes again have a quicker motion eastward, rise heliacally in the morning, when they are retrograde; but when direct in their motions, they rise heliacally in the evening. The heliacal rising or setting of the moon, happens when she is  $17^{\circ}$  distant from the sun; but for the other planets,  $20^{\circ}$  are required; and for the fixed stars, more or less according to their magnitude.

**HELIAEA**,  $\epsilon\lambda\iota\alpha\iota\alpha$ , in grecian antiquity, was the greatest and most frequented court in Athens for the trial of civil affairs. The judges who sat in it, were at least fifty, but the more usual number was either two or five hundred. When causes of great moment were to be tried, it was customary to call in the judges of the other courts: sometimes a thousand were called in, and then two courts are said to have been joined: sometimes fifteen hundred or two thousand were called in, and then three or four courts met together.

They had cognizance of civil affairs of the greatest weight and importance, and were not permitted to give judgment till they had taken a solemn oath to do it with impartiality, and to give sentence according to the laws, &c.

**HELIANTHUS**, the **GREAT SUN-FLOWER**, in botany, a genus of the syngenesia-polygamia-frustranea class of plants, the compound flower of which is radiated, with a multitude of cylindraceous hermaphrodite flowers on the disk, and a few very long ligulated female ones: the stamina are five filaments; and the seeds

are single, and contained in the cup. The flowers are yellow, and often more than a foot in diameter.

**HELIASTES**, in antiquity, one of the judges of the court of helixæ. See the article **HELIÆA**.

**HELICTERES**, the **SCREW-TREE**, in botany, a genus of the gynandria-decandria class of plants, the flower of which consists of five oblong petals, equal in breadth; and the fruit is composed of five unilocular capsules, containing a great many kidney-shaped seeds, and twisted spirally about one another.

**HELIOCARPOS**, in botany, a genus of the polyandria-digynia class of plants, the flower of which consists of four linear petals, considerably shorter and narrower than those of the cup: the fruit is a pedunculated, bilocular capsule, of a turbinated oval figure, containing single seeds of an oval shape.

**HELIOCENTRIC latitude of a planet**, the inclination of a line drawn between the center of the sun and the center of a planet, to the plane of the ecliptic, which may be thus determined.

If the circle *FGH* (plate *CXXIX*. fig. 2. n° 1.) represent the orbit of the earth round the sun, and the inner one, *ANBz*, be so placed as to incline to the plane of the other; (on which account it appears in the form of an ellipsis) then when the planet is in the node *z*, it will appear in the ecliptic, and so have no latitude. But if it move to *P*, then, being seen from the sun, it will appear to decline from the ecliptic, or to have latitude; and the inclination of the line *SP* to the plane of the ecliptic, is called the planet's heliocentric latitude; the measure of which is the angle *PSp*, supposing the line *Pp* to be perpendicular to the plane of the ecliptic.

This heliocentric latitude will be continually increasing till the planet come to the point *A*, which they call the limit, or utmost extent of it; and then it will decrease again, till it reach the other node *N*, when it will have no latitude; after which it will increase again, till it come to *B*, or its utmost latitude; and, lastly, decrease again, till the planet come to be in *z*, whence it set out.

**HELIOCENTRIC place of a planet**, in astronomy, the place of the ecliptic wherein the planet would appear to a spectator placed at the center of the sun.

The ingenious *Dr. Halley* gives the fol-

lowing method to find the heliocentric places of a planet, and its distances from the sun, which supposes only that the periodical time of the planet is known. Let *KLB* (*ibid*. n° 2.) be the orbit of the earth, *S* the sun, *P* the planet, or rather the point in the plane of the ecliptic, in which the perpendicular let fall from the planet meets that plane. And first when the earth is in *K*, observe the geocentric longitude of the planet, and having the theory of the earth, we have the apparent longitude of the sun, and consequently, the angle *PKS*. The planet, after it has completed an entire revolution, returns again to the point *P*, at which time suppose the earth in *L*; and there again, let the planet be observed, and find the angle *PLS*, the planet's elongation from the sun. Having the times of observations, we have the places of the earth in the ecliptic, or the points *K* and *L*; and, consequently, the angle *LSK*, and the sides *LS* and *SK*: wherefore we shall have the angles *SKL* and *SLK*, and the side *LK*. From the known angles *SKP* and *SLP*, take away the known angles *SKL* and *SLK*, and we shall have the angles *PKL* and *PLK* known; therefore in the triangle *PLK*, having all the three angles, and the side *LK*, we shall find the side *PL*; and in the triangle *PLS*, having the sides *PL* and *LS*, and the intercepted angle *PLS*, we shall have the angle *LSP*, which determines the heliocentric place, and its distance from the node according to the ecliptic, as also the side *SP*. But as the tangent of the geocentric latitude is to the tangent of the heliocentric, so is the curtate distance of the planet from the sun, to its curtate distance from the earth. But as the geocentric latitude may be found by observation, the heliocentric latitude will also be found; by which, and the curtate distance of the planet from the sun, we can find the true distance.

**HELIOCOMETES**, a phenomenon sometimes observed about sun-setting; being a large luminous tail, or column of light, proceeding from the body of the sun, and dragging after it, not unlike the tail of a comet; whence the name.

**HELIOSCOPE**, in optics, a sort of telescope, peculiarly fitted for viewing the sun, without hurting the eyes. See the article **TELESCOPE**.

As the sun may be viewed through coloured glasses, without hurt to the eyes.

if the object and eye-glasses of a telescope be made of coloured glass, as red or green, such a telescope will become an helioscope.

But Mr. Huygens only used a plain glass, blacked at the flame of a candle on one side, and placed between the eye-glass and the eye; which answers the design of an helioscope very well.

**HELIOSTATA**, in optics, an instrument invented by the late learned Dr. S Gravesande; who gave it this name, from its fixing, as it were, the rays of the sun in an horizontal direction across the dark chamber, all the while it is in use.

This instrument is an automaton, or piece of clock-work, whose parts are as follows. A A (plate CXXX.) is a frame in which a metalline speculum S is suspended, moveable about its axis by means of two small screws *a, a*. This frame is fixed to the piece C, which being hollow, is moveable upon the cylindric shaft P. This pillar is fixed on a triangular base or foot set perpendicular, by the three screws B, B, B.

On the back part of the speculum is fixed a long cylindric wire, or tail D, in a perpendicular position. By this it is connected to the second part of the heliostata, which is a common thirty-four hour clock, represented at H, the plane of which clock is set parallel to that of the equator in any given place. The clock is sustained on the column F G, in which it is moveable up and down by a thin lamina or plate that enters it as a case, and fixed by a proper height by two screws *d, d*, at the side. The whole is truly adjusted to a perpendicular situation by means of the three screws I, I, I, in the tripod L, L, M, and the plummet Q, whose capsis must answer to the point *o* beneath.

The axis of the wheel which moves the index N O, over the hour circle, is somewhat large, and perforated with a cylindric cavity approaching a little to a conical figure; and receives the shank of the said index N O very close and tight, that by its motion the index may be carried round. In the extremity, O, of the index is a small cylindric piece, with a cylindric perforation to receive the tail *t* of the fork T, yet so as to admit a free motion therein. In each side of the fork are several holes exactly opposite to each other, in which go the screws *r, r*, upon whose smooth cylindric ends moves the tubular piece R.

When the machine is to be fixed for use, another part is made use of to adjust it; which is called the positor, and is denoted by the letters V X Y Z.

The cylinder C is removed with a speculum from the foot P, and the brass column V X put on in its stead, and adheres more strictly to the pin *e*, that it may keep its position while the machine is constituted.

On the top of the column, about X as a center, moves the lever Y Z, so that it may be any how inclined to the horizon, and keep its position. The arm Y X may be of any length at pleasure; but the arm X Z is of a peculiar construction, and of a determinate length. To this arm, which extends no farther than *y*, is a sliding-piece Z *x*, sharp pointed at Z. By this the arm X Z is determined to a given length, the piece Z *x* being fixed by the screws *z z*. Upon this arm is drawn the short line *o x*, by which it may be lengthened in the whole, and is  $\frac{9}{10}$  of the whole length X Z, when shortest. The reason is, this arm is always to increase and decrease in proportion to the secant of the sun's declination to the radius X Z, when shortest; but the radius is to the secant of  $23^{\circ} 30'$  (the sun's greatest declination) as 10000000 to 10904411, or as 100 to 109. Now the reason of this construction of the arm X Z, is to find for any given day the distance of the center of the speculum S from the top *l* of the style *l N*, which must ever be equal to the secant of the sun's declination; for it must always be equal to the distance of the top of the said style, *l*, from the center of the cylinder R in the fork T, and that is always equal to the said secant of declination.

For since the style *l N* and the fork T are in a position parallel to each other, therefore the middle hole in the sides of the fork being (as they must be) of the same height above the end of the index O, as is the height of the style *l N*, it is evident that on an equinoctial day the sun's rays will pass directly through the perforation of the piece R, if it be put in a position parallel to the plane of the ecliptic, or that of the clock; and also that the top of the shadow of the said style will fall exactly on the said hole. In this case the top of the style is at the least distance from the central point of R, and therefore may be represented by radius; while in any other position above or below, the distance will increase in propor-

HELIOSTATA.

tion to the secant of the angle which the rays make with this first or middle ray, that pass by the top of the style, and through the hole R.

Now it may be demonstrated, that on any day of the year, if the clock and its pedestal be so fixed that the line of XII be exactly in the meridian, and that the position of R in the fork be such that the sun's rays go directly through it, and the shadow of the style's top fall just upon the hole; moreover, if the distance of the center of the speculum S from the top of the style I be made equal (by the positor) to the distance of the central point of R therefrom; and, lastly, the nail of the speculum DE passing through R; then if the clock be put into motion, the index N O shall carry about the tail of the speculum in such a manner, that at all times of that day, when the sun can come upon the speculum, it will reflect the rays constantly in one and the same position and direction all the time without variation.

The machine thus constituted, is placed in a box or case, and set in a window with one side open, exposed to the sun, and all the other parts close; so that when the room is made dark, and the solar microscope fixed to the fore-part of the box in which the heliostat is placed, just against the center of the speculum to receive the reflected horizontal beam, all the experiments of the darkened room are then performed as usual.

This is a very ingenious construction of a solar microscope-apparatus, but, we fear, too expensive and troublesome for common use. However, it is easy to see that this machine is capable of being greatly reduced; since it may be made to answer the end very well without a clock and the speculum may be glass instead of metal, and all fixed in one pedestal. See the article MICROSCOPE.

**HELIOTROPE**, *heliotropium*, in botany, a genus of the pentandria-monogynia class of plants, the corolla of which consists of a single petal; the tube is of the length of the cup; the limb is plane, divided lightly into five segments, and obtuse; the smaller segments stand alternate, and are acute; the large are placed between; the mouth is closed by five prominent squamulæ, which bending toward one another, form a little star: there is no pericarpium; the calyx remains unaltered, and contains four oval acuminate seeds.

A decoction of this plant purges phlegm and bile. It is good against the sting of serpents: it consumes warts, and provokes the menses, and the expulsion of the fœtus.

**HELIOTROPE**, in fossil history, a hard bluish-green jasper, with red variegations. See the article JASPER.

**HELIX**, in geometry, the same with spiral. See the article SPIRAL.

In architecture some authors make a difference between the helix and the spiral. A stair case according to Daviler, is an helix, or is helical, when the stairs or steps wind round a cylindrical newel; whereas the spiral winds round a cone, and is continually approaching nearer and nearer its axis.

**HELIX** also signifies the caulicoles, or little volutes, under the flower of the corinthian capital, called also urillæ.

**HELIX**, in anatomy, is the whole circuit or extent of the auricle outwards, in opposition to which the inner protuberance answering thereto, is called anthelix. See the article EAR.

**HELL**, *gehenna*, *tartara*, *hades*, *infernus*, &c. the place of divine punishment after death, in contradiction to heaven. See the article HEAVEN.

As all religions have supposed a future state of existence after this life, so all have their hell or place of torment, in which the wicked are supposed to be punished. The hell of the ancient heathens was divided into two mansions, the one called elysium, on the right hand, pleasant and delightful, appointed for the souls of good men; the other called tartara, on the left, a region of misery and torment, appointed for the wicked. The latter was only hell in the present restrained sense of the word. See the article ELYSIUM.

Of all the poets of antiquity, Virgil is the most particular in his description of hell; having carried his hero thither, and given him a full view of these infernal regions: for an account of which we must refer the reader to the sixth Æneid of that poet, where the many dreadful apparitions, as gorgons, harpies, chimæras, and the like, are strongly painted, and a description of Charon, the old ferryman of hell, his business, together with the officer of Minos and Radamanthus, two of the judges of hell, are very lively represented. The opening of the adamantine gate, discovers to Æneas the almost recesses of tartara, or hell, which according

according to the poet is twice as deep as the earth is distant from the skies. Here Æneas sees various persons condemned to punishment, as also the different kinds and forms of torture which are so numerous, that the poet concludes, *non mihi si linguæ centum, &c.*

" Had I an hundred mouths, an hundred tongues,

" And throats of brass inspired with iron lungs,

" I could not half these horrid crimes repeat,

" Nor half the punishments these crimes have met."

*Dryden.*

The antient philosophers were of opinion, that the infernal regions were at an equal distance from all the parts of the earth; nevertheless it was the opinion of some, that there were certain passages which led thither, as the river Lethe, near the Syrtes, and the æcherusian cave in Epirus. At Hermione it was thought, that there was a very short way to hell; for which reason, the people of that country never put the fare into the mouths of the dead to pay their passage. Ulysses, according to Homer, went by sea to the country of the Cimmerians, in order to go thither; and Æneas went by the lake of the cave of Avernus.

The Jews placed hell in the center of the earth, and believed it to be situated under waters and mountains. According to them there are three passages leading to it: the first is in the wilderness, and by that Korah, Dathan and Abiram descended into hell; the second is in the sea, because Jonah, who was thrown into the sea, cried to God out of the belly of hell; the third is in Jerusalem, because it is said the fire of the Lord is in Zion, and his furnace is in Jerusalem. They likewise acknowledged seven degrees of pain in hell, because they find this place called by seven different names in scripture. Though they believed that infidels, and persons eminently wicked, will continue for ever in hell; yet they maintained, that no Jew, who is not infected with some heresy, and has not acted contrary to the points mentioned by the Rabbins, will be punished therein for any other crime above a year at most.

The mahometans believe the eternity of rewards and punishments in another life. In the Koran it is said, that hell has seven gates, the first for the Mussulmans, the second for the Christians, the third for the Jews, the fourth for the Sabians, the

fifth for the Magians, the sixth for the Pagans, and the seventh for the hypocrites of all religions.

Among Christians, there are two controverted questions in regard to hell, the one concerns locality, the other the duration of its torments. The locality of hell, and the reality of its fire, began first to be controverted by Origen. That father interpreting the scripture account metaphorically, makes hell to consist not in external punishments, but in a consciousness or sense of guilt, and a remembrance of past pleasures. Among the moderns, Mr. Whiston advanced a new hypothesis. According to him the comets are so many hells appointed in their orbits alternately to carry the damned into the confines of the sun, there to be scorched by its violent heat, and then to return with them beyond the orbit of saturn, there to starve in these cold and dismal regions. Another modern author not satisfied with any hypothesis hitherto advanced, assigns the sun to be the local hell. As to the second question, *viz.* the duration of hell torments, we have Origen again at the head of those who deny that they are eternal; it being that father's opinion, that not only men, but devils, after a due course of punishment suitable to their respective crimes, shall be pardoned and restored to heaven. The chief principle upon which Origen built his opinion, was the nature of punishment, which he took to be emendatory, applied only as physic for the recovery of the patient's health. The chief objection to the eternity of hell torments among modern writers, is the disproportion between temporary crimes and eternal punishments. Those who maintain the affirmative, ground their opinions on the scripture accounts, which represent the pains of hell under the figure of a worm which never dies, and a fire which is not quenched; as also upon the words, " These shall go away into everlasting punishment, but the righteous into life eternal."

**HELLEBORE**, *helleborus*, in botany, a genus of the polyandria polygynia class of plants, with a rosaceous flower, composed of five or more roundish and large petals: the fruit is composed of several bicarinated capsules, containing a great number of roundish seeds. See plate CXXXI. fig. 1.

The root of this plant is the true black hellebore of the shops, which is a purge,

purge; but not a very safe one; being sometimes given in substance from ten grains to twenty. In tincture, it is principally used as an alterative, for attenuating the humours. It has been always famous in maniac cases, and is still given in them, tho' rather as an alternative than a purge: for at present, the use of black hellebore as a purge is out of doors; the chemical preparations of antimony and mercury having been found much more certain, and to answer as well all its purposes. The dose of the tincture is from 15 to 50 drops, which is given in hysseric cases, and obstructions of the viscera.

*White HELLEBORE*, in pharmacy, the root of the broad leaved veratrum. See the article VERATRUM.

White hellebore, given in powder or in infusion, is a very rough vomit; and, at present, is never used but when very desperate diseases call for such a remedy. It is a powerful sternutatory, and is sometimes used as such in soporose diseases; but the principal use made of it at present is externally, in unguents for the itch, among the common people.

*HELLENISM*, in matters of language, a phrase in the idiom, genius, or construction of the greek tongue.

This word is only used when speaking of the authors who writing in a different language, express themselves in a phraseology peculiar to the greek.

*HELLENISTIC*, or *HELENISTIC LANGUAGE*, that used by the grecian Jews who lived in Egypt and other parts where the greek tongue prevailed. In this language it is said the Septuagint was written, and also the books of the New Testament; and that it was thus denominated to shew that it was greek filled with hebraisms and syriacisms.

*HELLENODICÆ*, in grecian antiquity, the directors of the olympic games. See the article OLYMPIC.

*HELLESPONT* the entrance of the streights which divide Asia from Europe, and pass from the Archipelago to Constantinople. It is now called the Dardanelis, and is about two miles wide.

*HELM of a ship*, is a piece of timber fastened into the rudder, which comes forward into the steerage, or place where the person at the helm steers the ship, by holding the whipstaff in his hand, which is joined to the helm. They begin however to be left off, steering-wheels being used in their room.

There are several terms in the sea-lan-

guage relating to the helm; as, *bear up the helm*; that is, let the ship go more large before the wind. *Helm a mid-ship*, or *right the helm*; that is, keep it even with the middle of the ship. *Port the helm*, put it over the left side of the ship. *Starboard the helm*, put it on the right side of the ship.

*HELMET*, an antient defensive armour worn by horsemen both in war and in tournaments. It covered both the head and face, only leaving an aperture in the front secured by bars, which was called the visor.

It is still used in heraldry by way of crest over the shield or coat of arms, in order to express the different degrees of nobility, by the different manner in which it is borne. Thus a helmet in profile, is given to gentlemen and esquires: to a knight, the helmet standing forward and the beaver a little open: the helmet in profile and open, with bars, belongs to all noblemen under the degree of a duke: and the helmet forward and open, with many bars, is assigned to kings, princes, and dukes.

There is generally but one helmet upon a shield; but sometimes there are two, and even three: if there be two, they ought to face each other; and if three, the middlemost should stand directly forward, and the other two on the sides facing towards it.

*HELMINTHOLITHUS*, in natural history, a name given by Linnæus to petrified bodies resembling worms.

Of these he reckons four genera. 1. Petrified lithophyta, found in the mountains of Sweden. 2. Petrified shells. 3. Petrified zoophytes. 4. Petrified reptiles. See LITHOPHYTA, SHELL, &c.

*HELMONT*, a town of the Netherlands, in the province of dutch Brabant, situated on the river Aa: east longitude 5° 40', north latitude 51° 30'.

*HELMSTAT*, a town of Germany, in the circle of Lower Saxony, and dukedom of Brunwic: east long. 11° 15', north lat. 52° 20'.

*HELONIAS*, in botany, a genus of the hexandria-trigynia class of plants, without any flower petals; the fruit is an oval berry, containing only one cell, in which is a single oval seed.

*HELOTS*, in grecian antiquity, the inhabitants of Helos, a town of Laconia, conquered by the Spartans; who made them all prisoners of war, and reduced them into the condition of slaves.

The freemen of Sparta were forbidden the exercise of any mean or mechanical employment, and therefore the whole care of supplying the city with necessaries, devolved upon the Helots: the ground was tilled, and all sorts of trade managed by them, whilst their masters, gentlemen like, spent their time in all sorts of manly exercises. Notwithstanding the great usefulness of the Helots, they were treated in the most barbarous manner, and often murdered without any shew of justice. It was a thing common with the Spartans to force them to drink to excess, and then lead them in that condition into their public halls, that their children might see what a contemptible and beastly sight a drunken man is. They made them dance uncomely dances, and sing ridiculous songs; forbidding them expressly to use any that was serious and manly.

**HELPS**, in the manege. To teach a horse his lesson, there are seven helps or aids to be known: these are the voice, rod, bit or snaffle, the calves of the legs, the stirrups, the spur, and the ground.

The helps are occasionally turned into corrections.

**HELSINGFORD**, a port-town of Sweden, situated on the gulph of Finland, in  $24^{\circ} 6'$  east long. and  $60^{\circ} 8'$  north lat.

**HELSINGIA**, a province of Sweden, bounded by the Bothnic gulph on the east, and by Delecarlia on the west.

**HELSINGIC CHARACTER**, a peculiar kind of character, found inscribed on stones in the province of Helsingia: the runic and helsingic characters may be easily transformed into each other.

**HELSTON**, a borough of Cornwall, nine miles south-west of Falmouth: it sends two members to parliament.

**HELVE**, a term used among country people for the handle of a hatchet, pick-ax, mattock, or the like.

**HELVETIC**, something belonging to Helvetia, or Switzerland. See the article SWITZERLAND.

**HELVOETSLUYS**, a port-town of the United Netherlands, situated in the island of Voorn, in the province of Holland, five miles south of the Briel: it is one of the best harbours in Holland, and that to which the english packet always goes.

**HELXINE**, BUCK-WHEAT, in botany, a genus of the octandria-trigynia class of plants, the corolla of which is permanent, and consists of a single petal, divided into five obtuse, erecto-patent seg-

ments: there is no pericarpium, the corolla performs the office of it, and surrounds the seed, which is single, triquetrous, and acute.

**HEM**, in the ovens for baking calamine, a partition which separates the hearth from the oven itself: it is open at top, to let the flame pass over to bake the calamine.

**HEMERO-BAPTISTS**, a sect among the Jews, so called because they washed themselves every day, making holiness to consist in these daily ablutions.

They were pharisees in every thing, except that with the sadducees, they denied a resurrection. Probably these were the sect who found fault with our Saviour's disciples for eating with unwashed hands, D'Herbelot tells us, that the disciples of St. John Baptist, who, in the first ages of the church, were called hemero-baptists, and the number of whom is considerable among the Jews, have since that time formed a sect, or rather religion apart, under the name of mendai jahia.

**HEMEROBIUS**, in zoology, a genus of insects of the neureptera order, the characters of which are these: the palate is prominent, and has on each side two tentacula: the wings, being four in number, are deflex and tumid.

To this genus belong the golden-eye, a large beautiful fly, so called from the colour of its eyes; the formica-leo, and several other species.

**HEMEROCALLIS**, DAY-LILLY, in botany, a genus of the hexandria monogynia class of plants, the corolla of which is of an infundibuliform figure; the tube is short; the limb is patent, and divided into six somewhat reflex segments: the fruit is an ovato-trilobous, trigonal capsule, formed of three valves, and containing three cells: the seeds are numerous and roundish.

**HEMERODROMI**, in grecian antiquity, centinels and guards appointed for the security and preservation of cities, and other places.

They went out of the city every morning, as soon as the gates were opened, and kept patrolling all day about the place: sometimes also making excursions further into the country, to see that there were no enemies lying in wait to surprize them.

**HEMERODROMI** were also a sort of couriers among the antients, who only travelled one day, and then delivered their packets or dispatches to a fresh man, who run his day, and so on to the end of the jour-

ney. See COURIER and EXPRESS.

**HEMI**, a word used in the composition of divers terms, signifying the same with semi, or demi, viz. one half; being an abbreviature of *ἡμισυς*, which signifies the same. The Greeks suppressed the last syllable of *ἡμισυς*, in the composition of words.

**HEMICRANIA**, in medicine, a species of head-ach, wherein only one half or side of the head is affected. See HEAD-ACH.

**HEMICYCLE**, in architecture, is defined by Daviler to be an arch forming a perfect semicircle. See the articles ARCH and BRIDGE.

To construct such an arch of hewn stone, they divide the semicircle into a certain number of equal parts, and fashion an equal number of vousoirs, which will complete the arch: however, that there may be no joint in the middle, where the key-stone should be, they always take care that the number of vousoirs be an odd one.

**HEMICYCLIUM**, in antiquity, a part of the orchestra in the antient theatres: but Scaliger observes, that this part was only used, when some person was supposed to be just arrived from sea, as in Plautus's Rudens.

**HEMICYCLIUM** also signified a kind of sun-dial; being a concave semicircle, the upper cusp of which looked to the north. On the middle of the hemicyclium stood a style, whereof the point that corresponded to the center of the hemicycle, represented the center of the earth; and its shadow, being projected on the concavity of the hemicycle, which represented the space between the two tropics, pointed out not only the declination of the sun, and the day of the month, but likewise the hour of the day.

**HEMINA**, in roman antiquity, a liquid measure which, according to Arbuthnot, was equal to half a wine-pint english measure; its contents being 2,818 solid inches. See the article MEASURE.

**HEMIOLIA**, or **HEMIOLIUS**, among antient musicians, a sort of proportion now called sesquialteral. See the article SESQUIALTERAL.

**HEMIONITIS**, in botany, a genus of the cryptogamia-muscorum class of plants, the fructifications of which are arranged into lines, sometimes branched, often uniting with and intersecting one another.

**HEMIOPE**, in antiquity, a flute with small holes. See the article FLUTE.

**HEMIPLEGIA**, or **HEMIPLEXIA**, among physicians, a palsy of one half of the body. See the article PALSY.

**HEMISPHERIA**, **LADY-COW**, in zoology, a genus of beetles, with clavated and entire antennæ; and whose thorax, with the exterior wings, which are margined, constitutes an hemispheric figure. There are a great many species of lady-cows, the most common of which is that with reddish wings, and seven black spots on them; an insect too well known to need farther description. See the article COCCINELLA.

**HEMISPHERE**, *hemisphærium*, in geometry, the half of a globe or sphere, when it is supposed to be cut through its center in the plane of one of its great circles. Thus the equator divides the terrestrial globe into the northern and southern hemispheres: in the same manner the meridian divides the globe into the eastern and western hemispheres; and the horizon into two hemispheres, distinguished by the epithets upper and lower. See the articles SPHERE and GLOBE.

The center of gravity of an hemisphere, is  $\frac{3}{8}$  of the radius distant from the vertex.

**HEMISPHERE** is also used to denote a projection of half the terrestrial globe, or half the celestial sphere, on a plane, and frequently called planisphere.

**HEMISPHEROIDAL**, in geometry, an appellation given to whatever approaches to the figure of an hemisphere, but is not exactly so.

**HEMISTICH**, *ἡμιστίχον*, in poetry, denotes half a verse, or a verse not completed.

Of this there are frequent examples in Virgil's *Æneid*; but whether they were left unfinished by design or not, is disputed among the learned; such are, *Ferro accincta vocat*, *Æn. II. v. 614.* And, *Italian non sponte sequor*, *Æn. IV. v. 361.*

In reading common english verse, a short pause is required at the end of each hemistich, or half verse.

**HEMITONE**, in music, the same with a semitone, or half note. See TONE.

**HEMITRITÆUS**, among physicians, a kind of intermitting fever, being a semitertian. See FEVER and TERTIAN.

**HEMLOCK**, *conium*, in botany. See the article CONIUM.

*Water Hemlock*, *cicuta*. See CICUTA.

**HEMP**, *cannabis*, in botany. See the article CANNABIS.

Hemp is a useful plant, purchased at a

dear rate from foreigners, when it might be cultivated among ourselves, to the great benefit of the nation in general. It delights in warm, sandy, or somewhat gravelly soil; but it must be somewhat rich, and of a good depth. The best seed is that which is brightest, and retains its colour and substance in rubbing. Three bushels will sow an acre; but the richer the land is, the thicker it must be sown, and the poorer it is, the thinner. The time of sowing it, is from the latter end of March, to the end of April, according as the spring falls out; but the earlier it is sown the better. If it be a dry season, great care must be taken to preserve it from birds.

The first season for gathering it is about Lammas, when a good part of it will be ripe; that is, the light summer hemp which bears no seed, and is called *fimble-hemp*. When it is ripe the stalks grow white, and the leaves fall downwards, turning yellow at the top: it must then be pulled up, dried, bound up in bundles as big as may be grasped in both hands, and laid by for use. Care must be taken not to break what is left standing, because it is to grow till near Michaelmas before it will be fit to gather: this is usually called *karle-hemp*. When it is gathered, lay it in the sun three or four days to dry, and then stack or house it till the seed be threshed out.

An acre of hemp, in the best land, commonly yields about two or three quarters of seed, which, with the hemp unwrought, is often worth from 5 to 8 l. but if wrought, from 10 to 12 l. but the *fimble-hemp* is not worth above half as much as the other.

As to the method of preparing it, after the seeds are threshed out of the heads, the stalks are laid up in bundles and steeped in a standing water, the cleaner it is the better; they are fastened to poles, and left to soak about fifteen days; and when the substance of the stalk is almost rotten, the bundles are taken out and well dried. But flax, instead of being steeped in water, is usually exposed alternately to the moist air of the night, and the heat of the sun, by which means it receives a finer colour.

When hemp and flax are well penetrated and afterwards completely dried, they are bruised by handfuls on a block, with a kind of mallet; all the *bulen*, which is the inward substance of the stem, flies off in shivers, by the force of the blows,

and nothing remains in the hands of the beater but the thin bark in large threads, through the whole length of the stem. This parcel of threads is afterwards hung on a perpendicular board, and bruised with a wooden beetle, in order to shake out all the little straws that may happen to remain of the *bulen*. All the gross parts are now separated from the stem, and the threads of the bark receive their perfection from the comb or hatchel.

The refuse of this combing, which consists of all the threads which are too thick, is called *tow*, for the use of which see the article *Tow*.

Hemp and flax are the materials of a variety of profitable manufactures; for besides linen, great quantities of ticken of all finenesses, sail-cloth, incle, tape, lacing, girtwip, cordage, twine, nets, and many other things are made of them: and they furnish multitudes of other manufactures, which employ the poor, and bring, by their exports, profit to the nation. But as we are under the necessity of importing very large quantities of hemp from foreign countries, the production of this article among ourselves, and in our plantations, cannot be too plentifully cultivated, nor too highly encouraged.

For the laws relating to hemp and flax, see the article *FLAX*.

**HEMPSTEAD**, a market-town of Hertfordshire, twenty-nine miles north-west of London.

**HEN**, *gallina*, in ornithology, though used in a general sense to signify any female bird, is more particularly restrained to those of the order of *gallinæ*. See the article *GALLINÆ*.

**HEN-BANE**, a plant called by botanists *hyoscyamus*. See *HYOSCYAMUS*.

**HEN-HARRIER**, in ornithology, the falco with a brown back, and a variegated, black, and brown tail. See the article *FALCO*.

This is a considerably large species, and is equal to a well grown pullet in size: the head is small, and somewhat flattened at the top; the beak is large, and very robust; it is broad and thick at the base, very much hooked, and extremely sharp at the point; the base of it is covered with a thick yellow membrane, in which are situated the nostrils, and there are a kind of black hairs resembling whiskers.

**HENDECAGON**, in geometry, a figure that hath eleven sides, and as many angles,

In fortification, hendecagon denotes a place defended by eleven bastions.

**HENEBOB**, a town of Britany, in France, twenty-two miles north-west of Vanes.

**HENLEY**, a market-town of Oxfordshire, situated on the river Thames, twenty miles south-east of Oxford, and thirty-five west of London.

**HENLEY** is also a market-town of Warwickshire, seven miles south-west of Warwick.

**HEN-MOULD**, among farmers, denotes a black spongy soil fitter for grazing than for corn.

In some places, indeed, they give the name of hen-mould to a rich black earth mixed with whitish streaks, which is exceeding fertile.

**HENNEBURG**, a town of Germany, in the circle of Franconia, and the capital of the county of Henneburg: east long.  $10^{\circ} 27'$ , and north lat.  $50^{\circ} 40'$ .

**HENOTICON**, in church-history, a decree or edict of the emperor Zeno, made at Constantinople, in the year 482, by which he pretended to reconcile all parties under one faith. It is generally agreed that Peter, patriarch of Alexander, and Acacius, patriarch of Constantinople, were the authors of this decree, and that their design was to compliment the emperor with a right of prescribing regulations in matters of faith. The emperor, by this decree, arrogated to himself the right of being head of the church. Pope Simplicius, however, in the year 483, condemned the henoticon, and cited Acacius, the chief promoter of it, to appear before him at Rome; but it was not entirely suppressed till the year 518.

**HENRICO**, a county of the colony of Virginia, in North America.

**HENRY**, or **CAPE-HENRY**, the south cape of Virginia, at the entrance of Chesapeake-bay: west long.  $74^{\circ} 50'$ , north lat.  $37^{\circ}$ .

**HENTING**, among farmers, a method of sowing immediately before the plough, by which it is pretended, a great deal of charge is saved. See **SOWING**.

**HENTING-FURROWS**, those turned from each other at the bottom, in ploughing ridges. See the article **PLOUGHING**.

**HEPAR**, the **LIVER**, in anatomy. See the article **LIVER**.

**HEPAR SULPHURIS**, **LIVER OF SULPHUR**, in pharmacy, according to Quincy, is thus made; take of flowers of sulphur, four ounces; salt of tartar in powder, an ounce and half: let them be well

mixed together, and then melted in an earthen dish, and kept constantly stirring till the mass has acquired a red colour, care being taken that it does not catch fire.

**HEPAR UTERINUM**, in anatomy, the same with placenta. See **PLACENTA**.

**HEPATIC**, in medicine and anatomy, any thing belonging to the liver.

**HEPATIC ALOE**. See the article **ALOE**.

**HEPATIC DUCT**. See **PORUS BILIARIUS**.

**HEPATIC FLUX**, a flux of the belly, of a very singular kind, and so rarely met with, that many authors have confounded the accounts of it with those of dysenteries and hæmorrhoidal fluxes. The signs by which it is known are these; the patient voids by the anus a liquid matter resembling water in which raw flesh had been washed; this is attended with pains and a sense of weight and tension in the abdomen, and spastic motions about the loins, which sometimes extend themselves to the right side, toward the region of the liver. In some patients there is no sensation of any pain, or any particular symptom; and, in some, a tenesmus is constantly joined with this voiding of a bloody fluid.

The persons subject to this disease are men, and those chiefly between the age of eighteen and forty, for the most part; as also such as are of a sanguineo-phlegmatic habit, and of a sedentary life.

The antients supposed this to be owing to a debility of the liver, which was not able, in this case, properly to attract or retain the blood; but it seems rather to belong to the hæmorrhoidal discharges, where, when pure and proper blood is not voided, this fluid comes in its place. This flux is not dangerous at the time; but when it is long continued, it will at length wear down the patient's strength, and bring on bad habits.

This disease, according to Junker, is to be treated in the same manner as the hæmorrhoidal discharge, when obstructed; and attemperating and abstergent medicines are to be given with gentle purges: rhubarb, in doses from a scruple to two or more, is to be given every day, for a long time: after this, nitre, tartarium vitriolatum, the alkaline salts of plants, as of worm-wood, with the absorbent powders, such as crab's eyes; and to these may be added decoctions of small centaury, and the like herbs.

**HEPATIC VEIN**. See **BASILICA**.

**HEPATICA**, **LIVER-WORT**, in botany,

a species of anemone. See the article **ANEMONE**.

This plant is chiefly used in obstructions of the liver and viscera; as also in the scab, gonorrhœa, and fever.

**HEPATITIS**, in medicine, the name of an acute, continuous, and inflammatory fever, in which nature frequently and forcibly propels the humours through the liver, seemingly with an intent to resolve and absterge congestions and stases of the blood in that viscus. See the article **INFLAMMATION**.

The hepatitis is distinguished from all other fevers, by the seat of it in the liver, and by its being, of all other fevers, the most fatal. It differs, however, in degree, some cases depending on a more superficial, some on a deeper and more internal inflammation of the liver. It usually seizes the patient with a chillness, which is succeeded by a violent heat, attended with an insupportable thirst: the patient perceives a severe and heavy pain on the right side, about the seventh or eighth rib; and is affected with a violent tightness of the breast, and difficulty of breathing; the extremities are very apt to become cold; there are frequent nausea, and reachings to vomit, and a bilious matter is thrown up: the urine for the first days is reddish and thick, and about the fourth day usually begins to deposit a sediment; the remaining part of it being however still turbid; a very peculiar symptom is, that the patient frequently changes colour, being at times pale, and at other times brownish or yellowish; the yellowness principally affecting the eyes and face. In cases where the matter in the liver comes to a suppuration, all the symptoms become more severe; the heat is greater, the respiration more difficult, &c. Finally, the breaking of the tumour is known by a sudden remission of the pain, with a terrible faintness and lowness of the spirits, and a hectic; and when the matter is discharged into the cavity of the abdomen, it is known by the swelling of that part. The general causes of the hepatitis are a plethora and a derivation of blood into the liver, which there forms congestions and stases: this is brought on by violent motions of the body, by violent strainings, by taking astingents in inflammatory fevers, and by driving back the matter in cutaneous eruptions; and, finally, by applying cold external medicines to the regions of the liver, or by

cupping upon the part. Bleeding is very proper in the beginning of the disease; and after this, the bowels are to be kept gently open, not by stimulating purges, but by emollient clysters, and the mildest and gentlest cathartics. The mixtura simplex is a very valuable medicine given several times a day; and in the intermediate hours the following powder is to be given: take purified nitre, and tartarium vitriolatum, each two drams; crab's eyes, and the jaw of a pike reduced to powder and sated with lemon juice, of each four scruples; diaphoretic antimony, a dram: the dose of this mixed powder is a scruple. In the mean time the region of the liver should be bathed externally with spirit of wine camphorated, impregnated with saffron. Above all things, rest, moderate warmth, and a placid regimen are to be observed.

**HEPATOSCOPIA**, in antiquity, that branch of divination, which predicted future events by inspecting the entrails of animals, but especially the liver. See the article **DIVINATION**.

**HEPATUS**, in ichthyology, a species of labrus, with the lower jaw longer than the upper, a forked tail, and transverse black lines on each side.

**HEPHÆSTIA**, in grecian antiquity, an athenian festival in honour of Vulcan, the chief ceremony of which was a race with torches.

It was performed in this manner: the antagonists were three young men, one of whom, by lot, took a lighted torch in his hand, and began his course; if the torch was extinguished before he had finished the race, he delivered it to the second; and he, in like manner, to the third: the victory was his, who first carried the torch lighted to the end of the race: and to this successive delivering of the torch, we find many allusions in ancient writers.

**HEPSETUS**, in ichthyology, a fish otherwise called atherina. It is a long and slender fish, with a forked tail, and its back variegated with black spots.

**HEPTACHORD**, in the ancient poetry, signified verses that were sung or played on seven chords, that is, on seven different notes. In this sense it was applied to the lyre, when it had but seven strings.

One of the intervals is also called an heptachord, as containing the same number of degrees between the extremes.

**HEPTAGON**, in geometry, a figure consisting of seven sides, and as many angles.

In fortification, a place is termed an heptagon, that has seven bastions for its defence.

**HEPTAGONAL NUMBERS**, in arithmetic, a sort of polygonal numbers, wherein the difference of the terms of the corresponding arithmetical progression is 5. One of the properties of these numbers is, that if they be multiplied by 40, and 9 be added to the product, the sum will be a square number. See **NUMBER**.

**HEPTAMERIS**, in music, the seventh part of a meris; being, according to M. Sauveur, the forty-third part of the octave. See the article **OCTAVE**.

**HEPTANDRIA**, in botany, a class of plants, the seventh in order, comprehending the plants that have hermaphrodite flowers, and seven stamina in each. See **FLOWER**, **STAMINA**, &c.

Of this class there are only two genera, the *esculus* and *trientalis*. See **ESEULUS** and **TRIENTALIS**.

**HEPTANGULAR**, in geometry, an appellation given to figures which have seven angles.

**HEPTARCHY**, a government of seven persons: also a state or country divided into seven kingdoms, and governed by seven independent princes; in which sense it is particularly applied to the government of South Britain, when divided amongst the Saxons.

**HEPTATEUCH**, the seven first books of the Old Testament, containing the pentateuch, or five books of Moses, and the books of Joshua and Judges.

**HEPHTHEMIMERIS**, in ancient poetry, a verse consisting of three feet and an half, or seven half feet.

It likewise denotes a *cæsura* after the third foot of a verse. See **CÆSURA**.

**HERACLEA**, a port-town of Romania, in european Turkey, situated on the Propontis, sixty miles south-west of Constantinople; it was once a great city: east long. 28°, and north lat. 41°.

**HERACLEIA**, an ancient festival celebrated in honour of Hercules by several states of Greece.

**HERACLEONITES**, a sect of christians, the followers of Haracleon, who refined upon the gnostic divinity, and maintained that the world was not the immediate production of the Son of God, but that he was only the occasional cause of its being created by the demiurgus. The heracleonites denied the authority of the prophecies of the Old Testament, maintaining that they were mere random

sounds in the air; and that St. John the Baptist was the only true voice, that directed to the Messiah.

**HERACLEUM**, in botany, a genus of the pentandria-digynia class of plants, the general flower of which is difform and radiated; the single flowers of the disc consist each of five equal petals, but those of the radius consist of five unequal petals: the fruit is elliptic, compressed, and striated on each side in the middle, and contains two oval compressed seeds.

To this genus belongs the *sphondylium*, or cow's parsnep of authors.

**HERACLIDÆ**, or *return of the HERACLIDÆ into Peloponnesus*, in chronology, a famous epocha, that constitutes the beginning of profane history; all the time preceding that period being accounted fabulous.

This return happened in the year of the world 2862, an hundred years after they were expelled, and eighty after the destruction of Troy.

**HERAIA**, an ancient greek festival observed at Argos and some other places, in honour of Juno, in which two processions were made to the temple of that goddess, one by men in armour; and a second, in which the priestesses of Juno was drawn in a chariot by white oxen, and on their arrival at the temple, they offered an hecatomb.

Another festival of this name was celebrated every fifth year at Elis, at which sixteen matrons were appointed to weave a garment for the goddess: there were also games, at which young virgins contended for the victory.

This name was also given to a solemn day of mourning kept at Corinth for Medea's children, who were buried in the temple of Juno Aſtræa.

**HERALD**, an officer at arms, whose business it is to declare war, to proclaim peace, to marshal all the solemnities at the coronation, christening, marriage, and funeral of princes, to blazon and examine coats of arms, &c.

Heralds were formerly held in much greater esteem than they are at present, and were created and christened by the king, who pouring a gold-cup of wine on their head, gave them the herald-name; but this is now done by the earl-marshal. They could not arrive at the dignity of herald without having been seven years pursuing; nor could they quit the office of herald, but to be made king at arms. See **POURSUIVANT**.

The

The three chief heralds are called kings at arms, the principal of which is Garter; the next is called Clarenceux, and the third Norroy; these two last are called provincial heralds. See *KING at arms*. Besides these there are six other inferior heralds, *viz.* York, Lancaster, Somerset, Richmond, Chester, and Windsor; to which, on the coming of king Geo. I. to the crown, a new herald was added, styled Hanover herald; and another, styled Gloucester king at arms.

The kings at arms, the heralds, and four poursuivants are a college or corporation, erected by a charter granted by Richard III. by which they obtained several privileges, as to be free from subsidies, tolls, and all troublesome offices. See the article *COLLEGE*.

**HERALDRY**, the art of armoury and blazoning, which comprehends the knowledge of what relates to solemn cavalcades and ceremonies at coronations, instalments, the creation of peers, nuptials, funerals, &c. and also whatever relates to the bearing of arms, assigning those that belong to all persons, regulating their right and precedencies in point of honour, and restraining those who have not a just claim, from bearing coats of arms that do not belong to them. See *BLAZONING*, *ARMS*, *SHIELD*, &c.

**HERAT**, a city of Persia, in the province of Chorassan: east long.  $61^{\circ}$ , and north lat.  $34^{\circ} 30'$ .

**HERB**, in pharmacy, an appellation given to the stalks and leaves of plants, especially such as are fleshy and succulent, and die away every year; but is also frequently used to denote the leaves alone.

The term herb, therefore, denotes the stalks and leaves, in contradistinction to the flowers, seeds, and roots. See *PLANT*, *FLOWER*, *FRUIT*, *ROOT*, &c.

Quincy gives the following directions for the gathering and preserving of herbs. They should be gathered just when beginning to flower, as being then in greatest perfection; and this must be done when there is no rain or dew upon them, otherwise they will be apt to turn black in drying. They ought to be dried in the shade, as too great heat exhales their moisture too fast, and destroys their beautiful verdure. The fresher they are used the better, though some may be kept much longer than others. So long as the fresh colour they dry with continues, they may be trusted in medicine, but no longer. They are much better for de-

coction and distillation when dried than green, because their saline and volatile parts very difficultly mix with a menstruum, until their native phlegm be evaporated.

**HERB-TRUELOVE**, *herba paris*, in botany. See the article *PARIS*.

**HERBAGE**, in law, signifies the pasture provided by nature for the food of cattle; also the liberty to feed cattle in the forest, or in another person's ground.

**HERBAL**, in literary history, a book that treats of the classes, genera, species, and virtues of plants. See the articles *PLANT* and *BOTANY*.

**HERBAL** is sometimes also used for what is more usually called *hortus ficcus*. See the article *HORTUS*.

**HERBALIST**, the author of an herbal, or one who is skilled in plants.

**HERBE**, in the french academies, a reward, or some good stuff, given to a horse who has worked well in the manege.

**HERBORG**, a town in the circle of the Upper Rhine, and territory of Nassau: east long.  $8^{\circ} 15'$ , and north lat.  $50^{\circ} 36'$ .

**HERCINIAN FOREST**, a forest which antiently extended the whole length of Germany and Bohemia, some remains of which are still in being, *viz.* the Black Forest, Odenwald near Heidelberg, Stigewald in Wurtzburg and Bamberg, and Hartswald in Brunwic.

**HERCOLE**, a port-town of Tuscany, on the coast called *Stato del Presidii*: east long.  $12^{\circ}$ , and north lat.  $42^{\circ} 25'$ .

**HERCOLE** is also a little island, near the town of the same name.

**HERCULES**, in astronomy, a constellation of the northern hemisphere, said to contain from 28 to 95 stars.

**HERCULES-PILLARS**, in antiquity, a name given to mount Calpe in Spain, near Gibraltar, on the european side of the streights, and mount Avila on the african side.

**HERCULEUS MORBUS**, the *EPILEPSY*, in medicine. See *EPILEPSY*.

**HERD**, a company of eatable cattle of the larger sort, as cows, oxen, swine, deer, &c. also of wild beasts.

**HEREDITAMENTS**, whatever immoveable things a person may have to himself and his heirs, by way of inheritance; and which, if not otherwise bequeathed, descend to him who is next heir, and not to the executor, as chattels do.

This word extends to whatever is inheritable, be it real, personal, or mixed: and in conveyances, by the grant of hereditaments,

ments, manors, houses, lands, rents, &c. will pass.

**HEREDITARY**, an appellation given to whatever belongs to a family by right of succession, from heir to heir.

Some monarchies are hereditary, and others elective; and some hereditary monarchies descend only to the heirs male, as in France; but others, to the next of blood, as in Spain, England, &c. Thus the dominions of the emperor are distinguished into hereditary, which are those he derives from his ancestors by right of inheritance, and those he enjoys in quality of emperor by virtue of his election. Hereditary is also applied to offices and posts of honour annexed to certain families; thus the office of earl-marshal is hereditary in the family of Howard.

Hereditary is also figuratively applied to good or ill qualities, supposed to be transmitted from father to son: thus we say, virtue and piety are hereditary virtues in such a family: and that in Italy the hatred of families is hereditary. And indeed the gout, the king's evil, madness, &c. may really be hereditary diseases.

**HEREFORD**, the principal city of Herefordshire, situated on the river Wye, twenty-four miles north-west of Gloucester, and one hundred and twenty west of London: west long.  $2^{\circ} 42'$ , and north lat.  $52^{\circ} 6'$ .

It sends two members to parliament.

**HERESY**, the crime of obstinately persisting in opinions, that are contrary to the fundamentals of religion.

There is no law that expressly determines this offence, it being impossible to set down all the particular errors that may be said to be heretical, and in relation to which so many disputes have arisen; in general, however, those opinions that were supposed to be condemned by the scriptures, or the four first general councils, have been accounted heresy.

Heresy was antiently treason, and punished by burning the offender; but he forfeited neither lands nor goods, because the proceedings against him were *pro salute animæ*. At present, all punishments of death, and the old statutes which gave power to arrest or imprison persons for heresy, are repealed: though, by the common law, an obstinate heretic, being excommunicated, may be still imprisoned, on the writ *de excommunicato capiendo*, till he makes satisfaction to the church. And persons denying the truth of the christian religion, or the divine authority

of the scriptures, &c. are liable, for the second offence, to three years imprisonment, by 9 & 10 Will. III. cap. xxxii.

**HERETIC**, a general name for all such persons, under any religion, but especially the christian, as profess or teach religious opinions contrary to the established faith, or to what is made the standard of orthodoxy. The laws both of church and state were antiently very severe against those who were adjudged to be heretics: the principal of which were, first, the general note of infamy affixed to all heretics in common. Secondly, all commerce forbidden to be held with them. Thirdly, the depriving them of all offices of profit and dignity. Fourthly, the rendering them incapable of disposing of their estates by will, or of receiving estates from others. Fifthly, imposing on them pecuniary mulcts. Sixthly, proscribing and banishing them. Seventhly, inflicting corporal punishment on them, such as scourging, &c. before banishment. Besides these laws, which chiefly affected the persons of heretics, there were others which tended to the extirpation of heresy, such as those which forbade heretical teachers to propagate their opinions in public or private: those which denied the children of heretical parents their patrimony and inheritance, unless they returned to the church: such as ordered the books of heretics to be burnt. There were many other penal laws against heretics, from the time of Constantine to Theodosius junior, and Valentinian III. But the few already mentioned may be sufficient to give an idea of the rigour with which the empire treated such persons, who held or taught opinions contrary to the faith of the catholic church; whose discipline towards heretics was no less severe than the civil laws: but since these early times, the most horrid deaths, and the most excruciating tortures, have been invented. For the laws of England in relation to heretics, see the preceding article.

**HERISSON**, in fortification, a beam armed with a great number of iron-spikes, with their points outwards, and supported by a pivot, on which it turns.

These serve as a barrier to block up any passage, and are frequently placed before the gates, and more especially the wicket-doors of a town or fortress, to secure those passages, which must of necessity be often opened and shut.

**HERK**, a town of Germany, in the bishoprick of Liege, situated on a river of

of the same name, near its confluence with the Demer: east long.  $5^{\circ} 20'$ , and north lat.  $51^{\circ}$ .

**HERLING**, a market-town of Norfolk, twenty miles south-west of Norwich.

**HERMÆ**, among antiquarians, statues of the god Mercury, made of marble, and sometimes of brass, without arms or feet, and set up by the Greeks and Romans in the cross-ways.

Antiquity likewise furnishes us with compound hermæ, or statues of Mercury joined with some other deity, as Herm-Athena, or Mercury and Minerva; Herm-Hercules, or Mercury and Hercules; Herm-Eros, or Mercury and Cupid: and so of others.

**HERMÆA**, in antiquity, ancient greek festivals, in honour of the god Hermes, or Mercury. One of these was celebrated by the Pheneatæ, in Arcadia; a second by the Cyllenians, in Elis; and a third by the Tanagræans, where Mercury was represented with a ram upon his shoulder, because he was said, in a time of plague, to have walked thro' the city in that posture, and to have cured the sick; in memory of which, it was customary at this festival, for one of the most beautiful youths in the city, to walk round the walls, with a ram upon his shoulder.

A fourth festival of the same name was observed in Crete, when it was usual for the servants to sit down at the table while their masters waited: a custom which was also practised at the roman saturnalia.

**HERMANNIA**, AFRICAN MARSH-MALLOWS, in botany, a genus of the monadelphii-pentandria class of plants, with a roseaceous flower, the petals of which are semitubular at the base; the fruit is a roundish capsule, containing a great many small seeds.

**HERMANSTAT**, the capital city of Transilvania, subject to the house of Austria: east long.  $24^{\circ}$ , north lat.  $46^{\circ} 32'$ .

**HERMAPHRODITE**, a person of both sexes, or who has the parts of generation both of male and female.

It is now generally allowed, that there is no such thing as a true hermaphrodite; most, if not all those who pass for such, being mere women, whose clitoris is grown to an enormous size, and the labia pudendi become unusually tumid.

Among the insect-class of animals, indeed, hermaphrodites are very frequent: such are worms, snails, leeches, &c.

**HERMAPHRODITE FLOWERS**, among botanists. See FLOWER.

**HERMATHENA**, among antiquarians, a statue representing Mercury and Minerva both in one. See HERMÆ.

**HERMES**, or HERMÆ. See HERMÆ.

**HERMETIC**, or HERMETICAL, an appellation given to whatever belongs to chemistry, from Hermes Trismegistus, who is supposed to have been its inventor.

**HERMETICAL PHILOSOPHY**, that which undertakes to solve the various phenomena of nature, from the chemical principles, salt, sulphur, and mercury.

**HERMETICAL SEAL**, among chemists, a method of stopping glass-vessels, used in chemical operations, so closely, that the most subtle spirit cannot escape through them.

It is commonly done by heating the neck of the vessel in a flame, till ready to melt, and then twisting it closely together with a pair of pincers. Or, vessels may be hermetically sealed, by stopping them with a glass plug, well luted; or, by covering the vessel with another ovum philosophicum.

**HERM-HARPOCRATES**, in antiquity, a compound statue of Mercury and Harpocrates. See the article HERMÆ.

**HERMIT**, a devout person retired into solitude to be more at leisure for contemplation, and to disencumber himself from the affairs of the world.

An hermit is not reputed a religious, unless he has made the vows.

Paul the hermit is usually reckoned the first: though St. Jerom at the beginning of the life of that saint, says it is not known who was the first. Some go back to St. Anthony, some to John the Baptist, and others to Elias. However, several of the ancient hermits, though they lived in deserts, had nevertheless numbers of religious accompanying them.

There are also several orders and congregations of religious distinguished by the title of hermits; as the hermits of St. Augustin, of St. John the Baptist, of St. Jerom, of St. Paul, of St. James de Montlio, of St. William, of St. Benedict of Montefabalo, &c.

**HERMIT**, in zoology, the long-tailed squilla, with a soft tail, and the right claw the largest. See the article SQUILLA.

This grows to two inches and a half in length; the legs are slender and long, and the anterior ones have claws on them like the common crabs.

**HERMODACTYLS**, in pharmacy, a root supposed to be that of the plant colchicum. See the article COLCHICUM.

Hermō-

**Hermodyctyls** are brought us from Egypt and Syria, where the people eat them to make themselves fat. They use them medically, while fresh and just taken out of the earth, as a vomit and purge. The dried roots, as we have them in the shops, are a gentle purge, and have the credit of being peculiarly good in rheumatic disorders. The dose in powder is from a scruple to a dram, or more, but they are so weak a purge as seldom to be given alone: their proper correctives are the spices, ginger, cloves, and the like.

**HERMON**, a mountain on the east of Syria and Palestine, in Asia.

**HERNANDIA**, in botany, a genus of plants, the characters of which are not perfectly ascertained; the corolla of the male as well as the female flower, is divided into six segments: there is no pericarpium, the cup is very large, inflated and roundish, and intire at the mouth: the seed is an oval, sulcated, unilocular nut; the nucleus is globose.

**HERNGRUNT**, a town of Upper Hungary, situated north of Buda, near the Carpathian mountains: east long.  $19^{\circ} 20'$  north lat.  $48^{\circ} 47'$ .

**HERNIA**, in medicine, a preternatural tumour formed in the abdomen, particularly in the navel, inguen, and scrotum, by a protuberance of the intestines or omentum, and usually known by the name of rupture.

These tumours differ first, according to their place or situation: those formed at the navel are called *omphalocele*, or *exomphalus*. See *EXOMPHALUS*.

A hernia in the groin is called *bubonotele*, and that of the scrotum, *oscheocele*, &c. See the article *BUBONOCELE* and *OSCHEOCELE*, &c.

Hernias are also distinguished from the body or surface contained in, or forming, the tumour: when from a protuberance of the intestines, a hernia is termed *enterocele*; when from the omentum, *epiplocele*; if from flatulæ, *pneumatocele*; and if from water, *hydrocele*, &c. See the articles *ENTEROCELE*, *EPIPOCELE*, *PNEUMATOCELE*, *HYDROCELE*, &c.

Hernias are also distinguishable from circumstances less remarkable, as from the size, being either small, large, or enormous; from their consistence, being either hard, soft, fixed or moveable, capable of being returned into the abdomen, or not; which latter are called ad-

hesive ruptures: sometimes the parts prolapsed are so confined by stricture and inflammation, that the flatus and fæces cannot be returned, which kind of ruptures are called *incarcerated*: some are attended with pain; others without; or with sickness, vomiting, and other bad symptoms.

**HERNIA HUMORALIS**, a painful and inflammatory tumour, of one or both testicles, arising generally from a suppression of a virulent running in a gonorrhœa, or from too strong and stimulating cathartics, especially if the patient happens to take the least cold during their operation. See *GONORRHOEA*.

The cure of this symptom, according to Turner, must commence with bleeding; a bag-truss must be immediately provided, which may support the weight of the tumour, and contain and secure the proper applications: among which none excels a cataplasm of bean-meal, with simple oxymel; adding to it a little of the oil of roses, or ointment of elder, to preserve it from hardening and drying. During these applications, forbear all restraining or balsamic medicines, and purge the patient briskly with calomel and *pilulæ ex duobus*: but particular care must be taken that he gets no cold, by which method the swelling is usually in a few days dispersed, and the running always appears, which must be carried off by the same, or the like cathartics repeated at proper intervals. But if, notwithstanding, the pain and fluxion still increase with inflammation, threatening an abscess, the patient must be vomited with the turpeth mineral; such intervals being observed as may prevent any soreness of his chops, till the tumour subsides: then purge off the reliques; when, if any schirrhous hardness should remain, you may endeavour to disperse it with the *emplastrum diaphysuris*, the *emplastrum de ranis cum mercurio* & *de cicuta cum ammoniaco*, *ex ammoniaco*, the *diagalbanum*; or with suffumigation with vinegar.

**HERNIARIA, RUPTURE-WORT**, in botany, a genus of the *petandria-digynia* class of plants, having no corolla: the fruit is a small capsule placed in the bottom of the cup, covered, and hardly splitting; the seed is single, ovato-acuminated, and smooth.

This plant is of a refrigerating and drying quality. Its principal use is in curing an hernia; in wasting the stone

in the kidneys, and bladder; in inciding mucosities of the stomach and other parts, and bringing them away; in evacuating bile and water, and consequently curing the jaundice.

**HERO**, in the antient mythology, a great and illustrious person, of a mortal nature, though supposed by the populace to partake of immortality; and, after his death, placed among the number of the gods.

Heroes were persons partly of divine and partly of human extraction, being begot between a deity and a mortal, and coincides with what we otherwise call a demi god; such was Hercules, who was the son of Jupiter by Alcmena: accordingly Lucian describes a hero to be a medium between a god and a man, or rather a composition of both.

**HERO** is also used in a more extensive sense for a great, illustrious, and extraordinary personage; particularly in respect of valour, courage, intrepidity, and other military virtues.

F. Bouhours makes this distinction between a hero and a great man, that the former is more daring, fierce, and enterprising; and the latter more prudent, thoughtful and reserved. In this sense we say, Alexander was a hero, and Julius Cæsar a great man.

**HERO** of a poem, or romance, is the principal personage, or character therein. See the article **CHARACTER**.

The hero of the *Iliad* is Achilles; of the *Odysses*, Ulysses; of the *Æneid*, Æneas; of Tasso's *Jerusalem*, Godfrey of Bulloign; of Milton's *Paradise Lost*, Adam; though Mr. Dryden will have the devil to be Milton's hero, in regard he gets the better of Adam, and drives him out of *Paradise*.

Many of the critics find fault with the hero of the *Æneid*, for being too delicate, wanting the fire, firmness, and uncontrollable spirit, remarkable in the hero of the *Iliad*. Piety, tenderness, and submission to the gods, are virtues of the middle class of mankind; they do not strike enough for a hero who is to be the instrument of such notable exploits. In answering to this, F. Bossu observes, that Æneas's character was not to be formed on the model either of Achilles or Ulysses; nor to be of the same kind with them, as the fable and design of the *Æneid* were very different from those of the *Iliad* and *Odysee*. Virgil's design was to persuade the Romans to re-

ceive a new form of government, and a new master; who must have all the qualities requisite for the founder of a state, and all the virtues which make a prince beloved.

Virgil was restrained in his choice; his hero was to be of the genius of Augustus. The characters of Homer's two heroes, as being directly contrary to his design, he has thrown upon Turnus and Mezentius, who are the counter-parts to his hero. It is disputed whether it be necessary, that the hero of an epic poem be a good and virtuous man. Bossu maintains the negative. Between a hero in morality, and a hero in poetry, the same distinction may be made as between moral and poetical goodness. Hence, as the manners of Achilles and Mezentius are poetically as good as those of Ulysses and Æneas, so these two cruel and unjust men are as regular poetical heroes, as these two just, wife, and good men.

Whatever Aristotle may say in his book of morality, in his poetics he speaks another language. The hero of a poem, he observes, must neither be good nor bad, but between both: he must not be superior to the rest of mankind by his virtue and justice, nor inferior to them by his crimes and wickedness. In effect, reason, the nature of the poem, which is a fable, the practice of Homer, and the rules of Aristotle and Horace agree that it is so far from being necessary, that a hero be a faultless man, that it is not necessary he be an honest man.

It is likewise disputed, whether, the catastrophe is necessarily to leave the hero happy, or whether it be allowable to leave him unhappy.

The general practice of the heroic poets stand for the affirmative. In tragedy, according to Aristotle unhappy catastrophes are preferable to happy ones, and always much better received among the antients.

It is otherwise in the epopeia; but yet this does not exclude all unhappy conclusions. If the poet proposed his hero as a pattern of perfection for imitation, the misfortunes falling on him would suit very ill with the design; but this was doubtless the farthest thing from the intentions of the great masters of the epopeia. The only reason perhaps for this uniform practice of the poets is, that an epic poem containing an action of more extent than that of tragedy, the reader would not be so well satisfied if, after

*Fig. 1. HELLEBORE.*

*Fig. 2. The ASH-COLOURED HERON.*

*Fig. 3. HIERACIUM.*

after so many difficulties as the hero is brought to struggle with, he should not at last be brought off, but perish miserably.

**HEROIC**, something belonging to a hero, or heroine : thus,

**HEROIC AGE**, that age or period of the world wherein the heroes are supposed to have lived. The heroic age coincides with the fabulous age.

**HEROIC POEM**, that which describes some extraordinary enterprize; being the same with epic poem. See **EPIC**.

**HEROIC VERSE**, that wherein heroic poems are usually composed; or it is that proper for such poems. In the greek and latin, hexameter verses are usually denominated heroic verses, as being alone used by Homer, Virgil, &c. See the article **HEXAMETER**.

Alexandrine verses of twelve syllables were formerly called heroic verses; but later writers use verses of ten syllables.

**HEROIN**, a woman of an heroic spirit, or who makes the principal personage in an heroic poem. See **HERO** and **POEM**.

**HERON**, in ornithology, a bird of the arde-kind, with a hanging crest.

The common heron is a tall bird, measuring more than four feet from the point of the beak to the tip of the toes. Its head is covered with short white feathers; only from the hinder parts, there hangs a crest of very long black feathers; the upper part of its body is of a dusky bluish grey; the under part white, and the thighs yellowish.

The ash coloured heron from Hudson's Bay differs from the common heron, in being something bigger, of a browner ash-colour on its back, and in having no white feathers on its forehead. See plate **CXXXI**. fig. 2.

**HERPES**, in medicine, a bilious pustle, which breaking out in different manners upon the skin, accordingly receives different denominations.

If they appear single, as they frequently do in the face, the base is inflamed, and the top pointed; and having discharged a drop of matter, the redness and pain go off, and they dry away. There is another sort more corrosive and of greater malignity, when a cluster of pustles rise in a ring, accompanied with smart, and sometimes with great itching: this species is termed *serpigo*, and vulgarly the *tetter*, or *ring-worm*. It seizes the face, hands, and other parts of the body,

is of an obstinate nature, eating into the skin; and forsaking the place where it first appears, it spreads its taint into the adjacent parts. It neither forms matter, nor comes into digestion; but when rubbed, will sometimes emit a thin, sharp, watery, humour, and excites smart, heat, and itching.

Another kind of this disease appears in large clusters upon the neck, breast, loins, hips, and thighs, attended with a slight fever and inflammation: the heads are white and mattery, which are succeeded by a small round scab, resembling millet-seed, whence its name of *herpes miliaris*; and is commonly called *shingles*. Another species, from its degree of virulence and corrosion, is named *herpes exedens*, or *herpes depascens*. See the article **ULCER**.

The simple bilious pustle, which rises in the face, requires but little assistance from medicine; for though it burns, smarts, or itches a day or two, yet it naturally comes to a head, soon dries, and disappears.

The *serpigo* is sometimes very difficult to be exterminated, and after it appears dead, it will at certain seasons of the year, obstinately break out again.

Tho' bleeding at first is by some condemned, yet repeated purging, especially with cholagogue medicines is universally approved: these not succeeding, recourse must be had to mercurials, especially if there be the least suspicion of any old venereal taint remaining in the blood. Having removed the *cacochymy*, the physician may proceed to topics. Ambrose Paré, after a general evacuation, prescribes the following. Take of powder of oak-galls, pomegranate-peel, balsamines, and armenian bole, each half an ounce; of rose-water, half an ounce; of the sharpest vinegar, half an ounce; of goose-grease, and oil of myrtles, each six drams; of turpentine, half an ounce: make up into an ointment for use. Barbet imputes the cause of the herpes rather to the lymph, than to the bile and salt phlegm, blamed by the antients. In the military eruptions, called *shingles*, great care must be taken that the bilious *cacochymy* is purged off before the use of topics: the internal prescription for this purpose is the same with that in the *erysipelas*. See the article **ERYSIPÉLAS**. When the pustles are all ripened, their heads may be cut off with a pair of

scissars, and the humours absorbed with a soft rag, to prevent farther corrosion. Then a cerate of oil and wax may be laid over the parts, and kept on with a bandage, to prevent the pustles sticking to the dry linen. See **ERUPTION**.

**HERRING**, in ichthyology, a species of clupea, with the lower jaw longest, and without any black spoils. It is from five to eight inches in length, and between one and two in breadth. However, its size is far from being certain; since it varies not only on account of age, but according to the seas and places where it is caught. The back is of a dusky bluish colour, and is more blue in spring than any other times; the sides and the belly are of a silvery white; the fin on the back stands near the middle, and is of a whitish colour, and has nineteen rays; the pectoral fins are whitish, stand low, and have each eighteen rays; the ventral fins are very small and white; the pinna ani is near the tail, and has eighteen rays; the tail is of a greyish colour, forked, and furnished with eighteen rays.

We have been designedly particular in the description of this useful fish; the manner of fishing and curing which is delivered under the article **FISHERY**.

**Barrelling of HERRINGS**. See the article **Herring FISHERY**.

**HERRING-BUSS**, in naval affairs. See the article **BUSS**.

**HERSE**, in fortification, is a lattice or portcullice, made in the form of a harrow, and stuck full of iron-spikes.

It is usually hung by a rope, fastened to a moulinet, which is cut in case of surprise, or when the first gate is broken with a petard, to the end that it may fall and stop up the passage of the gate, or other entrance of a fortress.

These hersees are also often laid in the roads, with the points upwards, to incommode the march both of the horse and infantry.

**HERSILLAN**, in the art of war, is a strong plank or beam, about ten or twelve feet long, stuck full of spikes on both sides, and also used to incommode the march of the infantry or cavalry.

**HERSTAL**, a town of Germany, in the bishopric of Liege, situated three miles north of the city of Liege: east long.  $5^{\circ} 36'$  north lat.  $50^{\circ} 42'$ .

**HERTFORD**, or **HARTFORD**. See the article **HARTFORD**.

**HERWERDEN**, a town of Westphalia, subject to the king of Prussia; and remarkable for its protestant-nunnery: east longitude  $8^{\circ} 15'$ , and north latitude  $52^{\circ} 12'$ .

**HESDEN**, a town of Artois, near the confines of Picardy, and twenty miles south-west of St. Omers.

**HESPER**, *hesperus*, in astronomy, an appellation given to the planet Venus, when she sets after the sun. See **VENUS**.

**HESPERIDES**, in antiquity, the daughters of Hesperus, brother of Atlas, who kept a garden full of golden apples, guarded by a dragon: but Hercules having laid the dragon asleep, stole away the apples. Others say, that they kept sheep with golden fleeces that were taken away by Hercules.

Some think the hesperides were the daughters of a rich merchant of Miletus, who, on account of their beauty, were guarded by a man called Dragon; and that Hercules, by killing or bribing him, got them away.

**HESPERIDES** was also a name antiently given to the Cape Verd Islands. See the article **Cape VERD**.

**HESPERIS**, **DAME'S VIOLET**, in botany, a genus of the tetradynamia siliquosa class of plants, the corolla of which consists of four cruciform petals, of an oblong figure, of the length of the cup, a little reflex, and ending in small unguis: the fruit is a long pod, plane, compressed, striated, bilocular, bivalve, containing several oval, compressed seeds.

This plant is antiscorbutic, and diaphoretic, and very serviceable in the asthma, cough, and convulsions: the outward use of it is recommended against inflammations, cancers, a gangrene, sphacelus, and contagious diseases.

**HESSE-CASSEL** landgraviate, including Wetteravia, is a circle of the Upper Rhine, bounded by Westphalia and Brunswick on the north; by Franconia and Saxony on the east; by the river Maine on the south, and by another part of Westphalia, and the electorate of Mentz and Triers on the west: it is subject to the king of Sweden.

**HESSE-DARMSTAT**, is bounded by the river Maine, which divides it from Hesse-Cassel on the north; by the same river on the east; and by the Palatinate on the south and west.

**HETEROCLITE**, among grammarians, one of the three variations in irregular nouns,

nouns, and defined by Mr. Ruddiman, a noun that varies in declension; as *boc vas, vasis; hæc vasa, vasorum*.

Other grammarians take the word heteroclite in a larger sense, applying it to all irregular nouns. See ANOMALOUS.

The heteroclite nouns properly so called, or, according to the definition, are only three, *viz. vas, jugerum, and domus*.

**METERODOX**, in polemical theology, any thing contrary to the faith and doctrines of a true church.

**HETERODROMUS VECTIS**, in mechanics, a lever, wherein the fulcrum, or point of suspension, is placed between the power and the weight. See LEVER. In this kind of lever, the weight is elevated, or raised, by the descent of the power, and *vice versa*.

**HETEROGENEITY**, in physiology, that quality or property of bodies, which denominates a thing heterogeneous. See the next article.

The word is also used for the heterogeneous parts themselves. In which sense the heterogeneities of a body are the same thing with the impurities thereof.

Heterogeneity is a word of a very lax signification, and is brought by the chemists to serve almost for any thing they do not understand, so that the disagreement or inaptitude to mixture in any body is imputed to the heterogeneity of their parts.

**HETEROGENEOUS**, or **HETEROGENEAL**, something that consists of parts of dissimilar kinds, in opposition to homogeneous. See HOMOGENEOUS.

**HETEROGENEOUS**, in mechanics, such bodies whose density is unequal in different parts of their bulk; or they are such whose gravities in different parts are not proportionable to the bulks thereof: whereas bodies equally dense or solid in every part, or whose gravity is proportionable to their bulk, are said to be homogeneous.

**HETEROGENEOUS LIGHT**, is, by Sir Isaac Newton, said to be that which consists of rays of different degrees of refrangibility: thus the common light of the sun or clouds is heterogeneous; being a mixture of all sorts of rays.

**HETEROGENEOUS NOUNS**, one of the three variations in irregular nouns; or such as are of one gender in the singular number, and of another in the plural, as *boc cælum, bi cæli*. Heterogeneous, under which are comprehended, mixed nouns, are six-fold, 1. Those which are of the

masculine gender in the singular number, and neuter in the plural, as *bic tartarus, hæc tartara*. 2. Those which are masculine in the singular number, but masculine and neuter in the plural, as *bic locus, bi loci, & hæc loca*. 3. Such as are feminine in the singular number, but neuter in the plural, *hæc carbasus, & hæc carbasa*. 4. Such nouns as are neuter in the singular number, but masculine in the plural, as *boc cælum, bi cæli*. 5. Such as are neuter in the singular, but neuter and masculine in the plural, as *boc rastrum; bi rastri, & hæc rastra*; and, 6. Such as are neuter in the singular, but feminine in the plural number, as *boc epulum, hæc epulæ*.

**HETEROGENEOUS NUMBERS**, mixed numbers consisting of integers and fractions. See INTEGER and FRACTION.

**HETEROGENEOUS QUANTITIES**, are those which are of such different kinds, as that one of them taken any number of times, never equals or exceeds the other.

**HETEROGENEOUS SURDS**, are such as have different radical signs, as  $\sqrt[3]{aa}$ ,  $\sqrt[5]{bb}$ ,  $\sqrt[3]{9}$ ,  $\sqrt[7]{18}$ , &c. See SURD.

If the indices of the powers of the heterogeneous surds be divided by their greatest common divisor, and the quotients be set under the dividends; and those indices be multiplied crosswise by each others quotients; and before the products be set the common radical sign  $\sqrt{\phantom{x}}$ , with its proper index; and if the powers of the given roots be involved alternately, according to the index of each others quotient, and the common radical sign be prefixed before those products, then will those two surds be reduced to others, having but one common radical sign. As to reduce

$$\begin{array}{l} \sqrt[2]{aa} \text{ and } \sqrt[4]{bb} \\ 2) \sqrt[2]{aa} \quad (2 \sqrt[4]{bb} \quad \overset{1 \times 2}{\sqrt[4]{bb}} \sqrt[4]{aaaa} \end{array}$$

**HETEROPYRÆ**, in natural history, a genus of fossils, of the class of the siderochita, composed of various crusts, surrounding a nucleus of a different substance from themselves, and often loose and rattling in them. See the article SIDEROCHITA.

Of this genus Dr. Hill reckons seven species. 1. The hard heteropyra, with brown and purplish crusts, and a whitish green nucleus, being a very beautiful fossil of a smooth equal texture, considerably compact and close, generally determinate and regular in shape and size,

in

in form of an oblong oval figure, and about an inch in length, and half an inch in diameter. 2. The rough purplish heteropyra, containing a large nucleus of a very light earth. 3. The misshapen heteropyra, with ferrugineous, red, and dusky, yellow crusts, and a greenish, white nucleus. 4. The yellow, brown, and black-crusted heteropyra, with a whitish nucleus, being about four inches in length, and three in breadth, and two and a half in thickness, of an oblong form, a close compact texture, and very heavy. 5. The yellow, ferrugineous, and purplish-crusted heteropyra, with a pale yellow nucleus, from four to twelve inches in length, and about the third of its length in breadth, and nearly the same in thickness. 6. The coarse, yellow, and brown heteropyra, with a brownish yellow nucleus of an orbicular form, and between one and two inches in diameter. 7. The coarse heteropyra, with brown, black, and orange-coloured crusts, and a yellow nucleus, being of an oblong form, and about an inch and a half in length.

**HETEROSCI**, in geography, a term of relation denoting such inhabitants of the earth as have their shadows falling but one way, as those who live between the tropics and polar circles, whose shadows at noon, in north latitude, are always to the northward; and in south latitude, to the southward.

Thus we who inhabit the northern temperate zone, are heteroscii with regard to those who inhabit the southern temperate zone, and they are heteroscii with respect to us. Hence it follows, that only the inhabitants of the two temperate zones are heteroscii, though in reality there is always one part of the torrid zone whose inhabitants are heteroscii with respect to those of the rest, and with regard to those of one of the temperate zones, except at the time of the solstice, and even at this time all of the torrid zone are heteroscii with regard to those of one of the temperate zones; but as the people of the torrid zone have their shadows now on this, and then on that side, they are called amphiscii. See **AMPHISCII**.

**HETEROUSIANS**, a name composed of *heteros*, other, and *hoia*, substance, being given to a sect of Arians, who did not believe that the son of God was of a substance like to that of the father, which was the opinion of another branch of the Arians, who were from thence called hemo-

ousians; but that he was of another substance, different from that of the father.

**HEUCHERA**, in botany, a genus of the pentandria-digynia class of plants, the corolla whereof consists of five petals inserted into the edge of the cup; they are of the length of the cup, and of an ovato-linear figure: the fruit is an ovato-acuminate capsule, semibifid, terminating in two reflex points, and containing two cells: the seeds are numerous and small.

**HEW-HOLE**, in ornithology, a name given to the wood-pecker, from its making holes in trees.

**HEXACHORD**, in antient music, a concord called by the moderns a sixth.

Guido divides his scale by hexachords, and there are seven contained in it, three by *B quadro*, two by *B natural*, and two *B molle*; and it is for this reason that he divided his scale into six columns, in which he disposed the hexachords. See the article **GAMUT**.

The hexachord is two-fold, greater and less. The greater hexachord is composed of two greater tones, and two less, and one greater semitone, which make five intervals. The less hexachord is of two greater tones, one lesser, and two greater semitones. See **TONE**, &c.

**HEXAEDRON**, or **HEXAHEDRON**. See the article **HEXAHEDRON**.

**HEXÆDROSTYLA**, in natural history, a genus of fossils consisting of crystalliform columnar spars, terminated at their summit by a pyramid, but adhering irregularly to some other body at their base. See the article **SPAR**.

There are three species of this genus of fossils. 1. The slender hexædrostylum, with a long pyramid, being so pure and clear a spar, and so much of the ordinary figure of the hexangular crystal, that there is no doubt but it has often been mistaken for crystal: its most frequent size is nearly two inches in length, and a third of an inch in thickness, the pyramid being about one fourth of that length. 2. The hexædrostylum, with a long irregular pyramid, being of a moderately equal, but somewhat coarse and impure texture, and subject to spots of various earths and minerals, and often so altered by them, as not to be known, but by its figure, which it ever keeps regularly to: it is naturally of a dusky white, but moderately transparent, considerably heavy, and very soft. 3. The hexædrostylum, with a very short pyramid, being usually of a very pure, clear, and

and fine texture, but sometimes so debased by earthy admixtures, that it becomes very coarse, and frequently spotted, flawed and blemished: it is of various sizes, but about an inch and a half is its most frequent length, and with that the usual proportion is about half an inch in thickness, and the pyramid seldom takes up more than one eighth of the length.

**HEXAGON**, in geometry, a figure of six sides and angles; and if these sides and angles be equal, it is called a regular hexagon.

The side of every regular hexagon, inscribed in a circle, is equal in length to the radius of that circle. Hence, it is easy, by laying off the radius six times upon the circumference, to inscribe an hexagon in a circle.

To describe a regular hexagon on a given right line A B (plate CXXIX. fig. 3.) draw an equilateral triangle A C B, and the vertex C will be the center of a circle which will circumscribe the hexagon required A B D E F G.

As 1 is to 1.672, so is the square of the side of any regular hexagon to the area thereof, nearly.

**HEXAGON**, in fortification, is a place defended by six bastions.

**HEXAHEDRON**, in geometry, one of the five platonic bodies, or regular solids; being the same with a cube. See CUBE.

**HEXAMETER**, *carmen hexametrum*, in antient poetry, a kind of verse consisting of six feet; the first four of which may be indifferently, either spondees or dactyls; the fifth is generally a dactyl, and the sixth always a spondee. Such is the following verse of Horace:

1 2 3 4 5 6  
Aut pro|desse vo|lunt, aut |dele|tare po|eta.

Or this one of Homer:

1 2 3 4 5 6  
Σκίπτρω|μὲν τοι|δῶκε τε|τίμα|σθαί περ|πάντων.

Sometimes indeed, a spondee constitutes the fifth foot; whence such hexameter verses are called spondaic; as in this of Virgil.

1 2 3 4 5  
Cara De|um sōbōles ma|gnum Jovis|incre-|

mentum.

Epic poems, as the Iliad, Æneid, &c. consist wholly of hexameter verses; whereas elegies and epistles consist usually of hexameter and pentameter verses, alternately.

Such hexameter verses please most, wherein dactyls and spondees follow each

other in an alternate order: and next to these, such as abound most with dactyls, as:

1 2 3 4 5  
Lulere | quæ vel|lem cala|mo per | misit a-|

6  
gressi

Adspicis | ut veni|ant ad |candida|testa co-|  
lumbæ.

**HEXANDRIA**, in botany, a class of plants, the sixth in order; comprehending all those plants which have hermaphrodite flowers, and six stamina in each. See FLOWER and STAMINA.

To this class belong the narcissus, garlic, daffodil, lilly, &c.

**HEXAPLA**, in church-history, a work published by Origin, containing a part of the Old Testament in the original hebrew, with several versions of it in six columns; from whence it was called hexapla, or the six-fold edition.

**HEXAPYRAMIDES**, in natural history, a genus of spars formed into pyramids, composed of six sides or planes, affixed to no column, but adhering to some solid body by the bases of their pyramids. See the article SPAR.

**HEXASTYLE**, in architecture, a building with six columns in front.

**HEXHAM**, a market town of Northumberland, sixteen miles west of Newcastle.

**HEYDON**, a borough town in Yorkshire, thirty-seven miles south-east of York, and six miles west of Hull. It sends two members to parliament.

**HEYLINGENSTAT**, a town of Germany in the circle of Upper Saxony; subject to the elector of Mentz: east long. 10°, north lat. 51° 27'.

**HEYLSHEM**, a town of the Austrian Netherlands, in the province of Brabant, situated five miles south of Tirlemont: east long. 4° 55', north lat. 50° 53'.

**HEYRS**, in husbandry, young timber-trees usually left for standards, in the felling of woods or copses.

**HEYTSBURY** a borough town of Wiltshire, fourteen miles north-west of Salisbury, sends two members to parliament.

**HLÆNA**, or HYÆNA, in zoology. See the article HYÆNA.

**HIATICULA**, the SEA-LARK, in ornithology, a species of charadrius, with a black front, and a white line on it. See the article CHARADRIUS.

It is a very pretty bird, about the size of the common lark, or a little larger. The upper

upper part of its body is grey, and the belly white.

**HIATUS**, properly signifies an opening, chasm, or gap; but it is particularly applied to those verses, where one word ends with a vowel, and the following word begins with one, and thereby occasion the mouth to be more opened, and the sound to be very harsh.

The term hiatus is also used in speaking of manuscripts, to denote their defects, or the parts that have been lost or effaced.

**HIBISCUS**, in botany, a genus of the monadelphia polyandria class of plants, the corolla whereof consists of five petals, vertically cordated, having one prominence of the apex greater than the other, and coalescing at the base: the fruit is roundish, and contains five cells: the seeds are kidney-shaped.

The several species of this plant are in english called the chinese-rose, the abelmosch, the bladder alcea, and the gum-leaved-ketmia.

The seeds of the abelmosch were once kept in our shops, as a provocative and cordial; but they are now out of use.

**HICUP**, or **HICCUGH**, in medicine, a spasmodic affection of the stomach and diaphragm, arising from any thing that irritates and vellicates their nervous coats. When it proceeds from a slight error in diet, it will soon end spontaneously, or by drinking any thing which dilutes the acrid matter; but it is sometimes of a more dangerous kind, and may proceed from a hurt of the stomach, poison, an inflammation of the stomach, intestines, diaphragm, bladder, or the rest of the viscera. Sometimes, immediately before death, it may proceed from gangrenes of the outward parts. In acute fevers, and chiefly the malignant, it is often fatal.

When it happens in old or weak people from a plentiful meal, especially from hard and flatulent aliment, or from drinking cold liquors, a draught of generous wine, or a dram of any spirituous liquor, will generally take it away. Stomachic powders mixed with peruvian bark, and taken in generous wine, are also profitable. When it proceeds from acid humours in the stomach, absorbent and alkaline medicines are good. If it proceeds from an acute fever, or an inflammation of the stomach, it is a dangerous disease: however, dulcified spirit of nitre, joined to an alexipharmic, and given often, is proper; or a dram of diascordium

given in the evening, may perform a cure. If it proceeds from a gangrene or mortification, it is generally incurable; but peruvian bark, with medicines against internal inflammations, are most likely to succeed. If it is caused by poison, plenty of milk must be taken with oil. Fuller declares, that he does not know a better medicine than the julep of musk; and Allen says, that this affords, one would almost think, supernatural assistance.

**HICKWALL**, or **WITWALL**, in ornithology, names used in several parts of the kingdom for the lesser black and white woodpecker, with the three lateral long feathers of the tail variegated at the top. It is a small bird, hardly weighing more than an ounce. See the articles **PICUS** and **WOODPECKER**.

**HIDAGE**, in law-books, an extraordinary tax antiently paid to the king for every hide of land. Sometimes, indeed, it is used for being quit of this tax.

**HIDE**, the skin of beasts, but particularly applied to those of large cattle, as bullocks, cows, horses, &c. See the article **SKIN**.

Hides are either raw or green, just as taken off the carcase; salted or seasoned with salt, alum, and salt-petre, to prevent their spoiling; or curried and tanned. See the article **CURRYING**, **TANNING**, &c.

Hides make a considerable article of commerce, being subject to the following duties and drawbacks, on importation, and when exported again. Buff-hides pay each 3 s. 9  $\frac{5}{100}$  d. and draw back 3 s. 6  $\frac{5}{100}$  d. and besides pay for every pound weight 7 d. and draw back

$4 \frac{66\frac{2}{3}}{100}$  d. Cow or horse-hides in the hair, pay each 7  $\frac{18\frac{1}{2}}{100}$  d. and draw back 6  $\frac{46\frac{7}{8}}{100}$  d.

ditto tanned, pay each 2 s. 4  $\frac{72\frac{1}{2}}{100}$  d. draw back 2 s. 1  $\frac{87\frac{1}{2}}{100}$  d. and for every pound weight 3  $\frac{5}{100}$  d. draw back 2  $\frac{33\frac{1}{3}}{100}$  d. Cow-

hides of Barbary and Muscovy pay each 7  $\frac{18\frac{1}{2}}{100}$  d. draw back 6  $\frac{46\frac{7}{8}}{100}$  d. And besides

if dressed in oil, for every pound weight 7 d. draw back 4  $\frac{66\frac{2}{3}}{100}$  d. if tanned, the

pound weight 3  $\frac{5}{100}$  d. draw back 2  $\frac{33\frac{1}{3}}{100}$  d. if tawed, the hide 3 s. 6 d. draw back 2 s.

2 s. 4 d. India hides pay each  $11 \frac{96\frac{2}{3}}{100}$  d.

draw back  $10 \frac{78\frac{2}{3}}{100}$  d. and besides if dressed

in oil, for every pound weight 7 d.

draw back  $4 \frac{66\frac{2}{3}}{100}$  d. if tanned, for each

pound  $3 \frac{50}{100}$  d. draw back  $2 \frac{33\frac{1}{3}}{100}$  d. if

tawed, for each hide 3 s. 6 d. draw back

2 s. 4 d. Hides of horses, mares and geld-

ings, pay for every 20 s. of their value

upon oath 4 s.  $9 \frac{4\frac{5}{6}}{100}$  d. draw back 4 s.

$3 \frac{7\frac{5}{6}}{100}$  d. and besides for every hide, 2 s.

draw back 1 s. 4 d. Losh-hides pay each

1 s.  $10 \frac{80}{100}$  d. draw back 1 s.  $9 \frac{33\frac{1}{3}}{100}$  d. and

besides for every pound weight, 7 d. draw

back  $4 \frac{66\frac{2}{3}}{100}$  d. Red or Mulcovy hides

tanned, coloured, or uncoloured, pay

each 1 s.  $7 \frac{1\frac{5}{6}}{100}$  d. draw back 1 s.  $5 \frac{2\frac{5}{6}}{100}$  d.

and besides for every pound weight, 3 d.

draw back 2 d. All other hides, and

pieces of hides, not above particularly

charged, pay for every 20 s. value upon

oath, 4 s.  $4 \frac{5}{6}$  d. draw back 4 s.  $3 \frac{7\frac{5}{6}}{100}$  d.

and if tanned, for every pound weight,

$3 \frac{50}{100}$  d. draw back  $2 \frac{33\frac{1}{3}}{100}$  d. if dressed in

oil, for each pound 7 d. draw back

$4 \frac{66\frac{2}{3}}{100}$  d. and if tawed, each hide pays

3 s. 6 d. and draws back 2 s. 4 d.

For the duty on british hides, tanned,

&c. See the articles EXCISE, LEATHER,

PARCHMENT, &c.

Hides and calves-skins, tanned in Great

Britain, draw back, upon due exportation,

two third parts of the duties originally

paid for them; and besides a farther

allowance of one penny for every

pound weight of skin so dressed, there is

a draw-back of  $1\frac{1}{2}$  d. for every pound

weight manufactured into boots, shoes,

gloves, &c.

**HIDE of land**, was such a quantity of land as might be plowed with one plough within the compass of a year, or so much as would maintain a family; some call it sixty, some eighty, and some an hundred acres.

The distribution of this kingdom by hides of land is very antient, mention being made of it in the laws of king Ina. Henry I. had three shillings for every hide of land, in order to raise a

VOL. II.

dowry for his daughter: this tax was called hidage.

**HIDE-BOUND**, among farriers, a distemper in horses when the skin sticks so fast to the back and ribs, that the hand cannot separate the one from the other without great difficulty: his body is at the same time lean, his back-bones stand up, his guts are for the most part deficient in moisture, and his dung dry and more offensive than common.

If a horse become hide-bound by hard riding and ill keeping, he may be cured by good keeping. If it be the effect of a fever, or some other disease, if that be cured which is the cause, the effect will cease: but if he has no fever upon him, and he is hide-bound only from lowness of blood and spirits, give him boiled barley, white-water, or the like, and when his flesh is raised, harden it with good oats, beans, and moderate exercise.

**HIDEL**, in old law-books, denotes a sanctuary or place of protection.

**HIDROTICS**, in medicine, the same with sudorifics. See SUDORIFIC.

**HIERACIUM**, HAWKWEEED, in botany, a genus of the syngenesia-polygamia-æqualis class of plants, the compound flower of which is imbricated and uniform, consisting of a great number of equal, hermaphrodite corollulæ, which are linear, truncated, and quinquecostate: the stamina are five very short capillary filaments: the seeds are solitary, obtusely quadrangular, and winged with down. See plate CXXXI. fig. 3.

The leaves of this plant are esteemed cooling, and good in inflammations. They likewise strengthen the sight.

**HIERACITES**, *hieracite*, in church-history, christian heretics in the third century, so called from their leader Hierax, a philosopher of Egypt; who taught that Melchisedec was the holy ghost, denied the resurrection, and condemned marriage: he likewise held, that no one could be saved who died before he arrived at years of discretion. The disciples of Hierax taught that the word, or son of God, was contained in the father, as a little vessel is contained in a great one; from whence they had the name metagimionists, from the greek word *μεταγμιον*, which signifies contained in a vessel.

**HIERA PICRA**, in pharmacy, a powder prepared in the following manner: take

9 X

of

of the gum extracted from socotrine aloes, one pound; of winter's bark, so called, three ounces; powder them separately, and then mix them.

*Species of HIERA PICRA*, according to Quincy, is made thus: take of cinnamon, zedoary, asarum, the lesser cardamom seeds, and saffron, of each six drams; cochineal, a scruple; of the best aloes, twelve ounces; and let them all be made into a powder together.

*Simple HIERA PICRA*, is made by mixing the spices of hiera picra with despumated honey, or syrup of violets, into an electuary.

*Tincture of HIERA PICRA*, is made thus: take of the species of hiera picra, one ounce; of white-wine, one pound; digest and then strain off the fine liquor. It may be made in the same manner with a french spirit.

This may be so managed as to become a good alterant. It is generally given over night from two to three ounces; and sometimes only one spoonful at night, and it produces excellent effects in a cachexy, chlorosis, and obstructions of the menses.

**HIERARCHY**, among divines, denotes the subordination of angels. See the article **ANGEL**.

Some of the rabbins reckon four, others ten, orders or ranks of angels; and give them different names, according to their different degrees of power and knowledge. Dionysius the areopagite, the jesuit Celert, and many others, have gone so far as to settle a kind of ceremonial or rule for the precedence of angels, as seraphim, cherubim, thrones, dominions, principalities, &c.

**HIERARCHY** likewise denotes the subordination of the clergy, ecclesiastical polity, or the constitution and government of the christian church, considered as a society. The nature of this polity will be best understood, by looking back to the constitution of the antient christian church; which, as a society, consisted of several orders of men, *viz.* ἡγούμενοι, πρεσβυτεροι, and κατηχημενοι; that is, rulers, believers, and catechumens.

Under the rulers are comprehended the whole body of the clergy, *viz.* bishops, priests, and deacons. See the articles **BISHOP**, **PRIEST**, &c.

The believers were perfect christians, and the catechumens imperfect. See the articles **CHRISTIANS** and **CATECHUMEN**. It has been pretended, says Broughton,

that the bishops and presbyters were the same, which opinion has given rise to the presbyterians. See **PRESBYTERIANS**.

The bishops, presbyters, and deacons, therefore, according to him, constituted the three superior orders of the clergy; besides whom there were several inferior orders, as subdeacons, acoluthists, exorcists, readers, door-keepers, singers, catechists, stewards, &c. See the article **ACOLUTHI**, &c.

All these orders of the clergy, continues the same author, were appointed to their several offices in the church, by solemn forms of consecration or ordination, and had their respective privileges, immunities, and revenues: and by means of this gradation and subordination in the hierarchy, the worship and discipline of the primitive church were kept up.

How far the constitution of our own churches agrees with or has departed from the plan of the antient hierarchy, may be seen at one glance of the eye. We have the first general distinction of bishops, presbyters or priests, and deacons. Among the first, we retain only the distinction of archbishops, with the title likewise of primates and bishops; having no patriarchs or chorepiscopi: but as to the inferior orders of the clergy, as acoluthists, &c. they are all unknown to the church of England.

The unity and order of the christian church were secured by laws both ecclesiastical and civil. The ecclesiastical laws were, either rules and orders made by each bishop for the better regulation of his particular diocese; or laws made in provincial synods, for the government of all the dioceses of a province; or, lastly, laws respecting the whole christian church made in general councils. See **SYNOD**. The civil laws of the church, were the edicts made from time to time by the emperors, either restraining the power of the church, granting it new privileges, or confirming the old; and the breach of these laws were severely punished both by the church and state.

**HIERES**, a town of Provence, in France, situated on the Mediterranean, eight miles east of Toulon: east long. 6° 5', north lat. 43° 5'.

**HIERES** is also the name of several islands situated in the Mediterranean, near the coast of France, opposite to the towns of Hieres and Toulon.

**HIEROGLYPHICS**, in antiquity, mystical characters, or symbols, in use among the

the Egyptians, and that as well in their writings as inscriptions; being the figures of various animals, the parts of human bodies, and mechanical instruments.

But besides the hieroglyphics in common use among the people, the priests had certain mystical characters, in which they wrapped up and concealed their doctrines from the vulgar. It is said, that these something resembled the chinese characters, and that they were the invention of Hermes. Sir John Marsham conjectures, that the use of these hieroglyphical figures of animals, introduced the strange worship paid them by that nation: for as these figures were made choice of, according to the respective qualities of each animal, to express the qualities and dignity of the persons represented by them, who were generally their gods, princes and great men, and being placed in their temples, as the images of their deities; hence they came to pay a superstitious veneration to the animals themselves.

The meaning of a few of these hieroglyphics, has been preserved by antient writers. Thus we are told they represented the supreme deity by a serpent with the head of a hawk. The hawk itself was the hieroglyphic of Osiris; the river-horse, of Typhon; the dog, of Mercury; the cat, of the moon, or Diana; the beetle, of a courageous warrior; a new-born child, of the rising sun; and the like.

**HIEROGRAMMATISTS**, *ἱερογραμματισταί*, *i. e.* holy registers, were an order of priests among the antient Egyptians, who presided over learning and religion.

They had the care of the hieroglyphics, and were the expositors of religious doctrines and opinions. They were looked upon as a kind of prophets, and it is pretended that one of them predicted to an egyptian king, that an Israelite, (meaning Moses) eminent for his qualifications and achievements, would lessen and depress the egyptian monarchy. They were thought to be skilled in amulets and charms, in astrology and augury: by this means they had a great sway in the egyptian senate or council, and were always at court to assist the king with their advice. They were exempted from the public taxes, were esteemed of the highest quality, and bore a scepter like the king's: but after the conquest of Egypt by the Romans, they became very inconside-

rable, and dwindled into mere fortune-tellers. They wore a linen-coat, and paper-shoes; they bathed thrice a day and twice in the night in cold water, and in their religious worship used to beat and discipline themselves very severely.

**HIEROMANCY**, *ἱερομαντεία*, in antiquity, that part of divination which predicted future events from observing the various things offered in sacrifice. See **DIVINATION** and **SACRIFICE**.

**HIEROMENIA**, in antient chronology, a corinthian month, commonly called panemos; being the same with the athenian boedromion.

**HIEROMNEMON**, the name of an officer in the greek church, whose principal function it was to stand behind the patriarch at the sacraments, and other ceremonies of the church, and to shew him the prayers, psalms, &c. in the order in which they were to be rehearsed. He likewise assisted the patriarch in putting on his pontifical vestments; and assigned their places to those who sat round him, when seated on his throne. This office, in this latter respect, was the same as that of master of the ceremonies to the pope. The hieromnemon was commonly a deacon.

**HIEROPHANTES**, in grecian antiquity, the name by which the Athenians called those priests and priestesses who were appointed by the state to have the supervial of things sacred, and to take care of the sacrifices.

They were obliged to the strictest continency, in regard to the dignity of their ministry; for which reason they drank decoctions of hemlock, to extinguish carnal desires.

The ceremonies of initiation, into the mysterious rites of Ceres, was performed by the hierophantes; whose names were held in such veneration, that the initiated were expressly forbidden to mention them in the presence of the profane.

**HIEROPHYLAX**, an officer in the greek church, who was guardian or keeper of the holy utensils, vestments, &c. answering to our sacrista or vestry-keeper.

**HIEROSCOPY**, the same with hieromancy. See **HIEROMANCY**.

**HIGH**, *altus*, a term of relation, importing one thing's being superior or above another: thus we say, a high mountain, the high court of parliament, high relief, &c. See the articles **MOUNTAIN**, **PARLIAMENT**, &c.

**HIGH**, in music, is sometimes used in the same sense with loud, and sometimes in the same sense with acute.

**HIGH bearing cock**, a term used in speaking of fighting cocks, for one that is larger than the cock he fights with.

**HIGH-WATER**, the state of the tide when highest, or the time just before it begins to ebb. See the article **TIDES**.

**HIGH-WAY**, a free passage for the king's subjects, on which account it is called the king's high-way, tho' the freehold of the soil belong to the lord of the manor, or the owner of the land. Those ways that lead from one town to another, and such as are drift or cartways, and are for all travellers in great roads, or that communicate with them, are high-ways only; and as to their reparation, are under the care of surveyors.

By the 2 & 3 Phil. & Mar. c. 8. it is enacted, that constables and churchwardens of parishes, calling the parishioners together, shall yearly elect two honest persons to be surveyors of the high-ways, who are thereby authorized to order and direct the persons and carriages employed in amending them: and the persons so chosen, are to take upon them the execution of the office, on pain of forfeiting 20 s. The same statute has farther ordained, that certain days shall be appointed for working on the repairs of high-ways, on which every person having a plough-land, or keeping a draught or plough, is to send out one cart, provided with horses, tools, &c. and two able men attending; also clergymen, keeping a coach and horses, shall be obliged to send out a team, or shall forfeit 10 s. for every default therein: and every householder or cottager shall work on the said days, for the amendment of the high-ways, under the penalty of 1 s. 6 d. a day, leviable by distress, &c. Where a high-way lies within a parish, the parish is bound to repair it, unless it appears that the same ought to be repaired by some person, either by reason of tenure or prescription. On oath made, by the surveyors, of sums expended in repairing any high-way, justices of the peace may order them a rate not exceeding 6 d. in the pound; but money thus raised, shall not excuse working on the high-ways, where the statute-work and labour has not been performed. 3 & 4. Wil. & Mar. If a high-way leading through a field is out of repair, travellers may justify going out of the track, tho' there

be torn down; and in case a high-way is not sufficient, any passenger may break down the inclosure, and go over the land adjoining, till a sufficient way be made. All manner of injuries to high-ways that render them less commodious to travellers, are deemed nuisances; such as laying logs of timber in them, erecting gates, or making hedges across them, permitting boughs of trees to hang over them, &c. Persons neglecting to scour their ditches, whereby the ways are dangerous, after thirty days notice given by the surveyors, are liable to the forfeiture of 2 s. 6 d. for every eight yards not scoured; and not under 20 s. or exceeding 5 l. if they permit soil to lie in the high ways. Geo. I. c. 52. Posts with inscriptions ought to be set up by surveyors, where two or more cross roads meet, as a direction to travellers to the next market-towns, on the penalty of 10 s. 8 & 9 Wil. III. 7 Geo. II. c. 9.

**HIGH-WAY-MEN**, are robbers on the high-way, for the apprehending and taking of whom a reward of 40 l. is given by the statute of 4 & 5 Wil. & Mar.

**HIGHAM-FERRERS**, a borough town of Northamptonshire, twelve miles north-east of Northampton: it sends two members to parliament.

**HIGHNESS**, a title given to princes. Before king James I. the kings of England had no other title but that of highness; which was also the case of the kings of Spain before Charles V.

At present all the sons of crowned heads are stiled royal highness, as the electors of Germany are electoral highness.

**HIGHWORTH**, or **HIGWORTH**, a market town of Wiltshire, situated thirty miles north of Salisbury.

**HIIS TESTIBUS**, a phrase antiently added in the end of a deed, written in the same hand with the deed; upon which the witnesses were called, the deed read, and their names entered. See the article **WITNESS**.

*Hiis testibus* in subject deeds, continued till, and in, the reign of Henry VIII.

**HILARIA**, an antient roman festival, observed on the eighth of the calends of April, or the twenty-fifth day of March, in honour of the goddess Cybele. It was so called from the various expressions of joy and mirth on this occasion. The statue of the goddess was carried in procession through the streets of the city. The day was spent in masquerades of all sorts, and every one was permitted to appear

appear in what disguise he pleased. The day before the festival was spent in tears and mourning; the reason of which was probably this: Cybele represented the earth which, at that time of the year, begins to feel the kindly warmth of the spring, and to pass from winter to summer; so that this sudden transmutation from sorrow to joy, was an emblem of the vicissitude of the seasons, which succeeded one another.

**HILARODI**, in the ancient music and poetry, a sort of poets among the Greeks, who went about singing little gay poems or songs, somewhat graver than the ionic pieces, accompanied with some instrument. From the streets they were at length introduced into the tragedy, as the *magodi* were into comedy. They appeared dressed in white, and were crowned with gold. At first they wore shoes, but afterwards they assumed the *crepida*; being only a sole tied over with a strap.

**HILARODIA**, a poem or composition in verse, made or sung by a sort of rhapsodists called *hilarodi*. See the preceding article.

**HILARO-TRAGEDIA**, a dramatic performance, partly tragic, and partly comic. Scaliger holds the *hilaro-tragedia*, and the *hilarodia*, or poem sung by the *hilarodi*, to be the same thing. Others rather take the *hilaro-tragedia* to have been pretty nearly what we call a *tragicomedy*. Others again will have it to have been a pure tragedy, only terminating with a happy catastrophe, which brings the hero out of the wretched into the fortunate state. Suidas mentions one *Rhinton*, a comic poet of Tarentum, as the inventor of this kind of poetry.

**HILARY-TERM**, among lawyers. See the article **TERM**.

**HILDESHEIM**, the capital of a bishopric, surrounded by the territories of Brunswic, and subject to its own bishop: east long. 10°, north lat. 52° 17'.

**HILL**, in the natural history of the earth. See the article **MOUNTAIN**.

**HILUM**, among botanists, denotes the eye of a bean. See **BEAN** and **EYE**.

**HIN**, a hebrew measure of capacity for things liquid, containing the sixth part of an epha, or one gallon two pints, or 2.533 solid inches, english measure.

**HIND**, a female stag in the third year of its age.

**HIND-CALF**, a male-hart or hind in the first year. She fawns in April or May. See the article **HUNTING**.

**HIND**, or **HINE**. See the article **HINE**.

**HIND HAND**, in the manege. See the article **HAND**.

**HINDENI HOMINES**, signifies a society or class of men.

In the time of our Saxon ancestors, all men were ranked into three classes, and rated agreeably to the classes they were in; and if any one committed an injury, he was to make reparation according to the value of the person to whom it was done. The lowest were those worth 200 shillings, who were called *viriducenti*, or *twybindemen*, and their wives *twybindas*. The middle were valued at 600 shillings, and were termed *sixbindemen*, and their wives *sixbindas*: and the highest were valued at 1200 shillings, and were stiled *twelfbindemen*, and their wives *twelfbindas*.

**HINDON**, a borough town of Wiltshire, situated fourteen miles west of Salisbury: it sends two members to parliament.

**HINDOWN**, or **HENDOWN**, the capital of the country of the Hindowns, in the hither India: east long. 76° 30', north lat. 27°.

**HINE**, or **HIND**, a husbandman's servant. Thus the person who oversees the rest, is called the master hine.

**HINGES**, the joints on which gates, doors, lids, folds of tables, &c. hang and turn in opening, shutting, or folding. They are of different denominations, as butts, used by the joiners for hanging table-leaves, &c. (See plate CXXXII. fig. 1. n° 1.) Casement, for hanging casements upon (*ibid.* n° 2.) dove-tails, (n° 3.) and eses (n° 4.) for light doors and lockers; garnet cross, for hanging large doors or heavy scuttles in ships (n° 5.); port, for hanging ships ports (n° 6.); scuttle, particularly used for scuttles (n° 7.)

Thus these there are many others of different forms and uses, distinguished by different names, as casting, chest-black Lancashire, smooth-field coach, desk, dozen ware long, dozen ware short, weighty long, weighty short, lambs-heads, port side Lancashire, side smooth-field, side with squares, side with rising joints, Lancashire and smooth-field stalls; beds, box, trunk of several kinds; screw, shutter, Lancashire joints, and Lancashire dozen-ware with books.

Hinges of all kinds are prohibited to be imported.

**HINGHAM**, a market-town, ten miles south-west of Norwich.

**HINK**.

**HINKLEY**, a market-town, ten miles south of Leicester.

**HIP**, or **HAW**, in the materia medica, is reputed attenuant and diuretic. There is a very pleasant conserve of hips kept in the shops.

**HIP**, or **HAUNCH**, among farriers. See the article **HAUNCH**.

**HIP-SHOT**, is said of a horse that has sprained his haunches. See **STRAIN**.

**HIPS** in building, those pieces of timber placed at the corner of a roof.

The hips are much longer than the rafters, by reason of their oblique position, and are planted not with a right or square angle, but a very oblique one, and consequently are not, or at least ought not, to be square at any angle, (as rafters are not at all) but level at every one of them; and, which is more, as rafters have but four planes, these commonly have five. They are generally by country workmen called corners; and some call them principal rafters, and others sleepers. The truth is, hips and sleepers are much the same, only sleepers lie in the vallies, (and join at the top with the hips) but those surfaces or planes which make the back of the hip, are under the sides of the sleeper.

The backs of a hip are those two superficieses or planes on the outside of the hip, which lie parallel, both in respect of the length and breadth, with the superficieses of the adjoining side and end of the roof.

**HIP-GOUT**, *sciatica*. See the articles **GOUT** and **SCIATICA**.

**HIP-MOULD**, is by some used for the back of the hip, but others understand it to mean the prototype or pattern, commonly made of a thin piece of waincoat, by which the back and sides of the hip are set out.

**HIP-ROOF**, among carpenters, called also italian roof, is a roof which has neither gable-head, spread-head, nor jerken-head (by which is meant such heads as are both gable and hip at the same end;) for it is a gable or upright as high as the collar-beam, and then there are two short hips, which shut up with their tops to the tops of a pair of rafters, which country carpenters call singlars. A hip-roof has rafters as long, and with the angles of the foot, &c. at the ends of buildings, as it has at the sides; and the feet of the rafters at the ends of such buildings as have hip-roofs, stand on the

same plane, *viz.* parallel with the horizon, and at the same height from the foundation, with rafters on the sides of the roof.

**HIPPARCHUS's PERIOD**. See **PERIOD**.

**HIPPEUS**, in physiology, a kind of comet, so called from its resemblance to a horse. But the shape of this comet is not always alike, being sometimes oval, and sometimes imitating a rhomboides. Its train also is sometimes spread from the front, or fore part, and sometimes from the hind part.

Hence this class of comets is distinguished into equinus barbatus, equinus quadrangularis, and equinus ellipticus. See the article **COMET**.

**HIPPO**, in zoology, a species of serpent, with 160 scuta on the abdomen, and 100 squamæ on the tail. See **COLUBER** and **SERPENT**.

**HIPPOBOSCA** and **HIPPOBOSCUS**, in zoology, names given to the horse-fly, frequent about the bodies of horses, to whom it is very troublesome.

**HIPPOCAMPUS**, the **SEA HORSE**, in ichthyology, the square-bodied syngnathus, with no fin at the tail. It is five inches long, and where thickest, about an inch in diameter; the head is long, slender, and compressed, forming a kind of snout; the body is of a quadrangular figure, but the divisions are not equal, and in the thickest part it is hexangular or heptangular. See **SYNGNATHUS**.

It is a very singular and rare fish; the tail of which usually curls up in the drying, and its head being bent down, gives it a rude resemblance to a horse; whence the name. See plate **CXXXII. fig. 3.**

**HIPPOCASTANUM**, **HORSE-CHESNUT**, the same with the *esula* of Linnæus. See the article **ESULA**.

**HIPPOCENTAUR**, in antiquity, a fabulous animal, half man half horse.

What gave rise to the fable of hippocentaurs, was this. The Thessalians are said to have been the first inventors of the art of breaking horses; and being first seen on horseback, they seemed to make but one body with the horses; whence the origin of the fable.

**HIPPOCRAS**, an infusion of aromatic powders in wine, which is afterwards edulcorated with sugar and honey; being so called because that, when the infusion is finished, it is strained through Hippocrates's sieve.

It is prepared of various aromatics and other

Fig. 1. HINGES.

Fig. 2. HIPPOPOTAMUS.

Fig. 3. HIPPOCAMPUS.

Fig. 4. HIRUDO, the LEECH.

Fig. 5. HIS TRIX, the PORCUPINE FISH.

other ingredients, according to the different intentions to be answered.

**HIPPOCRATEA**, in botany, a genus of plants, whose characters are not justly ascertained: the calyx is a perianthium formed of a single leaf, patent, and lightly divided into five obtuse segments, larger than the corolla; the corolla is monopetalous, oval, truncated at the top, and undivided at the edges: the fruit is a capsule of a depresso-plane figure, patent, semitrifid, with trifid segments; and contains three cells, each of them bivalve, and the valves carinato-compressed: the seeds are oblong, and have a membranaceous ala.

**HIPPOCRATES'S SLEEVE**, a bag used to strain syrups and decoctions for clarification. See **CLARIFICATION**.

**HIPPOCREPIS**, COMMON HORSESHOE VETCH, in botany, a genus of the diadelphia-decandria class of plants: the corolla is papilionaceous; the vexillum cordated, seated in the unguis the length of the cup; the carina is lunulated and compressed: the fruit is a compressed plane pod, very long and reflex, and jointed: the seed is single in each joint, of an oblong and incurved figure.

**HIPPODROME**, in antiquity, the course where horse-races were performed.

**HIPPODROMUS**, in grecian antiquity, the boeotian name for the athenian month hecatombæon. See **HECATOMBÆON**.

**HIPPOGLOSSUS**, the TURBOT, in ichthyology, a species of pleuronectes, with the eyes on the right side, and the body smooth.

It grows to a considerable size, and is one of the most esteemed fish at our tables. The dorsal-fin reaches from the head to the tail, and has an hundred and five rays; the pectoral fins have each sixteen rays, and the ventral ones six. See the article **PLEURONECTES**.

**HIPPOMANE**, in botany, a genus of plants whose characters are not properly ascertained; the male and female flowers are produced distinct; the male flower has no corolla: the fruit is a large, globose berry, somewhat umbilicated, and containing only one cell: the seed is round and woody. The eating of this plant is said to make horses mad, whence its name *ἵππομανές*.

**HIPPOMANES** signifies the expressed juice of the tithymallus; as also a juice distilling from the genitals of a mare, in the time of her covering: some again take it for the secundines of a mare; and,

lastly, it signifies a fleshy substance adhering to the forehead of a colt newly foaled, which some imagine to have a virtue of procuring love, and promoting the birth.

**HIPPOMYRMEX**, the HORSE-ANT, in zoology, a species of ant, much larger than the common ant. See **ANT**.

**HIPPOPHAE**, the SWALLOW-THORN, or SEA BUCK-THORN, in botany, a genus of the dioecia-tetrandria class of plants, having no corolla; the calyx of the male flowers is divided into two parts, as is also the calyx of the female: the fruit is a globose, unilocular berry; the seed is single and roundish.

Hippocrates prescribes the juice of this plant to evacuate white phlegm; and also as a cathartic in other disorders.

**HIPPOPOTAMUS**, the RIVER-HORSE, a genus of quadrupeds, of the order of the jumenta, the characters of which are these: the fore teeth of the upper jaw are four, and placed in pairs; those of the lower jaw are prominent, and the intermediate ones are protended forward; the canine-teeth are single, and obliquely truncated; the teats are only two, and placed near the groin.

The hippopotamus is a native of Africa, passing a great part of its time under water, in the rivers of the Nile and Niger; but comes on shore to sleep and breed. It is a large unweildy animal, as big as an ox. See plate CXXXII. fig. 2.

**HIPPURIS**, in botany, a genus of the monandria-monogynia class of plants, having no corolla: the cup is scarce distinguishable; it consists of only two extremely small margins, standing opposite to one another on the head of the germen: there is no pericarpium; but after every flower there comes a seed, which is roundish and naked.

**HIPPURUS**, in ichthyology, the dolphin or coryphæa with a forked tail. See the articles **DOLPHIN** and **CORYPHÆA**.

**HIRCANIA**, in geography, the provinces of Persia in Asia, which lie on the southern shore of the Caspian sea.

**HIRCHFELD**, a city of Germany, in the circle of the upper Rhine, and langravate of Hesse Cassel, situated on the river Fulda, in east long. 9° 32', north lat. 50° 47'.

**HIRCI**, or **SANGUIS HIRCI**. See the article **SANGUIS**.

**HIRCUS**, in anatomy, a part of the auricle or outer ear, being that eminence next the temple. See **EAR**.

**HIRCUS**, a GOAT, in astronomy, a star of the

the first magnitude, the same with capella.  
See the article **CAPELLA**.

**HIRCUS** is also a name used by some writers for a comet encompassed, as it were, with a mane, seemingly rough and hairy.

**HIRCUS**, a denomination given to the rank smell exhaling from the armpits.

**HIRSBURG**, a town of Silesia, in the territory of Jawer, forty-four miles south-west of Breslaw, in east long. 15° 50', north lat. 50° 50'.

**HIRTELLA**, in botany, a genus of the triandria-monogynia class of plants, the corolla whereof consists of five equal petals: these are roundish and hollow, smaller than the cup, and deciduous: the fruit is an oval berry, broadest at the top, a little compressed, and obscurely trigonal: the seed is single, and of the figure of the cup.

**HIRUDO**, the **LEECH**, in zoology, a well known naked insect, with a flattened but not jointed body, and broader at the end than elsewhere, and the skin soft and glossy.

The common leech grows to two or three inches in length, and is of a blackish colour, variegated with yellow. See plate **CXXXII.** fig. 4.

The horse-leech is larger than the former species, black on the back, and lead-coloured on the belly. The snail-leech, is only about an inch in length, and of a whitish colour; and the great-tailed leech grows to an inch and an half in length, and is of a dusky-brown colour. See the article **LEECH**.

**HIRUNDO**, in ornithology, a genus of birds, of the order of the passerines; comprehending the common house-swallow, the field swallow, the martin, and the goat sucker.

The characters of the genus are these: the beak is very small, of a subulated figure, crooked, and depressed at the base; and the opening of the mouth is enormously wide.

The common swallow is about the size of the linnet: the upper part of the body is of a glossy bluish-black, the tail-feathers are spotted with white, and the breast and belly are of a snow-white.

**HIRUNDO**, the **SWALLOW-FISH** or **TUB-FISH**, in ichthyology, a species of trigla, with a somewhat prickly head, and with a remarkable pinnule at the pectoral fins: which are so long, as to be of use in flying, or raising itself above the water. Hence, by some inaccurate writers, it has been confounded with the exocoetus, or flying-

fish, properly so called. See the article **EXOCOETUS**.

**HISPANIOLA**, an island of America, in the Atlantic ocean, situated between 67° and 74° of west long. and between 18° and 20° north lat. being about 420 miles long from east to west, and 120 in breadth. It is frequently called St. Domingo, from the capital thereof.

**HISPID LEAF**, among botanists, on whose surface is covered with more thick and rigid hairs than the pilose leaves are.

**HISPID STALK**, among botanists, a stalk roughly hairy.

**HISSING LETTERS**, among grammarians, are S, X, and Z, so called on account of their harsh sound.

**HISTORICAL**, something that relates to history: thus we say, historical truth, historical style, historical narration of facts, &c. See the article **HISTORY**.

**HISTORIOGRAPHER**, a professed historian, or writer of history.

An historian of all authors spreads the most ample theatre; he erects the greatest tribunal on earth; for it is his office to sit supreme judge of all that passes in the world, to pronounce the destiny of the great ones of the earth, and fix their character with posterity; to do justice to virtue and worth, in bestowing eternity upon great and good actions, and fixing an everlasting mark of infamy on bad ones; to instruct all people and nations, and direct the conduct of ages; he therefore ought to be endowed with many great and uncommon qualifications. He must be a person of consummate knowledge of men and things, of sound judgment, uncommon sagacity and penetration, experienced in matters of state and war, of great integrity, firmness of mind, freedom of sentiment, and master of a pure, clear, nervous, and exalted style. An historian whose province it is to speak to kings and princes, to the great men of all ages and countries, and to be the common master and instructor of mankind, must not only write with purity, simplicity, and manly sense, but with dignity and elegance: he must reject all that is vulgar and low in style, make the majesty and sublimity of his expression comport with the dignity of his subject; must by an exact choice and propriety of words, a natural disposition of phrases, and a prudent moderate use of figures, give weight to his thoughts, force to his language, and imprint a character of greatness on all that he says. He must

at the same time represent things with an air of gravity and prudence, and not give a loose to the heat of imagination, or vivacity of wit; but discreetly suppress every thing that shall seem idle, languid, and unprofitable, and give every thing that just figure and proportion which is consistent with propriety and decorum. He must endeavour at a noble simplicity of thought, language, design, and ordinance, and carefully avoid all profuseness of false conceit, strained expression, and affected pompousness so inconsistent with the gravity, dignity, and noble character of history. In a word, he must write so as to be intelligible to the ignorant, and yet charm the wise; form and express such ideas as are great, and yet shall appear very common, and intermix no other ornament with his narration than what the modesty of truth can bear. He should be above the reach and power of hopes and fears, and all kinds of interest, that he may always dare to speak the truth, and write of all without prejudice; religiously observing never to abuse the public faith, nor to advance any thing upon common fame, which is always uncertain, but upon undoubted memoirs and faithful relations of such persons as have had a hand in affairs. He must always be upon his guard against the bias and affections of those who supply him with matter, and must not credulously give his assent to the historians that went before him, without enquiring narrowly into their character, and what influence they may have been under when they wrote, in order to make a just estimate of their weight and credit.

An historian, as to his matter, should choose subjects great in themselves, and such as are worthy of public fame and remembrance; and should make himself so far master of his matter, as to be able to cast it into what form he pleases, and to strike upon all his subjects the colours they are naturally disposed to bear, in order to make his lessons profitable to posterity, by regulating the heart and spirits of men, animating them to great and virtuous actions by illustrious examples, and cautioning them against vice, folly, cruelty, and injustice, by laying open the fatal consequences resulting from them. The course of his narration must proceed in the order of time in which the facts happened, in a pure, grave, uninterrupted series, such as may not improperly be compared to a great

VOL. II.

river flowing with composed majesty and stately smoothness; and when it falls in his way to introduce little occurrences, they must be so artfully interwoven with the great, in the thread of the narration, as to offer a seasonable entertainment and relief to the reader from the fatigue that too sedulous an attention to the great, requireth. He must also observe great judgment in the ordinance and disposition of events and their circumstances, so as to interest the reader, and let him into all his thoughts and views, by making his persons act as their character and temper inclined them; discovering their manners, sentiments, designs, motives, and operations as they really stand in a necessary dependence upon each other, and with so natural a connection, as to show nothing out of its place. His transitions, in which consists the great art of narration, and one of its principal beauties, must be natural and easy, arising from the difference of subject rather than expression. He must make a wise and judicious choice of circumstances, such as are proper to enlarge and improve the ideas of things, and to strike that light and colour upon them which most easily attracts belief and engages the mind; and must for that purpose always observe a due mixture of great and little circumstances, neither of which must be carried beyond nature, or be so minute, low, or frivolous, as to debase his subject. He must not only recite the bare events and actions of men, but also lay open the motives and principles from which they took their rise, and upon which they proceeded to their final issues. He must lay open the hearts of the actors, let his reader into the most important secrets of their councils and designs, and oblige him with a sight of those secret springs, which moved them to enterprizes, and of the causes of their success or miscarriage. He must be very sparing and cautious in the use of descriptions, which are to be introduced so far only as they serve to illustrate things that are essential to the main subject, and to enliven the narration: and even in that case, they must be succinct and elegant. The frequent use of harangues is disapproved of by many judicious persons; for these long formal harangues of generals to their soldiers, when in the presence of the enemy, and ready to enter upon action, which we find in many historians, are undoubtedly not only unnatural and

9 Y

impro-

improbable, but contrary to the truth of history. Nevertheless, a short speech suited to the subject, made by a person of eminent character has its proper beauty and animates a narration. A judicious historian ought not to admit any portraits into his work but those of the greatest persons, and such as are principally interested, and have the chief hand in affairs; and these must be real, natural and truly resembling their originals; expressive of their genius, the qualities of the head and heart, rather than descriptive of the external form of his personages. When such are finished with a masterly hand, with true judgment and success, they are not only great ornaments and embellishments in history, but of use to strip the hearts of men of their disguises, to lay open all their secret folds, and disclose the real springs of actions. It is a great fault in an historiographer to abound too much in reflections of his own; he therefore must not turn philosopher or moralist indifferently upon all occasions; for every man desires to be free in his judgment of the facts represented to him, and the consequences he is to draw from them, in which consists the greatest pleasure of the reader. But if an author should throw in, or mingle reflections of his own with his story, they must be such as arise naturally from the subject, and contain a great and noble sense in a few words; they must not be too fine spun or studied, nor have more brightness than solidity, but appear rather to be the reasoning of a wise statesman, than the affectation of a declaimer; nor must they be too frequent, or too loose and disjointed, but be enamelled in the body of the work. Digressions, if made with judgment, and not too wide and foreign from the subject, have also their proper grace and ornament in history; as they give an agreeable variety to the narration, and relieve the mind of the reader; but they must be introduced by the historian with an artful hand and great address; they must bear an alliance and connection with the purport of the history, and their length must be proportionably greater or less, as they are more nearly or remotely allied to the capital point of the story.

**HISTORY**, a description or recital of things as they are, or have been, in a continued, orderly narration of the principal facts and circumstances thereof.

History, with regard to its subject, is divided into the history of nature, and the history of actions. The history of nature (which is much the same with physiology) is a description of natural bodies, whether terrestrial, as animals, vegetables, fossils, fire, water, air, meteors, &c. or celestial, as the stars, planets, comets, &c. History of actions is a continued relation of a series of memorable events.

History with regard to its matter, is either natural, sacred, civil, ecclesiastic, literary, or personal. Natural history, is a description of the singularities of nature; its irregularities and prodigies; and the alterations it undergoes in the birth, progress, end, and use of things. Sacred history, is that which lays before us the mysteries and ceremonies of religion, visions or appearances of the deity, miracles and other supernatural things, whereof God alone is the author. Civil history, is that of people, monarchies, states, communities, cities, &c. Ecclesiastic history, is that which gives an account of the rise and establishment of the several religions and churches, of the rise and progress of the various opinions sects and heresies, &c. Literary history treats of arts and sciences, their original progress, and of the persons who have been most remarkable in discovering and promoting them. Personal history, is that which gives the life of one or more single persons, and is the same with what is called biography.

History with regard to its form, is either simple, figurate, or mixed. Simple history, is that which is delivered without art or ornament; being only a bare, and faithful recital of things, in the manner and order wherein they passed. Figurate history, is that which is further enriched with ornaments, by the wit and ingenuity of the historian; by laying open the characters of the principal persons, the secret springs and motives of the several events, &c. Mixed history, is that which besides the recital and ornaments of figurate history, calls in the proofs and authorities upon which the facts are founded; furnishing authentic memoirs, or original letters, manifestos, &c. to vouch the truth of what is advanced. See HISTORIOGRAPHER.

*Credibility, foundation, and nature of HISTORY.* Some choose to define history, a true and well grounded account of

of past events ; a definition equally applicable to all the kinds of it : for tho' in some of them, as the history of nature and literature, we meet with accounts of qualities and opinions ; of works of nature and art ; yet these have no other relation to history than as they are events, and are deduced from observations on past changes. And as to the grounds on which the credibility of an history is founded, they are derived partly from the events related, and partly from the evidence and character of such as relate them ; whence arises an internal and external credibility.

The interior credibility consists not only in the possibility of the event reported, but likewise in its probability ; which last consists in this, that the circumstances in which an event is reported to have happened be conformable or suitable thereto, or that there be some foundation for it in the connection of the circumstances, and that in parallel cases the same had frequently happened. Hence it is easy to conceive, that many events may appear improbable, nay incredible to some, through mere ignorance, or by separating them from their circumstances. This is the case with the frequent charges of incredibility brought against those numerous armies we read of in antient history, from confounding the regular armies of the moderns, with the tumultuous ones of the antients ; which were a kind of militia composed of all or the greater part of the fighting men of a country.

Under the external grounds of credibility are comprehended the genuineness of the original testimony, and the capacity and integrity of those who relate it : the evidence alledged must not only be ascribed to its true authors, but these must appear to be persons so circumstanced and inclined as to relate the truth, so as to add to it nothing false, nor omit any thing of consequence to the event reported. The first of these, or the genuineness of the original testimony, affects not only books and tracts, but public records and monuments of past events, statues, inscriptions, columns, edifices, &c. And to detect the fraudulent practices of former times, in forging evidences of this kind, requires great knowledge in the history not only of human societies, but of the opinions, sciences, languages, and customs of different times. And hence appears the ne-

cessity of great penetration, and capacity in an historian ; but above all, of great integrity and sincerity in relating the truth.

In trying the credibility of an event by the number of evidences brought in support of it, we ought to weigh : 1. How many historians, and other known sources, are really extant of any particular event. 2. The actual diversity of their testimonies. 3. Their agreement and contradiction ; and whether they cannot be reconciled. 4. The exterior and interior credibility of the contradicting narrations.

From what has been said, we may draw the following inferences. 1. That there is a real and demonstrable certainty of events, which ought not to be doubted or contested : and, indeed, scepticism in historical matters most commonly, if not always, proceeds from ignorance of the real nature of that certainty and its criterion, or from a consciousness of the indispensable necessity of unwearied diligence, of farther helps, and deeper reflection in examining and proving, than the conveniency of many will allow. 2. That the demonstrability of a fact, the credibility of an historian who reports, and the evidences of his whole work, ought never to be confounded or mistaken for one and the same thing : for an historian may be well worth credit, tho' he be not infallible, and even though he has actually committed errors in some of his reports. 3. The demonstrability of events has different degrees and limits, as reaching only so far as the records preserved will permit : and hence appears the necessity of well distinguishing such events, the reality or falsity of which can be proved, from events that are at best uncertain and doubtful. 4. That the credibility of events may gain new strength is evident ; since many facts cannot be known, till after the death of such as were either the actors or persons concerned in them : besides it frequently happens, that records and vouchers of transactions, long since past, are afterwards discovered, which till then were either unknown, or could not be confidently published by those who knew them, for want of such witnesses and proofs. 5. The credit of history can never decay by age, as some have erroneously asserted ; since facts, once established upon good evidence, must ever remain so, while the vouchers of such evidence are pre-

served : nay an account which formerly was uncertain, or even considered as improbable or false, may be vindicated and proved by late discoveries of historical writings and records.

*Usefulness of HISTORY.* That great advantage may be reaped from the study of history, will appear from the following considerations. 1. It proves an agreeable amusement, and relaxation: for though the mind is not wholly unactive in the study of history; yet, being a lighter and more entertaining employment, the faculties of the mind, when fatigued and almost exhausted with more intense employment, find actual repose, and are recruited and restored to vigour. 2. But beside the pleasure of studying history, it lays a foundation not only for general prudence, but for that particular kind, which the circumstances and situation of each man require. To become acquainted with the characters of men, the marks, sources, and effects of their passions and prejudices, the power and changes of their customs, and the like, is an essential and necessary step to prudence: and all this knowledge is considerably improved by history, which teaches us to make other men's experience our own, to profit by it, and to learn wisdom from their misfortunes. 3. History is of eminent use in promoting virtue, partly by a copious and pleasant instruction in a right and virtuous conduct in general, and partly by examples that intensify lead us to the practice of several virtues in particular. 4. Every other science receives great benefit from history. Philosophy, and practical mathematics have recourse to history, or to nature, through the medium of history, for most of their objects; and in many parts of these sciences, the whole force of the demonstration is founded on experiments; which would make but an indifferent figure, if the assistance of other men's experiments by the means of history were excluded: and the same holds of divinity, law, medicine, &c.

*Method of studying HISTORY.* Persons who read history merely for amusement, or, having in view some particular branch of learning, attend only to certain branches of history, are not confined to that order and connection, which is absolutely requisite for obtaining a proper knowledge of history; the most regular, as well as successful way of studying which, is, to begin with an epitome of universal

history, and afterwards apply to the history of particular nations and common-wealths: for the study of particular histories presupposes, or, to speak more properly, is only extending the knowledge of particular parts of universal history. Unless this be our plan, we shall only fill the memory with some events; which may be done without applying to history, or pretending to the knowledge of it.

**HISTORY**, in painting, denotes a picture composed of divers figures, or persons, representing some transaction, either real or feigned. See **PAINTING**.

**HISTRIO**, in the antient drama, signified an actor or comedian, but more especially a pantomime, who exhibited his part by gestures and dancing. See the article **DRAMA**.

**HISTRIX**, the **PORCUPINE**, in zoology. See the article **PORCUPINE**.

**HISTRIX**, the **PORCUPINE-FISH**, in ichthyology, the rough spotted ostracion, or globe-fish, beset with frequent small spines.

It grows to about twelve inches in length, and to eight or nine in diameter. It is brought to us dried from the eastern seas, and has been sometimes caught in the Mediterranean. See plate **CXXXII**. fig. 5.

**HITCH**, in the sea language, is to catch hold of any thing with a hook or rope, and by this means to hold it fast: thus when a boat is to be hoisted in, the sailors say, hitch the tackles into the ring-bolts of the boat; and when they are about to weigh anchor, hitch the fish-hook to the fluke of the anchor.

**HITCHEL**, or **HATCHEL**. See the article **HATCHEL**.

**HITCHING**, a market-town in Hartfordshire, fourteen miles north-west of Hartford, and thirty-two north-west of London.

**HITHE**, or **HYTHE**, in our old writers, denotes a port, wharf, or small haven, to embark, or land wares at; as *Queen-lithe*, &c.

**HITHE** is also one of the Cinque Ports in the county of Kent, situated on the english channel, six miles west of Dover.

**HIVE**, *alvare*, in country affairs, a convenient receptacle for bees. See **BEE**. There are several sorts of hives used in different counties of England, as wicker-hives, made of privet; willow, or hart-hives, daubed with cow-dung tempered with dust; or hives made with straw

straw bound with brambles. Some also, out of curiosity to see the bees work, have them made of wood with glass-windows, or sides; but these are very cold, so that bees seldom thrive in them. The most usual form of them is coical, or bell-shaped; and the best and warmest materials for making them are straw and oser, nicely twitted and matted together. Of these there should be kept several sizes, so as to suit a bigger or lesser swarm; and where you design to multiply your stock, make use of the small ones, and of the larger where you desire a great deal of honey. See **HIVING**, and **HONEY**.

**HIVING** of Bees, the placing a swarm of them in a hive, provided for that purpose. See the article **HIVE**.

When a swarm of bees has left an old hive, and is placed in the form of a cluster hanging down from the branch of some tree or shrub, turn up the hive, and shaking the bough, make them fall into it, and then set the hive upon a cloth on the ground; or if the bough be small, you may cut it off, and laying it on the cloth, set the hive over it: but if the bees are fixed on a branch near the ground, lay the cloth under it, then shake them down and place the hive over them. If it happen that some bees will obstinately keep to the place where they at first fixed themselves, after having tried in vain to sweep them off gently with a brush, rub the branch with the juice of wormwood, rue, elder, or of such other plants as they hate the smell of, and if this does not succeed, linen rags must be burnt under them, the smoke of which will soon drive them off, and make them join their companions. It sometimes happens, that the swarm is not placed so favourably as in the instances before-mentioned; they often hang themselves in long clusters, on the small branches of high trees, and in this case, many different expedients are to be used to have them, according to the circumstances of their position. The common method is for one man to climb the tree with a long staff in his hand, and another to mount a ladder placed against the tree, and to hold the hive under the swarm, while the other sweeps them into it with the staff; and when the bough on which they hang is so far from the body of the tree, that this is impracticable by the ladder, the hive is to be fixed to the end of a long pole, and by that

means held under the swarm while they are swept into it. When all this is impracticable, by reason of the great height of the branch on which the swarm hangs, a large cloth is to be spread on some of the lower branches, and the whole swarm swept down in a cluster upon it; this is then to be thrown carefully to the ground, and another person is to be ready there to warm the hive over the greater part of the cluster, and the rest will soon creep into it, and join them. If they are slow in doing this, they are to be driven in by burning linen rags about the places where they fly, the disagreeable smell of which will send them towards the hive, where finding their companions not incommoded with it, they will naturally remain.

Sometimes the bees that go out in a swarm fix upon a hole in a wall, or a hollow in the trunk of a tree. This is a much better choice for them than the branch of a tree; but it is much worse for the person who is to have them, for they are very difficult to be got out. The common way is to attack these swarms in the middle of a cold night, to enlarge the opening from without, and placing the hive under it, to scoop the bees out with a ladle, and put them into the hive.

It sometimes happens, that the swarms part, and light in sight of one another; in which case, if the lesser part are disturbed, they will fly to the greater: but if they are not in sight of each other, have them both in two several hives, and shaking the bees out of one hive on the cloth on which the other hive stands, place that hive over them, and they will all take to it.

If your swarm happens after the middle of June, and are small, put two or three of them together, even whether they arise the same day, or several days after; for by thus uniting them, they will labour the more carefully, gather store of honey, and stoutly defend themselves against all enemies. As to the manner of uniting them in one hive, it is thus performed: having spread a cloth on the ground, near the stool on which this united swarm is to stand, set a pair of rebs, or two supporters for the hive; then in the evening when it grows dark, knock down the hive out of which you intend to remove your bees upon the rest; then lift up the hive a little, and clapping it between your hands to shake out the bees that stick in it, lay it down sideways by those insects,

and

and set the stock or swarm to which you would add them, upon the refts over them; upon which they will immediately afcend from the cloth underneath into the hive, and if any remains in the other hive, they will haften after their companions. When you have gotten them all in, place the hive on the ftool, which fhould be done either that night, or early the next morning. Some reckon it better to place the hive in which the fwarm is newly put, with a view to its being drove into another, with the fkirts up-permoft, and to fet the other upon it, binding them about the fkirts with a towel, and in this manner to let them ftand till the morning, by which time all the bees will have afcended, fo that you may then fet the receiver on a ftool. Thus three or four fwarms may be put together. But they ought to be united the fame evening after they have fwarmed; becaufe after having made combs, they are the more unwilling to part from them. In thefe feveral methods of hiving bees, people ought to defend themfelves as carefully as poffible againft their ftings; the feureft way of doing which, is to have a piece of gauze, or coarfe mullin, large enough to come over the perfon's hat, and to reach down to the collar of his coat behind, and to his breaft before, which being kept at a little diftance from his face by his hat, he may fee what he does without the leaft danger: he ought alfo to fecure his hands by wearing a good pair of gloves; and woollen ones are the beft for this purpofe.

**HOACHE**, in natural hiftory, a kind of earth approaching to the nature of chalk, but harder, and feeling like foap; whence fome think that it is either the fame with our foap-rock of Cornwall, or very like it. The Chinefe difsolve it in water, till the liquor is of the confiftence of cream, and then varnifh their china-ware with it.

**HOACTLI**, in zoology, the name of an american bird defcribed by Nieremberg: it is of the fize of a common hen, the legs and neck are long; its head is black, and is ornamented with a beautiful creft of the fame colour; its whole body is of a fine white, but its tail is grey, as are alfo the upper fides of its wings; the wings have a greenifh caft, and the back fometimes has many black feathers; its feet are not webbed, its legs are of a pale whitifh colour; it has a circle of white, beginning at the eyes, and going round the head: it is common on the lakes of

Mexico, and builds among reeds and fedge. It bites very defperately.

**HOAR-FROST**. See **FROST**.

**HOAR-HOUND**, or **HOREHOUND**, *marrubium*, in botany. See **MARRUBIUM**.

**HOARSENESS**, *rauvedo*, in medicine, a diminution of the voice, fometimes attended with a preternatural afperity, or roughnefs thereof.

The part here affected, is the afpera arteria, and its larynx, which laft chiefly forms the voice. See the articles **ASPERA ARTERIA**, and **LARYNX**.

The proximate caufe is too great an effufion of thin lymph upon the part. It is a catarrhal affection from a too fharp falt, or acid lymph. Etmuller, in a very obftinate hoarfenefs, prefcribes fpermaceti as an approved remedy; as alfo, decoct. raporum, and rob. paffulorum. In an inveterate hoarfenefs, where a vifcid mucus, or thick lymph is the caufe, difolving and expectorating medicines are convenient; and above all, fyrop de eryfimo, oxymel filitit. and balf. fulph. Bleeding is to be avoided, for it prolongs the diftemper.

Sometimes worms in theinteftines are the caufes of hoarfenefs.

**HOBBY**, the name of a hawk, called by authors *subbuteo*.

It is a hawk of the lure, and not of the fift; and is very like the faker, only much lefs. It makes excellent fport with net and fpaniels; for when the birds fee the hobby, they dare not commit themfelves to the wing, but lie clofe to the ground, and fo are taken in the nets.

**HOCHSTET**, a town of Swabia in Germany, fituated twenty-five miles north-eaft of Ulm.

**HOD**, an inftrument ufed to carry bricks and mortar in, up ladders, &c. to build or repair houfes, &c. with.

**HODMAN**, an appellation given to a young ftudent admitted into Chrift's College in Oxford, from Weftminfter-School.

**HODNET**, a market town of Shropfhire, ten miles north-eaft of Shrewfbury.

**HODSDON**, a market-town of Hertfordfhire, feventeen miles due north of London.

**HOE**, in country affairs, a tool made like a cooper's addz, to cut upwards in gardens, fields, &c. This tool is commonly called the hand-hoe: for other forts of hoes fee the next article.

This inftrument is of great ufe, and fhould be more employed in hacking and clearing the feveral corners, cracks and patches

patches of land, in spare times of the year, which would be of no small advantage thereto.

*Prong Hoe.* See the article **PRONG**.

**HOEING**, according to Tull, is the breaking and dividing the soil by tillage, whilst the corn, and other plants are growing thereon.

It differs from common tillage (which is always performed before the corn or plants are sown or planted) in the time of performing it; and it is much more beneficial to the crops than any other tillage. This sort of tillage is performed various ways, and by means of different instruments. See **PLOUGH**.

Land, which before tilling would have yielded little, tho' the more it is tilled before sowing, the greater plenty of crop it yields, yet if tilled only before the sowing will always have some weeds, and they will partake of the advantage of the tillage as well as the corn. This is one reason for an after tillage, such as that by hoeing. But there is another consideration that yet more requires it, this is, that as soon as the ploughman has done his business by plowing and harrowing the land after sowing, the soil of its own accord begins to undo it all again by tending towards its original texture and specific gravity, the altering of which was the only business of all the former tillage. The breaking the particles of the earth, and making in it new pores and new superficies, is the great business of the plough and harrow, but as soon as their use is over, the earth begins to coalesce again to its own form, the particles unite together, and the artificial pores in a great measure close up. The seed is nourished in a worse ground than it was at first put into, and the more the plant grows up and requires a larger supply of food, the worse the pasture becomes: while nourishment is thus denied the growing plants, they are at the same time choked with weeds, which being of a harder nature than they, will grow with less supplies, and therefore thrive more vigorously and rob them of a great part of the little food the land before allowed them.

Transplanting is nearly allied to hoeing, but it is much inferior; the nature of this will not admit of its being a general thing, and even if it would, hoeing is better, for by transplanting, the plants can only be kept up to a certain period, after which they will not bear it; but

hoeing may be used to them with advantage, to their utmost standing, and makes them vigorous all the while. The roots of a plant are necessarily broken off in transplanting, and it requires some time for it to strike a whole set of new ones, and if the earth about it is not kept thoroughly moistened all this time, the new formed roots will not be able to shoot, and the plant will starve in the midst of plenty; but on the contrary, in hoeing the same advantage of a new pasture for the plant is obtained by breaking the particles of earth, and at the same time no more of the roots are broken off than can easily be supplied, and the rest remaining in their places, the plant continues growing without that stop and decay which must happen on transplanting, and which it recovers only by degrees.

One great benefit of hoeing, is, that it keeps plants moist in dry weather, the advantage of which to their growth is easily seen. This good office it performs on a double account; first as they are better nourished by hoeing, they require less moisture, and consequently carry off less; for these plants, which receive the greatest increase, having most terrestrial nourishment, carry off the least water in proportion to their augment, as is proved by Dr. Woodward's experiments. Secondly, the hoe, particularly the horse-hoe, for the other does not go deep enough, procures moisture for the roots from the dew that falls most in dry weather, and these dews seem to be the most enriching of all moisture, as it contains in it a fine black earth, which will subside from it in standing, and which seems fine enough to be the proper pabulum or food for plants.

For a comparative view of the profits arising from the common and horse-hoeing husbandry. See **HUSBANDRY**.

**HOG**, *sus*, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which are these: the upper fore-teeth are four in number, and are convergent; those of the lower jaw are eight, and are patulous: the canine teeth of the upper jaw are two, and very short; those of the under jaw are single, and exerted: the crown of the head is carinated, and the hoof is divided. See the article **SWINE**.

Besides the common hog, there are several other species, as, 1. The american hog, with the back bristly behind, and with

a naked tail. 2. The musk-hog, with a cyst, or gland on the back, in which is secreted a perfumed fluid; its tail is naked. 3. The babyroussa, with two teeth growing on the forehead.

**HOG'S DUNG** is, by Mortimer, reckoned one of the richest manures we are acquainted with, and the next in value to that of sheep's dung, and is found to be equal in virtue to twice the quantity of any other dung, except this. The antients seem to have been displeased with it, on account of its breeding weeds, but this is only accusing it of being too rich, for any dung will do this when laid too thick. It is an excellent manure for pasture-grounds, and excels all other kinds of dung for trees. The farmers who use this dung for their lands, generally take care to save it, by well paving the styes, and encrease the quantity by throwing in bean-stalks, stubble, and many other things of a like nature; and by good management of this kind many farmers have procured fifty or sixty loads of excellent manure a year, out of a small stye. The very best way of using this dung, is to mix it with horse-dung; and for this reason it is best to have the stye near the stable, that the two cleanings may be mixed in one heap, and used together. They have in many parts of Staffordshire a poor, light, shallow land, on which they sow a kind of white-pea: the land is neither able to bear this, nor any thing else, to advantage for their reaping; but when the peas are ripe, they turn in as many hogs as the quantity of pease will fatten, suffering them to live at large, and remain there day and night; in consequence of this the land will produce good crops of hay for several years afterwards; or if too poor for that, it will, at worst, raise grass enough to make it a good pasture-ground.

**HEDGE HOG**, *erinaceus*, in zoology, a genus of quadrupeds, the lateral fore-teeth of which are shorter than the others; the nostrils are ciliated; and the body, instead of hairs, is clothed, in the manner of that of the porcupine, with spines. See **QUADRUPED** and **PORCUPINE**.

Of this genus there are two species. 1. The erinaceous, with larger ears, or the common hedge-hog, being a little animal, considerably thick in proportion to its length, and which, when it draws itself together at the approach of danger, appears of an oval figure. The length of this creature is about seven inches; its

head small and oblong, broad towards the upper-part, and growing smaller towards the nose; the mouth is formed very much like that of the badger; the eyes are small, black, and protuberant; the ears are short and broad; the neck is short; the back broad and prominent; the legs short and robust; the feet formed like those of the dog; there are five toes on each, and one is shorter than the rest, in manner of a thumb. The other species is the white erinaceous, with very small ears, being larger than the common hedge-hog, but very like it in form.

**Musk-HOG**, *Tajacu*, in zoology. See the article **TAJACU**.

**HOG-STEER**, among sportsmen, denotes a wild boar three years old.

**HOG'S FENNEL**, a plant called by botanists *peucedanum*.

**HOG'S PLUM**, a plant otherwise called *Spondias*. See the article **SPONDIAS**.

**HOG'S WEED**, a plant called by Linnæus *boerhaavia*.

**HOGENHINE**, in our antient saxon laws, signifies one that came as a guest to an inn, and continued there the third night, from which time he was accounted of that family; so that if he offended against the king's peace, his host was to be answerable for him.

**HOGSHEAD**, in commerce, a measure of capacity, containing sixty-three gallons. See the articles **GALLON** and **MEASURE**.

**HOGUE**, a town and cape on the north-west point of Normandy in France, near which admiral Rook burnt the french admiral's ship called the *Rising-sun*, with twelve more large men of war: west longitude 2°, and north latitude 49° 50'.

**HOHIO**, a river of North America, which rising in the Apalachian mountains, near the confines of Carolina and Virginia, runs south-west, and falls into the river Mississippi.

**HOISE**, or **HOYSE**, a term used by seamen, for hawling up any thing into the ship, or the getting up a top-mast, yard, or the like.

**HOITLALLOTL**, in zoology, the name of an american bird, described by Nieremberg, and called by him *avis longa*. It is very remarkable for the swiftness of its running, and is of a very long shape, having also a long tail: its beak is also very long, black above, and grey underneath: its tail is green, and has all the splendor and beauty of the peacock's:

its

its whole body is of a whitish yellow, and, near the tail, of a blackish yellow; but the shoulders are black, with white spots. It does not fly high, nor very well, but runs so swiftly as is scarce to be conceived. It is but an ill tasted bird.

**HOKE-DAY**, the Tuesday after easter-week; which was the day on which the English conquered and expelled the Danes: this was therefore kept as a day of rejoicing, and a duty, called hoke-tuesday-money, was paid to the landlord, for giving his tenants and bondmen leave to celebrate it.

**HOLCUS**, **INDIAN MILLET**, in botany, a genus of the polygamia-monoecia class of plants, the corolla of which is a glume, furnished with a triple arista or awn; the stamina are three, the styles two, and the seed single.

**HOLD**, that part of a ship which lies between the keelson and the lower-deck; in which, divided by bulk heads, are the steward's room, powder room, bread-room, and the boatwain's and carpenter's store-rooms. In a merchantman, all the goods and lading in general, are stowed in the hold.

**HOLD-FAST**, a large piece of iron, in the shape of the letter S, fixed into a wall, to strengthen it. Also a tool used by joiners, carvers, &c. which goes through their benches, to hold fast such work as cannot be finished by its being held in the hand.

**HOLDE**, in old law books, signifies the bailiff of a city or town: and according to some writers, it also signifies a general.

**HOLDERNESS**, a peninsula in the east riding of Yorkshire, which has the German ocean on the east, and the river Humber on the south.

**HOLIBUT**, a name sometimes given to the turbot. See the article **TURBOT**.

**HOLLAND**, one of the United Provinces: it is about one hundred miles long, from north to south, and scarce thirty miles broad; but enjoys the greatest trade of any province in the world, and in point of strength and riches is equal to the other six united provinces. It is situated one hundred miles east of England, and is bounded on the north and west by the German sea, on the east by the Zuider-sea, and on the south by the provinces of Zealand and Utrecht.

**HOLLAND** is also the name of the south-east division of Lincolnshire.

**HOLLAND**, in commerce, a fine and close

kind of linen, so called from its being first manufactured in Holland. See the article **LINEN**.

**HOLLOW**, in architecture, a concave moulding, about a quarter of a circle, called by some a casement, and by others, an abacus.

**HOLLOW-SQUARE**, in the military art, a body of foot drawn up, with an empty space in the middle for colours, drums, and baggage.

**HOLLOW-TOWER**, according to Harris, is a rounding made of the remainder of two brisures, to join the curtain to the orillon, where the small shot are played, that they may not be so much exposed to the view of the enemy.

**HOLLY**, *aquifolium*, in botany, is ranked by Linnaeus among the ilices. See the article **ILEX**.

Holly-hedges make an excellent fence; but are liable to perish in severe winters. See the article **HEDGE**.

The timber of holly is the whitest of all hard wood, and therefore used by inlayers. It is also used by mill-wrights, turners, &c.

**Knee-HOLLY**, a name given to butcher's broom.

**Sea HOLLY**, a plant more usually called eryngium. See the article **ERYNGIUM**.

**HOLM** signifies an island in a river: also a hill or cliff.

**HOLM** is also a port and market-town of Cumberland, situated on Solway-frith, twenty miles west of Carlisle.

**HOLOCAUST**, a burnt offering, or sacrifice, wholly consumed by fire: of this kind was the daily sacrifice in the Jewish church. This was done by way of acknowledgment, that the person offering and all that belonged to him, were the effects of the divine bounty. The heathens, who also offered holocausts, probably considered them in the same light: and the disposing of sacrifices this way was the general custom, till Prometheus introduced the custom of burning only a part, and retaining the remainder for his own table.

**HOLOGRAPH**, among civilians, a will wholly wrote by the hand of the testator.

**HOLOMETER**, a mathematical instrument that serves universally for taking all measures, both on the earth and in the heavens.

**HOLOSTEUM**, in botany, a genus of the pentandria-trigynia class of plants, the corolla whereof is composed of five plane, patent, tridentated petals, broadest

towards the ends; the fruit is a cylindrico-conic capsule; the receptacle is free, obsoletely triquetrous, and has very short hairs; the seeds are numerous and triquetrous. There is a species of this genus, in which the stamina are only four instead of five.

**HOLSOM**, in the sea-language, is said of a ship that will ride well, without rolling or labouring.

**HOLSTEIN**, a dutchy of Germany, in the circle of Lower Saxony, one hundred miles long, and fifty broad. It is bounded by Sleswic or South Jutland on the north, by the Baltic sea and the dutchy of Sax-Lawenburg on the east, by the river Elbe on the south, and by the German sea on the west.

**HOLY-GHOST**, one of the persons of the holy Trinity. See **GOD** and **TRINITY**.

*Order of the HOLY-GHOST*, the principal military order in France, instituted by Henry III. in 1569. It consists of an hundred knights, who are to make proof of their nobility for three descents. The king is the grand-master, or sovereign, and as such, takes an oath on his coronation day, to maintain the dignity of the order.

The knights wear a golden-cross, hung about their necks by a blue silk ribbond, or collar. But before they receive the order of the Holy Ghost, that of St. Michael is conferred as a necessary degree; and for this reason their arms are surrounded with a double collar.

**HOLY-THURSDAY**, the same with ascension-day. See **ASCENSION**.

**HOLY-DAYS**, the same with festivals. See the article **FEAST**.

**HOLY-ROOD DAY**, a festival otherwise called the exaltation of the cross. See the article **CROSS**.

**HOLY-HEAD**, a cape and town in the isle of Anglesea, situated in the irish channel: west longitude  $4^{\circ} 45'$ , and north latitude  $53^{\circ} 26'$ .

**HOLY-ISLAND**, an island in the German sea, six miles south of Berwick upon Tweed: west long.  $1^{\circ} 42'$ , and north lat.  $55^{\circ} 45'$ .

**HOLY-WELL**, a town of North Wales, in Flintshire, ten miles east of St. Asaph.

**HOLYNESS** denotes purity, or a person free from sin.

**HOLYNESS** is also a title given to the pope, by those of his communion.

**HOMAGE**, in law, is the submission, loyalty, and service which a tenant promised to his lord, when he was first ad-

mitted to the land which he held of the lord in fee: also that owing to a king, or to any superior.

In the antient grants of lands and tene-ments in fee, the lord not only obliged his tenants to perform certain services, but likewise took a submission, with promise or oath that they should be true to him as their lord and benefactor.

The lord of the fee of lands, for which homage is due, takes it of every tenant as he comes to the land; but none can either do, or receive homage, except such persons as have estates in fee simple or tail, in their own right, or the right of another.

**HOMAGE AUNCESTREL**, is where a person and his ancestors, time out of mind, held land of the lord and his ancestors by homage. Such lord was to acquit his tenant against all other lords above him, and from all other service.

**HOMAGE-JURY**, a jury in a court-baron, consisting of tenants that do homage to the lord of the fee.

This jury makes enquiry into, and pre-sentments of defaults and deaths of tenants, and of admittances and surrenders into the lord's court.

**HOMAGER**, a person bound to do homage to another.

**HOMAGIO RESPECTUANDO**, a writ, by which the escheator was commanded to deliver lands to the heir of the king's tenant, notwithstanding his homage was not done.

**HOMAGIUM REDDERE** has been used to signify, to renounce homage; as where the tenant or vassal made a solemn declaration of disowning his lord, for which there was a form prescribed by the feudal-tory laws.

**HOMBERG**, a town of Germany, in the circle of the Upper Rhine, and landgraviate of Hesse, situated ten miles north of Francfort: east long.  $8^{\circ} 24'$ , north lat.  $50^{\circ} 20'$ .

**HOMBERG** is also a town of Germany, in the palatinate of the Rhine, and dukedom of Deuxponts: east long.  $7^{\circ} 6'$ , and north lat.  $49^{\circ} 20'$ .

**HOMER**, **OMER**, **CORUS**, or **CHOMER**, in jewish antiquities, a measure containing ten baths, or seventy-five gallons, and five pints, as a measure for things liquid; and thirty-two pecks and one pint, as a measure for things dry. The homer was most commonly a measure for things dry, and the greatest that was used among the Jews: it contained, according

ording to the Rabbins, ten ephaps, or thirty sata or saahs. Corus is the most usual term in the historical writers, and homer, omer, or chomer, among the prophets.

**HOMICIDE**, the slaying or killing a person. This is divided into two sorts, voluntary and casual: voluntary, is that which is done with deliberation, and a full purpose to kill; and, when done out of malice prepened, is murder: casual homicide, is where the death of a person happens by chance, or without any intention to kill; which is man-slaughter, or chance-medley.

**HOMILY**, in ecclesiastical writers, a sermon, or discourse, upon some point of religion, delivered in a plain manner, so as to be easily understood by the common people.

At the time of the reformation there were several of these homilies made and printed, and ordered to be read in such churches as were not provided with a sufficiently learned minister, in order to prevent unsound doctrine being taught in remote country places.

In the primitive church, homily rather meant a conference or conversation by way of question and answer, which made part of the office of a bishop, till the Vth century, when the learned priests were allowed to preach, catechize, &c. in the same manner as the bishops used to do.

There are still extant several fine homilies, composed by the antient fathers, particularly St. Chrysostom and St. Gregory.

**HOMINE ELIGENDO**, &c. in law, is writ directed to a corporation, for the election of a new person to keep one part of the seal, appointed for statutes-merchant, when a former party is dead.

**HOMINE REPLEGIANDO**, in law, is an antient writ that lies for bailing a person out of prison, where any one is confined without commandment of the king or his judges; or for any cause that is repleviable. This writ is directed to the sheriff, commanding him to replevy the prisoner.

In case a person takes away secretly, or keeps in his custody any person against his will, on oath made thereof, and a petition to the lord-chancellor, he will grant a writ of replegiari facias, upon which the sheriff returns an elongatus, and then there issues a capias in withernam, to take the party so offending.

**HOMINE CAPTO IN WITHERNAM**, in law,

is a writ for apprehending a person who has taken any other man or woman, and conveyed him or her out of the county, so that they cannot be replevied by law.

**HOMOCENTRIC**, the same with concentric. See the article **CONCENTRIC**.

**HOMOCHROA**, in natural history, a genus of fossils, consisting of stones composed of a crystalline matter, considerably debased by earth, and this of various kinds in the different species; but ever of one kind only in the same stone, which is thence always of one plain and simple colour, and never subject to veins or other variegations.

Of this genus authors reckon five species.

1. The white homochroum, from half an inch in diameter, to seven or eight inches. 2. The red homochroum, from one inch or less in diameter, to two or three. 3. The yellow homochroum of various sizes, from one inch or less in diameter, to six or seven. 4. The bluish homochroum, whose general size is two inches in diameter. And 5. The greenish homochroum, from half an inch to two inches in diameter.

All these species are of an orbicular form a compact and a close texture, and freely give fire with steel.

**HOMODROMUS VECTIS**, that kind of lever, in which the weight is in the middle, between the power and the fulcrum; or the power in the middle between the weight and the fulcrum.

**HOMOGENEOUS**, or **HOMOGENEAL**, an appellation given to things, the parts of which are similar or of the same nature and properties.

**HOMOGENEOUS LIGHT**, that whose rays are all of one colour and degree of refrangibility, without any mixture of others. See the article **COLOUR**.

**HOMOGENEOUS SURDS**, those which have the same radical character, or signs, as  $\sqrt[2]{a}$ , and  $\sqrt[2]{b}$ . See the article **SURD**.

**HOMOGENEUM COMPARATIONIS**, in algebra, is used by Vieta, for the absolute number in quadratic, cubic, &c. equations; which number always possesses one side of the equation, and is the product of the roots multiplied into one another. See the article **EQUATION**.

**HOMOLOGOUS**, in geometry, an appellation given to the corresponding sides and angles of similar figures, as being proportional to each other.

Thus, in two similar triangles ABC, DEF, (plate CXXXIII. fig. 1.) the sides

AB and DE, BC and EF, and AC and DF are homologous. And these triangles are to each other as the squares of their homologous sides. See the article TRIANGLE.

**HOMOLOGOUS THINGS**, in logic, those which agree in name, but are of different natures.

**HOMONYMOUS**, an appellation given to words which have two different significations, being the same with equivocal terms.

**HOMSOKEN**, a privilege enjoyed by every person, in his own house or home, which ought not to be invaded. See the article HAMSOKEN.

**HONAN**, a province of China, bounded by those of Xanfi and Pekin, on the north, by Xantong and Nankin on the east, by Suchuen on the south, and by Xenfi on the west; lying between  $33^{\circ}$  and  $37^{\circ}$  north latitude. Its capital is Caifum.

**HONDURAS**, a province of Mexico, in North America; which, including the country of the Moskito-indians, is situated between  $85^{\circ}$  and  $94^{\circ}$  west long. and between  $12^{\circ}$  and  $16^{\circ}$  north latitude.

**HONE**, a fine kind of whetstone, used for setting razors, pen knives, and the like. See the article COS.

Hones pay, on importation, a duty of  $9\text{ s. }6\frac{3}{4}\text{ d.}$  per hundred, and draw back  $8\text{ s. }7\frac{1}{2}\text{ d.}$

**HONEY**, *mel*, is, in general, a thick, viscous, and more or less fluid substance, of a whitish or yellowish colour, sweet to the taste, soluble in water, becoming vinous in fermentation, inflammable, liquable by a gentle heat, and of a fragrant smell.

There are three distinctions of honey, according to its purity, fluidity, and the manner in which it has been procured from the honey-combs. The first and finest kind is virgin-honey, or the first produce of a swarm, obtained from the combs without pressing; these being only set to drain, in order to its running out. The second kind is that known by the name of white-honey, being thicker than the former, and often indeed almost solid: it is procured by pressing the combs, but without the assistance of heat. The third and worst kind is the common yellow honey, obtained from the combs first heated over the fire, and then pressed.

Honey is prepared in the rectaria, or honey-glands of plants, situated in their flowers; the only office of the bees is to collect the small quantities lodged there,

and to amass them in stores capable of furnishing themselves with food, and us with a supply sufficient for our purposes. The bee that is out in search of honey, no sooner sees a flower that it likes, than it settles on it, and seizing on these glands, it sucks from them all the sweet juice they contain, which is either absolute honey, or very easily changed into such. The honey thus taken into the body of the bee, and deposited again into the cells of the honey-comb, is destined not only for the food of the young offspring, while unable to go out and help themselves, but for the sustenance of the bees themselves in bad weather, or when there is no food for them abroad.

Notwithstanding, however, that honey is known to be originally lodged in the flowers of plants, and might seem to be always ready in sufficient quantities for the bee; yet it is necessary that several circumstances concur, in order to its being fine and perfect in its kind. Among these are, a warm and serene state of the air, during the time in which the bees are most of all employed in making it, and a good state of health in the bee, as also its being made at a time when many fragrant plants are in flower, and in a place where such grow not too far off.

Honey taken out of the new combs early in the summer, is vastly preferable to that taken from the same hive in autumn. The reason of this is, that the bees, during the time of their making the former, have been in a more healthy and vigorous state, and that there have been fragrant flowers in greater number and perfection at that season, than later in summer.

Honey is an excellent pectoral, and is detergent, aperient, and diuretic. It should always be clarified, by melting it over the fire, either alone, or with the whites of eggs, taking off the scum, before it is used in medicine. The chemists pretend to have made an acid spirit from it, which is a solvent for gold; but we have only their assurance of it, no body else having ever seen such a liquor.

Honey, imported, pays  $7\text{ s. }8\frac{4}{10}\text{ d.}$  the barrel, and draws back  $6\text{ s. }9\text{ d.}$  Or each ton, imported, pays  $2\text{ l. }6\text{ s. }2\frac{4}{10}\text{ d.}$  and draws back  $2\text{ l. }0\text{ s. }6\text{ d.}$

**HONEY-COMB**, a waxen structure, full of cells, framed by the bees, to deposit their honey and eggs in. See BEE and WAX. The construction of the honey-comb seems one of the most surprising parts of the

the works of insects, and the materials of which it is composed, which, though evidently collected from the flowers of plants, yet do not, that we know of, exist in them in that form, has given great cause of speculation to the curious. The regular structure of the comb is also equally wonderful. When the several cells in it are examined, it should seem that the nicest rules of geometry had been consulted for its composition, and all the advantages that could be wished, or desired, in a thing of that kind, are evidently found in it. Each cell consists of six plane sides, which are all trapeziums, but equal to each other: the bottom of the cell is contrived with three rhombuses HKDI, DEFI, and FGHI (plate CXXXIII. fig. 2. n° 1.) so disposed as to constitute a solid angle at I, under the three equal angles DIH, DIF, and HIF, each of which is double the maximum angle of  $54^{\circ} 44' = DIK = DKI$ . Hence it comes to pass, that a less quantity of surface is sufficient to contain a given quantity of honey, than if the bottom had been flat, in the proportion of 4658 to 5550, as has been found by calculation; that is, nearly a fifth of the whole, so far as the figure in the end of the cells extends, in each; which fifth part of wax and labour saved, amounts to a vast deal in the whole comb. And if these admirable insects knew their advantage, they could not more nicely observe the rules of modern geometry. Hence we may observe, that though the rules of discovering the maxima and minima of quantities by fluxions, is a part of knowledge which the mathematicians have but lately acquired, and which they esteem the sublimity of human science, yet this very thing was imparted to these insects at the creation.

The method of making two sorts of cells in each comb, is also admirably contrived to save the expence of wax, since had they been made single, every comb must have had its peculiar base, and every set of cells their bottom of wax, whereas one bottom now serves for two cells; and there is but one plate of wax in the center of a double comb.

This structure occasions a very great sparing of the wax, or matter of the comb: but besides this there is another great advantage resulting from this structure, which is, that the angles arising from the forementioned combination of the bases, greatly strengthen the whole work.

The sides of the cells are all much thinner than the finest paper, and yet they are so strengthened by their disposition, that they are able to resist all the motions of the bee within them, as they are frequently obliged to be. The effect of their thrusting their bodies into the cells, would be the bursting of those cells at the top, were not this well guarded against. But to prevent this, the creatures extend a cord, or roll of wax, round the verge of every cell, in such a manner that it is scarce possible they should split in that particular part. This cord or roll is at least three times as thick as the sides of the cell, and is even much thicker and stronger at the angles of the cells, than else where, so that the aperture of each cell is not regularly hexagonal, though its inner cavity be perfectly so. See fig. *ibid.* n° 2.

The several combs are all placed parallel to one another (*ibid.* n° 3.) and there is such a space left between them, that the bees can easily pass: and often they place a part of the comb in a contrary direction to the rest, so that while the others are placed horizontally, these stand perpendicularly. The cells which have served, or are to serve for the habitation of the worms of the common, and of the male bees, are often made also at other times the receptacles of honey; but tho' these are indifferently made to serve either use, there are others destined only to receive honey.

The celerity with which a swarm of bees received into a hive, where they find themselves lodged to their minds, bring their works of the combs to perfection, is amazing. There are vast numbers at work all at once; and that they may not incommode one another, they do not work upon the first comb till it is finished, but when the foundation of that is laid, they go to work upon another, so that there are often the beginnings of three or four stories made at once, and so many swarms allotted to the carrying on the work of each. It would be a desirable thing to see the bees at work, in making these elegant and regular fabrics; but it is scarce possible to see any thing of this kind distinctly, even with the advantage of glass-hives; for, as Mr. Reaumur observes, no bee ever works singly upon this occasion, but wherever the fabric is erecting, there are numbers together trying to assist each other, and their motions are so swift, and so hid by their standing before one another,

that very little is to be seen of them. New bees are every moment going to the place, and old ones going away; and very frequently those which arrive late are dispatched away immediately after they arrive: there are only some very short moments in which the glass of the hives can give a view of the creatures regularly employed at their work; for the moment one sees a bee at work in building, that moment we see one either fly off, or else another get before her, so as to hinder the view: however, it is plain that the bee uses her teeth, in modelling and fashioning the wax.

**HONEY-COMB**, in gunnery, is a flaw in the metal of a piece of ordnance, when it is ill cast and spongy.

**HONFALIZE**, or the **HOFATISE**, a town of the austrian Netherlands, in the province of Luxemburg: east long.  $5^{\circ} 45'$ , and north lat.  $50^{\circ} 15'$ .

**HONFLEUR**, a port-town of France, in the province of Normandy, situated on the south side of the river Seyne, near the English channel: east longit.  $15'$ , and north lat.  $49^{\circ} 24'$ .

**HONITON**, a borough-town of Devonshire, twelve miles east of Exeter.

It sends two members to parliament.

**HONOUR**, a testimony of esteem or submission, expressed by words, actions, and an exterior behaviour by which we make known the veneration and respect we entertain for any one, on account of his dignity or merit. The word honour is also used in general for the esteem due to virtue, glory, and reputation. It is also used for virtue and probity themselves, and for an exactness in performing whatever we have promised; and in this last sense we use the term, *a man of honour*. But honour is more particularly applied to two different kinds of virtue, bravery in men, and chastity in women. Virtue and Honour were deified among the ancient Greeks and Romans, and had a joint temple consecrated to them at Rome: but afterwards each of them had separate temples, which were so placed, that no one could enter the temple of Honour, without passing through that of Virtue; by which the Romans were continually put in mind, that virtue is the only direct path to true glory. Plutarch tells us, that the Romans, contrary to their usual custom, sacrificed to Honour uncovered; perhaps to denote, that wherever honour is, it wants no covering, but shews itself openly to the world.

**HONOUR**, is also used for a signory or lordship, on which inferior lordships and manors depend; for as a manor consists of several lands, tenements, services, and customs, so an honour contains several manors, knights-fees, &c.

**HONOURS of the church**, are the rights and privileges belonging to the patron, &c. as a seat and sepulchre in the chancel, the being first served with the consecrated bread and wine, &c.

**HONOURS of the city**, are the public offices and employments thereof: thus he who has been constable, overseer of the poor, and churchwarden of his parish, common-council-man, alderman, and lastly mayor, has passed all the honours of the city. See the article **CITY**.

**HONOUR-COURTS**, are courts held within the honours or feignories.

**Funeral-HONOURS** are the ceremonies performed at the interment of the great, as hangings, hearses, funeral harangues, &c. See the article **FUNERAL**.

**Maid of HONOUR**, are six young ladies in the household of the queen, and prince's royal; the salary of those of a queen are 300l. per ann. each, and those of the prince's dowager of Wales, 200l.

**HONOUR-POINT**, in heraldry, is that next above the center of the escutcheon, dividing the upper part into two equal portions. See the article **POINT**.

**HONOURS and ruff**, a well-known game at cards, wherein all the duces are kept in the pack; by which means, as four play (two being of a side), twelve is dealt to each person, and there remain four for the stock, whereof the uppermost is turned up for trump; he that hath the ace of that suit, ruffs, that is, he takes in those four cards, and lays out four others in their place. The honours are the ace, king, queen, and knave; and he that hath three of these honours in his own hand, his partner not having the fourth, sets up eight by cards, that is two tricks; if he hath all four, then sixteen or four tricks; and here observe, that it is all one, if the two partners make three or four honours between them, as if one had them. If the honours are equally divided among the players, they then say, *honours are split*. If either side are at eight groats, any of the partners has the benefit of calling *can you?* provided he has two honours in his hand; and if his partner answers *one*, the game is up, which is nine in all: if he has more than two, he shews them directly, which answers the same

same purpose. However, if a trick be played before any of the gamesters call, they lose the benefit of *can you*, for that deal.

As to the value of the cards, the ace is the highest, then the king, queen, knave, ten, nine, &c. in order: but the least trump will win the highest card of any other suit.

In playing, vigilance and judgment do a great deal; for though you have but low cards, yet by playing them suitable to those in your partner's hand, so that he may either trump them, or play the best of that suit on the board, you may contribute much to gain the game. For this purpose, you ought to have a special eye to what cards are played out, by which means you will know what to play, if you lead, or trump securely and advantageously.

**HONOURARY**, something done or conferred upon any one, to do him honour. See the article **HONOUR**.

Honourary is sometimes understood of a person who bears or possesses some post or title, only for the name's sake, without doing any thing of the functions belonging to it, or receiving any advantage from it: thus we say, honourary counsellors, honourary fellow, &c.

Honourary is also used for a lawyer's fee; or a salary given to public professors in any art or science.

**HONOURARY SERVICES**, in law, such services as relate to the tenure of grand serjeantry, and usually annexed to honours.

**HONOURARY TUTOR**, a person of quality, appointed to have an eye over the administration of the affairs of a minor, while the onerary tutors have the real management of them.

**HOOD**, in falconry, a piece of leather, with which the head of a hawk, falcon, &c. is covered.

After a hawk is seeled, she should be fitted with a large easy hood, which is to be taken off and put on very often, watching her two nights, and handling her frequently about the head: when you perceive that she has no aversion to the hood, unseel her in an evening by candle-light, continuing to handle, hood, and unhood her as before, till at last she takes no offence, but will patiently endure handling: after unseeling, anoint with your finger and spittle, the place where the seeling-thread was drawn through; then hood her, and hold her on your fist all night; as soon as she is well reclaim-

ed, let her sit upon a perch, but every night keep her three or four hours on the fist; stroking, hooding, and unhooding her. This may also be done in the day-time, as soon as she has learned to feed eagerly, and without fear.

**HOOF**, *ungula*, the horny substance that covers the feet of divers animals, as oxen, horses, sheep, &c. See **HORN**.

A horse's hoof should be of a round, not longish figure; and its substance solid, tough, high, smooth, without any circles, somewhat shining, and of a dark colour, for that which is white is commonly brittle; in short, it ought to be of the colour of the hoof of a deer, and the whole foot round, but a little larger below than above, upright, and somewhat hollow on the inside, and so disposed that he may tread more on the toe than the heel.

The hoof of a horse is either perfect or imperfect: an imperfect hoof is one that wants any of the above qualities; and,  
1. May be broad and spreading out at the sides and quarters; such a horse has, for the most part, narrow heels, and will soon be flat-hoofed; he will neither carry a shoe long, nor travel far.  
2. Others are rugged or brittle-hoofed, which is a sign that it is too hot and dry. Some are long, which causes the horse to tread all upon his heels, and by that means to breed wind-galls.  
3. There are some crooked hoofs, broad on the outsides and narrow within, by which means the horse is splay-footed.  
4. Others have flat hoofs, and not hollow within, which give rise to the inconveniences above specified in the first sort of imperfect hoofs; but if it be too hollow, it will dry too fast, and make him hoof-bound.  
5. When the frush is broad, the heels will be weak and soft, and the horse will never tread boldly on the ground.  
6. Some have narrow heels; these are the tenderest of all, and the horse will grow hoof-bound.

**Bony Hoof**, is a round bony swelling, growing on the very top of a horse's hoof, which is always caused by some blow or bruise.

The method of cure is, first to digest the swelling, either with rotten litter, or hay boiled in stale urine, or with a plaster of stale wine-lees and wheat-flour boiled together, in order to ripen it, and bring it to suppuration, or to dissolve the tumour. If it come to a head, lance it in the lowest part of the softness, with a thin hot iron,

to let out the matter ; then tent it with turpentine, deer's suet, and wax, equal quantities of which should be boiled together ; and laying a plaster of the same salve over it, to keep in the tent till it be thoroughly well.

**HOOF-bound**, this disorder is a shrinking of the hoof at the top and at the heel, which makes the skin stare above the hoof, and grow over it.

This disorder may happen to a horse, either by keeping him too dry in the stable, by freight shoeing, or by some unnatural heat after foundering.

**HOOF-BRITTLE**, an infirmity in horses, proceeding either naturally, from the fire or dam ; or accidentally, from a surfeit falling down into the feet ; or from the horse's being formerly foundered.

For the cure, take unwrought wax, turpentine, sheep's suet, and hog's greafe, of each four ounces ; fallad-oil, a quarter of a pint ; and of dog's greafe, half a pound : boil them all together, and, with this mixture, anoint the hoof well for two or three days, especially at the setting on of the hair, and stop them with cow-dung and dog's greafe, melted together.

**HOOF-SWELLED**, a disorder that sometimes happens by a prick, or a young horse's being over-ridden, or too hard wrought, and which, if not speedily removed, will beget a wet spavin.

For the cure, take the strongest aqua fortis you can get, and first file or draw away the old hoof somewhat near, with a file or drawing-iron, then touch what is left of the hoof, three or four dressings or more, with the aqua fortis ; and anoint the foot with an ointment made of one pound of hog's greafe ; patch-greafe, three quarters of a pound ; venice-turpentine, five ounces ; new wax, three ounces ; and fallad-oil, three ounces ; all melted together over the fire : and by anointing the coffin of the foot quite up to the top, you will cause a new hoof to grow upon it.

**HOOF-LOOSENED**, a dividing of the horn or coffin of the hoof from the flesh, at the setting on of the coronet.

This disorder cannot be properly cured without the assistance of the farrier.

**HOOGSTRATEN**, a town of the austrian Netherlands in the province of Brabant, twenty miles north-east of Antwerp : east lon.  $4^{\circ} 45'$ , north lat.  $51^{\circ} 25'$ .

**HOOK**, a piece of iron or brass-wire bent and turned up at one end.

Hooks are a necessary sort of utensils, and being used for various purposes, are of several sorts : thus, boat-hooks (see pl. CXXXV. fig. 1. n<sup>o</sup> 1.) are for setting off boats ; can-hooks (*ibid.* n<sup>o</sup> 2.) are for hoisting casks into a ship : cant-hooks (n<sup>o</sup> 3.) are for turning or canting large masts, having at one end a ring for a hand-spike to go through, and at the other a claw ; laying-hooks (n<sup>o</sup> 4.) used by rope-makers, when laying of cordage ; rave-hooks (n<sup>o</sup> 5.) used by caulkers for picking the old oakum out of the seams of ships ; sheer-hooks (n<sup>o</sup> 6.) let into or put on the main and fore yards-arms of fire-ships, in order to fasten into an enemy's shrouds, sails, or rigging. Besides these there are draught-hooks, placed both behind and before the cheeks of a gun-carriage ; fish-hooks of several sizes, used for catching fish ; and a large sort in the same form, and called by the same name, used in ships for taking hold of the shank of the anchor, when it is to be hove up to the bow ; gamming-hooks, used when gammoning the bowsprit ; port-hooks, drove into the sides of a ship, to hang the ports upon ; puttock-hooks, for the plates to hook upon ; tackle-hooks, spliced into the straps of blocks, or ends of rope ; pot-hooks, to hang kettles or pots over the fire ; spinning-hooks, used by rope-makers to hang their threads on, as they spin them ; armour-hooks to lay arms upon, as guns, halberds, half-pikes, &c. chimney hooks, to set the tongs, fire-shovel, &c. against ; casement-hooks, curtain-hooks, hooks for doors, gates, &c. double line-hooks, single line-hooks, tenter-hooks, &c.

**HOOK-PINS**, are bolts made with a shoulder at one end, and used by carpenters in framing : these are drove through the mortices and tenants of the work, prepared for building or wharfing, *ibid.* n<sup>o</sup> 7.

**HOOKER**, in naval architecture, a vessel much used by the dutch, built like a pink, but rigged and masted like a hoy.

Hookers will lie nearer a wind than vessels with cross-sails can do. They are from fifty to two hundred tons burden, and with a few hands will sail to the East-indies.

**HOP**, *lupulus*, *humulus*, in botany, a genus of the *dioecia-pentandria* class of plants, neither the male nor female flower of which has any corolla ; the cup of the male flower is composed of five leaves ;  
that

that of the female is made up of only a single leaf, very large, and of an oval figure; the seed is single, roundish, covered with a coat, and contained within the cup.

Mortimer reckons four kinds of hops : 1. The wild garlic-hop. 2. The long and square hop. 3. The long white. And, 4. the oval hop. The first of these is not worth cultivating. The second is a good hop, but looking generally red towards the stalk, it will not fetch so good a price at the market. The long white hop is the most beautiful of all, and produces the greatest quantity : this kind and the oval will grow very well together. They delight in a deep rich garden-mould ; this may have sand among it, but never should have any clay : moory black land is what they are planted in, in Essex, but any light land will do. The hop sends its roots four or five yards deep, and for this reason it thrives best in that land where there is a good bottom below what is usually stirred, or manured, for agriculture. If the hop-land be wet, it must be laid up in high ridges, and drained in winter, that the roots be not rotted or chilled.

New land is found to succeed better with hops than old, and on this principle they are very cautious in their plantations in Kent, and look forward for the after-produce. When they make a new hop-ground, they plant it with apple-trees at a large distance asunder, and with cherry-trees between ; by this means when the hops have grown ten years, which they judge as much as they will do well, they place their account in the cherry-trees, which bear large crops ; these they gather for about thirty years, and then they cut them up, and depend upon their apple-trees only, which they find very large and strong by that time.

The dry stalks of hops should be burnt on the ground in winter, covering them with a little fresh earth as they burn. This makes together an excellent compost, to make the hills of. The land must be dug or plowed well, and laid very even, and then the places for the hills marked out by a line, and a stick put in every place where one is to be. A thousand hills may be made in an acre of ground, and six or seven plants set on every hill. From six to nine feet should be allowed between every hill, and the grounds in the hills should be better and richer than the common earth. Some plant hops in

March and April, but the most experienced people prefer the month of October, because they will then strike firm roots, and be strong and vigorous against spring. The largest plants are to be chosen ; and it is best to procure them from some rich ground, where the hills have been laid high ; they should be about eight or ten inches long, and have three or four joints or buds a-piece ; the holes for planting them are to be dug eight or ten inches deep, and about a foot over, and in each of these holes four plants are to be set, one in each corner : they may be covered an inch deep over the top, if planted in October ; but in spring, when they have shot from the joints, then they must not be buried : after this, the ground must be carefully kept clear of weeds.

*Dressing of Hops.* This is preparing the ground in winter and spring for the making a good summer-crop. In doing this, the hills upon which the plants stand must be all pulled down, and undermined on every side, till the spade comes near the principal root ; then shake off or remove with the hand the loose mould from the upper or loose roots, that you may see where the new roots grow out of the old sets. The old sets are to be carefully preserved, but the other roots may be cut away. Whatever time the hills are pulled down, the roots must not be cut till March. When the young hops are dressed for the first time, all the roots are to be cut away that grew the year before, and the sets are to be cut off within one inch of the same ; and every year after, they must be cut as close as may be to the old roots ; but to a weak hop, some of the shoots are to be left at the dressing. Those roots of the plant which grow downwards, are never to be injured, but only those which run horizontally are to be cut. The old roots and the young ones may be easily distinguished, in that the old ones are always red, and the young white. If there are by accident any wild hops got among the rest, the places where they grow are to be marked with sticks, or otherwise, at the time of their being gathered ; and after this, at the time of dressing the ground, that whole hill is to be destroyed, and a new one made with new plants in the room of it. When the roots are cut and dressed, the rich compost is to be put to them ; and the hills must not be made too high at first, lest they hinder the young shoots.

*Gathering and drying of Hops.* Hops blow in the latter end of July, in the beginning of August they bell, and they are sometimes ripe at the beginning of September, sometimes later. When they begin to change colour, are easily pulled to pieces, and their seeds look brown within them, they are ripe, and they are then to be gathered as quick as possible, for the least blast of wind will hurt them at this time.

The manner of gathering hops, is to take down four hills standing together in the midst of the garden, and to cut the roots even with the ground, then lay the ground level, and when it is swept clean, it makes a floor, on which the hops may be laid and picked. The hop-plants are first unwound from the poles, and then the people sit round and pick off the hops into baskets.

Care should be taken to dry the hops as fast as they are picked, for in lying undried they are apt to heat and change colour very quickly. If the quantity picked be so large that the kiln, in which they are to be dried, is over stocked, they must be spread thin upon a floor, and they will keep two or three days in that manner, without any harm. Indeed, where the quantity is but small, there is no need to have recourse to the kiln at all, for they will dry much better than any other way, by being laid thin upon a floor, and often turned. The drying of hops is the most material part of their manufacture; for if they be ill dried, they lose all their agreeable flavour; and great caution should be used, that they be all equally dried.

*Bagging of Hops* a term used by the farmers, who cultivate hops, for the last thing they have to do with them, in order to bring them to market; that is, the putting them up in large bags of coarse cloth, for carriage. When the hops have been picked and dried in the oost, or tin-floor, they are so brittle that they would break to pieces and be spoiled if they were immediately to be put up; they are therefore to lie together three weeks, or thereabouts, that they may become tough: if they are covered from the air by blankets in the heap, they may be bagged much sooner than if left open.

The manner of bagging them is this: a hole is made in an upper-floor, so large that a man may easily go up and down it; then a hoop is fitted to the mouth of the bag,

and so firmly sewed on, that it cannot be torn off; the bag is then let down thro' the hole, and the hoop remaining above, stops it from being pulled quite thro', being larger than the hole: a few hops are to be first thrown into the bag, and a person below is to take up a parcel of these in each corner of the bag, tying it with a packthread, this makes a sort of tassel, by which the bags are afterwards the easier managed and turned about. When this is done, one man must go down into the bag, and, while another casts in the hops, he must tread them down equally every way with his feet; when the bag is in this manner filled, it is to be ripped from the hoop, and sewed up, leaving two tassels at the corners, as at the bottom. A bag of hops thus prepared, may be kept for several years in a dry place.

The tops of this plant, being of a cooling quality, are eaten, when boiled, as an emollient. A decoction of hop-flowers is also accounted an antidote against poison, and cures the itch, as well as the sy-rup thereof, and is esteemed excellent in choleric and pestilential fevers. The heads and tendrils are good in the scurvy and most cutaneous diseases. Juleps and apozems are also prepared with hops for hypochondriacal and hysterical affections, and to promote the menses: but the chief use of this plant consists in preserving beer and other malt-liquors (in which the flower of this plant is a principal ingredient) from turning fower, and rendering it wholesome and grateful to the taste, &c.

Hops, the hundred weight, pay, on importation, 5l. 4s. 6d. and on exportation draw back 3l. 9s. 4½d. but if exported to Ireland, there is no drawback.

*HOPE*, or *Cape of Good-HOPE*. See the article *GOOD-HOPE*.

*HOPLITES*, in antiquity, an appellation given to such of the candidates at the olympic games, as ran races in armour.

*HOPPER*, a kind of basket, wherein the seed-corn is carried at the time of sowing. See the article *SOWING*.

It is also used for the wooden trough, in a mill, into which the corn is put to be ground. See the article *MILL*.

*HORARY*, something relating to an hour. Hence

*HORARY*, or *HOURLY*, or *HOURLY-CIRCLE of a globe*, is a small brazen circle, fixed upon the brazen meridian, divided into twenty-four hours,

hours, having an index moveable round the axis of the globe, which, upon turning the globe fifteen degrees, will shew what places have the sun an hour before or after us: for instance, if the index of the hour-circle be set at the upper XII. when the globe is rectified for London, and the globe turned 15 degrees from east to west, the index will point at the hour of I. which shews that all places under that meridian, and particularly Naples, have the sun an hour sooner than London has it: on the contrary, let the index be set at the upper XII. again, and the globe be turned 15 degrees from west to east, the index will point at XI. because all places under that meridian, particularly the Madeira-islands, have the sun an hour after London has it. For the several problems performable on the globes, by means of the horary circle, see the article **GLOBE**.

**HORARY CIRCLES, or LINES**, in dialling, are the lines or circles which mark the hours on sun-dials. See **DIAL**.

**HORARY MOTION of the earth**, the arch it describes in the space of an hour, which is nearly 15 degrees, though not accurately so, as the earth moves with different velocities, according to its greater or lesser distance from the sun. See **EARTH**.

**HORD**, in geography, is used for a company of wandering people, which have no settled habitation, but stroll about, dwelling in waggons, or under tents, to be ready to shift as soon as the herbage, fruit, and the present province is eaten bare: such are several tribes of the Tartars, particularly those who inhabit beyond the Wolga, in the kingdom of Astracan and Bulgaria.

A hord consists of fifty or sixty tents, ranged in a circle, leaving an open place in the middle. The inhabitants of each hord usually form a military company or troop, the eldest whereof is commonly the captain, and depends on the general or prince of the whole nation.

**HORDEOLUM, or CRITHE**, in medicine, a tubercle in the upper part of the eye-lid near the eye-brows, like a grain of barley, whence it takes its name; but it is commonly called a flye. For the cure of an hordeolum, Allen orders it to be covered over with white wax, or anointed with hen's grease, or fasting spittle; or to rub it with the body of a fly, the head being thrown away; or with the blood of a dove or partridge. If all these prove ineffectual, it must be extirpated

by cutting, or consumed by a liquid caustic; after which, let the plaster of the abbot de Grace be applied.

**HORDEUM, BARLEY**, in botany, a genus of the *triandria-trigynia* class of plants, the corolla whereof consists of two valves; the inferior valve is angular, of an ovato-acuminated figure, bellied, and longer than the cup, and terminates in a very long arista; the anterior valve is lanceolated, plane and smaller; the corolla serves as a pericarpium, surrounding the seed, and not letting it out; the seed is oblong, ventricose, pointed at each end, and marked with a longitudinal furrow.

For the culture and great use of this plant, see the article **BARLEY**.

For the bounty on the exportation of barley, see **CORN**.

**HORDICALIA, or HORDICIDIA**, in antiquity, a religious feast held among the Romans, wherein they sacrificed cattle big with young. This feast fell on April 15, on which day they sacrificed thirty cows with calf, to the goddess Tellus, or the Earth: part of them were sacrificed in the temple of Jupiter. The calves taken out of their bellies were burnt to ashes at first by the pontifices, afterwards by the eldest of the vestal virgins.

**HOREHOUND, marubium**, in botany. See the article **MARUBIUM**.

**Stinking HOREHOUND, ballotta**, in botany. See the article **BALLOTTA**.

**Bastard-HOREHOUND**. See the article **MARUBIASTRUM**.

**Base-HOREHOUND**, a name given by some to stachys. See the article **STACHYS**.

**Water-HOREHOUND, lycopus**, in botany. See the article **LYCOPUS**.

**HORIZON**, in astronomy and geography, that great circle which divides the heavens and the earth into two equal parts, or hemispheres, distinguishing the upper from the lower. See **SPHERE**.

The horizon is either sensible or rational. The sensible horizon is that circle, which, being discovered by our senses, limits our prospect. See the article **CIRCLE**.

When we are on terra firma, this circle commonly seems rugged and irregular, occasioned by the unevenness of the ground: but at sea, there are no such irregularities. The semi-diameter of this circle, varieth according to the height of the eye of the observer. If a man six feet high stood upon a large plain, or the surface of the sea, he could not see above three miles round.

The rational, or true horizon, is a great circle of the apparent celestial sphere, dividing it into two equal hemispheres, and serving as the limits of elevation or depression of celestial objects. This horizon being parallel to the sensible horizon, is distant from it by the semi-diameter of the earth, through whose center it passes: for the astronomers reduce the appearances of the heavens to a spherical surface, which is not concentric to the eye, but to the earth.

It divides the heaven and earth into two parts, the one light, and the other dark, which are greater or lesser, according to the condition of the place, &c. It determines the rising and setting of the sun, moon, or stars, in any particular latitude; for when any of these appear just at the eastern part of the horizon, we say, it rises; and when it does so at the western part, we say, it sets. And from hence also the altitude of the sun or stars is accounted, which is their height above the horizon.

This circle is divided by astronomers into four quadrants, or cardinal points. See the article COMPASS.

The poles of this horizon are the zenith and the nadir: and the innumerable circles drawn through these poles to the horizon, are called the vertical circles, or azimuths. See the articles ZENITH, NADIR, and AZIMUTH.

These two horizons produced to the fixed stars, will appear to coincide into one, since the earth, compared to the sphere in which the fixed stars appear, is but a point; therefore the two circles, which are but a point distant from each other, may be well considered as coinciding into one.

**HORIZON of a globe.** See the article GLOBE.

**HORIZONTAL**, something relating to the horizon; or that is taken in, or on a level with the horizon: thus we say, an horizontal plane, &c.

**HORIZONTAL DIAL**, that drawn on a plane parallel to the horizon, having its style elevated according to the altitude of the pole, in the place it is designed for. See the article DIAL.

**HORIZONTAL DISTANCE.** See the article DISTANCE.

**HORIZONTAL LINE**, in perspective, a right line drawn through the principal point parallel to the horizon; or it is the intersection of the horizontal and perspective planes. See the article PERSPECTIVE.

**HORIZONTAL PARALLAX.** See the article PARALLAX.

**HORIZONTAL PLANE**, that which is parallel to the horizon of the place, or nothing inclined thereto.

The business of levelling is to find whether two points be in the horizontal plane, or how much the deviation is.

**HORIZONTAL PLANE**, in perspective, a plane parallel to the horizon passing thro' the eye, and cutting the perspective plane at right angles.

**HORIZONTAL PROJECTION.** See the article PROJECTION and MAP.

**HORIZONTAL RANGE**, or **LEVEL RANGE**, of a piece of ordnance, is the line a ball describes, when directed parallel to the horizon, or horizontal line.

The horizontal ranges are the shortest: some pieces of cannon will make them six hundred paces, and some but one hundred and fifty; and the ball with the range of six hundred paces, will go from nine to thirteen feet in the earth. See the article GUNNERY.

**HORIZONTAL REFRACTION.** See the article REFRACTION.

**HORIZONTAL SHELTERS**, among gardeners, are defences disposed parallel to the horizon, for tender plants, blossoms, and fruits, in the spring, to defend them against blasts, and pinching nights.

Horizontal shelters, says Miller, have by some persons been greatly recommended to preserve fruit-trees, but with how little reason, or upon what slight experiments, every one that has ever made use of them will easily judge, especially those which are contrived by placing tiles in the walls, at certain distances; nothing being more obvious than that vegetables, when prevented from receiving the advantages of dews, rains, &c. these kindly benefits of heaven, grow weak, languid, and at last entirely decay: and from numbers of experiments, which have been lately made, we find that trees imbibe great quantities of nourishment through the pores of their leaves and branches, whereby they are rendered vigorous and healthy, even in such seasons, and upon such soils, where one would think it impossible they should receive much nourishment from the earth: to deprive them of this advantage, therefore, is no less than destroying them.

The only sort of shelter Mr. Miller approves of, for fruit-trees, is that made with two leaves of slit-deal, joined over each other, and a nted; these being fixed

ed upon the top of the wall, with pullies, to draw up and down at pleasure, form a sort of penthouse, which are let down in great rains, or cold nights, during the time that the trees are in flower, or the fruit is setting. But then, he observes, that these shelters should be removed away soon after the fruit is set, so that the trees may enjoy all the advantages of rain, dew, &c. in the summer, which are absolutely necessary to have healthy trees, or good fruit.

**HORMINUM, CLARY**, in botany, a genus of the *didynamia-gymnospermia* class of plants, reckoned by some a species of baum; the flower of which is monopetalous and ringent; the upper lip is hollow, and femibifid: the seeds are four in number, and contained in the cup. See plate CXXXV. fig. 2.

An infusion or decoction of clary, is esteemed good in the fluor albus, colic, flatulencies of all kinds, and hysterical complaints.

This plant is also said to be an antispasmodic, good against epilepsies, and in great esteem as a provocative to venery. It has also been commended as a vulnerary, and its juice is an ingredient in some ointments and plasters.

**HORMINUM** is also used as a species of sage. See the article **SAGE**.

**HORN, cornu**, in physiology, a hard substance growing on the heads of divers animals, particularly the cloven-footed quadrupeds; and serving them both as weapons of offence and defence.

The casting of the horns of deer is a singular phenomenon, the true reason of which seems to be a stoppage of the circulation; so that being deprived of the nourishing juice, they fall off much in the same manner as the leaves of trees do in autumn. About ten days after the horns are cast, the new ones begin to appear: these at first are soft and hairy, but they afterwards grow hard, and the creature rubs off the hair.

Horns make an article of commerce. Those of oxen or cows, imported, pay a duty of 1s. 7 $\frac{1}{2}$ <sup>0</sup>d. per hundred, and draw back on exportation, 1s. 5 $\frac{1}{2}$ <sup>0</sup>d. Those of harts or stags, pay on importation 5s. 9 $\frac{1}{2}$ <sup>0</sup>d. per hundred, and draw back 5s. 1 $\frac{1}{2}$ <sup>0</sup>d.

**HORN** is also a musical instrument of the wind-kind, chiefly used in hunting, to animate the hunters and the dogs, and to call the latter together.

The french horn is bent into a circle, and goes two or three times round, growing gradually bigger and wider towards the end, which in some horns is nine or ten inches over.

**HORN**, in architecture, sometimes denotes a volute. See the article **VOLUTE**.

To give a stroke with the **HORN**, among farriers, is to bleed a horse in the roof of the mouth with the tip of a stag's horn.

**HORN of plenty**. See **CORNUCOPIA**.

**HORNS of insects**, the slender oblong bodies projected from the heads of those animals, and otherwise called antennæ, or feelers.

The horns of insects are extremely various; some being forked, others plumose or feathered, cylindrical, tapering, articulated, &c.

As to the use of these parts, some have imagined they served to wipe and defend the eyes; others, that they served as feelers, lest the creature should run against any thing that might hurt it; and others there are, who think them the organs of smelling.

**HORN-BEAM, carpinus**, in botany. See the article **CARPINUS**.

**HORN-COOT**, a name sometimes given to the great horn owl. See **BUBO**.

**HORN-FISH**, a species of acus, otherwise called gar-fish. See the article **ACUS**.

**HORN-WORK**, in fortification, an out-work composed of two demi-bastions, joined by a curtain. See plate CXXXIII. fig. 4.

Its construction is very simple. From C the angle of the half-moon, they lay off eighty-eight fathoms to D; and on the center C, with the radius CD, describe the arch FDG, on which laying off DF DG each equal sixty fathoms, and drawing FG, this will be the exterior side of a polygon, whereon the two demi-bastions may be described in the usual way. The parapet of the horn-work is the same with that of the half-moon, and its moat is  $\frac{2}{3}$  of the great moat. Its curtain is usually defended by an half-moon, whose moat is  $\frac{2}{3}$  of that of the great half-moon, before the curtain of the place.

According to Vauban, none of the out-works is equal in strength to the horn-work, if placed before the bastion, and not as usual before the curtain.

**HORN-GELD**, a tax paid for feeding of horned beasts in the forest. See **FOREST**.

**HORNET, crabro**, in zoology, a species of apis with a black thorax, and double black spots on the segments of the body. See the article **APIS**.

**HORNET-FLY**, a two-winged fly, so called from its resemblance to the hornet.

**HORNSEY**, a market-town of the east riding of Yorkshire, thirty-five miles east of York.

**HOROGRAPHY**, the same with dialling. See the article **DIALLING**.

**HOROLOGIUM**, a general name for instruments to measure the hours, as a watch, clock, dial, &c. See the articles **WATCH**, **CLOCK**, &c.

**HOROPTER**, in optics, a right line **AB** (plate **CXXXIII**. fig. 2.) drawn through the point **C**, where the two optic axes, **HC** and **IC**, meet, parallel to the line **HI** which joins the centers of the two eyes, **H** and **I**.

It is called horopter, as limiting the bounds of distinct vision. See **VISION**.

**HOROSCOPE**, in astrology, is the degree of the ascendant, or the star that rises above the horizon at a certain moment, which is observed in order to predict some future event, as the success of a design, the fortune of a person who was at that instant born, &c.

The same name is also given to a scheme or figure containing the twelve houses, in which are marked the situation of the heavens and stars, in order to form predictions. See **HOUSE**.

**Lunar HOROSCOPE**, the point from whence the moon proceeds when the sun is in the ascending point of the east.

**HORSE**, *equus*, in zoology, a well known quadruped, the characters of which are these: the fore-teeth are six in number, the upper ones incurvated, and the inferior prominent: the canine teeth are not exerted, and are on each side separated by a space from the teeth: the hoof is undivided, and the teats are two, and placed in the groin.

The horse is one of the noblest quadrupeds we are acquainted with. In strength and natural fierceness, he is inferior to few, and yet easily tamed. The head is long, and large; the eyes large, and prominent; the ears erect, and beautiful; the neck is long and thick, and elegantly decorated with a mane; the body is rounded, and beautifully turned; the legs are strong, without being bulky; and the tail is long, and hairy all the way; the hairs being like those of the mane, only longer, thicker, and more beautiful.

Foreign horses or mares on their being landed in this kingdom, pay a duty of 11. 18s. 6d. and on their exportation, a

draw-back is allowed of 11. 13s. 9d. But British horses, mares, and geldings, on their exportation, pay only 5s. each.

**Hunting-HORSE**, ought to have a large, lean and long head, open ears, small, and standing upright; a forehead long, broad, and rising in the middle, like that of a hare; his eyes should be full, large, and bright; his nostrils wide and red within; his mouth large, deep in the wiles, and hairy; his thropple or wind-pipe large, loose, and straight when he is reined in with the bridle; his head should be set on his neck in such a manner, that a space may be felt between his neck and his choul; his crest should be firm, thin, and well raised; his neck long and straight, yet not loose and pliant; his breast strong and broad; his chest deep; his chine short; his body large; his ribs round like a barrel, his belly being hid within them; his fillets large; his buttocks rather oval than broad; his cambrels upright, and not bending; his legs clean, flat and straight; his joints short, well knit, and upright, especially betwixt the pasterns and the hoof, and with but little hair on his fetlocks; his hoofs black, strong, and hollow, and rather long and narrow, than big and flat; and his mane and tail long, and rather thin than thick. As to marks or colours, some do not scruple to affirm, that wherever a horse is met with that has no white about him, especially in his forehead, tho' he be otherwise of the best reputed colours, as bay, black, sorrel, he is of a dogged disposition, especially if he has a small pink eye, a narrow face, and a nose bending like a hawk's bill.

**HORSE-RACING**, a diversion more used in England than in all the world beside. Horses for this use should be as light as possible, large, long, and well shaped, nervous, of great mettle, and good wind, with small legs, and neat small shaped feet.

The rider ought to place himself on the horse with his knees firm, and his stirrups just at such a length, that when his feet are thrust home in them, he can raise himself a little in his saddle; for without that allowance, his legs will not be firm when he comes to run; the counterpoise of his body must be forward, to facilitate the horse's running, and his elbows close to his body; he must not sway to this side or that, but must take great care of his seat and hand; he should also take care not to hold himself by the bridle,

bridle, and not to twitch it back upon any occasion.

A plate being to be run for, every man that rides must be the just weight both at starting and at the end of the same heat: for if any one wants weight at coming in, he loses the heat, even tho' he came in first horse. Half an hour is allowed between every heat to rub down the horses, and at the warning of the drum and trumpet, the jockeys are to mount. If the same horse wins too heats running, or two heats out of three, he wins the plate; but if three heats are won by three different horses, a fourth is run, when he that wins two of the heats gains the plate. In these races, where there are more heats than one, it is sometimes a piece of policy in a rider to lose a heat, and for the ease of the horse to lie behind all the way, as much as he can, provided he brings him in within the distance-post: but when there is only a single heat to be run, he must push for all at that one time.

Horse-races are to be begun and ended the same day, and no plate, except the king's plates, shall be run for, that is under 50*l.* value, on the penalty of 200*l.* It is also ordained, that only one horse shall be entered by one person for the same plate, and if any person enters more, all the others will be forfeited. 13 Geo. II. c. 19.

*Backing a HORSE*, the breaking him to the saddle, or bringing him to endure a rider.

When this is done, which should be on some light plowed grounds, care must be taken that all the tackling be good and firm, and every thing in its due and proper place; then a person is to hold his head, and another to mount him; but this must not be done suddenly, or at a jerk, but very gradually and slowly, by several half risings and heavings. If he bears this patiently, the person is to seat himself firmly on his back; but if he be troublesome, and not tamed enough, the person is to forbear the attempt to mount, and he is to be trotted hard in the hand over the said plowed lands again, till he is willing to receive the rider quietly on his back. When this is done, the person who is on his back must cherish him, and the man who has his head must lead him a few paces forward; then he is to be cherished again. The feet are to be fitted well in the stirrups, and the toes turned out; afterwards the rider is

to shrink and move himself in the saddle, and the person who holds his head, is to withdraw his hand a little farther from the mouth. As the rider moves his toes forward, the holder must move him forward with the rein, till he is made to apprehend the rider's motion of body and foot, which must always go together, and with spirit, and will go forward without the other's assistance, and stay upon the restraint of the rider's hands.

When this is accomplished, let him be cherished, and have grass and bread to eat; and then let the rider mount and alight several times, cherishing him between each time; and thus he is to be managed till he will go on, or stand still at pleasure. This being done, the long rein may be laid aside, and the band about the neck, which are always used on this occasion, and nothing will be necessary but the trenches and cavesson, with the martingal. A groom must lead the way before; or another horse going only straight forwards, and making him stand still when desired. In this manner, by sometimes following, and sometimes going before another horse on the trot, the creature will by degrees be brought to know that it is his business to be quiet and governable.

*HORSE-SHOES*, plates of iron used for the defence of horses' feet. These are of several sorts.

1. That called the planch-shoe, or pancetlet. This shoe is exceeding good for a weak foot, as it keeps it from stones and gravel, and will last longer than any shoe: but it is said to make a good foot and bad leg, because it causes the foot to grow beyond the measure of the leg.

2. Shoes with calkins. These are intended to keep the horse from sliding; but however they do him more harm than good, because they prevent his treading even on the ground, by which means he is in danger of straining his foot, especially in stony places. Some indeed do not think a horse well shod, unless all his shoes be made with calkins, either single or double; the double ones are however less hurtful; for he will tread even with them than with those that are single; but then they must neither be too long nor sharp-pointed, but rather short and flat.

3. Shoes with rings. These were invented to make a horse lift his feet high, and were designed for horses that have tender hoofs: but what was intended for

a remedy, is highly prejudicial; for by adding either calkins, or these rings to his shoes, his heels are made weaker than they were before.

4. Shoes with swelling welts, or borders round them. These being higher than the heads of the nails, save them from wearing; and, if made of well-tempered iron, are both the best and most lasting shoes.

5. Some in passing mountains, where smiths are not easy to be met with, carry shoes about them, with vices to fasten them to the horse's hoofs, without the help of hammer or nail; but tho' this sort of shoe may save the horse's feet from stones, yet they pinch his hoof, and perhaps do him more injury than the stones themselves would do. On such occasions it is better to make use of the following shoe.

6. The joint-shoe is made of two pieces, with a flat rivet-nail joining them together at the toe, so that it may be made both wide or narrow, to serve any foot.

7. The patten-shoe; this is used for a horse that is burnt in the hip, stifle or shoulder; as it causes him to bear upon that leg the grief is on, and consequently makes him use it the better.

8. The panton or pantable shoe, which opens the heels, and helps hoof-binding. To which may be added the half panton-shoe, and the shoe proper for flat feet.

**HORSE-SHOE**, in fortification, is a small work sometimes of a round and sometimes of an oval figure, inclosed with a parapet, sometimes raised in the moat or ditch, or in low grounds, and sometimes to cover a gate, or to serve as a lodgment for soldiers.

**HORSE-SHOE-HEAD**, a disease in infants, in which the futures of the skull lie too open.

This is commonly a sign of a weak constitution, and a short life. The nurses usually embrocate the parts affected with brandy or rum, to which some add the white of an egg, or palm-oil.

**HORSE**, in a military sense, the same with cavalry. See the article **CAVALRY**.

The light horse, in an army, are all the regiments of horse, except the guards.

**HORSE**, in a ship, is a rope made fast to each yard arm, and on which the men stand to furl the sails. It is also a wooden frame with a rowel fixed in it, made use of by the riggers to woad ships-masts.

**HORSHAM**, a market-town and borough of Sussex, situated twenty miles north-west of Lewes, in west long. 22', north lat. 51° 10'. It sends two members to parliament.

**HORSHAM-STONE**, a greyish kind of slate, formerly used to cover houses, so called because brought from Horsham.

**HORTAGILERS**, in the grand seignior's court, upholsterers, or tapistery-hangers. The grand seignior has constantly four hundred hortagilers in his retinue when he is in the camp: these go always a day's journey before him, to fix upon a proper place for his tent, which they prepare first; and afterwards those of the officers, according to their rank.

**HORTICULTURE**, the same with gardening. See **GARDEN** and **GARDENING**.

**HORTULANUS**, in ornithology, a bird otherwise called emberiza flava, or the yellow-hammer. See **EMBERIZA** and **YELLOW-HAMMER**.

**HORTUS SICCUS**, a **DRY-GARDEN**, an appellation given to a collection of specimens of plants, carefully dried and preserved.

The value of such a collection is very evident, since a thousand minutæ may be preserved in the well-dried specimens of plants, which the most accurate engraver would have omitted. We shall, therefore, give two methods of drying and preserving an hortus siccus; the first by sir Robert Southwell, in Phil. Trans. n° 227, and the other by Dr. Hill, in his review of the works of the royal society, with the doctor's objections to sir Robert's method.

According to the former gentleman, the plants are to be laid flat between papers, and then put between two smooth plates of iron, screwed together at the corners, and in this condition committed to a baker's oven for two hours. When taken out, they are to be rubbed over with a mixture of equal parts of aquafortis and brandy; and, after this, to be fastened down on paper, with a solution of the quantity of a walnut of gum tragacanth dissolved in a pint of water.

To this the doctor objects, that the heat of an oven is much too uncertain to be employed in so nice an operation; and that the space of time, ordered for the continuing the plants in it, is of no information, unless the degree of heat, and even the different nature of the plant, as to its more or less succulency, and the firmness or tenderness of its fibres, be at-

tended

tended to. There are scarce any two plants perfectly alike in those particulars; and consequently the heat, and duration of heat, that is sufficient for one plant in a parcel, would destroy another. But besides this, he objects farther, that the acid destroys the colour of many plants, never recovers that of others lost in the drying, and frequently, after the plant is fixed down, rots both the paper it is fixed to, and that which falls over it.

As to the doctor's own method, it is as follows: take of a specimen of a plant in flower, and with it one of its bottom leaves, if it have any; bruise the stalk, if too rigid; slit it, if too thick; spread out the leaves and flowers on paper; cover the whole with more paper, and lay a weight over all. At the end of eighteen hours take out the plants, now perfectly flattened; lay them on a bed of dry common sand; sift over them more dry sand, to the depth of two inches, and thus let them lie about three weeks: the less succulent dry much sooner, but they take no harm afterwards. If the floor of a garret be covered, in spring, with sand two inches deep, leaving space for walking to the several parts, it will receive the collection of a whole summer, the covering of sand being sifted over every parcel, as laid in. They need no farther care, from the time of laying them, till they are taken up to be stuck on paper. The cement used by the doctor is thus prepared: early in the spring, put two ounces of camphor into three quarts of water in a large bottle; shake it from time to time; and when the first collected plants are ready for the fastening down, put into a pint of the water, poured off into an earthen vessel that will bear the fire, two ounces of common glue, such as is used by the carpenters, and the same quantity of *ichthyocolla* beat to shreds; let them stand six and thirty hours, then gently boil the whole a few moments, and strain it off through a coarse cloth. This is to be warmed over a gentle heat, when it is to be used, and the back of the plants smeared over thereby with a painter's brush: after this lay them on paper, and gently press them for a few minutes; then expose them to the air a little, and finally lay them under a small weight between quires of paper to be perfectly dried.

It is scarce to be conceived, how strongly the water becomes impregnated with the camphor by this simple process: a part of

it, indeed, flies off in the making of the cement and the using of it; but enough remains with the plant to prevent the breeding of insects in it. He farther observes, that plants may be dried very well without sand, by only putting them frequently into fresh quires of paper, or a few, by only pressing them between the leaves of a book; but the sand method preserves the colour best, and is done with least trouble.

Another method, much better than that of the oven, is the flattening and drying the plant, by passing a common smoothing-iron for linnen, over the papers between which it is laid: but for nice things, the most perfect of all methods is that by a common sand-heat, such as is used for chemical purposes. The cold sand is to be spread smooth on this occasion, the plant laid on it carefully flattened, and a thick bed of sand sifted over: the fire is then to be made, and the whole process carefully watched, till by a very gentle heat the plant be perfectly dried.

The colour of the tenderest herb may be preserved in this manner; and flowers that can be preserved no way else, may be managed perfectly well thus.

**HOSANNA**, a hebrew word, signifying *save now*, or *save we beseech thee*; from the frequent use of which, during the feast of tabernacles, the whole solemnity got the appellation of *hosanna rabba*.

**HOSE**, in commerce. See **STOCKING**.

**HOSEA**, a canonical book of the Old Testament, so called from the prophet of that name, its author, who was the son of Beri, and the first of the lesser prophets. He lived in the kingdom of Samaria, and delivered his prophecies under the reign of Jeroboam II. and his successors, kings of Israel, and under the reigns of Uzziah, Jotham, Ahaz, and Hezekiah, kings of Judah. His principal design is to publish the gross idolatries of the people of Israel and Judah, to denounce the divine vengeance against them, and to foretel the captivity in Assyria.

**HOSPITAL**, a place or building properly endowed, or otherwise supported by charitable contributions, for the reception and support of the poor, aged, infirm, sick, or helpless.

A charitable foundation laid thus for the sustenance and relief of the poor, is to continue for ever. Any person seized of an estate in fee, may, by deed inrolled in chancery, erect and found an hospital,

tal, and nominate such heads and governors therein as he shall think fit; and this charitable foundation shall be incorporated, and subject to the inspection and guidance of the heads and visitors nominated by the founder. Likewise such corporations shall have, take, and purchase lands, so as not to exceed 200 l. a year, provided the same be not held of the king; and to make leases, reserving the accustomed yearly rent.

Besides a multitude of alms-houses, or small hospitals, founded in England, particularly in and about London, by private men for the relief of the poor, there are a great many hospitals: the principal whereof are these,

**Royal HOSPITAL** for disabled soldiers, commonly called Chelsea-hospital.

This hospital was founded by king Charles II. carried on by king James II. and finished by king William and queen Mary. The building is very spacious and magnificent; the number of ordinary pensioners is about 500, besides the officers and servants of the house: the out and extraordinary pensioners are very numerous; and these upon occasion do duty in the several garrisons, from whence draughts are made for the army, &c. The pensioners are all provided with cloaths, diet, washing, lodging, firing, and have one day's pay in every week for spending-money. The qualifications required to be admitted of this body, are, that the candidate bring a certificate from his superior officer that he has been maimed and disabled in the service of the crown; or that he has served the crown twenty years, which must be made appear by the muster-rolls. To defray the charges of this hospital, there is a considerable sum paid yearly out of the poundage of the army; besides one day's pay of each officer and common soldier every year, which in time of war amounts to a very considerable sum. For the administration of this hospital, there is a governor, lieutenant-governor, major, treasurer, &c.

**Greenwich-HOSPITAL**, a retreat for seamen, who, by age, wounds, or other accidents, are disabled from service; and for the widows and children of such as are slain in the service.

This in point of magnificence and spaciousness, greatly excels even Chelsea-hospital. A good part of it was built in king Charles II's time. It was much promoted by king William, and finished

under queen Anne, king George I. and II. The number of pensioners entertained in this hospital, are about 1200; and to each hundred are allowed five nurses, being the widows of seamen. The pensioners are all cloathed in blue, and are allowed stockings, shoes, linnen, and twelve-pence a week for other necessaries: the victualling is according to the allowance of Chelsea-hospital, viz. four men to a mess, each mess to contain four pounds of flesh, a gallon of beer, &c. There are 100 boys, the sons of disabled seamen, who are maintained with the money arising by shewing the hospital and painting in the hall.

This hospital is administered by a governor, lieutenant-governor, &c.

**Christ's HOSPITAL**, by Newgate-street, formerly a convent of grey friars, being dissolved by king Henry VIII. was converted by his son Edward VI. into an hospital for poor children, called the blue-coat hospital, from the blue cloathing of the children, whose number amounts to about 900; the greatest part maintained in the house, and the others at nurse, at the charge of the foundation. The boys are yearly put to trades, and the girls to some honest service or trade. Here the boys have a grammar-school, from which the most improved scholars are yearly sent to the university: there is here also a stately writing school, and a mathematical school, founded by king Charles II. where forty youths are taught several parts of the practical mathematics, particularly navigation, to fit them for apprentices to masters of ships.

The officers of this hospital are a president, treasurers, governors, &c.

**St. Bartholomew's HOSPITAL**, at a small distance from Christ's hospital, did formerly belong to the same grey friars, but after the dissolution of the monasteries, king Henry VIII. left 500 marks a year to it for the relief of poor people: but it was much more largely endowed for the use of sick and lame persons only, by Edward VI. There are two other hospitals at the charge of this; one in King'sland, and the other, called the Lock, in Southwark, for the venereal disease only. It is computed that these three hospitals relieve five thousand poor sick and lame persons annually, six or seven hundred of which are in-patients at St. Bartholomew. This hospital is a large, sumptuous, new building of stone, erected with proper offices in the nature of a quad-

quadrangle. It is provided with able physicians and surgeons, &c. For the direction of it there is a president, treasurer, &c.

**Bethlehem, or bedlam HOSPITAL**, a stately hospital in Moorfields, for the cure and maintenance of poor lunatics, or distracted persons. This hospital, for elegance of structure and spacious conveniencies, is not to be equaled in Europe. It stands also in a good open air.

**St. Thomas's HOSPITAL**, in Southwark, is upon the same scheme and nature with St. Bartholomew. It is a noble extensive charity, was founded by king Edward VI. and rebuilt in 1701.

**Guy's HOSPITAL**, near St. Thomas's, was founded at the sole cost of Thomas Guy, bookseller of London, in 1722, who left 200,000*l.* to build, finish, and endow it. It was designed chiefly for incurables.

**Sutton's HOSPITAL**. See CHARTREUSE.

**Bridewell HOSPITAL**. See BRIDEWELL.

At Hoxton there is another hospital, founded by alderman Aske, for twenty poor old men of the haberdasher's company, and twenty poor boys to be there educated.

There are also two very beneficial charities or hospitals, one at Hyde-park-corner, and the other in Petty-france, Westminster, after the manner of those in London, and both very well attended.

In 1739, a long wished-for charity was established by charter for taking in and educating poor deserted young infants. The governors and guardians have purchased of the earl of Salisbury fifty acres of land in Lamb's conduit-fields, on which they have erected a large building for this charitable purpose, called the founding hospital.

About the year 1741, an infirmary or hospital in Goodman's fields was begun by charitable donations, for the relief of disabled poor seamen in the merchant service; and now they are near finishing a large stately building for this charitable undertaking near White-chapel-mount.

For several other charities of a like nature, tho' less considerable, in and about London, see the article WORKHOUSE.

**Camp-HOSPITALS**, are either general or regimental. The general hospitals are of two kinds, *viz.* the flying hospital, attending the camp at some convenient distance, and the stationary hospital, which is fixed at one place. In the choice

of both Dr. Pringle thinks it better to have them in towns than villages, as the former will afford larger wards, besides more of other conveniencies. These wards should be as airy as possible. Regimental hospitals are of the greatest importance, and therefore should be supplied with blankets and medicines from the public stores, with an allowance also for nurses and other necessaries. Barns, stables, granaries, and other out-houses, but above all churches, make the best hospitals from the beginning of June to October.

**HOSPITAL-FEVER**, a name given to the malignant catarrhal fever, as being frequent in hospitals. See the article MALIGNANT FEVER.

This sort of fever, according to Dr. Pringle, may be owing to a great many concurring causes, but the principal are foul and putrid air, occasioned by filth and impurity of any kind. Hence it is no wonder that it prevails in marshy countries, after hot seasons, and in populous cities, especially if low and ill aired, unprovided with common shores; or where the streets are narrow and foul, and the houses dirty; water scarce; and when jails and hospitals are crowded, and not ventilated, and kept clean; when in sickly times the burials are within the towns, and the bodies not laid deep; when slaughter-houses are also within the walls, or when dead animals or offals are left to rot in kennels, or on dunghills; when drains are not provided to carry off any large quantity of stagnating and corrupted water in the neighbourhood; when flesh meat make the greatest part of the diet, without a proper mixture of bread, greens, wine, or other fermented liquors; from the use of old musty grain, or what has been damaged by a wet season; or, lastly, when the fibres are relaxed by immoderate warm bathing.

When the disease comes on slowly, the symptoms are small interchanges of heats and colds, trembling of the hands, interrupted sleep, &c. but when it advances fast, the above symptoms are in a higher degree; and besides these, the patient is afflicted with a great lassitude, a nausea, pains in the back, a constant pain and confusion in the head, a dejection of spirits, &c. The method of cure varies according to the state of the disease, which may be distinguished into three periods: the first continuing as long as the

the person is able to go about ; the second beginning with his confinement ; and the third, when the pulse sinks, and the stupor comes on.

In the first as well as the other period, the cure is principally to be aimed at by removing the patient out of the foul air. When this cannot be done, the ward or room should be purified by making a succession of air by means of fires, or letting it in by doors and windows, or diffusing the steams of vinegar. The next thing to be done is to promote a diaphoresis, which in this period should only be attempted by mild sudorifics, as the *spiritus mindereri*.

When the fever is confirmed, contrayerva powders, with nitre, camphor, the common ptisan acidulated, and such medicines as are good in inflammatory cases, ought to be given. Costiveness is prevented by emollient clysters. But opiates are dangerous both in this and the third stage, in which the pulse sinks, and stupor is greater, a delirium impends, and the petechiæ often appear. When this is observed to be the case, the nitre and diaphoretic medicines are to make room for a decoction of snake-root, to which a small quantity of strong water may be added. It may also be given in substance from two to four scruples a day, with sensible good effects. Towards the decline of the fever, an equal quantity of peruvian bark may be joined with the root. Wine is also an excellent cordial at this period, and may be given either made into whey, or added to the panado ; being the only food proper for the patient. It may be taken from half a pint to a quart a day, according to the strength of the patient. Perhaps there is no rule of more importance than to give a strict charge to the attendants of the sick never to let the patient, when low, remain above two or three hours without taking something cordial and nourishing. If there be danger of a phrenitis coming on, it will be proper to call in the assistance of epispastics. Sinapisms too may be useful when the pulse is very much sunk. If a diarrhoea comes on in the decline of the fever, it is to be moderated by adding a few drops of the *tinctura thebaica*, to the full quantity of the alexipharmic decoction ; or by giving a spoonful or two of an astringent mixture. In proportion, however, to the putrid nature of the stools, astringents are to be used with the greatest

caution. When the fever is over, there are few but complain of a vertigo and want of rest ; a continuation of the deafness and other nervous symptoms, are frequently the consequence of great lowness, in which case the *pilulæ Mathæi* are to be given at night, with analeptics, and medicines of the strengthening kind.

**HOSPITALERS**, an order of religious knights, now known by the title of knights of Malta. See **MALTA**.

**HOSPITIUM**, a term used in old writers either for an inn or a monastery, built for the reception of strangers and travellers. See **INN** and **MONASTERY**.

**HOSPODAR**, a title borne by the princes of Walachia and Moldavia, who receive the investiture of their principalities from the grand seignior. He gives them a vest and standard : they are under his protection, and obliged to serve him, and he even sometimes deposes them ; but in other respects they are absolute sovereigns within their own dominions.

**HOST**, *hospes*, denotes either a person who entertains another, or the person so entertained ; but it is now generally used in the first of these senses.

**HOST**, or **HOAST**, *hostia*, in the church of Rome, a name given to the elements used in the eucharist, or rather to the consecrated wafer ; which they pretend to offer up every day, a new host or sacrifice, for the sins of mankind.

They pay adoration to the host, upon a false presumption, that the elements are no longer bread and wine, but transubstantiated into the real body and blood of Christ. See **TRANSUBSTANTIATION**.

**HOSTAGE**, a person given up to an enemy as a security for the performance of the articles of a treaty.

When two enemies enter into a treaty or capitulation, it is common for them mutually to give hostages as a security for their reciprocally performing the engagements they have entered into. An hostage becomes either an accessory or principal, according to the state of things. Thus, for example, he is an accessory, when a prince promises fidelity to another prince, and gives either his son, or some great lord, as a security for his performing his promise without any farther stipulation : for then these hostages are only an additional engagement of the prince ; and if he violate his word, they are not in any manner responsible for it. An hostage becomes a principal, when it is stipulated

stipulated that he shall be answerable for the event of things. For example, if a city promises to surrender within a certain time, in case it is not succoured, and for the security of this article gives hostages, these hostages are of the same nature as bail given to a creditor to secure a debt; so that if the succour arrives within the time, the promise becoming void, the hostages are discharged, and cannot be detained, just as the bail is discharged, if the original debtor pays the creditor; but if the succours do not arrive, and the city is guilty of a breach of faith, by refusing to surrender, then the hostages become principal, and may be punished for the breach of faith; just as a bail becomes the principal debtor, on the other debtor's becoming insolvent.

An hostage given for another person is free, in case that other person dies. According to the law of nations, hostages ought not to be put to death, unless they themselves have been guilty of some particular crime.

**HOSTEL**, or **HOTEL**. See **HOTEL**.

**HOSTIA**, **HOST**. See the article **HOST**.

**HOSTILITY**, denotes a state of war or enmity between two nations.

During a truce, all acts of hostility are to cease on both sides.

**HOT**, a relative term, importing the contrary of cold. See **HEAT** and **COLD**.

**HOT-BATH**. See the article **BATH**.

**HOT-BEDS**, in gardening, beds made with fresh horse-dung, or tanner's bark, and covered with glasses to defend them from cold winds.

By the skilful management of hot-beds, we may imitate the temperature of warmer climates; by which means, the seeds of plants brought from any of the countries within the torrid zone, may be made to flourish even under the poles.

The hot-beds commonly used in kitchen-gardens, are made with new horse-dung mixed with the litter of a stable, and a few sea-coal-ashes, which last are of service in continuing the heat of the dung. This should remain six or seven days in a heap, and being then turned over, and the parts mixed well together, it should be again cast into a heap, where it may continue five or six days longer, by which time it will have acquired a due heat. These hot-beds are made in the following manner: in some sheltered part of the garden, dig out a trench of a length, and width proportionable to the frames you intend it for; and if the ground be

dry, about a foot or a foot and a half deep; but if it be wet, not above six inches: then wheel the dung into the opening, observing to stir every part of it with a fork, and to lay it exactly even and smooth on every part of the bed, laying the bottom part of the heap, which is commonly free from litter, upon the surface of the bed: and if it be designed for a bed to plant out cucumbers to remain for good, you must make a hole in the middle of the place designed for each light about ten inches over, and six deep, which should be filled with good fresh earth, thrusting in a stick to shew the places where the holes are; then cover the bed all over with the earth that was taken out of the trench, about four inches thick, and put on the frame, letting it remain till the earth be warm, which commonly happens in three or four days after the bed is made, and then the plants may be placed in it. But if your hot-bed be designed for other plants, there need be no holes made in the dung; but after having smoothed the surface with a spade, you should cover the dung about three or four inches thick with good earth, putting on the frames and glasses, as before. In making these beds, care must be taken to settle the dung close with a fork; and if it be pretty full of long litter, it should be trod down equally on every part. During the first week or ten days after the bed is made, you should cover the glasses but slightly in the night, and in the day time carefully raise them, to let out the steam; but as the heat abates, the covering should be increased, and as the bed grows cold, new hot dung should be added round the sides of it.

The hot-bed made with tanner's bark, is, however, much preferable to that described above, especially for all tender exotic plants and fruits, which require an even degree of warmth to be continued for several months, which cannot be effected with horse-dung. The manner of making them is as follows: dig a trench about three feet deep, if the ground be dry; but if wet, it must not be above a foot deep at most, and must be raised two feet above the ground. The length must be proportioned to the frames intended to cover it, but it should never be less than ten or twelve feet, and the width not less than six. The trench should be bricked up round the sides to the above-mentioned height of three feet, and filled in the spring with fresh tanner's bark

that has been lately drawn out of their wats, and has lain in a round heap, for the moisture to drain out of it, only three or four days; as it is put in, gently beat it down equally with a dung-fork; but it must not be trodden, which would prevent its heating, by settling it too close: then put on the frame, covering it with glasses; and in about ten days or a fortnight, it will begin to heat; at which time, plunge your pots of plants or seeds into it, observing not to tread down the bark in doing it. These beds will continue three or four months in a good temper of heat; and if you stir up the bark pretty deep, and mix a load or two of fresh bark with the old when you find the warmth decline, you will preserve its heat two or three months longer. Many lay some hot horse-dung in the bottom of the trench under the bark; but this ought never to be practised unless the bed is wanted sooner than the bark would heat of itself, and even then there ought only to be a small quantity of dung at the bottom.

The frames which cover these beds, should be proportioned to the several plants they are designed to contain; if they are to cover the bananas or pineapple, the back part should be three feet high, and the lower part fifteen inches: if the bed be intended for taller plants, the frame must be made of a depth proportionable to them; but if it be for sowing of seeds, the frame need not be above fourteen inches high at the back, and seven in the front; by which means, the heat will be much greater.

**HOT-HOUSE**, in salt-making, the place where they dry the salt, when taken out of the boiling-pan: it is situated near the furnace, which, by means of funnels or tubes, conveys the heat into it.

**HOTCH-POT**, in law, is used for mixing of lands given in marriage with other lands in fee which fall by descent; as where a man possessed of thirty acres of land has issue only two daughters, and after his having given with one of them ten acres in marriage, he dies possessed of the other twenty: here she that is thus married, in order to gain her share of the rest of the land, must put her part given in marriage in hotch-pot; that is, she must refuse to take the sole profits of her lands, and cause it to be mingled with the other, so that an equal division may be made of the whole between her

and her sister; by which means, instead of only her ten acres, she has fifteen.

**HOTTENTOT-COUNTRY**, the most southern promontory of Africa, comprehending the cape of Good Hope, and the rest of the dutch settlements, situated between 15 and 35° of east long. and between 23 and 35° of south lat. Though mountainous, it is a most fruitful country. The hottentot-nations who inhabit the southern promontory, are sixteen in number; and as the natives are extremely useful to the Dutch, they suffer them to be governed by their own laws and customs. They are black, and in their flat noses, thick lips, and hair, resemble the negroes. It is remarkable, that all the women have a callous flap or skin which hangs over the pudenda.

**HOTTONIA, WATER-VIOLET**, in botany, a genus of the *pentandria-monogynia* class of plants, the flower of which consists of a single petal, the tube whereof is equal in length to the cup, and its limb plain, and divided into five ovate-oblong, emarginated segments: the fruit is a globose acuminate capsule, placed on the cup, and having only one cell, in which are contained a great number of round seeds.

**HOTTS, or HUTTS**, are the pounces and round balls of leather, stuffed; and tied to the spurs of fighting-cocks, to keep them from hurting one another in sparring.

**HOUDEN**, a market-town in the east riding of Yorkshire, fourteen miles south-east of York.

**HOUGH and HOUGHING**, in agriculture. See **HOE** and **HOEING**.

**HOUGH**, in the manege, is that joint of the hinder quarter which joins the thigh to the leg.

**HOVINGHAM**, a market-town of the east riding of Yorkshire, seventeen miles north-east of York.

**HOULSWORTHY**, a market-town of Devonshire, thirty-eight miles north-west of Exeter.

**HOUND**, a hunting dog, of which there are several sorts, as the grey-hound, gaze-hound, &c.

The grey-hound is valued for his swiftness, strength, and sagacity in pursuing the game. Those of the best sort have a long body, a sharp head, sparkling eyes, a long mouth, and sharp teeth; little ears with thin gristles, a straight, broad, and strong breast; his legs long, and his belly small; with broad shoulders,

ders, round ribs, fleshy buttocks, but not fat, and a long tail.

The best time to try and train greyhounds to the game, is at twelve-months old; they should be kept in a slip white abroad, till they can see their course, and a young dog should not be run till the game has been a considerable time on foot, lest being over-greedy of the prey, he strain his limbs. The huntsman is to lead them on his left hand, if he be on foot, and on the right if on horseback. For the method of entring greyhounds, see the article *ENTRANCE of hounds*.

The greyhound ought to be coursed three times a week, and rewarded with blood, which will encourage him to prosecute his game; but forget not to give the hare all the just advantage, that the greyhound may shew his utmost strength and skill before he reap the benefit of his labour. If he kill, take the hare from him, and cleaning his chops from the hare's wool, give him the liver and lights; then taking him up in your leath, lead him home, wash his feet with butter and beer, put him into his kennel, and half an hour after, feed him. Upon the couring days give him a toast and butter, or oil, in the morning, and nothing else, and then kennel him till he go to the course.

In the breeding of grey-hounds it should be observed, that the best dog upon an indifferent bitch will not get so good a whelp as an indifferent dog upon the best bitch: that the dogs and bitches ought as near as possible to be of an equal age, and not to exceed four years old; however, excellent whelps are frequently produced by breeding with a young dog and an old bitch.

The general food of a grey-hound ought to be chippings, crusts of bread, soft bones and gristles; the chippings should be scalded in beef, mutton, veal, or venison broth, and when it is pretty cool, made to float in good milk, and if this be given him morning and evening, it will keep him in a good state of body. But if he be poor, sickly and weak, take a sheep's head with the wool, break it to pieces, and boil it till it is very tender, and thickening the broth with oatmeal, feed your dog with the meat and broth morning and evening. If you design your grey-hound for a wager, give him the following diet-bread. Take half a peck of wheat-flour, and the same quantity of oatmeal, and having scattered in it an indifferent quantity of liquorice and

anniseeds, knead it up with the whites of eggs, and bake it in small loaves, then soak it in beef or other broths, and having walked and aired him, half an hour after sun-rise, and half an hour after sun-set, give him some of it to eat.

*Blood-HOUND*, is a dog remarkable for the keenness of his scent: he differs from the scotch sluck-hound, only in the largeness of his size, and in his not being always of the same colour; for these hounds are sometimes red, fanded, black, white, spotted, and of all the colours of the other hounds. Those who have a square and flat nose always pointed to the earth, are generally thought to have the best scent; they should likewise have a small head, brisk eyes, long ears hanging down, his legs of an equal length, his breast not deeper than his belly, and his tail nimble.

The blood-hound seldom barks, except in the chase; and on being set on by the voice of the huntsman, seeks about for the game, and not only keeps to it while it is living, but if it be by any accident killed or wounded, will find it out by the scent of the blood sprinkled on the ground.

*Gaze-Hound*. See *GAZE-Hound*.

*HOURL*, *bora*, in chronology, an aliquot part of a natural day, usually a 24th, sometimes a 12th.

But the word hour has not always been of the same signification; for in antient times an hour did indefinitely express a short space of time. It is thought too that antiently the four seasons of the year, wherein the sun finisheth its annual course, had the name of hours, because Horus instituted a certain year, consisting of three months, and for this reason the antients called spring, summer, autumn, and winter, hours, and the year itself horus: of which some footsteps appear in this, that the Greeks called their annals *Hori*; and the writers of them, *horographi*. However it be, the division of the day into hours is very antient, tho' the most antient hour is that of the twelfth part of the day.

An hour, with us, is a measure or quantity of time, equal to a 24th part of the natural day, or nychthemeron; or it is the duration of the 24th part of the earth's diurnal rotation. Fifteen degrees of the equator answer to an hour; tho' not precisely, yet near enough for common use.

The hour is divided into sixty minutes ; the minute into sixty seconds ; the second into sixty thirds, &c.

To find the hour of the day, the latitude of the place, the sun's declination, and his altitude must be given. Thus, Suppose the latitude is  $51^{\circ} 32'$ , the sun's declination  $18^{\circ}$  north, and his altitude  $40^{\circ}$ , to find the hour of the day.

The geometrical solution of this problem is performed by projecting stereographically on the plane of the meridian the oblique angled spherical triangle which is made by the complement of the latitude ; the complement of the sun's altitude, and the sun's distance from the elevated pole. Thus, with the chord of  $60^{\circ}$  (plate CXXXIV. fig. 1.) draw the primitive circle ZONH ; quarter it ; also draw the axis PCP thro' the poles, and the equinoctial  $\text{ECQ}$ , likewise the parallel of declination D  $\odot$  d equal  $18^{\circ}$  ; then draw parallel to the horizon HQ, the almazcancer or parallel of the sun's altitude  $= 40^{\circ}$  to cut the parallel of the sun's declination in  $\odot$  the place of the sun at that time. Then through  $\odot$  draw two great circles, one through Z and N the poles of the horizon, and the other thro' P and P the poles of the equinoctial, as Z  $\odot$  N, and P  $\odot$  P ; which form the oblique angled spherical triangle PZ  $\odot$

and the angle ZP  $\odot$  measured on the line of half tangents gives the hour of the day from twelve, viz.  $47^{\circ} 20'$  equal to 3 hours 9 minutes nearly, or to 51 minutes after eight in the morning, or 51 minutes before four in the afternoon. But by spherical trigonometry, having three sides given ; that is ZP  $38^{\circ} 28'$  the complement of the latitude, Z  $\odot$   $50^{\circ} 00'$  the complement of the sun's altitude, and P  $\odot$   $72^{\circ} 00'$  the sun's distance from the elevated pole (which is the declination added to  $90^{\circ}$ , when the latitude and declination are of a contrary name ; but if of one name, it is the complement of the declination) : and the angle ZP  $\odot$  the hour of the day is found by case 11. of spherical trigonometry, as follows. First add the complement of the latitude, complement of the sun's altitude, and the sun's distance from the elevated pole, into one sum. Secondly, From half that sum subtract the complement of the sun's altitude, noting the half sum, and the remainder. Then the complement arithmetical of the sines of the complement of the latitude, and the sun's distance from the pole, and the sines of the said half sum and remainder, added together ; the sine of half this sum, doubled, and subtracted from 180 degrees, gives the hour from noon.

Side	$\left\{ \begin{array}{l} \text{ZP Co. lat. } 38^{\circ} 28' \\ \odot \text{P Co. decl. } 72^{\circ} 00' \\ \text{Z } \odot \text{ Co. alt. } 50^{\circ} 00' \end{array} \right\}$	containing sides	$\left\{ \begin{array}{l} \text{S. co. ar. } - 0.206168 \\ \text{S. co. ar. } - 0.021794 \\ \text{S. } - 9.993660 \end{array} \right\}$
	Sum is, $160^{\circ} 28'$		half sum sides, $80^{\circ} 14'$ S. $- 9.993660$
	Half is, $80^{\circ} 14'$		remainder $30^{\circ} 14'$ S. $- 9.702019$
	Co. alt. $50^{\circ} 00'$		sum of the 4. $- 19.923641$
Remainder	$30^{\circ} 14'$		fine half sum $\left\{ \begin{array}{l} - 9.961820 \\ 66^{\circ} 20' \\ 66^{\circ} 20' \end{array} \right\}$

Which doubled gives  $132^{\circ} 40'$

This subtracted from  $180^{\circ} 00'$  leaves  $47^{\circ} 20'$  equal to 3 hours 9' nearly, the same as before.

By the same operation you may find the sun's azimuth PZ  $\odot$ , if instead of the complement of the sun's altitude you subtract the sun's distance from the pole, noting the half sum and remainder as before. And the rule will stand thus : To the complement arithmetical of the sines of the complement of the latitude, and complement of the sun's altitude, add the sines of the aforefaid half sum and remainder : then the sine of half the total of these four, doubled, and taken from 180 degrees, gives the sun's azimuth

from the north, in north latitude ; and from the south, in south latitude.

If the hour of the night is required, the height of some star must be taken. And it is found by adding to, or subtracting the right ascension of that star from that of the sun.

There are divers kinds of hours, used by chronologers, astronomers, dialists, &c. Sometimes hours are divided into equal and unequal. Equal hours are the 24th part of a day and night precisely, that is, the time wherein fifteen degrees of the equator mount above the horizon. These are also called equinoctial hours, because they are measured on the equinoctial ;

noſtial ; and astronomical, becauſe uſed by aſtronomers. They are alſo differently denominated, according to the manner of accounting them in different countries. Aſtronomical hours are equal hours, reckoned from noon, or mid-day, in a continued ſeries of twenty-four. Babyloniſh hours are equal hours reckoned in the ſame manner from ſun-riſe. The Italian hours, are alſo equal hours reckoned in the ſame manner too, from ſun ſetting. European hours are alſo equal hours, reckoned from midnight ; twelve from thence to noon, and twelve more from noon to midnight. Jewiſh, or planetary, or antient hours, are the twelfth part of the artificial day and night, each being divided into twelve equal parts. Hence, as it is only in the time of the equinoxes that the artificial day is equal to the night, it is then only that the hours of the day are equal to thoſe of the night : At other times they will be always either increaſing or decreaſing. And they will be the more or leſs unequal according to the obliquity of the ſphere.

**HOUSE**, *domus*, a habitation, or place built with conveniencies for dwelling in : thus, we ſay a town-houſe, country-houſe, &c.

A country-houſe is the villa of the antient Romans, the quinta of the Spaniards and Portugueſe, the cloſerie and caſſine of the French, and the vigna of the Italians.

It ought always to have wood and water near it ; theſe being the principal beauties of a rural ſeat. The trees make a far better defence than hills, as they yield a cooling, and healthy air, ſhade during the heat of ſummer, and very much break the ſeverities of the winter-ſeaſon.

It ſhould not be ſituated too low, on account of the moiſture of the air ; and, on the other hand, thoſe built on places expoſed to the winds are expensive to keep in repair. In houſes not above two ſtories high, and upon a good foundation, the length of two bricks, or eighteen inches, for the heading courſe will be ſufficient for the ground-work of any common ſtructure ; and ſix or ſeven courſes above the earth, to a water-table, where the thickneſs of the walls are abated, or taken in, on either ſide the thickneſs of a brick, *viz.* two inches and a quarter. But for large and high houſes of three, four, or five ſtories,

with garrets, their walls ought to be three heading courſes of bricks, or twenty-eight inches at leaſt, from the foundation to the firſt water-table ; and at every ſtory a water-table, or taking in, on the inſide, for the ſummers, girders, and joists to reſt upon, laid into the middle, or one quarter of the wall at leaſt, for the better bond. But as for the partition wall, a brick and half will be ſufficiently thick ; and for the upper ſtories, a brick length, or nine inch brick wall will ſuffice.

As to the regulations concerning the houſes in London, we have taken notice of them under the article **BUILDING**.

**Town-HOUSE**, a public hall, where the magiſtrates of a town, or borough, hold their meetings for the due adminiſtration of their polity.

**Work-HOUSE**, a place built at the charge of a county, town, or pariſh, where indigent, vagrant, and idle people, as alſo ſtrumpets, gameſters, and other rogues, are ſet to work, and furniſhed with clothing, diet, &c. Such are the London work-houſe, Bridewell, and that of the pariſh of St. Margaret, Weſtmiſter.

The juſtices, at their ſeſſions, are required to appoint governors, or maſters of ſuch houſes, whoſe office is to ſet the perſons committed to their charge to work, and to give them moderate correction by whipping, &c. if refractory ; and to render a true account every quarter ſeſſions, of perſons committed into their cuſtodies.

**HOUSE-BOTE**, in law, an allowance of timber out of the lord's woods, for the repairs of an houſe : this is otherwiſe called *estovers*.

**HOUSE** is alſo uſed for a noble family, or race of illuſtrious perſons, deſcended from the ſame ſtock.

**HOUSE**, in aſtrology, denotes the twelfth part of the heavens.

The diviſion of the heavens into houſes, is founded upon the pretended influence of the ſtars, when meeting in them, on all ſublunary bodies. Theſe influences are ſuppoſed to be good or bad, and to each of theſe houſes particular virtues are aſſigned, on which aſtrologers prepare and form a judgment of their horoſcopes. The horizon and meridian are two circles of the celeſtial houſes, which divide the heavens into four equal parts, each containing three houſes ; ſix of which are above the horizon, and ſix below

below it : and six of these are called eastern, and six western houses.

A scheme, or figure of the heavens is composed of twelve triangles, also called houses, in which is marked the stars, signs and planets so included in each of these circles. Every planet has likewise two particular houses, in which it is pretended, that they exert their influence in the strongest manner ; but the sun and moon have each of them only one, the house of the former being Leo, and that of the latter Cancer.

The houses in astrology have also names given them according to their qualities ; the first is the house of life ; this is the ascendant, which extends five degrees above the horizon, and the rest below it : the second is the house of riches : the third the house of brothers : the fourth, in the lowest part of the heavens, is the house of relations, and the angle of the earth : the fifth, the house of children : the sixth, the house of health : the seventh, the house of marriage, and the angle of the west : the eighth, the house of death : the ninth, the house of piety : the tenth the house of offices : the eleventh, the house of friends : and the twelfth, the house of enemies.

**HOUSE-BREAKING, or ROBBERING**, is the breaking into and robbing a house in the day-time, the same crime being termed burglary, when done by night ; both are felony, without benefit of clergy.

**HOUSE of Lords.** } See **PARLIAMENT**.

**HOUSE of Commons.** }  
**Green-HOUSE.** See the article **GREEN**.

**HOT-HOUSE.** See the article **HOT**.

**HOUSE-PAINTER.** See **PAINTER**.

**HOUSE-LEEK**, *sedum*, in botany. See the article **SEDUM**.

**HOUSEHOLD**, the whole of a family considered collectively, including the mistress, children, and servants. But the household of a sovereign prince includes only the officers and domestics belonging to his palace.

The principal officers of his majesty's household are, the lord steward, lord chamberlain of the household, the groom of the stole, the master of the great wardrobe, and the master of the horse.

The civil government of the king's house is under the care of the lord steward of the king's household, who, as he is the chief officer, all his commands are observed and obeyed. His authority extends over all the other officers and servants, except those of his majesty's

chapel, chamber, and stable, and he is the judge of all crimes committed either within the court or the verge. See the articles **LORD STEWARD** and **VERGE**.

Under him are the treasurer of the household, the comptroller, cofferer, the master of the household, the clerks of the green-cloth, and the officers and servants belonging to the accounting-house, the marshal, the verge, the king's kitchen, the household kitchen, the acatery, bake-house, pantry, buttery, cellar, pastry, &c. Next to the lord steward is the lord chamberlain of the household, who has under him the vice chamberlain, the treasurer, and comptroller of the chamber ; forty-eight gentlemen of the privy chamber, twelve of whom wait quarterly, and two of them lie every night in the privy-chamber ; the gentleman usher, the grooms of the great chamber, the pages of the presence-chamber ; the mace-bearers, cup-bearers, carvers, musicians, &c. See **LORD CHAMBERLAIN of the Household**.

The groom of the stole has under him the eleven other lords of the bed-chamber, who wait weekly in the bed-chamber, and by turns lie there a nights on a pallet-bed ; and also the grooms of the bed chamber, the pages of the bed-chamber and back stairs, &c. See **Groom of the STOLE**.

The master or keeper of the great wardrobe has under him, a deputy, comptroller, clerk of the robes, brusher, &c. and a number of tradesmen and artificers, who are all sworn servants to the king.

The master of the horse has under his command the equeries, pages, footmen, grooms, coachmen, farriers, sadlers, and all the other officers and tradesmen employed in his majesty's stables.

Next to the civil list of the king's court, is the military, consisting of the band of gentlemen pensioners, the yeomen of the guard, and the troops of the household : of which, the two first guard the king above stairs.

When the king dines in public, he is waited upon at table by his majesty's cup-bearers, carvers, and gentlemen sewers ; the musicians playing all the time. The dinner is brought up by the yeomen of the guard, and the gentlemen sewers set the dishes in order. The carvers cut for the king, and the cup-bearers serve him the drink with one knee on the ground, after he has first tasted it in the cover.

**HOUSING**, among bricklayers, a term used

used for a tile or brick that is warped, or cast crooked or hollow in burning.

Tiles are apt to be housing or hollow on the struck side, or that which was uppermost in the mould, and bricks on the contrary side.

**HOUSING**, or **HOUZING**, in the manege, is either boot or shoe-housing: the former is a piece of stuff made fast to the hinder part of the saddle, and covers the croupe of the horse, either for ornament, or to cover the horse's leannels, or to preserve the rider's cloaths from being dabbled with the sweat, &c. of the horse.

The housing, for such as ride with shoes, is commonly a piece of scarlet cloth embroidered with gold fringe, and put round the saddle so as to cover the croupe, and descend to the lower part of the belly, to save the gentleman's silk stockings when he mounts in his shoes.

**HOUSTONIA**, in botany, a genus of the *tetrandria-monogynia* class of plants, the corolla of which consists of a single petal, of a funnel-shape, with a patent limb divided into four roundish segments; the fruit is a roundish, didymous, bivalve capsule, with two cells, each containing a single seed.

**HOW**, or **HOB**. See the article **HOB**.

**HOWKER**, or **HOOKER**. See **HOOKER**.

**HOWLE**, among ship-carpenters, is said of a ship whose futtocks are scuffed and bolted into the ground timbers, and the plank laid on them to the orlop.

**HOY**, in naval architecture, a small vessel, fitted only with one mast. See **SHIP**.

**HOYE**, a town of Westphalia, capital of a county of the same name, and subject to the elector of Hanover; east long. 9°, north lat. 53° 5'.

**HOYSE**, or **HOISE**, in the sea-language. See the article **HOISE**.

**HOZING** of dogs, the same with expediting. See the article **EXPEDITE**.

**HUBERT**, or **St. HUBERT**, a town of the dutchy of Luxemburg, thirty miles south-east of Namur.

**HUCKSTER**, a person who sells provisions, or small wares, by retail.

**HUDSON'S BAY**, a large mediterranean sea of north America, situated between 51° and 63° of north lat. and of unequal breadth from 130 to 35 leagues.

**HUDSON'S STREIGHTS**, giving entrance into Hudson's Bay, lie between 65° and 75° of west long.

**HUDSON'S RIVER**, rises near the lake Champlain, in Canada, and falls into the Atlantic, a little below the city of New-York.

**HUDSON'S BAY Company**. See the article **COMPANY**.

**HUE AND CRY**, in law, the pursuit of a person who has committed felony on the highway.

If the party robbed, or any in the company of a person either robbed or murdered, go to the constable of the next town, and require him to raise hue and cry, and to pursue the offender, describing him; and giving an account as near as he can, of the course he steered; the constable is immediately to call upon the parish for aid in seeking after the felon, and if he cannot be found within the bounds of that parish, then he is to give the next constable warning, and he the next, till the offender be apprehended, or at least pursued to the sea-side. If persons are not ready at the summons of the sheriff, and cry of the county to engage in the pursuit, they may be fined: and in case the inhabitants of any hundred, after hue and cry is made, neglect to pursue the same, they shall be liable to pay one half of the damages recoverable against the hundred in which the robbery was committed.

In making the hue and cry, diligent search is to be made in all suspected places, and not only parish officers, but all private persons that pursue the hue and cry may arrest the bodies of such persons, as in their pursuit they shall find any ways suspicious, and carry them before a justice of the peace of the county where taken, and in that case, the arresting a person, tho' he should not be guilty, is lawful. 13 Edw. I. If the offender is not taken within forty days after the robbery is committed, the party robbed may make oath before a justice of the peace of the county where the robbery was committed, of the time and place of the robbery, and of what money he was robbed, and that he did not know any of the robbers; and afterwards, within twenty days such person may bring his action against the hundred, which must be sued out within a year after the robbery. 27 Eliz. By a late statute, notice of the robbery is to be inserted in the Gazette, describing the robber and robbery, &c. and process against the hundred, is not to be served on any inhabitant, except the high constable; who is to appear thereto, and to defend the action, &c. 8 Geo. II. c. 16.

**HUEGLY**, a large town in the East Indies, situated on an island in the most westerly branch

branch of the river Ganges, in the province of Bengal : east long.  $87^{\circ}$  north lat.  $23^{\circ}$ .

**HUER**, or **CONDER**, in the herring fishery. See **CONDER** and **FISHERY**.

**HUETTE**, a city of Spain, in the province of New Castile, sixty-seven miles east of Madrid : west long.  $2^{\circ} 45'$ , north lat.  $40^{\circ} 35'$ .

**HUGONIA**, in botany, a genus of the *decandria-pentagynia* class of plants, the corolla of which consists of five large, roundish, and patent petals : the fruit is a globose berry, containing only one hard and striated seed.

The hugonia, a shrub of eight or ten feet high, is a native of the East-Indies.

**HUGUENOTS**, a name given by way of contempt to the Calvinists of France.

The name had its rise in the year 1560 ; but authors are not agreed as to its origin. The most plausible opinion, however, is that of Palquier, who observes, that at Tours, the place where they were first thus denominated, the people had a notion, that an apparition or hobgoblin, called king Hugon, strolled about the streets in the night-time ; from whence as those of the reformed religion met chiefly in the night to pray, &c. they called them huguenots, that is, the disciples of king Hugon.

**HUISSIER**, a serjeant, usher, or beadle. See **SERJEANT**, **USHER**, &c.

**HULKS**, large vessels used in setting the masts of ships. See **SHIP**.

**MULL**, in the sea language, is the main body of a ship, without either masts, yards, sails, or rigging. Thus to strike a hull in a storm is to take in her sails, and to lash the helm on the lee-side of the ship ; and to hull, or lie a hull, is said of a ship whose sails are thus taken in, and helm lashed-a-lee.

**HULL**, in geography, a strong sea-port town in the east riding of Yorkshire, situated on the river Hull, near the mouth of the Humber, thirty-two miles south-east of York.

It is a place of good trade, and has a yard for building men of war and other vessels.

**HULLOCK** of a sail, is a small part of a sail, let loose in a great storm ; it is chiefly used in the mizen to keep the ship's head to the sea, when all the rest of the sail is made up, except a little at the mizen-yard-arm.

**HULPEN**, a town of the Austrian Netherlands, in the province of Brabant,

situated nine miles south-east of Brussels : east long.  $4^{\circ} 22'$ , north lat.  $50^{\circ} 42'$ .

**HULST**, the capital of the county of Woos, in dutch Flanders, situated fifteen miles north-east of Ghent : east long.  $3^{\circ} 50'$ , north lat.  $51^{\circ} 20'$ .

**HUMAN**, in general, is an appellation given to whatever relates to mankind : thus we say, the human soul, human body, human laws, &c. See the articles **SOUL**, **BODY**, &c.

In order to form a just idea of the human body, says Dr. Mead, it ought to be considered as an hydraulic machine contrived with the most exquisite art, in which there are numberless tubes, properly adjusted and disposed, for the conveyance of fluids of different kinds, as the blood, animal spirits, lymph, &c. See the articles **BLOOD**, **SPIRITS**, &c. The solids likewise make a very necessary part of the human body ; some, as the bones, serving as supports and levers to regulate its motions ; others, as the intestines and blood-vessels, serving to prepare and convey nourishment to its various parts ; and, finally, others, as the muscles, acting under the direction of the mind like so many ropes and pulleys. See the articles **BONE**, **INTESTINES**, **VEIN**, **ARTERY**, **MUSCLE**, &c.

As therefore health consists in regular motions of the fluids, together with a proper state of the solids, it is next to a miracle that so complicated a machine should hold out to extreme old age : for a body, such as ours, cannot possibly retain life for ever ; which is not difficult to account for, because the membranous fibres of the blood-vessels, which were made elastic in order to drive their included juices forward, become gradually harder, and at length rigid ; whence they are rendered incapable of executing their offices, and the secretions of the several parts are diminished by degrees : and that this is the case, appears from dissections of the bodies of very old people ; the insides of their arteries being sometimes found ossified here and there, whereby they had almost entirely lost their springiness ; and the orifices of the natural ducts, are often observed to be quite cartilaginous.

**HUMANITY**, the peculiar nature of man, whereby he is distinguished from all other beings. See the article **MAN**.

**HUMANITIES**, in the plural, signify grammar, rhetoric, and poetry, known by the name of *litera humaniores* ; for teaching

ing of which, there are professors in the universities of Scotland, called humanists.

See GRAMMAR, RHETORIC, &c.

**HUMBER**, a river formed by the Trent, the Ouse, and several other streams united. It divides Yorkshire from Lincolnshire, and falls into the German Sea at Hordeness.

**HUMBLE-BEE**, the english name of several species of apes, distinguished by their colours, black, tawney, reddish, &c. See the article APIS.

**HUMECTATION**, in pharmacy, the moistening, or preparing medicines by steeping them in water; either to soften and relax their solid parts, or to prevent the evaporation of their more subtil contents.

**HUMERUS**, in anatomy, the upper part of the arm, between the scapula and elbow.

The os humeri or brachii, as it is called, is articulated at one end with the scapula, and at the other to the ulna and radius. See the articles ARM, BRACHIUM, &c. As to the motion of the os humeri, it is evidently the most free and extensive of that of any bone in the human body; being furnished with several flexor and extensor muscles. See FLEXOR and EXTENSOR.

*Luxation of the HUMERUS.* This bone, from the length and laxity of its ligaments, the largeness of its motion, and the shallowness of the cavity in the scapula into which it is articulated, is very subject to be luxated.

As soon as this is discovered to be the case, the patient should be seated on the floor, or on a low stool, while two assistants stretch his arm; which being sufficiently extended, the surgeon ought to elevate the head of the humerus by means of a napkin, hung about his neck, and put under the arm-pit; and at the same time move it backward and forward, as he shall see occasion, till it is happily reduced into its place. See plate CXXXIV. fig. 2.

However, it often happens, that this force is incapable of extending the arm sufficiently; so that it becomes necessary to have recourse to machines, as the ambe of Hippocrates; which consists of a pillar or fulcrum A A (pl. CXXXV. fig. 3. n° 1.) and the moveable lever B C, which is bound to the arm in the manner represented in the figure by the ligatures E E E. When this is done, the end of the lever B is carefully and gradually

pressed downward, by which means the other end C is moved upward; and thus the luxated arm is both extended, and replaced at the same time.

This instrument having received many improvements since the days of Hippocrates, we shall here give the description of a portable one, invented by Mr. Freke. It consists of two boxes, A, A, (plate CXXXV. fig. 3. n° 2.) joined together by a hinge, F, in the middle; wherein are contained, when folded together, every thing necessary for reducing a dislocated shoulder.

The length of this instrument, when shut up, is one foot eight inches, its breadth nine inches, and its thickness three inches and a quarter. When it is opened, it is kept so by two hooks fixed on the backside of it; and, when one end of it stands on the ground, the other stands high enough to become a fulcrum, or support of the lever B B, which is fixed on a roller *b*, by a large wood-screw, which turning sideways, as well as with the roller, it obtains a circumrotatory motion, so that it will serve to reduce a luxation, either backward, forward, or downward. The roller on which the lever is fixed, is just the diameter of the depth of one of the boxes, into which are driven two iron pins, the ends of which are received by the two sides of the box, which are an inch thick. The lever is two feet four inches long, and is cut off and joined again by two hinges C, to fold up so as to be contained in the boxes. On the backside of it is a hook, to keep it straight. One other end of it is to hang over the roller about an inch and a half, which is to be excavated and covered with buff leather, for the more easy reception of the head of the os humeri. Two iron cheeks D are screwed on each side of the lever, to receive thro' them an iron roller, which has two holes thro' it, to receive two cords coming from a brace E, fixed on the lower head of the os humeri; for if it be applied on the muscular part of the arm, it never fails slipping down to the joint, before you can extend the limb. The iron roller has a square end, on which is fixed a wheel G, within the cheek notched round, which works as a ratchet, on a spring-ketch underneath the lever, by which it is stopped, as you wind it with a winch; and may at pleasure be let loose, as there shall be occasion for it, by discharging the ketch.

The brace E, compared with common bandages, is of more consequence than can easily be imagined by unexperienced persons. It consists of a large piece of buff leather, big enough to embrace the arm, sewed on two pieces of strong iron curved plates, riveted together, one of them having an eye at each end to fasten two cords in; the other is bent at the ends into two hooks, which are to receive the cords, after they have crossed over the arm above.

In order to keep the patient steady in his chair from coming forward, or letting the scapula rise up on depressing the lever, after the limb is extended by the winch, there must be fixed over the shoulder a girth, H, H, with two hooks at the ends of it, long enough to reach to the ground on the other side, where it must be hooked into a ring I, screwed into the floor for that purpose.

We ought not to omit observing here, that there are several other contrivances invented both by antient and modern surgeons for reducing a luxation of the humerus; some of which the reader will find described in Heister's Surgery, P. I. B. iii. c. 7.

**HUMIDITY**, that quality in bodies whereby they are capable of wetting other bodies. This differs very much from fluidity, and seems to be merely a relative thing, depending upon the congruity of the component particles of the liquor to the pores of such particular bodies, as it is capable of adhering to, penetrating a little into, or wetting. Thus, for instance, quicksilver is not a moist thing with regard to our hands or clothes, but may be called so in reference to gold, tin, or lead, to whose surfaces it will perfectly adhere, and render them soft and moist. Even water itself, which almost wets every thing, and is the great standard of moisture and humidity, is not capable of wetting every thing, for it stands or runs easily off in globular drops from the leaves of cabbages, and many other plants, and will not wet the feathers of ducks, swans, and other water-fowls. Add that the texture alone may cause the fluid to be humid, as is plain in that neither quicksilver, lead, or bismuth alone, will stick upon glass; yet being mixed together, they will form a mass that will do so, as appears from such a composition being frequently used in foliating looking-glasses.

**HUMIDUM RADICALE**, or *radical moisture*, among physicians, seems to amount to no more than the purest and most delicate part of the nutritious matter in a condition to be assimilated.

By too much heat, as in fevers, hætics, &c. this humidity is too hastily exhausted and spent.

**HUMILIS MUSCULUS**, one of the depressor-muscles of the eye. See **EYE**.

**HUMMING-BIRD**; *trochilus*, in ornithology, a genus of birds, of the order of the passerines, remarkable for being the smallest of all known birds. Their beak is of a subulated figure, but fine as a thread: it is longer than the head, and not perfectly straight: add to this, that they have a fine tube or pipe, which they can extend beyond the point of the beak. Of this singular genus, there are several elegant species. 1. The least species of all the humming birds is figured (plate CXXXVI. fig. 1.) of its natural bigness and shape: the upper part of its body is of a dirty brown, and the under part of a dirty white. 2. The little brown one, variegated with dark spots, is likewise figured (*ibid.* fig. 2.) as big as life. 3. The crested humming-bird, represented (*ibid.* fig. 3.) as big as the life, is a very elegant species: the top of the head, from the bill to the hinder part which ends in a crest, is first green, and, towards the hinder part, dark blue; both of a fine lustre: the upper part of its body is a dark green, intermixed with gold-colour: the quill-feathers are of a purple-colour, and the tail is of a bluish black. 4. The long-tailed, black-cap humming-bird; likewise engraved (*ibid.* fig. 4.) of its natural bigness, has an extremely long tail made up of only two feathers; which being of a very loose texture, are easily ruffled with the least breath of air: this is one of the largest species.

There are a great many other species of humming-birds, a description and figures of which may be seen in Edwards's History of Birds.

**HUMORISTS**, *gli humoristi*, a celebrated academy of learned men at Rome, first established by Paul Mancini. The device of this academy is a cloud; which being raised on vapours from the salt water of the sea, returns again fresh, with this hemistich from Lucretius, *Reddit agmine dulci*.

**HUMOROSI**, the name of another academy at Cortona in Italy, which must

not be confounded with that of the humorists.

**HUMOUR**, *humor*, in a general sense, denotes much the same with liquid or fluid. See the article **FLUID**.

The antients seem to have called the nutritious juices the radical humour; and to have constituted as a cause of diseases, a disproportion betwixt the innate heat and radical moisture or humour. They also made four humours in the blood. See the article **BLOOD**.

**HUMOURS** of the eye, are the crystalline, vitreous, and aqueous; for a description of which, see the articles **EYE**, **CRYSTALLINE**, &c.

**HUMOUR** is also used for the peculiar temper of a person, arising from the constitution and prevalence of this or that humour. See the articles **CONSTITUTION** and **TEMPERAMENT**.

We frequently impute to an unlucky or cross accident, says the Abbé du Bos, those chagrines whose origin is entirely in the intemperature of our humours, or in some disposition of the air, which oppresses our machine.

**HUMOUR**, in dramatic poetry, is esteemed a subordinate species of what is more usually called manners. See **MANNERS**. Every passion wears two different faces; one serious and solemn, fit only for tragedy; and the other merry and ridiculous, called humour, and proper for comedy. The english poets have excelled those of all other nations in this particular: and, indeed, ours is the only language that has a name for it.

To be always witty only becomes a few characters; so that it is necessary to call in the assistance of humour, to prevent the other dramatic persons from going into the common style and manner: hence humour may be looked on as the true spirit and wit of comedy. See **WIT**.

**HUMULUS**, the **HOP**, in botany. See the article **HOP**.

**HUMUS**, in natural history, the name by which Linnæus calls earth. See **EARTH**.

**HUNDRED**, *hundredum*, or *centuria*, a part or division of a county, which was antiently so called from its containing an hundred families, or from its furnishing an hundred able men for the king's wars. After king Alfred's dividing this kingdom into counties, and giving the government of each county to a sheriff, these counties were divided into hundreds, of which the constable was the chief officer. The grants of hundreds were

at first made by the king to particular persons; but they are not now held by grant or prescription; their jurisdiction being devolved to the county-court; a few of them only excepted, that have been by privilege annexed to the crown, or granted to some great subjects, and still remain in the nature of a franchise.

**HUNGARICUS MORBUS**, a disease so called from its being first observed in the imperial army, in 1556.

It is thought to have been a compound fever, partaking of the nature both of the bilious and hospital fevers. See **BILIOUS** and **HOSPITAL-FEVER**.

**HUNGARY**, a kingdom bounded by the Carpathian mountains, which divide it from Poland, on the north; by Transylvania and Walachia on the east; by the river Drave, which separates it from Sclavonia, on the south; and by Austria and Moravia on the west. It is one continued plain of 300 miles long, and is situated between 16° and 23° of east lon. and between 45° and 49° of north lat. It is now subject to the empress queen.

**HUNGARY-WATER**, a distilled water, so denominated from a queen of Hungary, for whose use it was first prepared.

Quincy gives the following directions for making it. Take of fresh gathered flowers of rosemary, two pounds; rectified spirits of wine, two quarts; put them together, and distil them immediately in balneo.

Or, Take of fresh tops of rosemary, one pound and a half; proof spirit, one gallon; and distil in balneo till five pints are obtained.

**HUNGER**, an uneasy sensation, which, creates an appetite or desire of food. See the article **FOOD**.

Hunger is by some attributed to a sharp acrimonious humour, which vellicates the coats of the stomach; others, who deny the existence of any such liquor, attribute it to the attrition or rubbing of the coats of the stomach; and others, again, account for it from the acidity of the blood.

**HUNGERFORD**, a market-town of Berkshire, situated on the river Kennet, twenty-four miles west of Reading.

**HUNGRY EVIL**, among farriers, an excessive desire in horses to eat, which sometimes proceeds from catching cold, or from travelling long in frost and snow, or thro' barren places.

For the cure, give him great slices of bread,

bread, toasted and steeped in sack, to comfort his stomach; or give him wheat-flour in wine or milk, a quart at a time. But there is nothing better than to feed him moderately several times a day with good bean-bread well baked, or with oats well dried and sifted.

**HUNNINGHEN**, a town of Germany, in the langraviate of Alsace, situated on the Rhine, three miles north of Basil: east long.  $7^{\circ} 35'$ , north lat.  $47^{\circ} 37'$ .

**HUNNOBY**, a market-town in the east riding of Yorkshire, situated thirty-four miles north-east of York.

**HUNTER**, a name given to a hunting-horse. See the article **HORSE**.

**HUNTING**, the exercise or diversion of pursuing four-footed beasts of game. See the article **GAME**.

Four-footed beasts are hunted in the fields, woods, and thickets, and that both with guns and grey-hounds.

Birds, on the contrary, are either shot in the air, or taken with nets and other devices, which exercise is called fowling; or they are pursued and taken by birds of prey, which is called hawking. See the articles **FOWLING** and **HAWKING**.

The pursuing of four-footed beasts, as badgers, deer, does, roebucks, foxes, hares, &c. properly termed hunting, is a noble exercise, serving not only to recreate the mind, but to strengthen the limbs, whet the stomach, and cheer up the spirits. However, all sorts of weather are not proper for hunting; high winds and rain being great obstacles to it. In the spring season, this diversion should be taken in the night-time with nets; in the summer, the morning is the most proper time for it; and in the winter, it should only be followed from nine in the morning till two in the afternoon. The general rule is, that you place yourself under the wind, where you design to wait for game.

Hunting is practised in a different manner, and with different apparatus, according to the nature of the beasts which are hunted, a description of whom may be found under their respective articles.

With regard to the seasons, that for hart and buck-hunting begins a fortnight after midsummer, and lasts till holy-rood-day; that for the hind and doe, begins on holy-rood-day, and lasts till candle-mas; that for fox-hunting begins at christmas, and holds till lady-day; that for roe-hunting begins at michael-mas, and ends at christmas; hare hunt-

ing commences at michaelmas, and lasts till the end of February; and where the wolf and boar are hunted, the season for each begins at christmas, the first ending at lady-day, and the latter at the purification.

When the sportsmen have provided themselves with nets, spears, and a hunting-horn, to call the dogs together; and likewise with instruments for digging the ground, the following directions will be of use to them in the pursuit of each sort of game.

**Badger-HUNTING**. In doing this, you must seek the earths and burrows where he lies, and in a clear moonshine-night go and stop all the burrows, except one or two, and therein place some sacks, fastened with drawing strings, which may shut him in as soon as he straineth the bag. Some use no more than to set a hoop in the mouth of the sack, and so put it into the hole; and as soon as the badger is in the sack and straineth it, the sack slippeth off the hoop and follows him into the earth, so he lies tumbling therein till he is taken. These sacks or bags being thus set, cast off the hounds, beating about all the woods, coppices, hedges and tufts, round about, for the compass of a mile or two, and what badgers are abroad, being alarmed by the hounds, will soon betake themselves to their burrows; and observe that he who is placed to watch the sacks, must stand close and upon a clear wind; otherwise the badger will discover him, and will immediately fly some other way into his burrow. But if the hounds can encounter him before he can take his sanctuary, he will then stand at a bay like a boar, and make good sport, grievously biting and clawing the dogs, for the manner of their fighting is lying on their backs, using both teeth and nails; and by blowing up their flins defend themselves against all bites of the dogs, and blows of the men upon their noses as aforesaid. And for the better preservation of your dogs, it is good to put broad collars about their necks made of greys skins.

When the badger perceives the terriers to begin to yearn him in his burrow, he will stop the hole betwixt him and the terriers, and if they still continue baying, he will remove his couch into another chamber, or part of the burrow, and so from one to another, barricading the way before them, as they retreat,

retreat, until they can go no further. If you intend to dig the badger out of his burrow, you must be provided with the same tools as for digging out a fox; and besides, you should have a pail of water to refresh the terriers, when they come out of the earth to take breath and cool themselves. It will also be necessary to put collars of bells about the necks of your terriers, which making a noise may cause the badger to bolt out. The tools used for digging out of the badger being troublesome to be carried on men's backs, may be brought in a cart. In digging, you must consider the situation of the ground, by which you may judge, where the chief angles are; for else, instead of advancing the work, you will hinder it. In this order you may besiege them in their holds, or castles, and may break their platforms, parapets, cased-mates, and work to them with mines and countermines, until you have overcome them.

Having taken a live and lusty badger, if you would make sport, carry him home in a sack, and turn him out in your court-yard, or some other inclosed place, and there let him be hunted and worried to death by your hounds.

There are the following profits and advantages which accrue by killing this animal. Their flesh, blood, and grease, tho' they are not good food, yet are very useful for physicians and apothecaries for oils, ointments, salves, and powders for shortness of breath, the cough of the lungs, for the stone, sprained sinews, colic-aches, &c. and the skin being well dressed, is very warm and good for antient people, who are troubled with paralytic distempers.

**Buck-HUNTING.** Here the same hounds and methods are used, as in running the stag; and, indeed, he that can hunt a hart or stag well, will not hunt a buck ill.

In order to facilitate the chase, the game-keeper commonly selects a fat buck out of the herd, which he shoots in order to maim him, and then he is run down by the hounds.

As to the method of hunting the buck: the company generally go out very early for the benefit of the morning, sometimes they have a deer ready lodged, if not, the coverts are drawn till one is rowz'd; or sometimes in a park a deer is pitched upon, and forced from the herd, then more hounds are laid on to run the chase; if you come to be at a fault, the

old staunch hounds are only to be relied upon till you recover him again: if he be sunk and the hounds thrust him up, it is called an imprime, and the company all sound a recheat; when he is run down, every one strives to get in to prevent his being torn by the hounds, fallow-deer seldom or never standing at bay.

He that first gets in, cries hoo-up, to give notice that he is down and blows a death. When the company are all come in they paunch him and reward the hounds; and generally the chief person of quality amongst them *takes say*, that is, cuts his belly open, to see how fat he is. When this is done, every one has a chop at his neck, and the head being cut off is shewed to the hounds to encourage them to run only at male deer, which they see by the horns, and to teach them to bite only at the head: then the company all standing in a ring, one blows a single death, which being done all blow a double recheat, and so conclude the chase with a general halloo of hoo-up, and depart the field to their several homes, or to the place of meeting; and the huntsman, or some other, hath the deer cast cross the buttocks of his horse, and so carries him home.

**Fox-HUNTING** makes a very pleasant exercise, and is either above or below ground.

1. Above ground. To hunt a fox with hounds, you must draw about groves, thickets, and bushes near villages. When you find one, it will be necessary to stop up his earth the night before you design to hunt, and that about midnight, at which time he is gone out to prey: this may be done, by laying two white sticks across in his way, which he will imagine to be some gin or trap laid for him; or else, they may be stopped up with black-thorns and earth mixed together.

At first, only call off your sure finders, and as the drag mends, add more as you dare trust them. The hound first cast off should be old and staunch, and when you hear such a hound call on merrily, you may cast off some others to him; and when they run it on the full cry, cast off the rest: thus you shall complete your pastime. The words of comfort are the same which are used in other chases. The hounds should be left to kill the fox themselves, and to worry and tear him as much as they please: some hounds will eat him with eagerness.

When

When he is dead, hang him at the end of a pike-staff, and halloo in all your hounds to bay him; but reward them with nothing belonging to the fox, for it is not good, neither will the hounds in common eat it.

2. Under ground. If in case a fox does so far escape as to earth, countrymen must be got together with shovels, spades, mattocks, pickaxes, &c. to dig him out, if they think the earth not too great. They make their earths as near as they can in ground that is hard to dig, as in clay, stony ground, or amongst the roots of trees; and their earths have commonly but one hole; and that is straight a long way in before you come at their couch. Sometimes craftily they take possession of a badger's old burrow, which hath a variety of chambers, holes, and angles.

Now to facilitate this way of hunting the fox: the huntsman must be provided with one or two terriers to put into the earth after him, that is to fix him into an angle; for the earth often consists of many angles: the use of the terrier is to know where he lies, for as soon as he finds him he continues baying or barking, so that which way the noise is heard that way dig to him. Your terriers must be garnished with bells hung in collars, to make the fox bolt the sooner; besides the collars will be some small defence to the terriers.

The instruments to dig withal are these; a sharp pointed spade, which serves to begin the trench, where the ground is hardest, and broader tools will not so well enter; the round hollowed spade, which is useful to dig among roots, having very sharp edges; the broad flat spade to dig withal, when the trench has been pretty well opened, and the ground softer; mattocks and pickaxes to dig in hard ground, where a spade will do but little service; the coal-rake to cleanse the hole, and to keep it from stopping up; clamps, wherewith you may take either fox or badger out alive to make sport with afterwards. And it would be very convenient to have a pail of water to refresh your terriers with, after they are come out of the earth to take breath.

After this manner you may besiege a fox, &c. in their strongest holes and castles, and may break their casemates, platforms, parapets, and work to them with mines and countermines till you

have obtained what you desired. But for the managing these dogs, see TERRIERS.

*Hare-HUNTING.* As, of all chases, the hare makes the greatest pastime; so it gives no small pleasure, to see the craft of this small animal for her self-preservation. If it be rainy, the hare usually takes to the high-ways; and if she come to the side of a young grove, or spring, she seldom enters, but squats down till the hounds have over-shot her; and then she will return the very way she came, for fear of the wet and dew that hangs on the boughs. In this case, the huntsman ought to stay an hundred paces before he comes to the wood-side, by which means he will perceive whether she return as aforesaid, which if she do, he must halloo in his hounds, and call them back, and that presently, that the hounds may not think it the counter she came first.

The next thing that is to be observed, is the place where the hare sits, and upon what wind she makes her form, either upon the north or south wind; she will not willingly run into the wind, but run upon a-side, or down the wind; but if she form in the water, it is a sign she is foul and measles: if you hunt such a one, have a special regard all the day to the brook-sides, for there, and near plashe, she will make all her crossings, doublings, &c.

Some hares have been so crafty, that as soon as they have heard the sound of a horn, they would instantly start out of their form, tho' it was at the distance of a quarter of a mile, and go and swim in some pool, and rest upon some rush bed in the midst of it; and would not stir from thence till they have heard the horn again, and then have started out again, swimming to land, and have stood up before the hounds four hours, before they could kill them, swimming and using all subtilties and crossings in the water. Nay, such is the natural craft and subtilty of a hare, that sometimes, after she has been hunted three hours, she will start a fresh hare, and squat in the same form. Others having been hunted a considerable time, will creep under the door of a sheep-coat, and there hide themselves among the sheep; or when they have been hard hunted, will run in among a flock of sheep, and will by no means be gotten out from among them, till the hounds are coupled up and the sheep driven into their pens. Some

of them (and that seems somewhat strange) will take the ground like a coney, and that is called, *going to the vault*. Some hares will go up one side of the hedge, and come down the other, the thickness of the hedge being the only distance between the courses. A hare that has been sorely hunted, has got upon a quickset hedge, and ran a good way upon the top thereof, and then leapt off upon the ground. And they will frequently betake themselves to furz-bushes, and will leap from one to the other, whereby the hounds are frequently in default.

Having found where a hare hath relieved in some pasture or corn-field, you must then consider the season of the year, and what weather it is; for if it be in the spring-time or summer, a hare will not then set in bushes, because they are frequently infested with pismires, snakes, and adders; but will set in cornfields, and open places. In the winter-time, they set near towns and villages, in tufts of thorns and brambles, especially when the wind is northerly or southerly. According to the season and nature of the place where the hare is accustomed to sit, there beat with your hounds, and start her; which is much better sport than traying of her from her relief to her form.

After the hare has been started, and is on foot, then step in where you saw her pass, and halloo in your hounds, until they have all undertaken it, and go on with it in full cry; then recheat to them with your horn, following fair and softly at first, making not too much noise either with horn or voice; for at the first, hounds are apt to overshoot the chace thro' too much heat. But when they have run the space of an hour, and you see the hounds are well in with it, and stick well upon it, then you may come in nearer with the hounds, because by that time their heat will be cooled, and they will hunt more soberly. But, above all things, mark the first doubling, which must be your direction for the whole day; for all the doublings that she shall make afterwards will be like the former, and according to the policies that you shall see her use, and the place where you hunt, you must make your compasses great or little, long or short, to help the defaults, always seeking the moistest and most commodious places for the hounds to scent in.

To conclude; those who delight in hunting the hare, must rise early, lest they be deprived of the scent of her foot-steps.

*Hart or Stag-HUNTING.* Gesner, speaking of hart-hunting, observes, that this wild, deceitful, and subtle beast frequently deceives its hunter, by windings and turnings. Wherefore, the prudent hunter must train his dogs with words of art, that he may be able to set them on, and take them off again at pleasure.

First of all, he should encompass the beast in her own layer, and so unharbour her in the view of the dogs, that so they may never lose her slot or footing. Neither must he set upon every one, either of the herd, or those that wander solitary alone, or a little one, but partly by sight, and partly by their footing and fumets, make a judgment of the game, and also observe the largeness of his layer.

The huntsman, having made these discoveries in order to the chace, takes off the couplings of the dogs, and some on horseback, the others on foot, follow the cry, with the greatest art, observation, and speed, remembering and intercepting him in his subtle turnings and headings; with all agility leaping hedges, gates, pales, ditches: neither fearing thorns, down hills nor woods, but mounting fresh horse, if the first tire; follow the largest head of the whole herd, which must be singled out of the chace; which the dogs perceiving, must follow; not following any other. The dogs are animated to the sport by the winding of horns, and the voices of the huntsmen. But sometimes the crafty beast sends forth his little squire to be sacrificed to the dogs and hunters, instead of himself, lying close the mean time. In this case, the huntsman must sound a retreat, break off the dogs, and take them in, that is, leam them again, until they be brought to the fairer game; which riseth with fear, yet still striveth by flight, until he be wearied and breathless. The nobles call the beast a wise hart, who, to avoid all his enemies, runneth into the greatest herds, and so brings a cloud of error on the dogs, to obstruct their farther pursuit; sometimes also beating some of the herd into his footings, that so he may the more easily escape, by amusing the dogs. Afterwards he betakes himself to his heels again, still running with the wind, not only for the sake of refreshment, but also because by this means

he can the more easily hear the voice of his pursuers, whether they be far from him, or near to him. But at last being again discovered by the hunters and sagacious scent of the dogs, he flies into the herds of cattle, as cows, sheep, &c. leaping on a cow or ox, laying the fore parts of his body thereon, that so touching the earth only with his hinder feet, he may leave a very small or no scent at all behind, for the hounds to discern. But their usual manner is, when they see themselves hard beset, and every way intercepted, to make force at their enemy with their horns, who first comes upon him, unless they be prevented by spear or sword. When the beast is slain, the huntsman with his horn windeth the fall of the beast, and then the whole company comes up, blowing their horns in triumph for such a conquest; among whom, the skillfullest opens the beast, rewards the hounds with what properly belongs to them, for their future encouragement; for which purpose the huntsmen dip bread in the skin and blood of the beast, to give to the hounds.

It is very dangerous to go in to a hart at bay, of which there two sorts, one on land and the other in water. Now if the hart be in a deep water, where you cannot well come at him, then couple up your dogs; for should they continue long in the water, it would endanger their surf-bating or foundering. In this case, get a boat, and swim to him, with dagger drawn, or else with rope that has a noose, and throw it over his horns; for if the water be so deep that the hart swims, there is no danger in approaching him; otherwise you must be very cautious.

As to a land-bay, if a hart be furnished, then you must consider the place; for if it be in a plain and open place, where there is no wood nor covert, it is dangerous and difficult to come in to him; but if he be on a hedge-side, or in a thicket, then, while the hart is staring on the hounds, you may come softly and covertly behind him, and cut his throat. If you miss your aim, and the hart turn head upon you, then take refuge at some tree; and when the hart is at bay, couple up your hounds; and when you see the hart turn head to fly, gallop in roundly to him, and kill him with your sword.

*Directions at the death of a HART or BUCK.*

The first ceremony, when the huntsman comes in to the death of a deer, is to cry, *we are haunch*, that the hounds may not

break in to the deer; which being done, the next is the cutting his throat, and there blooding the youngest hounds, that they may the better love a deer, and learn to leap at his throat: then the mort having been blown, and all the company come in, the best person, who hath not taken say before, is to take up the knife that the keeper or huntsman is to lay across the belly of the deer, some holding by the fore-legs, and the keeper or huntsman drawing down the pizzle, the person who takes say, is to draw the edge of the knife leisurely along the middle of the belly, beginning near the basket, and drawing a little upon it, enough in the length and depth to discover how fat the deer is; then he that is to break up the deer, first slits the skin from the cutting of the throat downwards, making the arber, that so the ordure may not break forth, and then he paunches him, rewarding the hounds with it.

In the next place, he is to present the same person, who took say, with a drawn hanger, to cut off the head of the deer. Which being done, and the hounds rewarded, the concluding ceremony is, if it be a stag, to blow a tripple mort; and if a buck, a double one; and then all who have horns, blow a recheat in concert, and immediately a general whoop, whoop.

*Otter-HUNTING* is performed with dogs, and also with a sort of instruments, called otter-spears; with which when they find themselves wounded, they make to land, and fight with the dogs, and that most furiously, as if they were sensible that cold water would annoy their green wounds.

There is indeed craft to be used in hunting them; but they may be caught in snares under water, and by river-sides; but great care must be taken, for they bite sorely and venomously; and if they happen to remain long in the snare, they will not fail to get themselves free by their teeth.

In hunting them, one man must be on one side of the river, and another on the other, both beating the banks with dogs; and the beast not being able to endure the water long, you will soon discover if there be an otter or not in that quarter; for he must come out to make his spraints, and in the night sometimes to feed on grass and herbs.

If any of the hounds finds out an otter, then view the soft grounds and moist places,

places, to find out which way he bent his head; if you cannot discover this by the marks, you may partly perceive it by the spraints; and then follow the hounds, and lodge him as a hart or deer. But if you do not find him quickly, you may imagine he is gone to couch somewhere farther off from the river; for sometimes they will go to feed a considerable way from the place of their rest, choosing rather to go up the river than down it. The persons that go a hunting otters, must carry their spears, to watch his vents, that being the chief advantage; and if they perceive him swimming under water, they must endeavour to strike him with their spears, and if they miss, must pursue him with the hounds, which, if they be good and perfectly entered, will go chanting and trailing along by the river side, and will beat every root of a tree, and osier-bed, and tuft of bull-rushes; nay, they will sometimes take water, and bait the beast, like a spaniel, by which means he will hardly escape.

**Roe-buck-HUNTING** is performed divers ways, and very easily in the woods.

When chased, they usually run against the wind, because the coolness of the air refreshes them in their course; therefore the huntmen place their dogs with the wind: they usually, when hunted, first take a large ring, and afterwards hunt the hounds. They are also often taken by counterfeiting their voice, which a skilful huntsman knows how to do by means of a leaf in his mouth. When they are hunted, they turn much and often, and come back upon the dogs directly; and when they can no longer endure, they take foil, as the hart does, and will hang by a bough in such a manner; that nothing of them shall appear above the water but their snout, and they will suffer the dogs to come just upon them before they will stir.

The venison of a roe-buck is never out of season, being never fat, and therefore they are hunted at any time; only that some favour ought to be shown the doe, while she is big with fawn, and afterwards till her fawn is able to shift for himself; but some roe-does have been killed with five fawns in their bellies.

He is not called, by the skilful in the art of hunting, a great roe-buck, but a fair roe-buck; the herd of them is called a bevy: and if he hath not bevy-grease upon his tail, when he is broken up, he is more fit to be dog's meat than man's meat.

The hounds must be rewarded with the bowels, the blood, and feet slit asunder, and boiled all together: this is more properly called a dole, than a reward.

**HUNTING-MATCH.** The first thing that is to be considered by one who designs to match his horse for his own advantage, and his horse's credit, is not to flatter himself with the opinion of his horse, by fancying that he is a swift, when he is but a slow galloper; and that he is a whole-running-horse (that is, that he will run four miles without a sob at the height of his speed) when he is not able to run two or three. Very probably some gentlemen are led into this error, by their being mistaken in the speed of their hounds, who, for want of trying them against other dogs that have been really fleet, have supposed their own to be so, when, in reality, they are but of a middling speed: and because their horse, when trained, was able to follow them all day, and upon any hour, to command them upon deep as well as light earths, have therefore made a false conclusion, that their horse is as swift as the best; but upon trial against a horse that has been rightly trained after hounds that were truly fleet, have bought their experience perhaps full dear. Therefore it is advisable for all lovers of hunting to procure two or three couple of tried hounds, and once or twice a week to follow after them a train-scent, and when he is able to top them on all sorts of earth, and to endure heats and colds stoutly, then he may better rely on his speed and toughness.

That horse which is able to perform a hare-chase of five or six miles briskly and courageously, till his body be as it were bathed in sweat; and then, after the hare has been killed, in a nipping frosty morning, can endure to stand till the sweat be frozen on his back, so that he can endure to be pierced with the cold as well as the heat; and then even in that extremity of cold, to ride another chase as briskly and with as much courage as he did the former; that horse which can thus endure heats and colds, is most valued by sportsmen. Therefore, in order to make a judgment of the goodness of a horse, observe him after the death of the first hare, if the chase has been any thing brisk; if when he is cold, he shrinks up his body, and draws his legs up together, it is an infallible sign of want of vigour and courage: the like may be done by the slackening of his girths after the first chase,

and from the dulness of his teeth, and the dulness of his countenance, all which are true tokens of faintness, and being tired ; and such a horse is not to be relied on, in case of a wager.

Here it will not be improper to take notice of the way of making matches in former times, and the modern way of deciding wagers. The old way of trial was, by running so many train-scents after hounds, as was agreed upon between the parties concerned, and a bell-course, this being found not so uncertain, but more durable than hare-hunting ; and the advantage consisted in having the trains led on earth most suitable to the qualifications of the horses. But now others choose to hunt the hare till such an hour, and then to run this wild-geese-chace, a method of racing that takes its name from the manner of the flight of wild-geese, which is generally one after another ; so the two horses after running of twelvescore yards, had liberty, which horse soever could get the leading, to ride what ground he pleased, the hindmost horse being bound to follow him, within a certain distance agreed on by articles, or else to be whipped up by the triers or judges which rode by ; and whichever horse could distance the other, won the match.

But this chace was found by experience so inhuman, and so destructive to good horses, especially when two good horses were matched ; for neither being able to distance the other, till both were ready to sink under their riders through weakness, oftentimes the match was fain to be drawn, and left undecided, though both the horses were quite spoiled.

This brought up the custom of train-scents, which afterwards was changed to three heats, and a straight course ; and that the lovers of horses might be encouraged to keep good ones, plates have been erected in many places in England. The fever of these before you come to the course, if your horse be fiery and mettled, the better ; and the shorter the distance, the better. Also, above all things, be sure to make your bargain to have the leading of the first train, and then make choice of such grounds where your horse may best show his speed, and the fleetest dogs you can procure : give your hounds as much law before you as your triers will allow, and then, making a loose, try to win the match with a wind ; but if you fail in this attempt, then bear your horse,

and save him for the course ; but if your horse be slow, but well-winded, and a true spurred nag, then the more train-scents you run before you come to the straight course, the better. But here you ought to observe to gain the leading of the first train ; which, in this case you must lead upon such deep earths, that it may not end near any light ground : for this is the rule received among horsemen, that the next train is to begin where the last ends, and the last train is to be ended at the starting-place of the course ; therefore remember to end your last on deep earths, as well as the first.

**HUNTINGDON**, the capital of Huntingdonshire, situated on the river Ouse, fifty-six miles north of London : west lon.  $15^{\circ}$ , and north lat.  $52^{\circ} 23'$ .

It sends two members to parliament.

**HUQUAM**, a province of China, bounded by Honan on the north, and by Quamsi and Canton on the south ; lying between  $25^{\circ}$  and  $30^{\circ}$  of north latitude.

**HURA**, the **SAND-BOX-TREE**, in botany, a genus of the *monoecia monadelphica* class of plants, the male flowers of which are arranged in an imbricated amentum ; the antheræ are sessile, and adhere to the amentum ; the female flower has neither calyx nor corolla ; its style is funnel-shaped, and the fruit is a capsule consisting of twelve cells, in each of which is contained a single seed.

**HURDLES**, in fortification, twigs of willows or osiers interwoven close together, sustained by long stakes, and usually laden with earth.

Hurdles, called also clays, are made in the figure of a long square ; the length being five or six feet, and the breadth three, or three and an half : the closter they are woven, the better. They serve to render batteries firm, or to consolidate the passage over muddy ditches ; or to cover traverses and lodgments, for the defence of the workmen, against the fire-works, or the stones, that may be thrown against them.

**HURDLES**, in husbandry, certain frames, made either of split timber, or of hazel-rod, wattled together, to serve for gates in inclosures, or to make sheepfolds, &c.

**HURDS**, or **HOARDS**, of flax, or hemp, the coarser parts separated in the dressings, from the tear or fine stuff.

**HURLE-BONE**, in a horse, a bone near the middle of the buttock, very apt to go out of its sockets with a hurt or strain.

**HURLERS**,

**HURLERS**, a number of large stones set in a square figure, near St. Clare, in Cornwall, so called from an odd opinion held by the common people, that they are so many men petrified, or changed into stones, for profaning the sabbath-day, by hurling the ball, an exercise for which the people of that county have been always famous. The hurlers are oblong, rude, and unhewed. Some suppose them to have been trophies erected in memory of some battle; others take them for boundaries, to distinguish lands; and others hold them to be sepulchral monuments.

**HURON**, a vast lake of north America, situated between  $84^{\circ}$  and  $89^{\circ}$  west long. and between  $43^{\circ}$  and  $46^{\circ}$  north lat. from whence the country contiguous to it is called the country of the Hurons, whose language is spoken over a great extent in the southern parts of north America. See the article **ALGONQUIN**.

**HURRERS**, a name formerly given to the cappers and hat-makers of London.

**HURRICANE**, a furious storm of wind, owing to a contrariety of winds. See the article **WIND** and **WHIRLWIND**.

Hurricanes are frequent in the West-indies, where they make terrible ravages, by rooting up trees, destroying houses and shipping, and the like.

The natives, it is said, can foretel hurricanes by the following prognostics: 1. All hurricanes happen either on the day of the full, change, or quarter of the moon. 2. From the unusual redness of the sun, the great stillness and at the same time turbulence of the skies, swelling of the sea, and the like, happening at the change of the moon, they conclude there will be a hurricane next full-moon; and if the same signs be observed on the full-moon, they may expect one next new-moon.

As to the cause of hurricanes, they undoubtedly arise from the violent struggle of two opposite winds. Now as the wind betwixt the tropics is generally easterly, and upon the sun's going back from the northern tropic, the western winds pour down with violence upon those parts, the opposition of these contrary winds cannot fail to produce an hurricane.

Hurricanes shift not through all the points of the compass, but begin always with a north wind, veer to the east, and then cease; and their shifting between these two points is so sudden and violent, that it is impossible for any ship to veer with

it; whence it happens that the sails are carried away, yards and all, and sometimes the masts themselves wreathed round like an osier.

**HUSBAND**, *maritus*, a man joined or contracted with a woman in marriage.

By marriage the husband has power over his wife's person; but if he threaten to kill her, &c. she may make him find surety of the peace: he has likewise power over the wife's estate; and if she have fee, he gains a freehold in her right. He also gains her chattels real, as terms for years, &c. and all personal chattels in the possession of the wife, are the husband's; but where the wife is out of possession, or the chattels are debts, or things in action, in case they are not recovered by him and his wife, the husband shall not be entitled to have them. A husband cannot alien the lands of his wife, only by fine wherein she joins; or make leases of her estate, but where she is made a party, and the rent reserved to husband and wife, and the heirs of the wife, &c. nor shall the wife's own acts, as to her estate, bind even herself without a fine levied, when she is examined by writ, if she does it freely, &c.

The husband shall be tenant by the courtesy of his wife's land, after her death, where issue is born between them; and the wife shall have dower in her husband's lands, after his decease; also her necessary apparel, &c. and if she survives the husband, she shall have her terms for years, or chattels real, again, where the husband has not altered the property: yet in a husband's life-time the wife is disabled to make any contract without his consent, unless it is for necessities according to his degree and estate; and notwithstanding she may use the goods of her husband, she may not dispose of, or pawn them; though, if she take them away, it is not felony in her. As a husband is not obliged by his wife's contract, without notice and assent; so he is not bound by the receipt of his wife, for his money. Although a wife be very lewd, if she lives with her husband, he is chargeable for all necessities for her; and so he is in case he runs away from her, or turns her away. It is otherwise if she goes away from the husband; then, as soon as such separation is notorious, whoever gives her credit, does it at his peril, and her husband is not liable, unless he takes her again; though here, if the husband receives her, or comes after her, and lies

with her but one night, that may make him chargeable for her debts.

**HUSBANDRY**, denotes much the same with agriculture. See **AGRICULTURE**. As there is no subject of more general advantage than the cultivation of lands, we have given the operations and improvements thereof, under a great variety of articles, as **PLOWING, FALLOWING, INCLOSURES, DRAIN, HEDGE, DITCH, SOWING, WEEDING, HOEING, CORN, PASTURE, HAY, &c.**

The New Method of Horse-hoeing Husbandry, written by the ingenious Jethro Tull, has now been published some years, so that a pretty good judgment may be formed of the performance. See the article **HOEING**.

Every man, who has considered the principles upon which this method of culture is founded, may discern how far his theory is consistent with nature; though, it is probable, few have as yet made sufficient experiments, to be fully informed of its worth. How it has happened, that what proposes such advantages, has been so long neglected in this country, may be matter of surprize to those who are unacquainted with the characters of the men on whom its practice depends; but to those who know them thoroughly, it can be none: for it is certain that very few of them can be prevailed on to alter their usual methods, though their continuing therein, renders them unable to maintain their families and pay their debts: but what is still more to be lamented, those who are averse to improvements, dissuade others also from thinking of them. But as the methods commonly used, together with the mean price of grain, have every where reduced the farmers so low that they pay their rents very ill, and in many places throw up their farms, the cure of these evils is certainly an object worthy of the public attention: for if the proprietors must be reduced to cultivate their own lands, which cannot be done by the hands of these obstinate and indocile people, it is easy to discern on which side his ballance of profit and loss will turn. This consideration, together with many others which might be urged, hath induced us to recommend this treatise to the serious attention of all who wish well to their country; in hopes that some may be prevailed on, from a regard either to the public good or their own interest, to give the method proposed in a fair and impartial trial; for

could it be introduced into several parts of Great Britain, by men of generous and benevolent principles, their example might, in time, establish the practice, and bring it into general use; which is scarce to be expected, by any other means.

It is therefore to such only as are qualified to judge of a theory, from the principles on which it is founded, that we do ourselves the honour to address them, to give this essay an attentive reading, and to try the experiments with proper care. As a motive to this, it is to be observed, that, though the method of culture proposed by Mr. Tull, has made little progress in England, it is not likely to meet with the same neglect abroad, especially in France, where a translation of his book was undertaken, at one and the same time, by three different persons of consideration, without the privacy of each other; but afterwards two of them put their papers into the hands of the third, M. Du Hamel du Monceau, of the Royal Academy of Sciences at Paris, and of the Royal Society of London, who has published a book, intitled, *A Treatise on Tillage, on the principles of Mr. Tull*. The ingenious author has, indeed, in some measure altered the method observed by Mr. Tull, in his book; yet has very exactly given his principles and rules; but as he had only seen the first edition of the Horse-hoeing Husbandry, so he is very defective in his descriptions of the ploughs and drills, which in that was very imperfect, and was afterwards amended by Mr. Tull, in his additions to that essay. One of the principal reasons for taking notice of this book, is to shew the comparison this author has made between the old method and the new. By his calculation, the profits arising from the new are considerably more than double those of the old. For, according to him, the profits of twenty acres of land, for ten years, amount, at  $10\frac{1}{2}$  d. per livre.

liv. l. s. d.

By the old method to 3000, or 131 3 0  
By the new method to 7650, or 334 13 9  
Which makes a prodigious difference in favour of the latter. As this computation was made by one who cannot be supposed to have any prejudice in favour of Mr. Tull's scheme, it will naturally find more credit with the public, than any comparison made by Mr. Tull himself, or by those who approve his practice. There have appeared no objections against Mr. Tull's principles or practice, that may

may not be equally urged against every sort of improvement: one of the principal is, its being impracticable in common fields, without the concurrence of every one who occupies land in the same field. But does not this equally affect the old husbandry? for every such person is obliged to keep the turns of plowing, fallowing, &c. with the other occupiers; so that if any of them were inclinable to improve their lands, by sowing grass-feed, or any other method of culture, they are under the same difficulties as they would be, were they to practice Mr. Tull's method.

Others object, that the introducing this sort of husbandry is unnecessary, since the improvements made by grass-seeds are so very considerable: besides, the returns made by the fold and dairy being much quicker than by grain, they engage the farmer to mix ploughing and grazing together. But this can have no weight; for it is well known, that in the farms where the greatest improvements have been made by grass-seeds, the dressing required for the arable-land often runs away with most of the profit of the whole farm, especially when the price of grain is low. If this be the situation of the most improved farms, what must be the case of those which chiefly consist of arable-land, where most of the dressing must be purchased at a great price, and often fetched from a considerable distance. This, together with the great expence in servants and horses, unavoidable in arable farms, shew the advantages the grazier has over the ploughing farmer. It is therefore much to be wished, that the practice of mixing the two sorts of husbandry, were more generally used in every part of the kingdom; and here we apprehend Mr. Tull's method of culture would be the surest way to improve both. For though Mr. Tull chiefly confined the practice of his method to the production of grain, yet it may be extended to every vegetable which is the object of culture in the fields, gardens, and woods; and perhaps may be applied to other crops to equal if not to greater advantage than to corn. In the vineyard it hath been long practised with success; and it may be used in the hop-ground with no less advantage. For the culture of beans, pease, woad, madder, and other large-growing vegetables, and for lucern, saintfoin, and the larger grasses, we conceive it the most profitable method, since in all

these crops, one sixth part of the seed now commonly sown, will be sufficient for the same quantity of land, and yet the crop will be much greater. It may also be used with equal advantage in our colonies in America in the culture of sugar-canes, indigo, cotton, and rice.

It has been objected that it is practicable only on such lands as are soft and light, and not at all on stiff or stony ground: but the hoe-plough has been long used in vineyards, where the soil is stronger and abounds with stones full as much as any part of this country; though the use of this plough is attended with some difficulties upon such land, for wheat, or plants of low growth, whose roots may be in danger of being turned out of the ground, or their tops buried by the clods or stones; yet none of the larger growing plants are subject to these inconveniencies. Besides, the stronger the soil is, the more benefit it will receive from this method of culture, if the land be thereby more pulverized; which will certainly be the consequence, where the method laid down by Mr. Tull is duly observed.

But as most instruments, in their first use, are attended with some difficulty, the hoe-plough has been complained of as cumbersome and unweildy both to the horse and ploughman. But it is proper here to observe, that the swing-plough, commonly used in the land about London, will do the business of the hoe-plough in all ground that is not very strong or very stony; and that where it is so, the foot-plough, made proportionably strong; will completely answer all purposes: but then, when these are used to hoe corn, the board on the left hand of the plough, answering the mould-board, must be taken off, otherwise, so much earth will run to the left side, as to injure the crop when it is low.

The drills are excellent instruments, yet we imagine them capable of farther improvements. Parallel grooves, at about an inch asunder, round the inside of the hopper, would shew the man who follows the drill, whether or no both boxes vent the seed equally. By an hitch from the plank to the harrow, the latter may be lifted to a proper height, so as not to be in the way when the ploughman turns at the head-land. Two light handles on the plank, like those of the common plough, would enable the person who follows the drill, to keep it from falling off the middle of the ridge: it may be useful al-

so in wet weather, to double the drill; by which means two ridges may be sown at the same time, the horse going between them: for the planks of two drills, each plank having one of the shafts fixed to it, may be joined end to end by two flat bars of iron, one on each side, well secured by iron-pins and screws; and by corresponding holes in the planks and bars, the distance between the drills may be altered, according to the different spaces between the ridges.

We shall now annex a computation of the

expence and profit both of the old method of culture and the new, experimentally tried by a gentleman of veracity, in a country where the soil was light and chalky, that is, of the same nature with that from whence Mr. Tull drew his observations. In the new husbandry, every article is put at its full value, and the crop of each year is four bushels short of the other; though, in several years experience, it has equalled, and generally exceeded, those of the neighbourhood in the old way.

### An Estimate of the Expence and Profit of Ten Acres of Land, in Twenty Years.

#### I. In the Old Way.

The first year for wheat costs 33l. 5s. viz.	1. s. d.	
First ploughing at 6s. per acre	3 0 0	
Second and third ditto, at 8s. per acre,	4 0 0	1. s. d.
Manure, 30s. per acre,	15 0 0	22 0 0
Two harrowings and sowings, at 2s. 6d. per acre,	1 5 0	
Seed, three bushels per acre, at 4s. per bushel,	6 0 0	
Weeding, at 2s. per acre,	1 0 0	
Reaping, binding, and carrying in, at 6s. per acre,	3 0 0	11 5 0
Second year for barley costs 11l. 6s. 8d. viz.	33 5 0	
Once ploughing, at 6s. per acre,	3 0 0	
Harrowing and sowing, at 1s. 6d. per acre,	0 15 0	
Seed, four bushels per acre, at 2s. per bushel,	4 0 0	
Weeding, at 1s. per acre,	0 10 0	
Cutting, raking, and carrying, at 3s. 2d. per acre,	1 11 8	
Grass-seeds, at 3s. per acre,	1 10 0	11 6 8
Third and fourth years, lying in grass, cost nothing.	44 11 8	
So that the expence of ten acres in four years comes to 44l. 11s. 8d.	222 18 4	
and in twenty years to	35 0 0	
First year's produce is half a load of wheat per acre, at 7l. per acre	20 0 0	
Second year's produce is two quarters of barley per acre, at 1l. per acre	15 0 0	
Third and fourth years grass is valued at 1l. 10s. per acre	70 0 0	
So that the produce of ten acres in four years, is	350 0 0	
And in twenty years it will be	222 18 4	
Deduct the expence	127 1 8	
And there remains clear profit on ten acres in twenty years by the old way		

#### II. In the New Way.

First year's extraordinary expence is	
For ploughing and manuring the land, the same as in the old way	22 0 0
Ploughing once more, at 4s. per acre	2 0 0
Seed, nine gallons per acre, at 4s. per bushel,	2 5 0
Drilling, at 7d. per acre,	0 5 10
Hand-hoeing and weeding, at 2s. 6d. per acre,	1 5 0
Horse-hoeing, six times, at 10s. per acre,	5 0 0
Reaping, binding, and carrying in, at 6s. per acre,	3 0 0
The standing annual charge on ten acres is	13 15 10
Therefore the expence on ten acres in twenty years is	275 16 8
Add the extraordinaries of the first year, and the sum is	297 16 8
The yearly produce is at least two quarters of wheat per acre, at 1s. 8s. per quarter, which on ten acres in twenty years amounts to	560 0 0
Therefore, all things paid, there remains clear profit on ten acres in twenty years, by the new way	262 3 4

So that the profit on ten acres of land, in twenty years, in the new way, exceeds that in the old way by 135 l. 1 s. 8 d. an ample encouragement to practise a scheme, by which so great an advantage will arise from so small a quantity of land in the compass of a twenty-one years lease. It ought also to be observed, that Mr. Tull's husbandry requires no manure at all, though we have here, to prevent objections, allowed the charge of it for the first year; and moreover, that though the crop of wheat from the drilling plough is here put only at two quarters on an acre; yet Mr. Tull himself, by actual experiment and measure, found that the produce of his crop of drilled wheat, amounted to almost four quarters on an acre.

**HUSBRECE**, the same with burglary. See the article **BURGLARY**.

**HUSGABLE**, antiently signified house- rent, or some tax imposed upon houses.

**HUSK**, the same with what botanists call the calyx, or cup of a flower. See the article **CALYX**.

Petiver of the verticellate plants, as sage, rosemary, and the like, says, that it is an erroneous tho' general opinion, that the flowers of these plants contain their principal medicinal virtues; the husks being the part in which this is lodged. Thus, for instance, the fine scent of hungary-water is not owing to the flowers but husks of rosemary; since the flower alone, when clean picked of them, yields very little odour. See **HUNGARY-WATER**.

**HUSO**, the **ISINGLASS-FISH**, in ichthyology, the smooth-bodied accipenser, a river-fish larger than the sturgeon, or common accipenser. See **ACCIPENSER**. It is said to grow to twenty-four feet in length, and is thick in proportion: the rostrum or snout is long, and furnished with cirri; but its mouth is very small in proportion to the size of the fish, and is furnished with no teeth. It has only one serrated long fin on the back, a pair of pectoral and another of belly-fins, beside that near the anus. It is more frequent in the Danube than in any other part of the world. See plate **CXXXV. fig. 4.** The ichthyocolla or isinglass of the shops, famous as an agglutinant, and for fining of wines, is the produce of this fish, made by boiling down its membranous parts to a jelly. See **ICHTHYOCOLLA**.

**HUSSARS**, a kind of irregular cavalry, armed with the sabre and bayonet, are retained in the service of most princes on the continent.

They are very resolute partisans, and better in an invasion or hasty expedition, than in a set battle.

**HUSSITES**, the disciples of John Hus, a Bohemian, and curate of the chapel of Bethlehem at Prague; who, about the year 1414, embraced and defended the opinion of Wickliff of England, for which he was cited before the council of Constance, and, refusing to renounce his supposed errors, he was condemned to be burnt alive, which sentence was accordingly executed upon him at Constance. It is evident in what the pretended heresy of John Hus and Jerom of Prague, who suffered with him, consisted, from the answer they made to the council, when they were admonished to conform to the sentiments of the church: they were lovers, they said, of the holy gospel, and true disciples of Christ; that the church of Rome, and all other churches of the world, were widely departed from the apostolical tradition; that the clergy ran after pleasures and riches, lorded it over the people, affected the highest seats at entertainments, bred horses and dogs, and the revenues of the church, which belonged to the poor members of Christ, were consumed in vanity and wantonness; and that the priests were ignorant of the commandments of God, or if they did know them, paid but little regard to them. The followers of Hus were also called calixtins, taberites, and bohemian brethren.

**HUSTINGS**, a court held in Guildhall before the lord-mayor and aldermen of London, and reckoned the supreme court of the city. Here deeds may be inrolled, recoveries passed, out-lawries sued out, and replevins and writs of error determined. In this court also is the election of aldermen, of the four members of parliament for the city, &c.

This court is very antient, as appears by the laws of Edward the confessor.

Some other cities have likewise had a court bearing the same name, as Winchester, York, &c.

**HUSUM**, a port-town of Sleswic or south Jutland, situated on the German sea; subject to the duke of Holstein Gottorp: east long. 8° 30', north lat. 54° 40'.

**HUT**, a small cottage; also a soldier's lodge, otherwise called a casern. See the article **CASERN**.

**HUTHERFIELD**, a market-town in the west riding of Yorkshire: west long. 1° 34', north lat. 53° 37'.

**HUXING**

**HUXING** *of a pike*, a method of catching that fish, performed in the following manner: a person takes thirty or forty as large bladders as he can get, blows them up, and ties them close together; then at the mouth of each he ties a line, which is longer or shorter according to the depth of the water; and at the end of the line is fastened a baited hook: they are then put into a pond with the advantage of the wind, that they may gently move up and down the water. When a mackerel-pike has swallowed the hook, and is almost spent, he is taken out of the water.

**HUY**, a strong town in the bishopric of Liege, situated on the Maes, sixteen miles north-east of Namur: east long.  $5^{\circ} 15'$ , north lat.  $50^{\circ} 35'$ .

**HYACINTH**, *hyacinthus*, in botany, a genus of the *hexandria-monogynia* class of plants, the flower of which consists of a single companulated petal, divided into six reflex segments at the limb: the fruit is a roundish capsule, lightly ridged with three corners, and divided into three cells, each of which usually contains two roundish seeds.

There is a great variety of these beautiful flowers, all of which are propagated by seeds, or off-sets from the old bulbs.

**HYACINTH**, in natural history, a genus of pellucid gems, whose colour is red with an admixture of yellow.

The hyacinth, tho' less striking to the eye than any other red gems, is not without its beauty in the finest specimens. It is found of various sizes, from that of a pin's head to the third of an inch in diameter. Like common crystal, is sometimes found columnar, and sometimes in a pebble-form; and is always hardest and brightest in the larger masses.

Its colour is a dull or deadish red, with an admixture of yellow in it; and this mixed colour is found in all the variety of tints, that a prevalence of the red or of the yellow in different degrees is capable of giving it.

Our jewellers allow all those gems to be hyacinths or jacinths, that are of a due hardness with this mixed colour; and as they are of very different beauty and value in their several degrees and mixture of colours, they divide them into four kinds; three of which they call hyacinths, but the fourth, very improperly, a ruby. 1. When the stone is in its most perfect state, and of a pure and bright

flame-colour, neither the red nor the yellow prevailing, in this state they call it hyacintha la belle. 2. When it has an over proportion of the red, and that of a dusky colour than the fine high red in the former, and the yellow that appears in a faint degree in it, is not a fine, bright, and clear, but a dusky brownish-yellow, then they call it the saffron hyacinth. 3. Such stones as are of a dead whitish-yellow, with a very small proportion of red in them, they call amber-hyacinths. And, 4. When the stone is of a fine deep red, blended with a dusky and very deep yellow, they call it a rubacelle. But tho' the over-proportion of a strong red in this gem has made people refer it to the class of rubies, its evident mixture of yellow, shews that it truly belongs to the hyacinths.

The hyacinth la belle is found both in the East and West Indies. The oriental are the harder, but the american are often equal to them in colour. The rubacelle is found only in the East Indies, and is generally brought over among the rubies, but it is of little value: the other varieties are found in Silesia and Bohemia.

Our druggists usually keep under the names of hyacinths, small garnets, some of them of the smooth pebble-kind, somewhat resembling the native rubies, and others angular. They have the former from Poland, the latter principally from Bohemia: but neither of them are true hyacinths. They have sometimes, tho' rarely, the third kind, or amber-hyacinths; and if any stress were to be laid on the virtues of this stone, these are the only kind that can lay any claim to it. They have also a very small and bad kind of the amber-hyacinth, whiter than those received among the jewellers, which are found in the beds of rivers in Bohemia; these, they would persuade us, are true oriental hyacinths, but beside our knowing that the same are found in Bohemia, the want of hardness in the very finest of them, is an evident proof of the contrary. The antients have attributed great virtues to this gem; and later writers have even made it the basis of a cordial and astringent confection, which takes its name from it. It is generally said to be cordial, restorative, and moderately astringent; and some have added that it is hypnotic. But the ostentation of bringing the most costly things into medicines, rather than any rational opinion

of their virtues, seems to have given the original hint of introducing the gems into it; and if there were nothing else against it, one would be cautious of their getting into use, were it only from the uncertainty of what apothecaries meet with under their names at the druggists.

**HYACINTHIA**, an ancient grecian festival, observed at Amyclæ in Laconia, in the month Hecatombæon, in memory of the beautiful young Hyacinthus, son of Amyclos king of Sparta. It continued three days, during the first of which they shewed all imaginable signs of grief for the death of Hyacinthus: upon the second and third day, various spectacles were exhibited, and hymns sung in honour of Apollo: they likewise offered multitudes of victims, and gave rich entertainment to their friends.

**HYADES**, in astronomy, seven stars in the bull's head, famous among the poets for the bringing of rain.

The principal of them is in the left eye, called by the Arabs Aldebaran. See the articles **TAURUS** and **ALDEBARAN**.

**HYDATIDES**, in medicine, little transparent vesicles or bladders, full of water, sometimes found solitary, and sometimes in clusters, upon the liver, and various other parts, especially in hydropical constitutions.

But in a particular sense, the hydatid is a disease of the eye-lids, called also aquila. St. Yves informs us, that there sometimes comes on the edge of the cartilages of the eye-lids, or on the conjunctiva, an elevation like the bladders which appear on the skin after burns. They are as big as a pea, or a lentil; are filled with a very clear liquor, and have the name of hydatides from the lymph which they contain. Sometimes a serosity is extravasated between the conjunctiva and the membrane which covers it: it separates these membranes, and in the movement of the eye, a sort of wrinkle appears, which shews that a serosity stagnates between these membranes, and produces the swelling. This disease is not at all dangerous; it is a little troublesome when it seizes only part of the conjunctiva. The surest remedy is to prick it dexterously with the point of a lancet, and to lay it open according to the longitudinal direction of the tumour, without any other application.

**HYDATOIDES**, the same with the aqueous humour of the eye. See **EYE**.

**HYDATOSCOPIA**, called also hydro-mancy, a kind of divination or method of foretelling future events by means of water. See **HYDROMANCY**.

**HYDE**, or **HIDE**. See the article **HIDE**.

**HYDNUM**, in botany, a genus of fungi, called by some erinaceus: it is an horizontal fungus, echinated, or beset with sharp-pointed fibres on its under part. See the article **FUNGUS**.

**HYDRA**, in astronomy, a southern constellation imagined to represent a water-serpent.

The number of stars in this constellation in Ptolemy's catalogue is 25, and in the britannic catalogue, 68.

**HYDRAGOGUES**, ὑδραγωγὰ, among physicians, remedies which evacuate a large quantity of water in dropfies. See the article **DROPSY**.

Quincy observes, that the strongest cathartics chiefly answer to the character of hydragogues, in that by their forcibly shaking and velicating the bowels, and their appendages, they squeeze out water enough to make the stools appear little else.

The principal hydragogues, in the common opinion, are the juices of elder, of the root of iris, of soldanella, mechoacan, jalap, &c. In the general, all sudorific, aperitive, and diuretic medicines are truly hydragogues.

**HYDRANGÆA**, in botany, a genus of the *decandria-digynia* class of plants; the corolla whereof consists of five equal, roundish petals, greater than the cup: the fruit is a roundish didymous capsule; the two permanent styles make two beaks to it, and is rendered angular by many ribs: it is coronated by the cup, and divided into two cells by a transverse membrane: the seeds are numerous, angular, acuminate, and very small.

**HYDRARGYRUM**, a name given to mercury or quicksilver. See the article **MERCURY**.

**HYDRAULICS**, the science of the motion of fluids, and the construction of all kinds of instruments and machines relating thereto.

The laws of the motion of fluids, and the causes of their descent or rise below or above the common surface or level of the source or foundation, have been already delivered under the article fluid; and the art of conducting fluids into pipes, canals, drains, &c. as also the art of raising them, with the several ma-

chines employed for that purpose, as syphons, pumps, syringes, fountains, fire-engines, mills, &c. are described under their proper heads. See the articles **SYPHON, PUMP, SYRINGE, FOUNTAIN, ENGINE, MILL, &c.**

**Hydrostatics** explain the equilibrium of fluids at rest; upon removing which equilibrium motion ensues, and hydraulics commence.

**Hydraulics**, therefore, suppose hydrostatics, and the generality of writers, from the immediate relation between the two, join them together, and call them both either hydraulics or hydrostatics. See the article **HYDROSTATICS**.

**HYDRELÆUM**, in pharmacy, a mixture of common oil with water, which, taken internally, is emetic; but applied externally, is anodyne, and promotes suppuration.

**HYDRENTEROCELE**, in surgery, a species of hernia, wherein the intestines descend into the scrotum, together with a quantity of water. See **HERNIA**.

**HYDROCANISTERIUM**, an engine which spouts water in great quantities, and to considerable heights, in order to extinguish accidental fires in houses. See the article **ENGINE**.

**HYDROCELE**, in surgery, denotes any hernia arising from water, but is particularly used for such a one of the scrotum which sometimes grows to the size of one's head, without pain, but exceeding troublesome to the patient.

Tho' authors, says Sharp, mention several kinds of this disease, there are but two; the first is when the water is contained in the tunica vaginalis; the second, when it is contained in the cellular membrane of the scrotum. This last is always complicated with an anasarca, a kind of dropsy which consists in the extravasation of the water which lodges in the cells of the membrana adiposa. The hydrocele in this case is easily known, for the skin is shining and soft, yielding easily to a slight impression, which will remain pitted some time. The penis is also sometimes prodigiously swelled by the liquor which insinuates into the cellular membrane. There are none of these symptoms in the dropsy of the tunica vaginalis.

In the dropsy of the cellular membrane of the scrotum, some recommend the puncture with a trocar; others, to make small apertures here and there with the

point of a lancet; others, to put a small skane of silk through the skin with a needle, and to let it remain as a seton till all the water is drained off. But the two first methods yield very little relief, and the last may be more likely to induce a gangrene. Nor is there occasion for any operation at all, because the cellular membrane of the scrotum, is nothing but a continuation of the membrana adiposa, and therefore scarifications made in the skin of the small of the legs, will effectually empty the scrotum; yet sometimes there falls so great a quantity into the scrotum, that the distension is very painful, threatening a mortification: likewise the prepuce is very often so excessively dilated and twisted, that it hinders the patient from making water. In these cases, there should be an incision made on each side of the scrotum, three inches in length, quite through the skin into the cells which contain the water, and likewise two or three half an inch long in any part of the penis with a lancet or knife. The dropsy of the tunica vaginalis, is caused by an excessive accumulation of a serosity which is naturally separated in the internal surface of that tunic, in a small quantity, to moisten and lubricate the testicle.

This disorder is not often the effect of any accident. It never diminishes when once begun, but generally continues to encrease, but in some persons not so quick as others. It is tense and smooth, and ceases before or when it arrives at the rings of the abdominal vessels. When the testicle is encreased in size, the tumour is rounder, and, if not attended with an enlargement of the spermatic vessels, the cord may be easily distinguished between the tumour and the abdomen.

As to the cure, the author above-mentioned has found little success from inward medicines or outward applications, and therefore thinks it most advisable to wait till the tumour becomes troublesome, and then to tap it with a lancet. If the orifice of the skin slips away from that of the tunic, and prevents the egress of the water, you may introduce a probe, and by that means secure the exact situation of the wound. When the tunica vaginalis is very tense, the testicle itself cannot be easily distinguished; but there will be no danger of wounding it, if the inferior part of the scrotum is opened with a lancet not too long. During the

evacu-

evacuation, the scrotum must be regularly pressed ; and after the operation, a little piece of dry lint and sticking-plaster are sufficient. This is called a palliative cure, but it now and then proves an absolute one. It is dangerous to attempt a radical cure by making a large wound, either by incision or caustic, and therefore that method should be discarded.

**HYDROCEPHALUS**, in surgery, a preternatural distention of the head, to an uncommon size, by a stagnation and extravasation of the lymph, which, when collected within side of the bones of the cranium, the hydrocephalus is then termed internal ; as it is external, when retained betwixt the common integuments and the cranium.

The first kind of the disorder is seldom to be met with but in infants ; and if it is advanced to any great degree, is a dangerous case, and generally incurable. If the disorder is in its first stage, and but beginning to shew itself, it will be most advisable, according to Heister, to try what may be done by medicines, such as gentle and repeated purges, to draw the humours downwards, with corroborating medicines, internally ; while externally there is applied a large compress dipt in lime-water and spirit of lavender, or hungary water, which compress must be retained by a proper bandage. See the article **BANDAGE**.

The external hydrocephalus is distinguished by the softness of the head and skin externally ; but in the internal hydrocephalus, the head feels as hard as usual, and yet it is much more distended and enlarged. Though the external hydrocephalus is not without danger, yet it may be much more easily cured than the internal, but with the greater difficulty, as it is of a longer standing. According to the same author, the cure must be attempted as well by internal as external remedies at the same time ; such as cathartics, diaphoretics, diuretics, attenuating and strengthening medicines for internal use : and externally may be applied a compress dipped in the fomentation before-mentioned for the internal hydrocephalus. In this case the repeated chewing of tobacco in the mouth, to discharge the serosities from the head by spitting, is advisable : some foment the head with fumes of burning spirit of wine highly rectified, but if all these means prove unsuccessful, recourse must then be had to chirurgical helps, among

which you ought first to try a blister applied behind the ears on the occiput and neck, and if this does not altogether answer the intention, you may add scarification and cupping upon the same parts. See **CUPPING**.

**HYDROCERATOPHYLLUM**, in botany, a plant otherwise called ceratophyllum. See **CERATOPHYLLUM**.

**HYDROCHARIS**, the **LITTLE WATER-LILLY**, in botany, a genus of the *diccaneandria* class of plants, the male flower of which has a spathe, and is composed of three large, plain, and roundish petals ; the female flower is like the male one, only without any spathe : the fruit is a coriaceous and roundish capsule, consisting of six cells, in which are contained a great number of very small and roundish seeds.

**HYDROCORAX**, the **WATER-RAVEN**, in ornithology, a species of bucceros, with a small head and bluish back.

This bird is about the bigness of the common raven, and is a native of Tartary and China ; from whence its beak is often brought over to us as a curiosity, on account of its size, as being seven inches in length, and in the largest part, about the middle of the gibbosity, near three inches in diameter.

There is also another species, about the bigness of our common crow, the head of which is of a deep greenish cast, but with an admixture of black : the body too is of a greenish colour.

**HYDROCOTYLE**, **MARSH-PENNY-WORT**, in botany, a genus of the *pentandria-digynia* class of plants, the universal corolla of which is uniform in figure, though not in situation ; and the single corollæ are formed of five ovato-acute, patent petals : the fruit is orbicular, erect, and composed of two compressed and semi-orbicular seeds.

This plant is common with us in damp places, and is suspected of hurting sheep that feed on it ; whence it is sometimes called white-rot. See the article **ROT**.

**HYDROGRAPHY**, *ὕδρυγραφία*, the art of measuring and describing the sea, rivers, lakes, and canals.

With regard to the sea, it gives an account of its tides, counter-tides, soundings, bays, gulphs, creeks, &c. as also of the rocks, shelves, sands, shallows, promontories, harbours, the distance and bearing of one port from another, with every thing that is remarkable, whether out at sea, or on the coast.

**HYDROMANCY**, a method of divination by water, practised by the antients in this manner. They filled a cup or bowl of water: then fastening a ring to a piece of thread tied to their finger, held it over the water, and repeated a certain form of words, desiring to be satisfied with regard to their enquiry; and if the question was answered in the affirmative, the ring would strike the sides of the bowl of its own accord.

Another kind of hydromancy was to look upon the water in which the figure of several daemons used to appear. This expedient Numa is said to have made use of, to settle the ceremonies of religion.

This way of divination is said to have been used first by the Persians, and afterwards approved by Pythagoras.

**HYDROMEL**, among physicians, water impregnated with honey, either before or after fermentation.

Vinous hydromel, commonly called mead, is said to be good for the gravel. See the article MEAD.

**HYDROMETER**, an instrument to measure the gravity, density, velocity, force, &c. of water and other fluids. See the articles WATER and FLUID.

The hydrometer is one of the most useful instruments of the philosophic kind; for tho' the hydrostatical ballance be the most general instrument for finding the specific gravities of all sorts of bodies, yet the hydrometer is best suited to find those of fluids in particular, both as to ease and expedition.

This instrument should be made of copper, since ivory imbibes spirituous liquors, and thereby alters its gravity; and glass is apt to break. The most simple kind, used for finding the strength of spirits, consists of a copper-ball *Bb* (plate CXXXVII. fig. 1. n<sup>o</sup> 1.) with a brass-wire, *AB*,  $\frac{1}{4}$  of an inch thick, soldered into it. The upper part of this wire being filed flat on one side, is marked proof at *m*, because it sinks exactly to this mark in proof-spirits. There are other two marks at *A* and *B*, to shew whether the liquor be  $\frac{1}{10}$  above or below proof, according as the hydrometer sinks to *A* or emerges to *B*, when a brass-weight as *C* or *K* has been screwed on at the bottom *c*. There are also weights to be screwed on, for shewing the specific gravities of fluids quite to common water. The round part of the wire above the ball, may be marked so as to represent river-water when it sinks to *RW*,

(*ibid.* n<sup>o</sup> 2.) the weight which fits the instrument for river-water being screwed on at *c*: also when put into spring-water, mineral water, sea-water, and water of salt-springs, it will emerge or rise gradually to the marks *SP*, *MI*, *SE*, *SA*; and, on the contrary, when put into Bristol-water, rain-water, port-wine, and mountain-wine, it will successively sink to the marks *br*, *ra*, *po*, *mo*.

Another kind, which serves to distinguish the specific differences of fluids to great nicety, consists of a large hollow ball *B*, (*ibid.* n<sup>o</sup> 3.) with a smaller ball *b* under it, partly filled with quick-silver or small shot, and screwed on to the lower part of the former, in order to render it but little specifically lighter than water: it has also a small short neck at *C*, into which is screwed the graduated brass-wire *AC*, which by its weight causes the body of the instrument to descend in the fluid, with part of the stem.

When this instrument is swimming in the liquor, contained in the jar *ILMK*, the part of the fluid displaced by it, will be equal in bulk to the part of the instrument under water, and equal in weight to that of the whole instrument. Suppose the weight of the whole were 4000 grains, then it is evident we can by this means compare together the different bulks of 4000 grains of various sorts of fluids. For if the weight *A* be such as shall cause the areometer to sink in rain-water, till its surface comes to the middle point of the stem *20*; and if, after this, it be immersed in common spring-water, and the surface is observed to stand  $\frac{1}{10}$  of an inch below the middle point *20*; it is evident that the same weight of each water differs in bulk only by the magnitude of  $\frac{1}{10}$  of an inch in the stem.

Now suppose the stem were ten inches long, and weighed 100 grains, then every tenth of an inch would be one grain weight; and since the stem is of brass, and brass is about eight times heavier than water, the same bulk of water will be equal to  $\frac{1}{8}$  of a grain; and consequently to the  $\frac{1}{8}$  of  $\frac{1}{1000}$  part, that is, a 32000th part of the whole bulk, which is a degree of exactness as great as can be desired. Yet the instrument is capable of still greater exactness, by making the stem or neck consist of a flat thin slip of brass, instead of one that is round or cylindrical: by this means we increase the surface, which is the most requisite thing;

*Fig. 1. HYDROMETERS.*

*Fig. 2. HYPOTHENUSE.*

*Fig. 3. HYDROPHYLLUM.*

thing; and diminish the solidity, by which the instrument is rendered more exact.

In order to adapt this instrument to all sorts of uses, there ought to be two different stems to screw on and off in a small hole at *a*. One stem should be such a nice thin slip of brass, or rather of steel, like a watch-spring set straight, as we have just mentioned, on one side of which ought to be the several marks or divisions, to which it will sink in various sorts of waters, as rain-water, river-water, spring-water, sea-water, salt spring-water, &c. And on the other side you mark the division to which it sinks in various lighter fluids, as hot bath-water, Bristol water, Lincomb water, Cheltenham-water, port wine, mountain, madeira, and various other sorts of wine. But in this case the weight *A* on the top must be a little less than before, when it was used for the heavier waters.

But, in case of trying the strength of spirituous liquors, a common cylindric stem will do best, because of its strength and steadiness; and this ought to be so contrived that, when immersed in what is called proof-spirit, the surface of the spirit may be upon the middle point *20*; which is easily done by duly adjusting the small weight *A* on the top, and making the stem of such a length that, when immersed in water, it may just cover the ball, and rise to *a*; but, when immersed in pure spirit, it may arise to the top at *A*; then by dividing the upper and lower parts *a 20*, *A 20*, into ten equal parts each, when the instrument is immersed in any sort of spirituous liquor, it will immediately shew how much it is above or below proof.

This proof-spirit consists of half water and half alcohol, or pure spirit, that is, such as when poured upon gunpowder, and set on fire, will burn all away, and permit the powder to take fire, which it will, and flash as in the open air. But if the spirit be not so highly rectified, there will remain some phlegm or water, which will make the powder wet, and unfit to take fire. This proof-spirit of any kind, weighs seven pounds twelve ounces per gallon.

The common method of shaking the spirits in a vial, and by raising a crown of bubbles, to judge by the manner of their rising or breaking away whether the spirit be proof or near it, is very precarious,

and capable of great fallacy. There is no way so easy, quick, certain, and philosophical, as this by the aræometer, which will demonstrate infallibly the difference of bulks, and consequently specific gravities, in equal weights of spirits, to the 30, 40, or 50 thousandth part of the whole, which is a degree of accuracy, beyond which nothing can be desired.

**HYDROPHACE**, in botany, a name sometimes given to the lemma of Linnæus. See the article **LEMNA**.

**HYDROMETRY**, *υδρομετρία*, a term sometimes, tho' rarely, used to denote the mensuration of fluids, their gravity, velocity, &c. and consequently comprehending both hydraulics and hydrostatics. See **HYDRAULICS** and **HYDROSTATICS**.

**HYDROMPHALUS**, in medicine and surgery, a tumour in the navel, arising from a collection of water.

The hydromphalus is distinguished from other tumours of the navel by its being very soft, and yet not tractable and obedient to the touch, so as to diminish or enlarge by compressing it. See the article **EXOMPHALUS**.

When viewed, placed between the eye and the light, the hydromphalus is found transparent. It is to be dissolved by emollient and resolute medicines. It is also cured by a puncture made in the middle of the navel.

**HYDROMYSTES**, a name antiently given to certain officers in the greek church, whose business was to make holy-water, and sprinkle it on the people. See the article **HOLY-WATER**.

**HYDROPARASTATÆ**, a sect of heretics, the followers of Tatian.

This sect were called also encratitæ, apotactitæ, saccophori, severiani, and aquarians.

The hydroparastatæ were a branch of the manichees, whose distinguishing tenet was that water should be used in the eucharist instead of wine.

**HYDROPHANÆ**, in natural history, a genus of semi-pellucid gems, composed of crystal and earth; the latter ingredient being in large proportion, and mixed imperfectly, as in the chalcedony; and giving a general cloudiness or mistiness to the stone, but of so imperfect and irregular an admixture, as not to be capable of so good a polish as the chalcedony; and appearing of a dusky and foul surface, till thrown into water, in which they become lucid, and in some degree transparent,

rent, either in part or totally ; also changing their colour, which returns to them on being taken out of the water.

To this genus belong the oculus beli of authors, or whitish-grey hydrophanes, variegated with yellow, and with a black central nucleus ; and the oculus mundi, or lapis mutabilis, which is likewise a whitish-grey kind without veins.

**HYDROPHOBIA**, *ὑδροφοβία*, in medicine, an aversion or dread of water ; a terrible symptom of the rabies canina.

This disease generally proceeds from the bite of a mad dog, and almost always arises from the infection communicated by the bite of a mad animal ; yet it has been observed to arise spontaneously in some animals affected with acute diseases ; and we have an instance in the medical essays by Dr. Innes at Edinburgh, of a young man that had this symptom attending an inflammation of the stomach. Almost all kinds of animals may be afflicted with this disorder, and may infect other animals, and even men, as dogs, cats, wolves, foxes, horses, asses, mules, horned cattle, hogs, monkees, and cocks : but it most frequently attacks dogs, wolves, and foxes, without any previous contagion.

A hot climate ; excessive heats and sudden colds ; a long, hot, and dry season ; feeding much upon putrid, stinking, verminous flesh ; want of water ; worms generated in the kidneys, guts, brains, or nostrils, are the preceding causes of madness in these animals. When they are going to run mad, they appear dejected, shun company, and hide themselves : they will not bark, but seem to mutter or murmur, and are averse to food and water ; they will fly upon strangers, but retain some regard for their master : their ears and tails hang down, and they walk along as if they were sleepy. This is the first degree of the disease ; and though the bite is then bad, it is not at the worst. Afterwards, they begin to pant, hang out their tongues, froth at the mouth, and gape ; sometimes they seem dull and half asleep ; sometimes they will run, but not directly forward, and soon cease to know their masters ; their eyes are dejected, look watry and dusty ; their tongues are of a lead-colour ; they fall away suddenly, and grow raging mad. A bite at this time is incurable, and the nearer they are to death, with the more dreadful symptoms it is attended.

There is scarce any poison infectious so many ways as this, for it takes effect through the cloaths, without fetching blood ; by the breath of the animal drawn into the lungs ; by a touch of the froth, if recent ; by handling the wound, or instrument which was the death of the animal ; or by handling things which have been infected by any of the former means. Again, there is scarce any poison which produces such terrible effects, and causes such a wonderful change in the person infected. When it begins to work, it is most violent and quick ; and yet, as it is said, will lie dormant for twenty years together before it exerts itself. This diversity depends upon the heat of the season, the degree of the disease in the infected animal, and the temperature of the person bit ; for the bilious are soonest affected with it, the phlegmatic and hydropic the least : likewise something may be attributed to the way of living, diet, and medicines.

A healthy man infected with this contagion, according to Boerhaave, finds the effects of it discover themselves in the following order : there is a pain in the place where he was bit or received the contagion, and then wandering pains in the other parts, chiefly those that are near it ; a lassitude, heaviness, listlessness of the whole body ; inquiet troubled sleep, and terrible dreams, with convulsions and subultus of the tendons ; continual inquietude, sighs, sadness, love of solitude : thus ends the first degree of the disease. Afterwards all the symptoms encrease with a prodigious swiftness and oppression about the præcordia ; a difficult sighing, respiration, horror, a shaking and trembling at the sight of any liquid, pellucid things ; loss of appetite ; an incredible anxiety ; trembling and terrible convulsions, almost forcing the patient into a rage when any liquid is touched with the lips or tongue ; then a vomiting of dark, bilious, viscid matter, or porraceous bile ; an increased heat ; a fever, continual watching, a priapism, a confused series of wild and extravagant thoughts : here the second degree of the disease may be said to terminate. Now all the symptoms grow worse and worse : the tongue hangs out, and is rough ; the voice is hoarse ; strange horrors, starting and wild looks at the sight of water ; a frothing at the mouth ; a voluntary inclination to spit at the by-standers ; also to bite them ; the patient foams at the mouth,

mouth, gnashes with the teeth, and would do mischief if not forcibly held. His pulse and breathing fail; there is a cold sweat; the highest fury: yet during all this time, which is wonderful, the patient continues in his senses, and is afraid of doing harm. On the fourth day from the first degree of the disease, the patient falls into convulsions with great difficulty of breathing, and then dies.

The prevention and cure of this disease, except in a few instances, are very doubtful and uncertain. The preventive cure, according to Boerhaave, consists in making deep scarifications, as soon as possible, after the bite, in the part affected and those adjacent to it, that they may make a considerable discharge of blood; and then applying large cupping-glasses thereon; or it may be burnt pretty deep with an actual cautery. Then it should be made to suppurate by some corrosive application proper for that purpose; and during all that time, it should continually be fomented with a pickle made with vinegar and salt: this should be continued for six months at least: the garments he had on at the time of the bite should be cautiously laid aside, or destroyed. He should likewise, with all convenient speed, be dipt in a river, or the sea, making him believe that he is going to be drowned: this is to be often repeated; for the effect consists in terrifying the mind, and not in the salt water, as is commonly supposed: then he should be often and strongly purged with rhubarb, agaric, and the juice of elder-bark. He should be put into a sweat every morning fasting, with a mixture of aromatic vinegar, sea-salt, and hot water: his feet and hands should also be daily fomented in a warm bath, and he should wash his head, mouth, and fauces. Let him often drink cold water, and throw it up again, by vomiting; and let his drink be acidulated. His aliment should be most light and laxative, and often taken in such a quantity as to vomit it up again. He should likewise abstain from things that are too spicy, from wine, from heating things, from violent exercises, and from commotions of the mind.

The cure should be attempted when the disease is in the first degree; and, in the beginning of the second, by treating it as highly inflammatory; by letting blood from a large orifice even to a deliquium; by giving clysters soon after with nitrous or moderately salt water, thus: take

barley water, ten ounces; nitre, two drams; elder vinegar and honey of roses, each an ounce: make a clyster. Or take rue-water, ten ounces; sea-salt, two drams; vinegar impregnated with marygold-flowers, six drams; common honey, an ounce: make a clyster.

These may be repeated boldly, and with less caution than in other cases. After this let the patient be blindfolded, and thrown into a pond of cold water; or let cold water be thrown upon him, till the dread of it almost ceases: then let a large quantity be forced down his throat; let this be his treatment daily, and at night let sleep be procured.

Hoffman's sentiments on this head are greatly different from those of Boerhaave. The antients, says he, were of opinion, that all poisons were of a cold nature, because they observed that a more free afflux of blood to the external parts was restrained by spasms, for which reason they prescribed heating things, and particularly generous wines, as an universal antidote: these Celsus seems to have followed; and informs us, that the practice of old was to put the patient into a bath, and to make him sweat as long as his strength would permit, at the same time keeping the wound open, that the virus might be discharged from it; and then to give him plenty of good generous wine: this being done for two or three days, they judged him out of danger. This practice of the antients, Hoffman thinks most effectual, and condemns immersion in cold water, &c. as Boerhaave does the practice of administering acrid, drying, and heating medicines.

This may give some light into the nature of the pulvis antilyssus published by Dr. Mead, and received into the dispensatory of the college, wherein pepper is one of the ingredients. Take of the powder of ash-coloured liverwort, four drams; and of the powder of black pepper, two drams: this powder mixt together, is to be taken in warm milk in the morning fasting for four mornings together. After this the doctor orders the patient to be put into a cold bath, pond or river, for thirty days successively, early in the morning, and before breakfast: he is to remain in it with his head above water, no longer than a minute.

Dr. Sault, from his own experience, recommends another method of cure by mercurial frictions upon the cicatrices, and

and the parts adjoining, for three days successively, and then every other day : besides this, he orders the patient to take a dram and a half of *Palmarius's powder*. Dr. James is of opinion, that a vomit or two of *mercurius emeticus flavus* would be proper, the dose of which is from two to eight grains ; not omitting the *cinnabarine powder*, nor going into the cold bath in the morning for a month.

**HYDROPHORIA**, in grecian antiquity, a solemnity held at Athens and Ægina, in memory of those that perished in the deluge.

**HYDROPHYLLUM**, in botany, a genus of the *pentandria-monogynia* class of plants, the corolla whereof consists of a single campanulated petal, divided into five erect, obtuse, and emarginated segments : the fruit is a globose capsule, formed of two valves, and containing only one cell, with a single, roundish, and large seed. See plate CXXXVII. fig. 3.

**HYDROPIC**, a dropsical patient ; or a person swelled and bloated with the abundance of water. See **DROPSY**.

**HYDROPOTA**, in medicine, a person who drinks nothing but water.

It has long been controverted among physicians, whether or no the *hydropotæ* live longer than other persons.

**HYDROPS**, in medicine, the same with dropsy. See the article **DROPSY**.

**HYDROSCOPE**, an instrument antiently used for the measuring of time.

The hydroscope was a kind of water-clock, consisting of a cylindrical tube, conical at bottom : the cylinder was graduated, or marked out with divisions, to which the top of the water becoming successively contiguous, as it trickled out at the vertex of the cone, pointed out the hour.

**HYDROSTATICAL BALANCE**, a kind of ballance contrived for the easy and exact finding the specific gravities of bodies, both liquid and solid.

This instrument is of considerable use in estimating the degree of purity of bodies of all kinds ; the quality and richness of metals, ores, minerals, &c. The proportion in any mixture, adulteration, or the like : of all which the specific weight is the only adequate measure. The doctrine of the hydrostatical ballance is founded on this theorem of Archimedes, that a body heavier than water, weighs less in water than in air, by the weight of as much water as is equal to it in bulk.

We have a new hydrostatical ballance, the parts of which are as follow : A B (plate CXXXVIII. n<sup>o</sup> 1.) is the foot on which it stands ; CD is a pillar supporting a moveable brafs plate EF, fastened thereto by the screw in the knob *e*. In the end of this plate is fixed an upright piece IK, supporting another plate GH ; which slides backwards and forwards thereon, and is moveable every way about it. In the end of this plate, at H, is fixed (by a nut beneath) a wire LM, taped with a fine thread from one end to the other ; upon this moves the swan-neck slip of brafs NO, to which a very exact ballance is hung at the point N ; to one of whose scales P is appended the heavy body R, by a fine horse-hair or piece of silk S : the weight of the said body R in the air, is expressed by the weight put into the scale Q to make an equilibrium therewith, which being destroyed by immersing the solid in the fluid TV, contained in the glass WV, is again restored by weights put into the scale P. So that the weights in the scale Q compared with those in the scale P, shew at once the specific gravity of the solid R to that of the fluid TV.

The specific gravity of fluids is readily determined by weighing one and the same solid body in them severally ; for since we suppose the ballance in equilibrium with the body suspended in the air, the equilibrium will be destroyed when the solid is immersed in the fluid, and must be then restored by weights put into that scale to which the body is appended. These weights will severally express the gravities of an equal bulk of the respective fluids ; and consequently they may be thus compared with each other, or all of them with the gravity of common water, as usual, and disposed in a proper table ; making water 1.000. See *Table of specific GRAVITIES*.

In the same manner, if divers solids are first weighed in air, and then afterwards immersed in the same fluid, as water, for instance, the equilibrium will be destroyed ; which will be restored, as before, by putting in so much weight as is equal to the weight of the same bulk of water : the gravity, therefore, of every solid is thus compared with water, and consequently with each other.

But in this, and many other cases, it is required to be very exact in weighing bodies, even beyond what is attainable by the nicest mechanism of this instrument.

*Fig. 1.*  
HYDROSTATICAL BALLANCES

*N<sup>o</sup> 2.*  
The improved  
HYDROSTATICAL  
BALLANCE

*Fig. 2.* HYPERICUM, S<sup>t</sup> John's Wort.

ment. We shall therefore give the reader an account of an improvement of the common ballance in this respect; and it is the more pertinent in this place, as this instrument serves equally for exactness in common as in hydrostatical matters.

The figure of the machine represents the ballance in its hydrostatic use, *ibid.* n<sup>o</sup> 2. We shall first describe the machine, then shew the new contrived artifice for exactness; and, lastly, give an instance of its universal use. VCG is the stand or pillar fixed in the table. From the top at A hangs, by two silk strings, the horizontal piece or bar BB; from which is suspended, by a ring at *i*, the fine beam of a ballance *b*, which is kept from descending too low on either side by the gentle springing piece *txyz*, fixed on the supporter M. The harness is annulated at *o*, to shew distinctly the perpendicular position of the examen, by the small pointed index fixed above it.

The strings by which the ballance is suspended passing over two pullicies, one on each side the piece at A, go down to the bottom on the other side, and are hung over the hook at *v*; which hook, by means of a screw P, is moveable about  $1\frac{1}{4}$  inches backwards and forwards, and therefore the ballance may be raised or depressed so much. But if a greater elevation or depression be required, the sliding piece S, which carries the screw P, is readily moved to any part of the square brass-rod VK, and fixed by means of a screw.

The motion of the ballance being thus provided for, the rest of the apparatus is as follows: HH is a small table fixed upon a piece D, under the scales *d* and *e*, and is moveable up and down in a long slit in the pillar above C, and fastned at any part with a screw behind. At the point in the middle of the bottom of each scale is hung by a fine hook a brass-wire *ad, ac*. These pass through two holes *m, m* in the table; and to the wire *ad* is suspended a curious cylindric wire *rs*, perforated at each end for that purpose. This wire *rs* is covered with paper graduated by equal divisions, and is about five inches long.

In the corner of the table at E, is fixed a brass-tube in which a round wire *bl* is so adapted as to move neither too hard nor too freely by its flat head I. Upon the lower part of this moves another tube Q, which has friction enough to cause it to remain in any position required; to

this is fixed an index T, moving horizontally when the wire *bl* is turned about, and therefore may be easily set to the graduated wire *rs*.

To the lower end of the wire *rs* hangs a weight L, and to that a wire *pn* with a small brass ball *g*, about  $\frac{1}{4}$  of an inch in diameter. On the other side, to the wire *ac*, hangs a large glass bubble R by a horse-hair. Let us at present suppose the weight L taken away, and the wire *pn* suspended from S: and on the other side let the bubble R be taken away, and the weight F suspended in its room at *c*. This weight F we suppose to be such as will keep in equilibrio with the several parts appended to the other scale, at the same time that the middle point of the wire *pn* is in the surface of the water in the vessel N. The wire *pn* is to be of such a size, that the length of one inch shall weigh four grains. Hence it is evident, since brass is eight times heavier than water, that for every inch the wire sinks in the water, it will become half a grain lighter, and half a grain heavier for every inch it rises out of the water: consequently, by sinking two inches below the middle point, or raising two inches above it, the wire will become one grain lighter or heavier. And therefore, if when the middle point is at the surface of the water in equilibrio, the index T be set to the middle point *a* of the graduated wire *rs*, and the distance on each side *ar* and *as* contain a hundred equal parts; then, when in weighing bodies the weight is desired to the hundredth part of a grain, it may be easily had by proceeding in the following manner.

Let the body to be weighed be placed in the scale *d*, and put the weight X in the scale *e*; and let this be so determined, that one grain more shall be too much, and one grain less too little. Then the ballance being gently moved up or down by the screw P, till the equilibrium be nicely shewn at *o*; and then if the index T be at the middle point *a* of the wire *rs*, it shews that the weights put into the scale *e*, are just equal to the weight of the body. By this method we find the absolute weight of the body; the relative weight is found by weighing it hydrostatically in water, as follows.

Instead of putting the body into the scale *e*, as before, let it be appended with the weight F at the hook *c*, by a horse-hair as at R, supposing the vessel of water O

were away ; then the equilibrium being made, the index T standing between *a* and *r*, at the 36th division, shews the weight of the body put in 1095.36 grains. As it thus hangs, let it be immersed in the water of the vessel O, and it will become lighter by much ; the scale *e* will descend till the beam of the balance rests on the supporter *z*. Then suppose 100 grains put into the scale *d* restores the equilibrium precisely, so that the index T stands at the 36th division above *a* ; it is plain the weight of an equal bulk of water would, in this case, be exactly 100 grains.

After a like manner may this balance be applied to find the specific gravities of fluids, which will not be difficult from what has been said.

*Bradford's new HYDROSTATICAL INSTRUMENT*, a new invention for weighing coin, and discovering its defect either of weight or purity.

It consists of a thin, flat, brass-ruler, about half a foot long ; on each side of which are two graduated lines, those on the upper side being marked A and W (plate CXXXIX. fig. 1. n° 1.) and those on the under side B and W, *ibid.* n° 2. There is also a small chain and pincers wherein to fix any piece of money intended to be weighed and proved ; together with two pair of center-pins, marked A and B, *ibid.* n° 2 and 3, whereof the former pair A are to be used for proving all pieces of gold not exceeding the value of 36 s. and the other pair marked B, for all pieces from 36 s. to 72 s. or 3 l. 12 s. Lastly, there is a sliding-piece or index C, (*ibid.* n° 3.) by the motion of which backwards and forwards upon the ruler, the value of any piece suspended in the pincers is found upon the graduated lines already mentioned ; whereof those marked A and B are called *statical* lines, as being calculated for weighing the piece in air ; and those marked W, W, are called *hydrostatical* lines, as serving to point out the alloy or adulteration of the piece weighed. A whole division on each line, is equal to the weight or value of 1 s. in gold ; a half division to 6 d. and a quarter division to 3 d.

To prove a guinea: first suspend it in the pincers, and then placing the inside of the sliding-piece C to 21 on the line A, on the upper side of the ruler, which must move freely on the center-pins marked A ; and if the guinea and sliding-piece exactly ballance each other, the

guinea is full weight : if not, move the slider backward or forward, till they equiponderate, and the division cut by the inside of the slider is the true weight ; for instance, suppose it rests at 20  $\frac{1}{2}$ , then does the guinea weigh only 20 s. 6 d. In the next place, to prove the alloy of this piece, let the slider be brought to the division 20  $\frac{1}{2}$  upon the hydrostatical line marked W ; for whatever division is cut by the slider, in weighing on the statical line, it must be placed at the same on the hydrostatical line adjoining. Then let the piece, together with the pincers, and the brass-link whereon it is suspended, be immersed in water, (*ibid.* n° 3.) as far as the notch in the said link ; and if the instrument acts in equilibrio, or the piece sink deeper in the water, the guinea is standard-gold : but if the slider must be moved farther backward before it will equiponderate, the guinea is adulterated. If alloyed with silver, allow 2 s. for every penny it wants in the hydrostatical weight ; and then, if the number of pence the piece is deficient in weight hydrostatically, when doubled, exceed the number of shillings it weighs statically, you may conclude it is adulterated with some baser metal than silver. However, a more speedy method of discovering whether a piece of gold be adulterated or not, without moving the slider more than once, is this : when you have weighed a piece statically, bring the slider to the division on the hydrostatical line expressing its weight ; and immersing the piece and pincers as before, so that the surface of the water may be exactly at the notch or mark on the long link, if the instrument doth not then equiponderate, gently lower your hand that holds the fluid till the instrument comes to an equilibrium ; at which time, if the guinea be a counterfeit, great part of the pincers will appear above water ; and if a 36 s. piece be tried, not only the pincers, but a small part of the coin will appear above the surface, if the piece be counterfeit. This last method is sufficiently near the truth for common practice.

If you should have occasion to weigh and prove a very small piece of gold, as 2 s. 3 d. or 4 s. 6 d. the method is to put the said piece in the pincers with some other piece that has been proved before ; by which means, the weight and alloy of the small piece may be easily discovered, as above. And if the piece be  
above

Fig. 1. BRADFORD'S HYDROSTATIC INSTRUMENT.

N<sup>o</sup> 2.

Fig. 2. HYPNUM.

Fig. 3. H Y S S O P.

above 36 s. then the slider is to be placed according to the divisions of the statical and hydrostatical lines on the under side of the instrument; which is fitted to the standard of the mint, that makes the guinea to weigh 129 grains.

**HYDROSTATICS**, that part of philosophy which treats of the nature, gravity, and pressure of fluids, all which have been explained and illustrated under the article FLUID.

The application of hydrostatics to the several uses of life, will be evident from the following instances. Having first premised that a cubic foot of common water weighs nearly 1000 ounces averdupois, or 62 pounds and a half, which may be reduced to troy-weight by considering that the averdupois pound is to the troy pound as 17 to 14, and the averdupois ounce to the troy ounce, as 51 to 56. Hence to find the quantity of pressure against a sluice or bank that pens the water, we have this rule: multiply the area of the sluice under water by the depth of the center of gravity in feet, and the product again by  $62\frac{1}{2}$ ; this last product will be the number of pounds required. Example: admit the length of a sluice to be 20 feet, and the depth of the water 5, then will the area under water be 100 square feet; which multiplied by  $2\frac{1}{2}$ , the depth of the center of gravity, gives 250 cubic feet; which again multiplied by  $62\frac{1}{2}$ , gives 15625 lb. equal to 7 tons nearly.

Again; since the weight of bodies is always as the specific gravities in equal bulks, it follows that the numbers in the table of specific gravities, do also express the number of averdupois ounces contained in a cubic foot of each respective sort of matter therein mentioned. See the article GRAVITY.

Therefore, if the magnitude of any body be multiplied by the specific gravity, the product will be its absolute weight.

Another useful hydrostatic problem, is to find the magnitude of any thing when the weight is known; which is done by dividing the weight by the specific gravity, and the quotient is the magnitude sought. Also by knowing the magnitude and weight, we can find the specific gravity by dividing the weight of the magnitude in cubic feet.

Having found by the hydrostatic balance the specific gravity of gold to silver as 19 to 11, and supposing any compound thereof, as Hiero's crown, whose speci-

fic gravity is 16, to determine the proportion and weight of the gold and silver employed in making it, say, as the difference of the specific gravities of the compound and the lighter ingredient, *viz.* 5, is to the difference of the specific gravities of the heavier ingredient and the compound, *viz.* 3, so is the bulk of gold to that of silver made use of; that is, if the whole crown were divided in 8 parts, the gold would consist of 5, and the silver of 3: then the magnitudes 5 and 3 multiplied by the specific gravities 19 and 11, severally, will give the numbers 95 and 33, which express the proportion of the gold to that of the silver. See HYDROSTATIC BALANCE. But how great the usefulness and importance of hydrostatic knowledge is to physicians, chemists, apothecaries, jewellers, goldsmiths, &c. will appear by reading Mr. Boyle's excellent *Medicina Hydrostatica*, in which book the skilful author proposes the following uses to be made of hydrostatic knowledge, *viz.*

1. To explore the nature and difference of fossils, by finding their specific gravities. For since the most pure and homogeneous kinds of stones are in gravity to water as about  $2\frac{1}{2}$  to 1, and tin, the lightest of metals, is to water in gravity as about 7 to 1, if a stony substance be found to have a greater proportion of gravity than that of  $2\frac{1}{2}$  to 1, it must be probable that it has in it some adventitious matter of a metalline nature; or is at least commixed with some mineral body more heavy than pure stone, and may therefore very probably be usefully applied to some medicinal purposes. As instances of this kind, he mentions the lapis hæmatites, lapis lazuli, and lapis calaminaris, all which have their uses in physic.

2. He proposes this method as very certain to determine whether a body, supposed to be a stone of the mineral kind, be so indeed. Thus corn which, says he, some take to be a plant, and others a lithodendron, but most reckon it among precious stones, is in gravity to water as 2,68 to 1, which favours the last opinion: thus a calculus humanus and a bezoar were found as 1,7 and 1,5 to 1; and therefore too light, to be of the same species with the common stone.

3. A third use which he proposes is to discover the resemblance or difference between bodies of the same denomination, and thereby to collect and ascertain their

several degrees of goodness respectively. Whence he argues the necessity of this sort of knowledge to physicians, chemists, apothecaries, druggists, to the goldsmith, the merchant, the miner, &c.

4. A fourth use is to discern genuine stones from counterfeit ones, which may be of great help to jewellers: here he gives instances of factitious coral, and factitious gems, and a bezoar, which he found out that way not to be genuine, tho' a great price was set on the latter.

5. Hence mercury is said to have a different gravity, being sometimes  $13 \frac{1}{2}$ , and sometimes above 14 times heavier than water; and hence a notable difference may arise in weather glasses at the same time, and in the same place, even to a whole inch, from the different gravity of the mercury in the one and in the other: therefore, those who publish registers of the weather, ought to find out and declare to the world the specific gravity of the quicksilver they use in their barometers.

6. These he enumerates over and above what we have taken notice of a mechanical and geometrical nature, and to let us know the high value he had for this science, he expresses himself thus: "As little skill as I have in hydrostatics, I would not be debarred from the use of them for a considerable sum of money; it having already done me acceptable service, and on far more occasions than I myself at first expected, especially in the examen of metals, and mineral bodies, and of several mineral productions," with much to the same purport.

**HYDROTICS**, among physicians, signify medicines more usually called sudorifics. See the article **SUDORIFICS**.

**HYGIENE**, from *hygieia*, health, that part of medicine which prescribes rules for the preservation of health; which depends, in a great measure, on the prudent use of the non-naturals, air, diet, exercise, sleep, passions of the mind, retention and excretions. See **AIR**, **DIE T**, **EXERCISE**, &c.

**HYGROMETER**, a machine, or instrument whereby to measure the degrees of driness, or moisture of the air, or rather of the atmosphere. See the articles **AIR**, and **ATMOSPHERE**.

There are divers sorts of hygrometers; for whatever body either swells or shrinks, by dryness or moisture, is capable of being formed into an hygrometer. Such are woods of most kinds, particularly

ash, deal, poplar, &c. Such also is catgut, the beard of a wild oat, &c. Stretch an hempen cord or lute-string, as A B. (plate CXL. n<sup>o</sup> 1.) along a wall, bringing it over a pulley, B; and to the other end D, fix a weight E; into which fit an index G. On the same wall fit a plate of metal HI, divided into any number of equal parts, and the hygrometer is complete. For it is known from experience that moisture sensibly shortens the length of cords or fiddle-strings; and that as the moisture evaporates, they return to their former length. The weight, therefore in the present case, upon an increase of the moisture of the air, will ascend; and upon a diminution of the same, it will descend.

Hence, as the index G will shew the spaces of ascent and descent; and those spaces are equal to the increments and decrements of the length of cord, or gut, A B D; the instrument will discover whether the air be more or less humid now, than it was at another given time.

But if a more sensible and accurate hygrometer be required, strain a whip-cord or fiddle-string, over several pulleys B, C, D, E, F, and G. (*ibid.* n<sup>o</sup> 2.) and proceed as in the former example. Nor does it matter whether the several parts of the cord A B, B C, C D, &c. be parallel to the horizon as expressed in the figure or perpendicular to the same.

The advantage of this above the former hygrometer, is, that we have a greater length of cord in the same compass; and consequently greater contraction or dilatation.

Another method of construction, which is more simple, is thus. Fasten a hempen cord or fiddle-string, A B, (*ibid.* n<sup>o</sup> 3.) to an iron-hook; and let the other end, B, descend upon the middle of a horizontal board, or table, E F; near B, hang a leaden weight or ball of a pound, C, and fit an index C G. Lastly, from the center B describe a circle, which divide into any number of equal parts. Or, instead of the table or board, draw two concentric circles on the ball K from I, (n<sup>o</sup> 4.) and divide them into any number of equal parts, and fix an index N O, to any proper support N. So that it may almost touch the divisions of the ball. Here the cord or gut twisting or untwisting will shew the change of moisture, &c. by the successive application of the index to the divisions of the circle.

Or thus: provide two wooden frames, A B

# HYGROMETERS.

AB and CD, (n<sup>o</sup>. 5.) with grooves therein; and between these grooves fit two thin leaves of ash, AEFC, and GBDH, so as they may easily slide either way. At the extremes of the frames A, B, C, D, confine the leaves with nails, leaving between them the space EGHF, about an inch wide. On I fasten a slip of brass dented, IK; and in L a little dented wheel, upon whose axis, on the other side of the machine an index is to be put. Lastly, from the center of the axis, on the same side, draw a circle, and divide it into any number of equal parts. Now, it is found from experience, that ash wood readily imbibes the moisture of the air, and swells therewith; and as that moisture slackens, shrinks again; upon any increase of the moisture of the air, the two leaves AF and BH growing turgid, will approach nearer each other: and, again, as the moisture abates, they will shrink, and again recede. Hence, as the distance can neither be increased nor diminished without turning the wheel L, the index will point out the changes in respect of humidity, or ficcidity. From this contrivance it was that Mr. Coniers in the Philosophical Transactions made the following observations for five or six years.

1. That the pannels will move by shrinking most in summer, and swelling most in winter; but will vary from this according to the change, to the then more or less heat or cold, moisture or drought, that the temper or season, such as spring or fall, do produce; it being then more apt to swell or shrink on the sudden, but not attaining then to the highest shrinking or swelling, as in summer and winter it doth. 2. That for the most part, especially in the spring and summer-time, this motion happens only in the day-time; for then generally all night it rests, and moves very seldom. 3. That one kind or manner of this motion happens in dry, fair weather, but sometimes in the forepart of the forenoon, and sometimes not until the latter part of the forenoon, and then at that time it relaxes or swells the deal for about two or three hours; more, seldom; less, often; and then all the afternoon after it shrinks; nay, sometimes even when a small rain hath newly fallen, or is then falling. 4. This shrinking is gradual very often, or for the most part a little after a moist time, viz. the first day after moisture it shrinks a little; the second,

more, and so yet more, according to the then season of the year, and as it is then inclined to moisture or drought, the alteration of the wind, and the heat or cold at that time. 5. The wind's being in the north, north-east, and east, winter and summer, for the most part at that time the deal shrinks, in the night also as well as in the day, but not so much; which is a sign of drying weather, and sometimes of frost or cold in winter, heat or scorching in summer, in a clear day. But on the contrary, the south wind's blowing, or the west and south-west, the deal always relaxes that day, or at least is at a stay, provided this happen in the day-time; for then if in the night, not so much; and so this will do some considerable time before rain. 6. By a constant observation of this instrument, you may be able to guess at the wind's situation without a weather-cock, provided you have by you a common and a sealed thermometer. 7. Also you may know the time of the year: for in the spring it moves quicker, and more in winter; in summer it is more shrunk than in the spring; in autumn less in motion than in summer.

It is to be observed, that all the hygrometers above described become by degrees less and less accurate, and at length undergo no sensible alteration at all from the humidity of the air.

The following is much more lasting. Take a nice balance (*ibid.* n<sup>o</sup>. 6.) and place in it a sponge, or other body, which easily imbibes moisture; and let it be in equilibrio, with a weight hung at the other end of the beam. Now if the air become moist, the sponge becoming heavier, will preponderate; if dry, the sponge will be raised up. This balance may be contrived two ways; by either having the pin in the middle of the beam, with a slender tongue a foot and a half long, pointing to the divisions on an arched plate fitted to it; or, the other extremity of the beam may be made so long as to describe a large arch on a board placed for the purpose, as is represented in the figure.

To prepare the sponge, it may be necessary to wash it in water; and when dry again, in water or vinegar, wherein sal armoniac, or salt of tartar, has been dissolved, and let it dry again, then it is fit to be used.

In the last mentioned hygrometer, Mr. Gould, in the Philosophical Transactions, instead

instead of a sponge, recommends, oil of vitriol, which is found to grow sensibly lighter or heavier, in proportion to the lesser or greater quantity of moisture it imbibes from the air; so that being saturated in the moistest weather, it afterwards retains or loses its acquired weight, as the air proves more or less moist. The alteration in this liquor is so great, that in the space of fifty-seven days, it has been known to change its weight from three drachms to nine; and has shifted an index or tongue of a balance thirty degrees. A single grain, after its full increase, has varied its equilibrium so sensibly, that the tongue of a balance, only an inch and a half long, has described an arch one third of an inch in compass, (which arch would have been almost three inches if the tongue had been one foot) even with so small a quantity of liquor; consequently, if more liquor, expanded under a large surface, were used, a pair of scales might afford as nice an hygrometer as any kind yet invented. The same author suggests, that oil of sulphur per campanum, or oil of tartar per deliquium, or the liquor of fixed nitre, might be substituted in lieu of the oil of vitriol.

But among all the inventions the following seems best calculated both for dispatch and accuracy. A (*ibid.* n<sup>o</sup> 7.) represents a thin piece of sponge, so cut as to contain as large a superficies as possible. This hangs by a fine thread of silk, upon the beam B, and is exactly balanced from another thread of silk at D, strung with the smallest lead shot, at equal distances, and so adjusted as to cause the index E to point at G, in the middle of the graduated arch F G H when the air is in a middle state between the greatest moisture and the greatest dryness. I, shews a little table or shelf for that part of the silk and shot which is not suspended to rest upon.

**HYLE**, or **HYLEC**, among alchemists, denotes their first matter, or the original chaos of things.

**HYLEG**, or **HYLECH**, in astrology, signifies a planet, or the point in the heavens which at a person's nativity, is accounted the significator of life. See **NATIVITY**.

**HYMEN**, in anatomy, a membrane, sometimes of a circular, sometimes of a semilunar figure, and sometimes of a form different from both. It is always found in young girls, and stops a part of the vagina. In these it has a small aperture,

and a longer in adults who have not conversed with men. After the first coitus it is not to be found: it is always destroyed by it, and if it has not been injured before, some blood always follows the rupture of it.

In the heathen mythology, Hymen was the god of marriage, and new-married women offered sacrifices to this deity. He was represented crowned with sweet marjoram, and sometimes with roses; carrying in one hand a torch, and in the other a flame-coloured veil, to represent the blushes of a virgin.

**HYMENÆA**, in botany, a genus of the *polygamia triœcia* class of plants, the flower of which is papilionaceous, and its fruit a large legumen or pod, of an ovato-oblong figure, obtuse, and unilocular, with numerous oval seeds, surrounded with fibres and a farinaceous matter.

**HYMENÆAL**, something belong to marriage, so called from hymen. See the articles **HYMEN** and **MARRIAGE**.

The hymenæal song is otherwise called epithalamium. See **EPITHALAMIUM**.

**HYMN**, a religious song. The hymns sung in the christian church, as distinguished from the psalms, are pieces of poetry composed by pious, but not inspired authors.

The use of music in religious worship has prevailed in all nations from the remotest ages. The ancient heroes were of opinion, that it appeased the anger of the gods, for which reason their public devotion was generally attended with a concert of voices and instruments.

Music has likewise been consecrated to religion, both by the Jews and Christians; and the former made use of trumpets, drums and cymbals, joined with the voices of the levites and people: but the music of the ancient christians was plain and solemn, and consisted only in singing hymns, or psalms, with joint voices.

The priscillianists pretended to shew, among their apocryphal writings, the hymn which our blessed Lord sung with his disciples, after his last supper. But it is generally supposed, that they sung the hymn which the Jews were used to sing after eating the passover.

**HYOIDES**, in anatomy, a bone which adheres to the base of the tongue.

In young subjects the os hyoides is composed of three bones, a base, occupying its middle part, and two lateral ones, called its horns. In adults there are often,

overlooked

at the junctures of these with the base, two other frustæ, very small, and thence overlooked by most writers : these are nearly of the shape of a wheat-corn, and may therefore be called *ossa triticea* : there are ligaments fixed to these, by means of which they adhere to the styloide processes. And, finally, in these ligaments themselves, sometimes, tho' very rarely, there are found some other little bones. Vesalius met with six of these ; and some others after him have reckoned eleven bones to the formation of the *os hyoides*. The use of the *os hyoides* is to give a firm basis to the tongue : and therefore several muscles of the tongue and larynx, serving to the necessary motions of both, are inserted into it.

**HYOSCYAMUS**, **HEN-BANE**, in botany, a genus of the *pentandria monogynia* class of plants, the flower of which consists of a single infundibuliform petal, with a short cylindrical tube, and an erectopatent limb lightly divided into five obtuse segments, one of which is broader than the rest : the fruit is a capsule of an ovato-obtuse figure, with a line marked on each side ; it contains two cells, with numerous seeds.

The root of this plant, according to Dale, is an excellent refrigerant and emollient, but is said to occasion madness ; for which reason, it is very rarely used internally. Its seeds are recommended in an hæmoptysis, and hæmorrhages ; but those of the white henbane are said to be much milder and safer.

**HYOTHYROIDES**, in anatomy, a muscle of the larynx, which serves to raise it, and constrict the glottis.

**HYPÆTHROS**, or **HYPÆTHRON**, in antient architecture, a kind of temple open at the top.

Vitruvius says, it was an open building or portico, which had no roof or covering, as the temple of Jupiter Olympius, built by Cassatius, a roman architect at Athens.

**HYPALLAGE**, among grammarians, a species of hyperbaton, consisting in a mutual permutation of one case for another. Thus, Virgil says, *dare classibus auro*, for *dare classes auro* ; and again, *necdum illis labra admovi*, for *necdum illa labris admovi*.

**HYPANTE**, or **HYPERPANTE**, a name given by the Greeks to the feast of the presentation of Jesus in the temple.

This word, which signifies lowly or humble meeting, was given to this feast,

from the meeting of old Simon and Anna the prophets in the temple, when Jesus was brought thither.

**HYPATE**, in antient music, an appellation given to the lowest chord of a tetrachord. Thus hypate hypaton, was the lowest chord of the hypaton tetrachord, and answered to our B natural of the lowest octave of the organ ; or to the lowest *mi* of Guido's scale. The hypate meson was the last note of the hypaton, and the first of the meson tetrachord. See the article **DIAGRAM**.

**HYPECOUM**, *wild CUMIN*, in botany, a genus of the *tetrandria-digynia* class of plants, the corolla whereof consists of four petals ; the two exterior petals are broad, trilobated, and obtuse, and are placed over-against one another ; the two interior ones stand alternately with the others ; they are lightly divided into three segments, of which the middle one is hollow, compressed, and erect : the fruit is a long, compressed pod, incurved, and articulated : the seeds are of a roundish figure, but compressed, and are placed singly in the articulations of the pod.

This plant is an opiate.

**HYPER**, *ὑπερ*, a greek preposition, frequently used in composition, where it denotes excess ; its literal signification being above, or beyond.

**HYPERBATON**, in grammar, a figurative construction inverting the natural and proper order of words and sentences. The several species of the hyperbaton are the anastrophe, the hysteron-proteron, the hypallage, synchysis, tmesis, parenthesis, and the hyperbaton, strictly so called. See **ANASTROPHE**, &c.

**HYPERBATON**, strictly so called, is a long retention of the verb, which completes the sentence, as in the following example from Virgil.

*Interea reges : ingenti mole Latinus  
Quadrifugo vehitur curru, cui tempora  
circum*

*Aurati bis sex radii fulgentia cingunt,  
Solis avi specimen : bigis it Turnus in albis,  
Bina manu lato crispans hastilia ferro :  
Hinc pater Æneas Romanæ stirpis origo,  
Sidereo flagrans clypeo & cælestibus armis ;  
Et juxta Ascæus magnæ spes altera Romæ :  
Procedunt castris.*

**HYPERBOLA**, in geometry, the section **GEH** (Plate **CXLI**. n.º 1.) of a cone **ABC**, made by a plane, so that the axis, **EF**, of the section inclines to the opposite leg of the cone, **BC**, which in the parabola is parallel to it, and in the ellipse

ellipsis intersects it. The axis of the hyperbolic section will meet also with the opposite side of the cone, when produced above the vertex, at D.

Definitions. 1. If at the point E (*ibid.* n<sup>o</sup> 2.) in any plane, the end of the rule EH be so fixed, that it may be freely carried round, as about a center; and at the other end of the rule H there is fixed the end of a thread shorter than the rule, and let the other end of the thread be fixed at the point F in the same plane; but the distance of the points EF must be greater than the excess of the rule above the length of the thread; then let the thread be applied to the side of the rule EH by the help of a pin G, and be stretched along it; afterwards let the rule be carried round, and in the mean time let the thread kept stretched by the pin be constantly applied to the rule: a certain line will be described by the motion of the pin, which is called the hyperbola. But if the extremity of the same rule, which was fixed in the point E, is fixed in the point F, and the end of the thread is fixed in the point E, and the same things performed as before; there will be described another line opposite to the former, which is likewise called an hyperbola; and both together are called opposite hyperbolas. These lines may be extended to any greater distance from the points E, F, *viz.* if a thread is taken of a length greater than that distance. 2. The points E and F are called the foci. 3. And the point C, which bisects the right line betwixt the two focus's, is called the center of the hyperbola, or of the opposite hyperbolas. 4. Any right line passing thro' the center, and meeting the hyperbolas, is called a transverse diameter; and the points in which it meets them, their vertices: but the right line, which passes thro' the center, and bisects any right line terminated by the opposite hyperbola's, but not passing thro' the center, is called a right diameter. 5. The diameter which passes thro' the foci, is called the transverse axis. 6. If from A or a, the extremities of the transverse axis, there is put a right line AD equal to the distance of the center C from either focus, and with A, as a center, and the distance AD, there is a circle described, meeting the right line, which is drawn thro' the center of the hyperbola at right angles to the transverse axis, in B b; the line B b, is called the second axis. 7. Two di-

ameters, either of which bisects all the right lines parallel to the other, and which are terminated both ways by the hyperbola or opposite hyperbolas, are called conjugate diameters. 8. Any right line not passing thro' the center, but terminated both ways by the hyperbola or opposite hyperbolas, and bisected by a diameter is called an ordinate applied, or simply an ordinate to that diameter: the diameter likewise, which is parallel to that other right line ordinately applied to the other diameter, is said to be ordinately applied to it. 9. The right line which meets the hyperbola in one point only, but produced both ways falls without the opposite hyperbolas, is said to touch it in that point, or is a tangent to it. 10. If thro' the vertex of the transverse axis a right line is drawn equal and parallel to the second axis, and is bisected by the transverse axis, the right lines drawn thro' the center and the extremities of the parallel line are called asymptotes. 11. The right line drawn thro' the center of the hyperbola, parallel to the tangent, and equal to the segment of the tangent betwixt the asymptotes, and which is bisected in the center, is called the second diameter of that which is drawn thro' the point of contact. 12. A third proportional to two diameters, one of which is the transverse, the other second to it, is called the *Latus rectum*, or parameter of that diameter, which is the first of the three proportionals. And, 13. Lastly, n<sup>o</sup> 5. If upon two right lines A a, B b, mutually bisecting each other at right angles, the opposite hyperbolas AG, ag are described; and if upon the same right lines there are described two other opposite hyperbolas BK, bk, of which the transverse axis B b, is the second axis of the two first; and the second axis of the two last, A a, is the transverse axis of the two first; these four are called conjugated hyperbolas, and their asymptotes shall be common.

Prop. I. (*ibid.* n<sup>o</sup> 2.) The square of the half of the second axis is equal to the rectangle contained by the right lines betwixt the foci and the vertex's of the transverse axis.

Let A a be the transverse axis, C the center, E and F the foci, and B b the second axis, which is evidently bisected in the center C, from the definition; let A B be joined: then since (by def. 6.) A B and C F are equal; the squares of

# HYPERBOLA.

AC and CB together will be equal to the square of CF, that is, (6. 2.) to the square of AC and the rectangle A Fa together; wherefore taking away the square of AC which is common, the square of CB will be equal to the rectangle A Fa.

Prop. II. If from any point G (*ibid.* n° 3, 4.) of the hyperbola, a right line GD is drawn at right angles to the transverse axis Aa, and if from the same point there is drawn the right line GF to the focus nearest to that point; the half of the transverse axis CA will be to the distance of the focus from the center, *viz.* CF, as the distance of the perpendicular CD, is to the sum of the half of the transverse axis, and the right line drawn to the focus.

Let GE be drawn to the other focus, and on the axis aA produced, let there be set off AH equal GF; then with the center G, and the distance GF, describe a circle cutting the axis aA in K and F, and the right line EG in the points L and M: then since EF is double CF, and FK double FD, EK shall be also double CD; and since EL or Aa, is double CA, and LM double GF or AH, EM shall also be double CH: but because of the circle EL or Aa: EF::EK:EM: and taking their halves, it will be as CA:CF::CD:CH.

Prop. III. (*ibid.* n° 3, 4.) the same things being supposed, if from A the extremity of the transverse axis nearest to the point G, there is set off a right line AH on the axis produced, equal to the distance of the point G from the focus F, nearest to the said extremity; the square of the perpendicular GD shall be equal to the excess of the rectangle EHF, contained under the segments betwixt H (the extremity of the right line AH) and the foci, above the rectangle ADa contained under the segments cut off betwixt the perpendicular and the extremities of the axis.

For since the right line CH is any how cut in A, the squares of CA and CH together will be equal to twice the rectangle ACH, and the square of AH, (7. 2.) *i. e.* because CA, CF, CD, CH are proportionals, to twice the rectangle FCD, and to the square of AH or GF; that is, to twice the rectangle FCD and the squares of FD and DG, that is, to the squares of FC, CD, and DG, (7. 2.) wherefore the two squares of CA and

CH are equal to the three squares of FC, CD, and DG; and taking away the squares of CA and CF from both sides, the remaining rectangle EHF, will be equal to the remaining rectangle ADa, and to the square of DG (6. 2.)

Prop. IV. (*ibid.* n° 3, 4.) If from any point G of the hyperbola, there is drawn a right line parallel to the second axis Bb, meeting the transverse axis Aa in D; the square of the transverse axis shall be to the square of the second axis, as the rectangle contained under the segments of the transverse axis betwixt the parallel and its extremes, to the square of the parallel.

Prop. V. (*ibid.* n° 4.) If from any point G of the hyperbola there is drawn a right line parallel to the transverse axis Aa, meeting the second axis in N; the square of the second axis, shall be to the square of the transverse, as the sum of the squares of the half of the second axis and its segment betwixt the center and the right line, to the square of the line itself; that is,  $CB^2:CA^2::CB^2+GD^2:CA^2+$  the rectangle ADa; that is, as  $CB^2+CN^2$  is to  $CD^2$  or  $GN^2$ .

Prop. VI. (*ibid.* n° 5.) It is another property of the hyperbola, that the asymptotes, Dd, Ee, do never absolutely meet with the curve. See ASYMPTOTE.

Prop. VII. If through any point F (*ibid.* n° 5.) of the hyperbola, there is drawn a right line IFL parallel to the second axis, and meeting the asymptotes in I and L; the rectangle contained under the right lines which are intercepted betwixt the asymptotes and the hyperbola, is equal to the square of the half of the second axis, that is,  $CB^2=IFL=IHL$ .

Prop. VIII. (*ibid.* n° 6.) If from any point F of the hyperbola, there is drawn to the transverse diameter, AB, a right line ordinately applied to it FG; and from the extremity of the diameter there is drawn AH perpendicular to it, and equal to the *latus rectum*; the square of the ordinate shall be equal to the rectangle applied to the *latus rectum*, being of the breadth of the abscissa betwixt the ordinate and the vertex, and which exceeds it by a figure like and alike situated to to that which is contained under the diameter and the *latus rectum*.

For join BH, and from the point G let there be drawn CM parallel to AH, and meeting BH in M, and through M let there be drawn MN parallel to AB meeting AH in N, and let the rectangle

MNHO, B AHP, be completed. Then since the rectangle AGB, is to the square of GF, as AB is to AH, *i. e.* as GB is to GM, *i. e.* as the rectangle AGB is to the rectangle AGM; AGB shall be to the square of GF, as the same AGB to the rectangle AGM: wherefore the square of GF is equal to the rectangle AGM, which is applied to the *latus rectum* AH, having the breadth AG, and exceeds the rectangle HAGO, by the rectangle MNHO, like to B AHP; from which excess the name of hyperbola was given to this curve by Apollonius.

Prob. I. n° 7. An easy method to describe the hyperbola, having the transverse diameter DE, and the foci N, *n* given. From N, at any distance, as NF, strike an arch; and with the same opening of the compasses with one foot in E the vertex, set off EG equal NF in the axis continued; then with the distance GD, and one foot in *n*, the other focus, cross the former arch in F. So F is a point in the hyperbola: and by this method repeated may be found any other point *f*, further on, and as many more as you please.

An asymptote being taken for a diameter; divided into equal parts, and through all the divisions, which form so many abscissæ continually increasing equally, ordinates to the curve being drawn parallel to the other asymptote; the abscissæ will represent an infinite series of natural numbers, and the corresponding hyperbolic, or asymptotic spaces, will represent the series of logarithms of the same numbers. See LOGARITHM.

Hence different hyperbolas will furnish different series of logarithms; so that to determine any particular series of logarithms, choice must be made of some particular hyperbola. Now the most simple of all hyperbolas is the equilateral one, *i. e.* that whose asymptotes make a right angle between themselves.

For the locus of any hyperbola. See the article LOCUS.

For the quadrature of the hyperbola. See the article QUADRATURE.

Ambigonal hyperbola is that which has one of its infinite legs inscribed, and the other circumscribed.

Equilateral hyperbole is that wherein the conjugate axes are equal.

Apollonian hyperbola is the common hyperbola, or the hyperbola of the first kind; thus called in contradistinction

to the hyperbolas of the higher kinds, or infinite hyperbolas: for the hyperbola of the first kind, or order, has two asymptotes; that of the second order has three; that of the third, four, &c.

HYPERBOLÆON, in antient music, the upper or last tetrachord or fourth.

It was thus called from its being high or shrill, when compared with the other fourths. It was conjoint to another below it, called diezeugmenon. See the articles DIAGRAM and DIEZEUGMENON.

HYPERBOLE, in rhetoric, a figure, whereby the truth and reality of things are excessively either enlarged, or diminished. See the article EXAGGERATION.

The word is greek, ὑπερβολή, superlatio; formed of the verb υπερβαλλειν, *exsuperare*, to exceed, surpass by far.

The character of an hyperbole is to exaggerate or extenuate the idea of the things spoken of, beyond the bounds of truth, or even probability. As, he ran swifter than the wind: he went slower than a tortoise, &c. Hyperboles, says Seneca, lie without deceiving; they lead the mind to truth by fictions; they convey the sentiment intended, tho' by expressing it in terms which render it incredible. The hyperbole promises too much, in order to make you conceive enough.

Aristotle observes, that hyperboles are the favourite figures of young authors, who love excess and exaggeration; but that philosophers should not use them without a great deal of reserve. The pitch to which an hyperbole may be carried, is a point of great delicacy. To carry it too far, is to destroy it: it is of the nature of a bowstring, which by immoderate tension, slackens; and frequently has an effect quite contrary to that intended.

Those hyperboles are best, which are latent, and are not taken for hyperboles. For this reason they should scarce ever be used but in a passion, and in the middle of some important incident: such is the hyperbole of Herodotus, speaking of the Lacedæmonians, who fought at Thermopylæ: "They defended themselves for some time with the arms" "that were left them, and at last with" "their hands and teeth; till the Barbarians, continually shooting, buried" "them as it were, with their arrows." Now what likelihood is there, that naked men should defend themselves with their hands and teeth against armed men; and that

that so many persons should be buried under their enemies arrows? Yet does there appear some probability in the thing, by reason it is not fought for the sake of the figure, but the hyperbole seems to arise out of the subject itself. Of the like kind is that passage in a comic poet mentioned by Longinus; "He had lands in the country no larger than a Lacedæmonian epistle."

**HYPERBOLIC**, or **HYPERBOLICAL**, something relating either to an hyperbole, or an hyperbola. See the article **HYPERBOLE** and **HYPERBOLA**.

Thus we say, an hyperbolic expression; an hyperbolic image, &c.

**HYPERBOLIC CONOID**. See **CONOID**.

**HYPERBOLIC CYLINDROID**, is a solid figure, whose generation is given by Sir Christopher Wren, in the Philosophical Transactions. Thus, two opposite hyperbolas being joined by the transverse axis, and through the center a right line being drawn at right angles to that axis; and about that, as an axis, the hyperbolas being supposed to revolve; by such revolution, a body will be generated, which is called the hyperbolic cylindroid, whose bases, and all sections parallel to them, will be circles. In a subsequent transaction, the same author applies it to the grinding of hyperbolic glasses; affirming, that they must be formed this way or not at all.

Hyperbolic leg of a curve, is that which approaches infinitely near to some asymptote.

Sir Isaac Newton, reduces all curves, both of the first and higher kinds, into those with hyperbolic legs, and those with parabolic ones. See the article **CURVE**.

**HYPERBOLIC LINE** is used by some authors for what we call the hyperbola itself. In this sense, the plane surface, terminated by the curve line, is called the hyperbola, or hyperbolic space; and the curve line that terminates it the hyperbolic line.

**HYPERBOLIC MIRROR**. See **MIRROR**.

**HYPERBOLIC SOLID**. See **CUBATURE**.

**HYPERBOLIFORM FIGURES**, are such curves as approach, in their properties, to the nature of the hyperbola; called also hyperboloides.

**HYPERBOLOIDES**, are hyperbolas of the higher kind, whose nature is expressed by this equation:  $ay^m \times x^n = bx^m(a + x^n)$ : especially if  $m > 1$ , or  $n > 1$ , e.g.  $ay^3 = bx^2(a + x)$ .

**HYPERCATALECTIC**, in the greek and latin poetry, is applied to a verse, which has one or two syllables too much, or beyond the regular and just measure: as,

*Musæ sorores sunt Minervæ.* Also, *Musæ sorores Palladis lugent.*

The greek and latin verses are distinguished, with respect to their measure, into four kinds, acatalectic, catalectic, brachycatalectic, and hypercatalectic. See **ACATALECTIC**, &c.

The hypercatalectic is also called the hyperpreter.

**HYPERDULIA**, in the church of Rome, a species of worship paid to the holy virgin; being greater than the dulia, or worship paid to the saints, but less than the latria or supreme worship paid to the deity. See **ADORATION** and **WORSHIP**.

**HYPERICOIDES**, a plant otherwise called ascyrum. See **ASCYRUM**.

**HYPERICUM**, *St. JOHN'S WORT*, a genus of the *polyadelphia polyandria* class of plants, the flower of which consists of five oblong, obtuse, patent petals: the fruit is a roundish capsule, with two, three or five cells, containing a great number of oblong small seeds. See pl. CXXXVIII. fig. 2.

This genus comprehends the androsæmum and ascyrum of Tournefort.

*St. John's wort* is recommended as a vulnerary, detergent, and diuretic: it resolves coagulated blood, destroys worms, and promotes the menses and urine.

**HYPERMETER**, in the antient poetry the same with hypercatalectic. See the article **HYPERCATALECTIC**.

**HYPERSARCOSIS**, in medicine and surgery, an excess of flesh, or rather a fleshy excrescence, such as those generally arising upon the lips of wounds, &c. See **WOUND** and **EXCRESCENCE**.

**HYPERTHYRON**, in the antient architecture, a sort of table used after the manner of a frieze, over the jaumbs of doric doors and gates, and the lentils of windows. It lies immediately under the corona, and our workmen usually call it the king-piece.

**HYPHEN**, an accent, or character, in grammar, implying that two words are to be joined, or connected into one compound word, and marked thus -, as pre-established, five-leaved, &c.

Hyphens also serve to connect the syllables of such words as are divided by the end of the line.

**HYPNOTIC**, in the materia medica, such medicines as any way produces sleep, whether called narcotics, hypnotics, opiates, or soporifics.

Authors are of various opinions in regard to the manner wherein hypnotics operate. See the article **NARCOTICS**.

**HYPNUM**, in botany, a genus of mosses of the *cryptogamia* class of plants, consisting of stalks and leaves, and producing membranaceous capsules; these capsules stand on pedicles, which grow on the axes of the leaves, and have at their base a kind of squamous covering, formed of a matter quite different from the leaves of the plant: the capsules of the hypnum have all their calyptræ; they are of different shapes, but usually long; likewise the squamous involucrem at the base of the pedicle is called by Dillenius perichætum, and is the greater characteristic of the hypna, no mosses of any other genus having it in this form. See plate **CXXXIX.** fig. 2.

**HYPOCAUSTUM**, among the Greeks and Romans, a subterraneous place, wherein was a furnace, to heat the baths. See the article **BATH**.

Another sort of hypocaustum was a kind of kiln, to heat their winter-parlours. Among the moderns, it is that place where the fire is kept, that warms a stove or hot-house.

**HYPOCHOERIS**, in botany, a genus of the *syngenesia-polygamia-aqualis* class of plants, the compound flower of which is imbricated, uniform, and consists of numerous hermaphrodite small flowers, that are all equal; the partial flower is monopetalous, ligulated, linear, truncated, and divided into five segments; there is no pericarpium; the cup is connivent and globose-accuminated; the seed is single, oblong, and ending in a subulated pedicle, covered with down.

**HYPOCHONDRIA**, in anatomy, that part of the body on both sides, which lies under the spurious ribs, and is extended to the ilia; comprehending not only the muscles, but the internal viscera.

**HYPOCHONDRIAC PASSION**, a spasmodico-flatulent affection of the stomach and intestines, arising from a preternatural constitution of the peristaltic motion, caused by the stagnation of the blood and vital fluids between the nervous and muscular coats of the intestines.

This disease is attended with such a train of symptoms, that it is a difficult task to enumerate them all; for there is no part

of the body that is not, sooner or later, a sufferer by its tyranny. It begins with tensions and windy inflations of the stomach and intestines, an uncertain appetite, sometimes quite decayed, and sometimes strong; the aliments are ill digested; breeding acid and viscid crudities; there is a pressing heavy pain in the stomach, chiefly after meals; a violent heart burn, very acid belchings and vomiting, bringing up such acid stuff that the teeth are not only set on edge, but the very linnen or sheets sometimes corroded; In the intestines, about the navel, there are felt heavy excruciating pains; in the gross intestines the pains are more acute. Sometimes there is a looseness; sometimes a most obstinate costiveness, with a retention of the wind; which when it breaks out, either upwards or downwards, is attended with an alleviation of the symptoms; but they soon rage again, with as great a violence as ever. The urine is generally thin, limpid, and pale; but sometimes it has a copious sediment mixed with fabulous concretions, and often apes a fit of the gravel. In the breast there is a great straitsness, a difficulty of breathing, and a fluttering and palpitation of the heart. As the disease increases, the patient is troubled with the head-ach, a noise in the ears, with difficulty of hearing; the eyes are clouded, some have double vision, or a pain and dryness of the eyes, and in the tongue a most troublesome burning pain, fixed to a certain space, with a plentiful excretion of spittle. At length the animal functions are impaired, the mind is disturbed on the most trivial occasions, and is hurried into the most perverse commotions; the patient entertains wild and extravagant fancies, the memory grows weak, and the reason fails. Some symptoms affect the whole body, which is covered with blotches, or copious sweats; the strength decays, the limbs are languid and unapt for labour; the body becomes tabid, the joints are tormented sometimes with a blunt, and sometimes with a cutting pain; at last, all the secretions, especially the sanguineous, are perverted. In short, as Dr. Sydenham observes, it imitates all kinds of distempers so exactly, as to require the utmost sagacity of a physician, to distinguish it from an essential disease of any part.

The remote causes of this disorder are, an hereditary disposition to it, a sedentary studious life, sadness, cares, trouble

of mind, intense thinking on a single subject, a cold and moist constitution of the air; gross, impure, flatulent diet; tedious diseases, not rightly treated; the suppression of the hæmorrhoids and menses, and other periodical fluxes of the blood; hard labour in child-bearing, &c.

Though hypochondriacs are never perfectly well, yet they are generally worst in the autumnal and winter seasons. Women generally suffer most about the time when their menses ought to flow. And it is worthy of observation, that those affected with this disease, are seldom attacked with continual, epidemic, or contagious fevers, not even with the plague itself.

As to the prognostics, if the disease be recent, and left to itself, it is not dangerous; but if it be inveterate, and not skilfully treated, or a bad regimen is followed; it is attended with more grievous symptoms, and produces obstructions, and schirri of the viscera, a cachexy, a dropsy, an hectic, a convulsive asthma, an incurable melancholy or madness, &c. But if it be caused by a suppression of the menses, or bleeding piles, the disease will be cured by restoring the flux.

As continual fear and diffidence are symptoms of this disease, the patients are always foreboding terrible things, and live in constant dread, which renders them fickle, impatient, and prone to run from one physician to another; therefore, when a cure is attempted, they must be encouraged and persuaded to be patient, and then the following indications may be pursued: 1. To correct and evacuate the acid, viscid, bilious filth, and flatulentordes from the primæ viæ, which yield continual fuel to this disease. 2. The spasms being appeased, to restore the natural order of the peristaltic motion of the intestines, and to recover it from a languid state, that there may be a due concoction of the aliment, a laudable chyle and other fluids generated. 3. To disperse the stagnated juices, in order to render the circulation of the blood equable through the abdomen and the rest of the body; and to free the fluids from all acrimony, after facilitating the excretions by urine, and through the skin. 4. And, lastly, to corroborate the whole nervous system.

To answer the first intention, nothing is better in the fit than clysters made with

emollient herbs, water-gruel strained, camomile-flowers, the tops of yarrow; the oils of sweet almonds, dill, camomile, linseed, &c. adding a carminative species made of carraway, dill, but more especially cumin-seeds. These should be repeated if the spasms render them ineffectual. Nor must gentle laxatives of manna, rhubarb, and cream of tartar be neglected. If there be a great deal of acid filth in the stomach, crab's eyes alone will purge. To correct theordes in the primæ viæ, give the absorbent, precipitating, and antispasmodic powders, such as crab's eyes, mother of pearl, petrified nitre, prepared amber, cinnabar, tartar vitriolate, with a little castor. It will also be proper to take a decoction of any of the following things, in bed, to promote a diaphoresis, viz. balm, veronica, betony, daisy-flowers, camomile-flowers, fennel-seed, &c.

To restore the digestive power of the stomach, give essence of orange-peel, tincture of tartar, dulcified spirit of nitre, &c.

The paroxysms are relieved by a tepid pediluvia, made of wheat-bran, water, and camomile-flowers, in which the feet should be put pretty deep.

Out of the fit, to discuss the stagnation of the blood, bleeding in the foot will be necessary, especially at the equinoxes, and at other times, as occasion shall require; but this should be after laxatives and pediluvia. If there be a disposition to an hæmorrhoidal flux, leeches should be applied every month; and the patient should also take balsamic pills, with antispasmodic nitrous powders.

To strengthen the nervous system, nothing is better than chalybeates; for they by a gentle striction, restore the nerves to their former strength. Outwardly, a saponaceous plaster, with camphire, may be laid to the hypochondria, with no small advantage.

In a thin bilious habit of body, a milk-diet is good, if the first difficulty can be got over, viz. its coagulating in the stomach; otherwise it will not be sufficient to sustain the body in due strength. But nothing is more friendly, nor gives greater energy to the blood and spirits, than moderate exercise, and particularly riding on horseback almost every day, and for a considerable time together; nor does riding in a coach want its salutary effects.

**HYPOCYSTIS**, in pharmacy, an inspissated juice, obtained from the sessile asarum

rum, much resembling the true egyptian acacia. See the article *ASARUM*. They gather the fruit, while unripe, and exprefs the juice, which they evaporate over a very gentle fire, to the consistence of an extract, and then form into cakes, and expose them to the sun to dry.

*Hypocyst* is an astringent, and that of considerable power; it is good against diarrhoeas and hæmorrhages of all kinds, and may be used in repellent gargarisms in the manner of the acacia; but it is very rarely met with genuine in our shops, the german acacia being usually sold under its name.

**HYPOGASTRIC**, an appellation given to the internal branch of the iliac artery. See the articles *ARTERY* and *ILIAC*.

**HYPOGASTRIC VEINS** arise on each side from the iliacs; and send out branches to the rectum. See the article *VEIN*.

**HYPOGASTRIUM**, in anatomy, the lower part of the abdomen. See the article *ABDOMEN*.

**HYPOMOCHLION**, in mechanics, the same with fulcrum. See *FULCRUM*.

**HYPOPHYLLOCARPODENDRON**, in botany, a plant called by Linnæus leucodendron. See *LEUCODENDRON*.

**HYPOPITYS**, in botany, a plant otherwise called *monotropa*. See the article *MONOTROPA*.

**HYPOPYON**, in medicine, a collection of purulent matter under the cornea of the eye. See the article *EYE*.

As to the cure of an hypopyon, it should first be attempted by violently shaking the patient's head, in a supine posture, and pressing the eye before, with the fingers, in order to remove, or at least loosen the matter.

But if this proves unsuccessful, the patient being seated as in the couching for a cataract, an incision is made with a lancet, through the cornea, below the pupil, and about the space of a line from the white of the eye, and that large enough to discharge the matter and aqueous humour; pressing the eye gently by the fingers, and taking care lest you wound the uvea: then a compress, moistened with a proper collyrium, is to be applied every third or fourth hour to the eye. If the matter be too thick to be discharged, the needle, which is also employed for making setons, is to be used. The instruments should be wrapped up, so that only the point be bare. In this case, St. Yves advises to introduce a small probe,

or inject some cold water with a syringe, and continue this till the whole pus be dissipated, after which the wound may be healed.

**HYPORCHEMA**, in the greek poetry, a poem, consisting of divers kinds of verse, and of different lengths; but always full of short, or pyrrhic feet.

**HYPOSTASIS**, among divines, signifies a person, or substance; chiefly used in speaking of the persons of the Trinity. See the article *TRINITY*.

**HYPOSTASIS**, in medicine, denotes the sediment of urine.

**HYPOTHECA**, in the civil law, the same with mortgage in the common law. See the article *MORTGAGE*.

**HYPOTHENAR**, in anatomy, the abductor muscle of the little finger. See the article *ABDUCTOR*.

**HYPOTHENUSE**, in geometry, the longest side *AC* (plate *CXXXVII*. fig. 2.) of a right-angled triangle *ABC*; or it is that side which subtends the right angle *B*.

Euclid, lib. I. proposition *XLVII*. demonstrates, that, in every rectilinear right-angled triangle, the square of the hypotenuse *AC* (*ibid.*) is equal to the squares of both the other sides *AB*, *CB*; or, that  $AC^2 = AB^2 + CB^2$ .

This celebrated problem was discovered by Pythagoras, who is said to have sacrificed a hecatomb to the Muses, in gratitude for the discovery.

**HYPOTHESIS**, in general, denotes something supposed to be true, or taken for granted, in order to prove or illustrate a point in question.

An hypothesis is either probable or improbable, according as it accounts rationally or not for any phenomenon: of the former kind we may reckon the copernican system and Huygens's hypothesis concerning the ring of saturn; and the ptolemaic system may be esteemed an instance of the latter. See the article *COPERNICAN*, &c.

Hypotheses, however elegant and artful, ought to be first proved by repeated observations and constant experience, before they are received as truths. See the article *EXPERIMENTAL PHILOSOPHY*.

**HYPOTHETICAL PROPOSITIONS**. See the article *PROPOSITION*.

**HYPOTRACHELION**, in architecture, denotes a little frieze in the tuscan and doric capitals, between the astragal and annulets, called likewise *colerin*, *gorgerin*, &c. By some it is applied to the neck

neck of any column, or that part of the capital thereof, below the astragal.

**YPOTYPOSIS**, in rhetoric, signifies a lively description.

**YPOZOMA**, in anatomy, a membrane that separates two cavities : such is the diaphragm.

**YPSILOIDES**, in anatomy, the same with the os hyoides. See the article **HYOIDES**.

**YSSOP**, *hyssopus*, in botany, a genus of the *didynamia-gymnospermia* class of plants, the flower which is monopetalous and ringent, the upper lip being erect, roundish, and emarginated, and the lower one divided into three short segments, the middle one of which is hollow and cordated ; the flower is succeeded by four small seeds, which are roundish and of a brown colour. See plate CXXXIX. fig. 3.

Hyssop is attenuant and discutient, and is recommended in disorders of the lungs, when they are loaded with a foul and thick matter ; it strengthens the stomach and assists digestion ; and by its acrimony, and power of attenuating the viscous matter in the lungs, promotes expectoration, and is therefore good in asthma : its good effects in the stomach are of the same kind, depending on its attenuating and absterging the viscous phlegm lodged there, which impedes the discharge of its proper functions. It is also good in diseases of the head.

It is best taken in infusion, in the manner of tea, not made so strong as to be disagreeable to the palate, and often repeated. A simple water of it, which retains much of its taste, smell, and virtues, is kept in the shops ; they used also to have a syrup of it, but that has of late been disregarded.

Externally, hyssop is greatly recommended in bruises ; the blackness settling under the eyes from blows is carried off very readily by a cataplasm of the leaves, or only a little bundle of them sewed up in a linnen-rag, and applied to the part : and Ray gives us an account from Mr. Boyle, of a violent contusion of the thigh, from the kick of a horse, very happily cured by this herb, boiled as a cataplasm ; he tells us, the violent pain was almost instantly removed, and the very mark and blackness taken off in a few hours.

**HYSTERIC**, or **HYSTERIC PASSION**, in medicine, a spasmodico-convulsive affection of the nervous system, proceeding from the womb, and caused by the retention or corruption of the blood and

lymph in its vessels ; and more or less infesting the nervous parts of the whole body, by means of the nerves of the os sacrum, the loins, and the whole spinal marrow.

Hoffman, contrary to the sentiments of Willis, will not allow the uterus to be a nervous part ; for he affirms that the hysteric passion, which is attributed to a vice in the womb, is owing to spastic, convulsive, and epileptic disorders, all which arise from a fault of the genus nervosum. But Astruc observes, that the effects of impressions are various, according to the degree of their intensity : thus, tickling the nose with a feather, will cause sneezing ; of the fauces, vomiting ; while a violent impression only causes simple pain ; which is the case of the uterus in the hysteric passion : for the causes of this disease, from observation, are the preternatural oscillations of the uterine arteries, on the approach of the menses, or their suppression, when they are distended with blood ; an irritation of the uterus from the fluor albus ; various tumours in the uterus ; the acrimony of the feminal fluids. These affections of the uterus draw the other parts into consent, as poisons in the stomach produce convulsions, a syncope, and sweats. This disease has been very improperly confounded with the hypochondriac passion : for a strangulation of the fauces, an intercepted breathing even to suffocation, a fainting away, a loss of voice, a profound sleep, are the true, proper, and essential signs and symptoms of this uterine disease.

An hysteric fit is, according to Hoffman, generally preceded with a pressing pain of the forehead, temples, or eyes, with an effusion of tears, a dimness of sight, a dulness of the mind and senses, a loathing of all things. When the fit comes on, the patient is exceeding colicive, and yet has a strong stimulus to discharge her urine, which is as clear as water ; the breathing is uneasy, difficult, and short ; and a languor seizes the whole body : to these succeed a pain in the loins, a great shivering and shaking ; the belly is hard and inflated ; afterwards the navel is drawn inwards, and outwardly leaves a great pit ; then they feel a sort of a globe arise from the lower part of the belly to the hypochondria and diaphragm ; soon after the heart begins to flutter and beat with a hard, unequal, and sometimes intermitting pulse ; the extreme parts grow cold,

cold, the fauces are straitened, the face pale, the breathing exceeding difficult, the voice ceases, the pulse is almost imperceptible, and there is such a stricture of the belly that no flatus can be emitted, nor no clyster given. In some there are convulsions of the head and limbs; others lie in a profound sleep, without sense or motion; others have their face and neck look red and inflamed, with a strong pulse; and others again break out into immoderate laughter, and regaining their voice, say a great many silly things.

When they begin to come to themselves, the pulse, which was before weak, languid, and obscure, becomes brisk, soft, and strong; heat returns to the extreme parts, the face looks ruddy, the wind forces its way upwards, there is a rumbling in the belly, and at length the patients, waking as it were out of a profound sleep, have their voices, senses, and motion restored; yet they complain of a heavy pain in the head, a languor of the body, feet, and thighs. Some have continued in a fit so long, that they have been laid out for dead.

The hysteric passion attacks women that are pregnant, or in child-bed; widows that are full of blood, after some grievous passion of the mind; or maids, after a sudden suppression of the menses.

This disease, according to the last mentioned writer, may be caused by whatever promotes a more plentiful afflux of the blood and genital fluid to the uterine parts, or impedes the eruption of the menses, or occasions their suppression: hence maids and widows are most subject thereto; also women of a sanguine and bilious constitution, who live high, drink generous wines, feed on high-seasoned aliment, and are subject to violent passions and commotions of the body and mind: on the other hand, those who live a sedentary life, feed on coarse, acid, low diet, who have omitted usual bleeding, who are oppressed with sorrows, cares, and disappointments, are liable to this disease; for by these the blood is thickened, the solid parts weakened, and consequently the flowing of the menses rendered more difficult. Likewise, sudden terror, and the body being exposed to uncommon cold during the time of the menstrual flux, by giving it a check, procure hysteric spasms. Some are subject to the same disorder from the smell of perfumes.

However dreadful and cruel this disease

may appear, yet it is not very dangerous in itself, unless ill managed, or the patient be exceeding weak and valetudinary: it is most apt to turn into convulsions and an epilepsy.

In the cure, it must be carefully observed, whether the woman is plethoric, or exhausted of blood and strength. In the former case, the spasms or convulsions are more violent and copious; bleeding is a present help, and many have been brought to themselves who were seemingly dead, if the florid colour of their face had not shewn to the contrary.

In the fit it will be proper to apply fetid things to the nose, such as foetida, preparations of castor, partridges feathers burnt, &c. For women in child-bed, a girdle made of russia leather, and bound pretty tight, is excellent. Likewise clysters made with roots and seeds of lovage, which are specifics, camomile-flowers, elder-flowers, veronica, the carminative seeds boiled in whey; to which may be added oil of elder, dill, or camomile. Externally plasters made of opopanax, bdellium, galbanum, sagapenum, and asa foetida, may be applied to the navel. Some greatly recommend fumigations for the uterus, of musk, civet, storax, and benjamin.

Inwardly, the patient may take thirty or forty drops of tincture of castor, in cold water; or if she can swallow them, the following pills: take myrrh, sagapenum, opopanax, asa foetida, saffron, and the theriaca andromache, of each half a dram; adding sometimes six or eight grains of camphire and laudanum opiatum. From each scruple of this must ten pills be made, two of which are to be taken every hour, with a due quantity of water of camomile-flowers.

Some hysterial disorders, according to Dr. Mead, observe the lunar phases, and partake of the nature of an epilepsy: they seldom require bleeding, and purging should be used with caution. Emetics are of greater service, especially a little before the fit. In the fit, the Dr. observes, the best medicines are those which repair the loss of spirits, as russian castor, gum ammoniac, and salt of amber, in pills. Take gum ammoniac, two drams; russian castor, one dram; salt of amber, half a dram; with a sufficient quantity of the peruvian balsam: make this mass into small pills, and let the dose, which is one scruple, be repeated as occasion requires.

Out of the fit, he prescribes native cinnamon, and wild valerian-root, as most proper for correcting the juices.

To prevent its degenerating into a chronic disease, particularly the hypochondriac passion, Hoffman advises that care should be taken to keep the menses regular, which must be done by balsamics, composed of myrrh and amber, with bitter and carminative extracts, especially zedoary and orange-peel, made into an elixir with a moderately spirituous menstruum : this frequently helps the digestion, and promotes a regular menstrual discharge.

But it is necessary to observe, that, in hysterical cases, the same remedies have a different effect on different women : some cannot bear fetid medicines, which to others are an immediate relief : some have fallen into a terrible syncope, and have come to themselves by sprinkling cold water on the face, when more powerful and spirituous things have failed. Others cannot endure hot things inwardly, nor outwardly, as baths, fomentations, liniments, and nervous applications. Anodynes and opiates, which procure ease and rest to some, are very injurious to others who are greatly debilitated, and whose nerves are weak. Some have recovered from a violent paroxysm by a draught of cold water, which given to others has increased the disorder.

When purging is necessary, it will be best to prescribe currants, well saturated with a gentle decoction of rhubarb.

Sydenham prescribes the peruvian bark, morning and evening, in a scruple at a time, as an excellent remedy in hysterical convulsions.

In the fits, besides the remedies already mentioned, Astruc recommends a few grains of civet, or musk, alone, or tied in a thin rag, and introduced into the vagina, which helps to discharge the morbid and noxious humours of the uterus. Out of the fit, he observes that mirth and exercise have alone often cured this distemper. The best remedies are castor, asa foetida, galbanum, sagapenum, and myrrh ; five grains in powder is a dose, or ten drops of the tinctures ; as also gentle purges of cassia, manna, or infusion of senna.

**HYSTERIC COLIC**, a common symptom of the hysterical passion, attended with a most

violent pain about the pit of the stomach ; as also with a vomiting of a greenish humour, and great sinking of the spirits. After a day or two the pain goes off, but upon the slightest motion or perturbation of the mind it soon returns again.

Neither bleeding nor cathartics have any place in the cure. According to Sydenham, it will be proper first to advise the patient to drink upwards of a gallon of posset-drink, to clear the stomach of its impurities, by throwing it up again, that the paregoric may not be hindered ; afterwards give twenty-five drops of the thebaic tincture, in an ounce of the spirit of cinnamon-water. This last is to be repeated, at due intervals, till the symptoms disappear ; that is, the effect of one dose must be known, before another is given : yet sometimes in plethoric bodies, if the strength will permit, it is better to prepare the way by bleeding and purging, or both, for an anodyne.

But if the hysterical colic comes on by fits, the following may be used in the intervals, or when the fit is off ; take large doses of the balsam of Peru, that is, twenty, thirty, or forty drops, in a spoonful of the finest and whitest sugar : this may be taken twice or thrice in a day.

**HYSTEROLOGY**, the same with hysteroproteron. See the next article.

**HYSTERON PROTERON**, in grammar and rhetoric, a species of the hyperbaton, wherein the proper order of construction is so inverted, as that the part of any sentence which should naturally come first is placed last, as in this of Terence, *valet & vivit*, for *vivit & valet* ; and in the following of Virgil, *moriamur & in media arma ruamus*, for *in media arma ruamus & moriamur*.

**HYSTEROPHORUS**, a plant called by Linnæus parthenium. See the article **PARTHENIUM**.

**HYSTEROPOTMI**, ὑστεροποτμοι, in grecian antiquity, the same with deuteropotmi. See the article **DEUTEROPOTMI**.

**HYSTERO TOMIA**, ὑστεροτομία, in anatomy, an anatomical dissection of the uterus or womb. See the article **UTERUS**.

**HYSTERO TOMOTOCY**, ὑστεροτομοτομία, among chirurgical writers, the same with the cesarian section. See **CÆSARIAN**.

**HYSTRIX**, or **HISTRIX**, in zoology. See the article **HISTRIX**.

**HYTHE**, or **HITHE**. See **HITHE**.

## I.

**I**, or i, the ninth letter, and third vowel of the alphabet, is pronounced by throwing the breath suddenly against the palate, as it comes out of the larynx, with a small hollowing of the tongue, and nearly the same opening of the lips and talk as in pronouncing *a* or *e*. Its sound varies; in some words it is long, as *high*, *mind*, &c. in others short, as *bid*, *hid*, *fin*, &c. in others again, it is pronounced like *y*, as in *collier*, *onion*, &c. and in a few, it sounds like *ee*, as in *machine*, *magazine*, &c. No english word ends in *i*, *e* being either added to it, or else the *i* turned into *y*.

But besides the vowel, there is the *jod* consonant; which because of its different pronunciation, has likewise a different form, thus *J*, *j*. In english, it has the soft sound of *g*; nor is used, but when *g* soft is required before vowels, where *g* is usually hard: thus we say, *jack*, *jet*, *join*, &c. instead of *gack*, *get*, *goin*, &c. which would be contrary to the genius of the english language. See the article *ENGLISH*.

**I**, used as a numeral, signifies no more than one, and stands for so many units as it is repeated times: thus **I**, one; **II**, two; **III**, three, &c. and when put before a higher numeral, it subtracts itself, as **IV**, four; **IX**, nine, &c. but when set after it, so many are added to the higher numeral, as there are **I**'s added: thus **VI** is 5 + 1, or six; **VII**, 5 + 2, or seven; **VIII**, 5 + 3, or eight. The ancient Romans likewise used **IO** for 500, **CIO** for 1000, **IOO** for 5000, **CCIOO** for 10,000, **IOOO** for 50,000, and **CCCIOO** for 100,000. Farther than this, as Pliny observes, they did not go in their notation; but when necessary, repeated the last number, as **CCCIOOO**, **CCCIOOO** for 200,000; **CCCIOOO**, **CCCIOOO** for 300,000; and so on.

**I**, used as an abbreviature, is often used for the whole word *Jesús*, of which it is the first letter.

**JAAR**, a river of the bishopric of Liege, which falls into the Maes, at Maestricht.

**JABAJAHITES**, a modern sect of Mahometans, who teach that the knowledge

of God extends not to all things, but is perfected by experience; and that he governs the world according to the course of contingent events, as not having had from eternity a perfect knowledge of all things future. This doctrine is looked upon, by the other musfulmen, as impious and blasphemous.

**JABLUNKA**, a town of Silesia, in the territory of Trefsch: east long. 18°, north lat. 49° 37'.

**JABOTAPITA**, in botany, the same with the *ochna* of Linnæus. See *OCHNA*.

**JACATRA**, or *BATAVIA*. See *BATAVIA*.

**JACCA**, a city and bishop's see of Arragon, in Spain, sixty miles north of Saragossa: west long. 50°, and north lat. 42° 50'.

**JACEA**, *KNAPWEED*, in botany, is comprehended by Linnæus among the *centauria*. See *CENTAURIA*.

**JACENT**, a termed applied by Helmont to nature, when a disease is risen to a head, and the morbid matter strives to suppress the vital flame.

**JACK**, in mechanics, an instrument of common use for raising heavy timber, or very great weights of any kind. See plate *CXLII*. fig. 1. n° 1.

But as the wheel-work of it is shut up in the strong piece of timber *CB*, we have given a representation of it (*ibid*. n° 2.) where you must suppose the rack *AB* at least four times as long in proportion to the wheel *Q*, it being here so much contracted; and the teeth, which will then be four times more in number, to be contained about three in an inch. Then if the handle *HP* be seven inches long, five turns of it, that is five times twenty-two inches, or 110 inches, will be the velocity of the power; whilst the weight raised by the claw *A*, or depressed by the claw *B*, moves one inch: for 'as the pinion of the handle has but four leaves, and the wheel *Q* twenty-three, there must be five revolutions of the handle to turn the wheel once round; whose three-leaved pinion, *R*, will in that revolution just move the rack *AB* three teeth or one inch.

This might have been also known without seeing, or even knowing, the number of the teeth of the wheel and pinions,

by

*Fig. 1. JACK.*

*Fig. 2. JACKALL.*

*Fig. 3. JASMINE.*

*Fig. 4. IBEX.*

by measuring a revolution of the handle in n° 1. and comparing the space gone through by it with the space gone through by the ends of the rack A or B.

Sometimes this machine is open behind, from the bottom almost up to the wheel Q, to let the lower claw, which in that case is turned up at B, draw up any weight; and when this is effected to a sufficient height, it is prevented from falling down again by putting the end of the hook S (*ibid.* n° 1.) fixed to a staple, over the curved part of the handle at b.

All parts of this machine must be made very strong, but chiefly those which immediately sustain the weight.

The common kitchen jack is a compound engine; where the weight is the power applied to overcome the friction of the parts, and the weight with which the spit is charged; and a steady and uniform motion is obtained by means of the fly. See the article FLY.

JACK, in ichthyology, a name sometimes given to the lucius or pike. See the article LUCIUS.

JACK-FLAG, in a ship, that hoisted up at the sprit-sail top-mast head. See FLAG.

JACK-DAW, in ornithology, a species of *corvus*, with a black and grey head, a brownish black body, and the wings and tail black.

It is one of the smallest of the crow-kind, but an erect and well-shaped bird. See the article CORVUS.

JACKALL, in zoology, an animal of the dog-kind, with a slender snout. See the article CANIS.

It is a very beautiful creature, and so like a dog, as to be mistaken at first sight for some mongrel breed of that animal. See plate CXLII. fig. 2.

Its size is that of a small hound; and, in the East, where it is a native, there are vast packs of them, often more than 200 in a company, which hunt animals they would never dare to attack single. It is not impossible that lions and other beasts of prey may be alarmed by the cries of these animals in their chase, and fall in and rob them of their prey; but the general opinion of their attendance on the lion, is fabulous.

JACOB'S STAFF, a mathematical instrument otherwise called cross-staff. See the article CROSS-STAFF.

JACOBÆA, RAGWORT, in botany, is ranked by Linnæus in the same genus with *senecio*. See *SENECIO*.

JACOBÆASTRUM, a plant otherwise called othonna. See OTHONNA.

JACOBÆOIDES, a species of *solidago*. See the article SOLIDAGO.

JACOBINE, or JACK, in ornithology, a very small sort of pigeon, with a range of feathers inverted quite over the hinder part of the head; bearing some resemblance to a friar's hood, whence the name.

JACOBINE MONKS, the same with the dominicans. See DOMINICANS.

JACOBITES, a term of reproach bestowed on the persons, who vindicating the doctrines of passive-obedience and non-resistance with respect to the arbitrary proceedings of princes, disallow of the late revolution, and assert the supposed rights, and adhere to the interests of the late abdicated king James and his family.

JACOBITES, in church-history, a sect of christians in Syria and Mesopotamia; so called either from Jacob, a Syrian, who lived in the reign of the emperor Mauricius; or from one Jacob, a monk, who flourished in the year 550.

The jacobites are of two sects, some following the rites of the latin church, and others continuing separated from the church of Rome. There is also at present a division among the latter, who have two rival patriarchs, one of whom resides at Caramit, and the other at Derzapharan. As to their belief, they hold but one nature in Jesus Christ; with respect to purgatory and prayers for the dead, they are of the same opinion as the Greeks, and other eastern christians: they consecrate unleavened bread at the eucharist, and are against confession, believing that it is not of divine institution.

JACOBITE MONKS, religious, of the sect of jacobites, in Armenia, Mesopotamia, &c.

JACOBUS, an antient gold-coin worth twenty-five shillings. See COIN.

JADE-STONE, the name given to a hard, greyish-green species of jasper, of which the Turks generally make the handles of the sabres of great people. See the article JASPER.

JAFFA, antiently called JOPPA, is a port-town of Palestine in asiatic Turkey, situated thirty miles north-west of Jerusalem: east long. 36°, north lat. 32° 20'.

JAFNAPATAN, a port-town at the north end of the island of Ceylon, in the East Indies; subject to the Dutch: east long. 79°, north lat. 10°.

JAGENDORF, a city of Silesia, twelve miles north-west of Tropolaw: east long. 17° 6', north lat. 50° 8'.

*St.* JAGO, the chief of the Cape Verd islands, in Africa, 300 miles west of Cape Verd; subject to Portugal: west long.  $24^{\circ}$ , north lat.  $15^{\circ}$ .

*St.* JAGO, the capital of the island of Cuba, 100 miles north-west of Jamaica: west long.  $76^{\circ} 30'$ , north lat.  $20^{\circ}$ .

*St.* JAGO, the capital of the province of Chili, in south America, situated six miles west of the mountains of Andes, and eighteen east of the Pacific ocean: west long.  $77^{\circ}$ , south lat.  $35^{\circ}$ .

JAGO DE LA VEGA, or Spanish Town, the capital of Jamaica, situated at the south-east part of the island, about seven miles north-west of Port Passage and the bay of Port Royal: east long.  $76^{\circ} 30'$ , north lat.  $18^{\circ} 20'$ .

JAGODNA, a town of european Turkey, in the province of Servia, situated on the river Moraw: east long.  $22^{\circ}$ , north lat.  $43^{\circ} 20'$ .

JAICZA, a city of european Turkey, in the province of Bosnia, fifty miles north-east of Bosnageraio: east long.  $18^{\circ}$ , north lat.  $45^{\circ} 5'$ .

JALAP, *jalapa*, in botany, a plant of the *pentandria-monogynia* class, called by Linnæus *mirabilis*. See MIRABILIS. Jalap-root is compact and firm, of a wrinkled surface, and of the deepest brown colour within, most disagreeable to the taste, and which takes fire most readily, and burns most briskly when held to the flame of a candle.

With us it is of use in extemporaneous prescription, given in the form of boluses and draughts. Its dose is from twenty to thirty or thirty-five grains. Its common correctives are ginger and cream of tartar; but nature has indeed prepared it so well to our hands, that it needs no addition. The best method of giving it is in a draught made with white-wine, and prepared at least twelve hours before the time when it is to be taken; in which case, the wine has power to open the body of the medicine, and prepare it for acting with the greater ease.

It is an excellent purgative in dropical and all other cases where ferous humours are to be evacuated. The only caution necessary in the use of it is, that it should not be given in acute fevers, nor to persons of dry and hot constitutions; for in these cases, it is liable to the same mischiefs as other acrid purgatives, and will sometimes bring on heat and inflammations in the viscera.

The preparations of jalap in use with us,

are a tincture, an extract, and a resin. To prepare the tincture, take of the root of jalap, eight ounces, put it into a quart of proof-spirit, and after digestion strain off the spirit.

This tincture purges briskly, and is of use in all cases where the root in substance is proper; its dose is from half a dram to two drams.

The extract is made thus: pour upon jalap-root powdered, rectified spirit of wine, and with a due heat draw a tincture, then boil the residue several times in water: after straining, draw off the spirit from the first tincture till it begins to thicken; inspissate also the strained decoctions; then mix the two extracts, and with a gentle fire reduce them to the consistence of a pill.

The two extracts will thus unite into an uniform mass, and retain all the virtues of the root. This extract is of the same virtue as the former tincture, and its dose is from ten to twenty grains.

To prepare the resin, take any quantity of the root of jalap well bruised, pour on it as much spirit as will rise four inches above the root; digest them in a sand heat till the tincture is extracted; filtrate the tincture; then distil off one half of the spirit; pour to what remains a sufficient quantity of water, and the resin of the jalap will be precipitated to the bottom in the form of turpentine. Wash it several times in fresh water, and dry it for use by a very gentle heat.

This purges the most violent of all the preparations of jalap; its dose is from ten to twelve grains; but the extract is greatly preferable to it on all occasions.

JALOFFS, a country and people of Africa, lying on the north side of the river Gambia, near its mouth: west long.  $14^{\circ}$ , north lat.  $13^{\circ} 40'$ .

JAM, or JAMB, among carpenters, &c. See the article JAMB.

JAMAGOROD, a town of the province of Ingria, in Russia, situated twelve miles south-east of Narva: east long.  $28^{\circ}$ , north lat.  $59^{\circ} 15'$ .

JAMAICA, an island of America, situated in the Atlantic ocean, between  $76^{\circ}$  and  $79^{\circ}$  of west longitude, and between  $17^{\circ}$  and  $18^{\circ}$  odd minutes north latitude, near 5000 miles south-west of England, 100 miles south of the island of Cuba, and 350 miles north of Terra Firma. The island lies east and west, and is about 140 miles long, and 60 broad. The wind sets on the shore almost all the day in every

every part of the island, and off the shore in the night ; it sometimes hails, but the people there never see frost or snow. The produce of the island is chiefly sugar, but there is plantations of coffee, of the cocoa or chocolate tree, of indico, tobacco, pepper, cotton, woods for dying, and the mahogany and machineel wood, ginger, medicinal drugs and gums. The common diseases of the country are fevers, fluxes, and the dry gripes.

JAMAICA-PEPPER, *pimenta*, or *pimenta*, in the materia medica. See PIMIENTA.

JAMAICA-WOOD, a name sometimes given to brazil. See the article BRAZIL.

JAMANA, the chief town of a province of Arabia, also of the same name : east long.  $47^{\circ} 15'$ , north lat.  $25^{\circ}$ .

JAMB, or JAUMB, among carpenters, an appellation given to door-posts, as also to the upright posts at the sides of window-frames.

JAMBS, among bricklayers, &c. denote the upright sides of chimnies, from the hearth to the mantle-tree.

JAMBA, a city of the hither India, and the capital of the province of the same name, situated 220 miles north-east of Delli : east long.  $82^{\circ}$ , north lat.  $31^{\circ}$ .

JAMBIC, in antient poetry, a sort of verse, so called from its consisting either wholly, or in great part, of iambus's. See the article IAMBUS.

Ruddiman makes two kinds of iambic, viz. dimeter and trimeter ; the former containing four feet, and the latter six. And as to the variety of their feet, they consist wholly of iambus's, as in the two following verses of Horace.

1	2	3	4	5	6
Dim.	Inar	fit æ	fluo	sius	
Trim.	Suis	æ	psaro	ma vi	rili us

ruit.  
Or, a dactylus, spondeus, anapæstus, and sometimes tribrachys, obtain in the odd places ; and the tribrachys also in the even places, excepting the last. Examples of all which may be seen in Horace, as :

Dimeter.					
1	2	3	4	5	6
Canidi	a tra	Etæ	vit	dapes	
Vide	re prope	rantes	domum		

Trimeter.

Quò quò|
 scèle| | sti rui| | tis au| | cur dex| | teris. || Prins| | que cæ| | lus si| | det in| | terius| | mari. |
| Aliti| | bus at| | que can| | bus homi| | cid bo| | etorem. |
| Parvum| | que lepo| | r aut ad| | venenam| | laqueo| | gruem. |

AMBOLIFERA, in botany, a genus of the *actandria-monogynia* class of plants,

the flower of which consists of four petals, and is of an infundibuliform shape.

JAMBUS, in antient poetry, a simple foot consisting of a short and a long syllable, as *pior*. See the article FOOT.

JAMBY, a town on the east side of the island of Sumatra, in the East Indies, situated in  $101^{\circ}$  east long. and in  $1^{\circ} 30'$  south lat.

JAMES, or *knights of St. JAMES*, a military order in Spain, first instituted about the year 1170, by Ferdinand II. king of Leon and Galicia. The greatest dignity belonging to this order is grand master, which has been united to the crown of Spain. The knights are obliged to make proof of their descent from families that have been noble for four generations, on both sides : they must also make it appear that their said ancestors have neither been Jews, Saracens, nor Heretics ; nor have ever been called into question by the inquisition. The novices are obliged to serve six months in the galleys, and to live a month in a monastery ; they observe the rule of St. Austin, making no vows but of poverty, obedience, and conjugal fidelity.

St. JAMES'S DAY, a festival of the christian church observed on the 25th of July, in honour of St. James the greater, son of Zebedee.

Epistle of St. JAMES, a canonical book of the New Testament, being the first of the catholic or general epistles ; which are so called, as not being written to one but to several christian churches.

This general epistle is addressed partly to the believing and partly to the infidel Jews ; and is designed to correct the errors, soften the ungoverned zeal, and reform the indecent behaviour of the latter ; and to confirm the former under the great hardships they then did, or shortly were to suffer, for the sake of christianity.

JAMES-TOWN, once the capital of Virginia in America, and of James-county, situated in a peninsula on the north side of James, or Pohatan river, in west long.  $76^{\circ} 30'$ , north lat.  $37^{\circ} 30'$ .

JAMPNUM, a word formerly used in fines of lands, &c. where it denotes gorsy ground ; it is supposed to be derived from the french *jaune*, yellow ; because the flowers of furze or gorse are of that colour.

JANEIRO, a province of Brazil, in south America, situated between  $44^{\circ}$  and  $49^{\circ}$  of west long. and between the tropic of capricorn and  $22^{\circ}$  of south lat.

JANIKAW,

**JANIKAW**, or **JANOWITS**, a town of Bohemia, situated forty-five miles south-east of Prague.

**JANITOR**, in anatomy, a name used by some affected writers for the pylorus. See the article **PYLORUS**.

**JANITRIX**, in anatomy, a name given to the vena portæ. See **VENA**.

**JANIZARIES**, an order of the turkish infantry, reputed the grand signior's guards, and the main strength of the ottoman army.

The janizaries were at first composed only of the sons of christians, delivered up as a tribute by their parents, in return for the privilege of enjoying liberty of conscience; and were taken at twelve years of age, to the end that forgetting their country and religion, they might know no other parent besides the sultan. Of late, however, this custom has been left off, the fine for the free exercise of their religion being generally paid in money. Their dress, which is given them by the grand signior every year, on the first day of ramazan, is a long vest with short sleeves, which they tie about their waists with a linnen-*dash* striped with many colours, and adorned at both ends with gold or silver fringe, and over this they wear a loose upper vest of blew cloth. They wear no turban, but instead of it a felt cap, and a long hood of the same stuff, which hangs over their shoulders; and on days of ceremony, they adorn themselves with long feathers stuck in a case in the front of their bonnets. The arms of the janizaries in Europe are, in time of war, a fusil, or a musquet, and a cartouch-box, which hangs at their left side: but in Asia, where powder and fire-arms are more scarce, they carry a bow and arrows with a poignard.

Their pay is from two alpers a day to twelve; for when they perform some important service, or have children, their pay is increased. All the turkish infantry are at present generally called by the name of janizaries, but such only are really so, who derive their institution from Ottoman I. and their peculiar privileges from Amurath III. which do not amount to above 25000 men: however, their being exempted from the payment of taxes, and the performance of public duties, induce abundance of persons to bribe the officers to take them under their protection, and to make them pass for janizaries, without receiving any pay. By means of this intermixture of

the real janizaries with those admitted by corruption, their number at present amounts to above 100,000. And yet not accounting any but such as are effectively janizaries, their body has sometimes been so formidable as to dethrone the ottoman monarchs, and suddenly to change the whole face of the empire.

**JANIZARIES** are also certain officers at Rome, otherwise called *participantes*. See the article **PARTICIPANTES**.

**JANSENISTS**, in church-history, a sect of the roman-catholics in France, who follow the opinions of Janſenius, bishop of Ypres, and doctor of divinity of the universities of Louvain and Douay, in relation to grace and predestination.

In the year 1640, the two universities just mentioned, and particularly father Molina and father Leonard Cellſus, thought fit to condemn the opinions of the jesuits on grace and free-will. This having set the controversy on foot, Janſenius opposed to the doctrine of the jesuits the sentiments of St. Augustine, and wrote a treatise on grace, which he entitled *Augustinus*. This treatise was attacked by the jesuits, who accused Janſenius of maintaining dangerous and heretical opinions; and afterwards, in 1642, obtained of pope Urban VIII. a formal condemnation of the treatise wrote by Janſenius: when the partisans of Janſenius gave out that this bull was spurious, and composed by a person entirely devoted to the jesuits. After the death of Urban VIII. the affair of janſenism began to be more warmly controverted, and gave birth to an infinite number of polemical writings concerning grace; and what occasioned some mirth, was the titles which each party gave to their writings: one writer published, *The torch of St. Augustin*, another found snuffers for St. Augustin's torch, and father Veron formed a gag for the janſenists, &c. In the year 1650, sixty-eight bishops of France subscribed a letter to pope Innocent X. to obtain an enquiry into, and condemnation of the five following propositions, extracted from Janſenius's *Augustinus*: I. Some of God's commandments are impossible to be observed by the righteous, even though they endeavour, with all their power, to accomplish them. II. In the state of corrupted nature, we are incapable of resisting inward grace. III. Merit and demerit in a state of corrupted nature, does not depend on a liberty which ex-

cludes

cludes necessity, but on a liberty which excludes constraint. IV. The semipelagians admitted the necessity of an inward preventing grace for the performance of each particular act, even for the beginning of faith, but they were heretics in maintaining that this grace was of such a nature, that the will of man was able either to resist or obey it. V. It is semipelagianism to say, that Jesus Christ died, or shed his blood, for all mankind in general.

In the year 1652, the pope appointed a congregation for examining into the dispute in relation to grace. In this congregation Janfenius was condemned, and the bull of condemnation, published in May 1653, filled all the pulpits in Paris with violent outcries and alarms against the heresy of the janfenists. In the year 1656, pope Alexander VII. issued out another bull, in which he condemned the five propositions of Janfenius. However, the janfenists affirm, that these propositions are not to be found in his book; but that some of his enemies having caused them to be printed on a sheet, inserted them in the book, and thereby deceived the pope. At last Clement XI. put an end to the dispute by his constitution of July 17, 1705; in which, after having recited the constitutions of his predecessors in relation to this affair, he declares, "That in order to pay a proper obedience to the papal constitutions concerning the present question, it is necessary to receive them with a respectful silence." The clergy of Paris, the same year, approved and accepted this bull, and none dared to oppose it.

This is the famous bull *unigenitus*, so called from its beginning with the words *unigenitus dei filius*, &c. which has occasioned so much confusion in France.

JANUARY, in chronology, the first month of the year, so called from Janus, one of the ancient roman deities, painted with two faces; one whereof was supposed to look towards the new year, and the other towards the old. See the articles YEAR, MONTH, &c.

JAPAN, or *islands of JAPAN*, are situated between 130° and 144° of east long. and between 30° and 40° north lat.

JAPAN-EARTH, *catechu*, in the materia medica. See the article CATECHU.

JAPANNING, the art of varnishing and drawing figures on wood, &c. in the manner as is done by the natives of Japan.

The method of preparing woods for japanning is as follows. 1. Take plasterer's size, dissolve it over the fire, and mix it with whiting finely powdered, till it is of a good body, but not too thick.

2. By means of a strong brush lay your work over with the former mixture, and letting it dry very well, repeat this till the wood is perfectly plain, or the pores and crevices sufficiently filled up; and when it is thoroughly dry, rub the work over with a wet rag till it is rendered as smooth as possible: this work is called water-planing. 3. After this, wash over the work with the thickest of seed-lac varnish till it is very smooth, letting it stand to dry between every washing. 4. In a day or two's time, you may varnish it over with black, or whatever other colour you design, and when it is dry, finish it by polishing. See the article VARNISH.

After the same manner carved figures are to be primed, also frames, cabinets, stands, tea-tables, &c. saving that these are not to be polished, and therefore do not require so great a body of varnish; but for the tops of tables, boxes, sides of cabinets, &c. when the wood is ordinary and rough grained, as deal, oak, &c. you may use common joiners glue dissolved in water till it is fine and thin, into which put the finest saw-dust, till it is indifferently thick: then with a brush lay your wooden-work over with it, and when it is dry, repeat it so often till all the roughness and grain of the wood is sufficiently hidden; and two or three days after let it be scraped with a scraper, as pear-tree and olive-wood are done, to make it as smooth as possible: then varnish it as before directed. This if well done might not come behind any other work either for beauty or durability; but, however, those woods that are firm and close-grained, are chiefly to be chosen.

Method of taking off japan patterns. 1. Having laid your ground, whether black, or of any other colour, and rendered it fit for drawing; and having your draught or design before you on paper, either drawn or printed, do as follows. 2. Rub this draught or print all over the back-side with whiting, or fine chalk; wiping off all that whiting which lies loose upon the paper, then laying this paper upon the table, or piece of varnished-work, with the whited side next it upon the very place where you would have that figure made, with a needle,

not sharp-pointed, fixed in a wooden handle, and called a tracing-pencil, go over and trace as much of the drawing as you think proper: thus, by means of the whiting, you will have the gross form of the draught, and such other lines as will be a direction to you how to perform what you would have done. 3. Having done this, if you draw in gold-size, use fine cinnabar mixt with gum-water, and with a small pencil dipt into it, go over all the lines made by the chalk: this will hold it so as not to come off. 4. If you work your metals or colours in gum-water, then trace over your design with gum-water mixt with gold or brass-dust, by either of these ways when it is dry and finished, viz. either in gum-water or gold-size, you may compleat and finish your work.

Method of japanning wood. The wood being prepared as before directed, it is japanned with black, as follows. 1. Take of the thickest lac-varnish, six ounces; and lamp-black, enough to colour it: with this wash over your piece three times, letting it dry thoroughly between each time: again, with the same varnish, wash it over three other several times, letting it dry as before, and rush it smooth between each washing. 2. Then take the following: of thickest seed-lac varnish, six ounces; and venice turpentine, one ounce; wash over your work with it six times, letting it stand twelve hours between the three first and the three last varnishes. 3. Your work being thus far done, take the following japan-varnish: of the finest seed-lac varnish, six ounces; of lamp-black, a sufficient quantity; mix them, and with that let your work be washed twelve times, standing twelve hours betwixt the first six and the last six washing. 4. Then letting it stand to dry for six or seven days, polish it with tripoli and a rag, as before directed: but in polishing you must work at it only till it is almost smooth, and then let it stand by for two days: afterwards polish it again, almost enough; then let it stand for six days, after which finish the polishing of it; finally, clear it up with oil and lamp-black, by which means you will have a good black japan scarce at all inferior to the true japan.

For a white japan. 1. Lay the ground with ising-glass size mixed with as much whiting scraped into it as will make it of a proper thickness; with this whiten your work once over, and being tho-

roughly dry, do it over again; and in like manner repeat it the third time; after which let it stand for twelve hours, covering it from dust; rush it with Dutch rushing as near the grain of the wood as is proper. 2. Then taking first ising-glass size, and flake white, so much as will make the size of a fair body, mix them well together, and with this go over your work three several times, letting it dry between each time, and rush it as before. 3. Then take white starch boiled in fair water, till it is somewhat thick, wash over the whole work twice with it, blood-warm; letting it dry as before. 4. Letting it stand for a day or two, it being first washed with redified spirit of wine, to clear it from the dust, dip a pure clean pencil into the finest white varnish, and do over the work six or seven times; and if this be well done, it will give a finer gloss than if it were polished: if it be not well done, polishing will be necessary, for which reason you must give it five or six varnishes more. In polishing you must make use of the finest tripoli; and instead of lamp-black and oil, must use putty and oil, and conclude with white starch mixed with oil.

Common red japan. 1. Take ising-glass size, fine vermilion, a sufficient quantity, as much as is proper; with the former mixture do your work over four times: first warming it by the fire, letting it dry each time, and rushing it as before. 2. This being done, wash it over eight times with ordinary seed-lac varnish, and let it by for twelve hours: then rush it again, but slightly, to make it lock smooth. 3. And, lastly, for an exquisite outward covering, wash it ten times with the best lac-seed varnish; let it lie seven days to dry, and then polish it with tripoli, and clear it up with oil and lamp-black.

A deeper red japan may be made by mixing fine sanguis draconis, in powder, with the varnish; and a pale red japan may be had by mixing so much white lead with it, as to make it, of whatever degree of paleness you please.

Blue japan. 1. Take gum-water what quantity you please, and a sufficient quantity of white lead; grind them well upon a marble; take ising-glass size what quantity you please, and of the finest and best smalt, a sufficient quantity; mix them well together; then add to them of the white lead, ground as before, so much

much as will give it a sufficient body; mix all together to the consistence of a paint. 2. Do your work over with this mixture three or four times, till you perceive the blue to lie with a good and fair body, letting it dry thoroughly between each time: if your blue is too pale, put more smalt among your size, without any white lead, and so *vice versa*.

3. Then rush it smooth, and go over it again with a stronger blue; and when it is dry, wash it three times with the clearest ising-glass size alone, and let it stand for two days to dry, covering it. 4. Warm your work gently at the fire, and with a pencil varnish it over with the finest white varnish, repeating it seven or eight times, letting it stand to dry two days as before. After which repeat again the washes seven or eight times in like manner. 5. Let it now stand for a week, and then polish it as before, and clear it up with lamp-black and oil.

**Chestnut-coloured japan.** Take indian red, grind it with ising-glass size upon a porphyry-stone, till they are as soft and as fine as butter: then mix a little white lead, which grind strongly; and, lastly, lamp-black, in due proportion.

**A tortoise-shell japan.** First lay a white ground, as before directed; then with proper colours, as vermilion, auripigment, &c. duly mixed with turpentine-varnish, streak and cloud or shadow the white ground with any irregular fancy at pleasure, in imitation of tortoise-shell: then let it stand to dry, and striking it here and there with reddish-yellow varnish, mixed with a little cinnabar, cloud the work up and down, touching it up also with varnish mixed with lamp or ivory-black. Having done this, varnish it five or six times over with the finest white varnish, letting it dry between every washing.

**Japanning with gold size.** The size being laid over that part only which you intend to gild, as already directed, let it remain there till it is so dry, that when you put your finger on it, it be glutinous and clammy, but not so moist that the particles should come off with your fingers. It is in this temper that the gold is to be applied: then take a piece of washing-leather, or the like, and wrapping it round your fore-finger, dip it in the gold-dust, and rub it where your gold-size is laid; for it will stick no where but on the size, and if any gold-dust lies about your work, brush it away with a

fine clean varnishing-brush. Then, with your pencil, draw that part with gold-size also which is designed for your copper, and letting it dry as in the former case, cover it over with copper-dust in the same manner. Having done this, lay your silver-size, and when it is dry, as before, lay on your silver-dust, as in the two former. But it is to be observed, that the metalline colours are to be laid successively one after another, letting each be covered and thoroughly dry before you enter upon a distinct colour. After all these, the other colours which are not metalline are to be laid on with gum-water, reserving the rock, &c. for the last part of the work. Let your size be of a due consistence, neither too thick nor too thin, that it may run smooth and clean. See the article **SIZE**.

**Japanning metals with gum-water.** Take gum-water, put it into a muscle-shell, with which mix so much of your metal or colour as may give it a proper consistence, so that it may run fine and smooth; having prepared and well mixed your metals and colours, lay on your design; your gum-water, being thoroughly dried, you are to run it over with fine seed-lac varnish, and afterwards polish and clear it.

**Laying speckles or strewings on japan work.** To do this, either on outside or inside boxes, drawers, &c. mix your speckles with ordinary lac-varnish, so much as may make it fit to work, but not so thick as for colour, and mix them well with a proper brush. Warm the work to be done gently by the fire, and with a pencil wash it over with the former mixture, and when it is dry repeat it again, and so often till your speckles lie as thick and even as you desire. When it is thoroughly dry, go over and beautify the work three or four times with seed-lac varnish mixt with turpentine, and so let it dry, and the work is finished, except you have a mind to polish it. But if you polish it, you must wash it eight or ten times over with the best seed-lac varnish, letting it stand to dry every time, and afterwards polish it, as before directed. All sorts of coloured speckles may be thus used, except those of silver, the laying on of which requires the best and finest of the lac-varnish, or the best white varnish, which must make it fit for polishing; but if you have not a mind to polish it, fewer washes of the varnish will be sufficient.

Japanned and laquered ware of the East Indies, pay duty for every 100l. gross value at the sale 38l. on importation, and the drawback is 35l. 12s. 6d. on exportation.

**JASMINE**, *jasminum*, in botany, a genus of the *diandria-monogynia* class of plants, the flower of which is monopetalous, with a long cylindraceous tube, and a plain limb, divided into five segments: the fruit is a smooth, oval, and bilocular berry, containing two large oblong seeds, covered with a membrane, and convex on one side and concave on the other. See plate CXLII. fig. 3.

According to Dale, the flowers of white jasmine are emollient, aperient, and heating; and with these intentions prescribed in difficult breathing, the cough, pleurisy, pain of the intestines, &c.

**Finnet leaved JASMINE**, the same with *quamoclit*. See *QUAMOCLIT*.

**Ilex-leaved JASMINE**, a plant otherwise called *lantana*. See *LANTANA*.

**Indian JASMINE**, a distinct genus of plants called by Linnæus *nyctanthes*.

**Red-JASMINE**, *plumeria*, in botany. See the article *PLUMERIA*.

**Scarlet-JASMINE**, the same with *bignonia*, or trumpet-flower. See *BIGNONIA*.

**JASMINOIDES**, a plant otherwise called *lycium*. See the article *LYCIUM*.

**JASMINOIDIS SPECIES**, the name used by Dillenius for the *cestrum*. See *CESTRUM*.

**JASPACHATES**, a name given by the antients to a species of agate, from its being truly a composition of agate and the genuine matter of jasper.

**JASPER**, in natural history, a genus of scrupi, of a complex irregular structure, of great variety of colours, and emulating the appearance of the finer marbles, or semipellucid gems.

The great characteristic of jaspers is, that they all readily strike fire with steel, and make not the least effervescence with aquafortis.

Jaspers, tho' commonly reckoned among the precious stones, ought undoubtedly to be ranged among the scrupi; being only opaque crystalline masses, variously defaced with an earthy admixture: and to this last ingredient it is that they owe all their variety of colours, as white, green, red, brown, and bluish.

The several kinds of nephritic stone, and the lapis divinus or jade, are all genuine jaspers; but the hard, bright, green jasper of the East Indies, seems to be the true medicinal kind. It is found in

masses of various sizes and shapes, but the more usual standard as to size, is between four and six inches in diameter; but there are masses of it found of a foot or more in diameter, and others no larger than a horse-bean. It is generally simple and unmixed; but if it be variegated at all, it is always with white, and this is disposed not in streaks or veins, but in clouds. It is capable of a very fine polish, and when the white clouds are well disposed, is very beautiful, and in pieces not too thick, is tolerably pellucid, when held up against the light.

It is recommended as an astringent, and ordered to be taken in powder against hæmorrhages of all kinds. The antients wore it as an amulet to prevent abortion, and tied it, on this occasion, to the belly of the person; and they were of opinion that it was able to stop hæmorrhages by being only worn on the arm. At present we give no credit to any thing of this marvellous kind, and consequently the virtues of this, as well as of the other semi-pellucid gems, is greatly out of repute.

**JASPI-CAMEA**, in natural history, the dull, broad-zoned, green and white cameo; being a very elegant species much resembling the common cameo in all things but colour. See *CAMEA*.

**JASPONYX**, in natural history, the purest horn-coloured onyx, with beautiful green zones, which are composed of the genuine matter of the finest jaspers. See the articles *JASPER* and *ONYX*.

**JASQUES**, a port-town of Persia, situated on the gulph of Ormus: east long. 58°, north lat. 25°.

**JATRALIPTA**, or *JATRALIPTES*, in grecian antiquity, an officer of the gymnasium, whose employment it was to appoint the *athletæ*.

**JATRALIPTES** is also an appellation given to physicians, who pretend to cure all diseases by external unctions.

**JATROPHA**, the *CASSADA-PLANT*, in botany, a genus of the *monœcia-polyandria* class of plants, the male flower of which is monopetalous, and of a saucer or funnel-like shape, with a very short tube, and the limb divided into five segments: the stamina are ten subulated filaments, alternately shorter: the female flower is roseaceous, consisting of five petals; and the fruit is a roundish, trilocular capsule, with a roundish seed in each cell. See the article *CASSAVA*.

**JAVA**, an island of the East Indies, situated

ated between  $102^{\circ}$  and  $113^{\circ}$  of east longitude, and between  $5^{\circ}$  and  $8^{\circ}$  of south latitude; being about 700 miles long from east to west, and one hundred broad.

*AVA the less*, or *BALLY*, a small island on the east of Java Major, and separated from it by a narrow channel.

*AVELIN, basta*, in antiquity, a sort of spear, five feet and an half long; the shaft of which was of wood, with a steel point.

Every soldier, in the roman armies, had seven of these; which were very light and slender.

*AUNDICE*, in medicine, a disease which is principally discovered by the yellow tincture of the skin, but most distinctly in the coats of the eyes, where it gives the first notice of its invasion.

The symptoms, according to Sydenham, are heaviness, inactivity, lassitude of the whole body, anxiety, uneasiness about the hypochondria, sickness at the stomach, oppression in the breast, difficult respiration, a dry and harsh skin, costiveness, hard white excrements, yellow high-coloured urine, which will tincture linnen or paper with a saffron hue: there is a bitter taste in the mouth, and all objects seem to be discoloured.

The immediate cause of a jaundice, says Towne, is an obstructed excretion of the bile from the vesicula fellea and liver into the duodenum, which being forced back upon the liver, mixes with the blood, by which it is carried into the whole body, whence the skin and urine will be tintured with the colour of the bile. See the articles *BILE* and *LIVER*.

This obstruction may be occasioned by any thing in the duct that plugs up the passage, or by external pressure which closes its mouth; or by spasms contracting the fibres thereof. Hence we may see why the jaundice succeeds the flatulent colic, why pregnant women are subject to it, and why spasms of hypochondriacal and hysterical persons produce the same effect. Sudden frights, the generation of too great plenty of bile, schirrous tumours, or ulcers of the liver, obstructions of the menses, obstinate intermitting fevers, and the bites of venomous animals, will also produce this disease.

Hoffman thinks emetics highly proper in the cure of a jaundice, if the disease does not proceed from violent anger, spasms of the stomach, a cardialgia, a spasmodic colic, or a stone lodged in the cystic

duct, exciting a violent uneasiness about the precordia; and that when a bilious fordes lodging in the duodenum, and closing up the orifice of the ductus choledochus intercepts the passage of the bile, or when a tenacious, moveable, and not highly concreted bilious matter plugs up the hepatic ducts, emetics are of singular efficacy in evacuating it. A scruple of ipecacuanha, with a grain of tartar emetic, will be a proper dose; or two grains of tartar emetic in a draught of generous wine, or in an infusion of manna, drinking water-gruel after it.

In this case, Huxham, after emetics, thinks cathartics will be proper, compounded of aloetics and mercurials. Then saponaceous attenuants, preparations of tartar, and volatiles, and last of all chalybeats; but the last are not to be given till the humours are sufficiently attenuated, otherwise an incurable schirrus of the liver may ensue. He also recommends the terra foliata, otherwise called tartarum regeneratum, and, by the college, sal diureticus, as the greatest dissolvent and the most powerful remedy in this disease. Its dose is from five grains to a scruple, and upwards.

Saponaceous medicines are often given with the same intention in this disease with success, thus: take castile soap, three ounces; powder of the rhapontic plant, and species of hiera picra, of each half an ounce; as much of the syrup of orange-peel as is sufficient to make an electuary, of which the patient is to take from half a dram to a whole dram twice a day. After some time, with the above precaution, may be added half an ounce of steel-filings: or take gum ammoniac, two drams; powder of squills, one dram; castile soap, three drams; and a sufficient quantity of white sugar: make ten pills out of every dram, three of which are to be taken every morning, and as many at night going to bed.

These are attenuants which should be preceded with gentle purgatives; for Hoffman affirms, that all drastic purgatives are prejudicial, as they increase spasms, throw the blood into violent commotions, and impair the strength: therefore, besides these which Huxham has directed above, the following formula may be sometimes proper. Take of good rhapontic powder, half a dram; cream of tartar, one dram; simple cinnamon-water, three ounces, and syrup of roses, two drams, for a draught.

When a jaundice succeeds the colic, Sydenham is of opinion that all purgatives are to be omitted, rhubarb only excepted; and this is not to be prescribed without evident reason: but if the jaundice comes on without any preceding colic, then the purgatives already mentioned may be given; and if the disease does not yield to this method, the doctor is of opinion that chalybeate waters will be proper.

In a stubborn jaundice, Allen recommends æthiops mineral.

When a jaundice is attended with a hæmorrhage, it is always dangerous in the opinion of Huxham, because it denotes a most acrimonious and dissolved state of the blood; in which case he thinks attenuants, aloetics, volatiles, and chalybeats, little better than poison; whereas acids, diluents, demulcents, and mineral waters, are very beneficial. Hemp-seed boiled in milk till it breaks, is often advantageous: the dose is five ounces twice a day. Or an emulsion of white poppy-seeds and sweet almonds after moderate bleeding, if the patient is feverish, and the pulse will allow it, and gentle purging.

Sylvius observes that many children are afflicted with this distemper soon after they are born, and that some are often born with it. It is his opinion, that this disease may often arise, without any obstruction of the biliary duct.

The remedies, which cure the jaundice, are not so safely given to children as to adults; however, the following powder, given in the nurse's milk twice or three times a day, seldom fails of curing this disease in children. Take english saffron and bezoar mineral, of each one grain; and being beat to powder, let them be mixed. When the body is bound, the best purgative is rhubarb, and particularly the syrup of succory with rhubarb.

**JAU-RAIA**, in botany, the same with the *rajania* of Linnaeus. See **RAJANIA**.

**JAW**, *maxilla*, in anatomy. See the article **MAXILLA**.

In fractures of the lower jaw, after the patient is commodiously seated against the light, and his head held firm by an assistant, the surgeon is to introduce the thumb or fore-finger of one hand into his mouth, applying his other hand externally; and by this means, to press the fragments of the jaw on each side, till they have regained their former situation, which may be known by the re-

gular disposition of the teeth. When properly reduced, they must be covered internally first with a plaster, and then a compress dipt in spirit of wine; and another compress, sewed to a piece of paste-board in the form of a half jaw, is to be laid on externally. These are to be kept on by the bandage with four heads, perforated in the middle to let in the chin. But whenever the jaw is found to be fractured on both sides, it is usual to apply internally, after the compress dipt in spirit of wine, another made of thin paste-board, perforated in the middle, and accommodated to the figure of the chin. The patient should live upon broths and soups, and avoid all talking, till the jaw is grown firm; and at the same time take care not to lie flat either on the back or face.

The lower jaw is indeed seldom luxated, because held very firm by strong ligaments and muscles; but when this happens, whether from a blow, or by opening the mouth too wide in yawning, the chin is distorted on the opposite side, and the mouth gapes open; and when luxated on both sides, then the mouth not only gapes open, but the chin also hangs down. When the luxation is only on one side, the cure is usually not so very difficult; but when both heads are dislocated, and not properly restored to their places, it always occasions the worst of symptoms, as violent pains, inflammations, convulsions, fevers, vomitings, and at length death. But if an expert surgeon comes in time, the luxation is not very difficult to reduce.

When this happens, the patient is to be directly seated on a low stool, so that an assistant may hold his head firmly back against his breast; then the surgeon is to thrust his two thumbs as far back into the patient's mouth as he well can; but they are to be first wrapped round in a handkerchief, to prevent them from slipping or being hurt; and his other fingers are to be applied to the jaw externally: when he has got firm hold of the jaw, it is to be strongly pressed, first downwards, then backwards, and lastly upwards, but so as that all may be done in an instant, by which means the elapsed heads of the jaw may be easily shoved into their former cavities: but the surgeon ought to be always careful to snatch his thumbs quickly out of the patient's mouth, lest they should be compressed, bruised or bit, by reducing the jaw into its place.

If the jaw be out on one side only, every thing is to be done in the same manner; only observing that the luxated side is to be forced more strongly downwards and backwards than the sound one. As for bandages, there seems no great occasion for them in this case, unless the luxation has remained some time before it was reduced; for then it may not be improper to apply, for several days, the four-headed bandage, with some strengthening spirit, which may be taken off when the patient intends to eat.

**JAWER**, a city of Silesia, capital of the dutchy of Jawer, situated in  $16^{\circ} 12'$  east long. and  $51^{\circ} 8'$  north lat.

**JAZY**, a city of european Turkey, capital of Moldavia, situated on the river Pruth, in east long.  $28^{\circ} 40'$ , north lat.  $47^{\circ} 15'$ .

**IBERIA**, the antient name of Spain, as well as of Georgia in Asia.

**IBERIS**, **SCIATICA-CRESS**, in botany, a genus of the *tetradynamia filiculosa* class of plants, the corolla whereof consists of four unequal petals, vertically oval, obtuse, and patent; the fruit is a little pod erect, roundish, compressed, surrounded by an acute bifid margin on the upper side, and containing two cells: the seed, in each cell, is single and roundish.

**IBEX**, in zoology, an animal of the goat-kind, with extremely long nodose horns, which bend backwards, and are of a blackish colour, and annulated on the surface. The body is of a dark dusky colour, and is less in proportion to the height than that of the common goat: it has a great resemblance to the deer-kind; the legs are also perfectly like those of the deer, straight, elegant, and slender. It is frequent in many parts of Europe, and, notwithstanding its vast horns, runs and leaps with surprising force and agility. See plate CXLII. fig. 4.

**IBIS**, a bird which was very useful to the Egyptians for destroying serpents, locusts, and caterpillars; and, on that account, had divine honours paid it. It is all over black, and about the size of the curlew, with the head of a cormorant, and the long neck of a heron.

**IBURG**, a town of Westphalia, in Germany, twelve miles south of Osnabrug.

**ICE**, *glacies*, in physiology, a solid, transparent, and brittle body, formed of some fluid, particularly water, by means of cold. See **FROST** and **FREEZING**.

The younger Lemery observes, that ice is only a re-establishment of the parts of water in their natural state; that the

mere absence of fire is sufficient to account for this re-establishment; and that the fluidity of water is a real fusion, like that of metals exposed to the fire; differing only in this, that a greater quantity of fire is necessary to the one than the other. Gallileo was the first that observed ice to be lighter than the water which composed it: and hence it happens, that ice floats upon water, its specific gravity being to that of water as eight to nine. This rarefaction of ice is owing to the air-bubbles produced in the water by freezing; and being considerably large in proportion to the water frozen, render the body so much specifically lighter: and these air-bubbles growing large, acquire a great expansive power, so as to burst the containing vessels, though ever so strong. It has been imagined, that this bursting of the vessels by frozen water, was owing to the contraction of the solid parts of the vessel upon the ice, and not to the internal expansion; but the florentine academicians shewed the contrary by the following experiment: they filled a hollow globe of pure gold with cold water, then, soldering up the orifice, exposed it to a freezing air; having first fitted to it a metallic ring, somewhat less than a great circle of the sphere, and carefully marked the part of the sphere where the edge of the ring touched it. While the water froze in the globe, they observed the external surface to be so much enlarged, that the metallic ring remarkably ascended towards the vertex from the greatest horizontal circle: whence the globe expanded much more than the ring contracted by the cold; as was plain from comparing this ring with another, originally made of the same size.

But snow-water, or any water long boiled at the fire, freezes slower, and affords a more solid ice, with fewer bubbles, than other water not so treated. And pure water long kept in vacuo, and froze afterwards there, freezes much sooner with the same degree of cold, than water unpurged of air, and exposed to the atmosphere; whilst ice thus made of water from which the air was extracted, is much harder, more ponderous, equable, and transparent than common ice. Whence it is certain, that the air naturally contained in water, being brought together by the freezing cold, occasions its greater rarefaction and levity: and in this manner ice has been procured, that would not float upon water. If finely powdered

ed sea-salt, sal gem, or sal ammoniac be put to powdered ice or snow, in a freezing season, and they be well mixed together, the salts will immediately begin to dissolve, and the coldness grow much more intense; and this, so far as we yet know, to a certain degree, whatever were the degrees of cold in the bodies before their mixture. Alcohol also being thus mixed with ice, increases its coldness: the pure, saline, and acid spirits of sea-sal, nitre, aqua fortis, and aqua regia, the stronger they are, the more intense cold they produce when mixed with ice.

Hence, to make the most perfect ice, we should take the purest water, and perfectly purge it of air by the air-pump, and then freeze it in the severest frost: thus we shall obtain ice of the greatest hardness, density, purity, transparency, and gravity; the true physical characters of ice to the senses: tho' even this ice, so far as we now know, would immediately melt into water with a heat of thirty degrees. Whence it follows, that the most natural cold cannot convert pure water into stone, crystal, or gems; for this artificial cold is above forty degrees stronger than that, where water is said to be frozen into rock-crystal: for by all the experiments that have been made, no increase of cold has made ice at all more difficult to melt than common ice.

**ICE-HOUSE**, a building contrived to preserve ice for the use of a family in the summer-season.

Ice-houses are more generally used in warm countries, than with us, particularly in Italy, where the meanest person who rents a house, has his vault or cellar for ice. However as ice is much more used in England than it was formerly, it may not be amiss to give some directions for the choice of their situation, for the manner of building them, and for the management of the ice.

As to the situation, it ought to be placed upon a dry spot of ground; because wherever there is moisture, the ice will melt: therefore in all strong lands which retain the wet, too much pains cannot be taken to make drains all round them. The place should also be elevated, and as much exposed to the sun and air as possible.

As to the figure of the building, that may be according to the fancy of the owner; but a circular form is most proper for the well in which the ice is to be preserved, which should be of a size and

depth proportionable to the quantity to be kept; for it is proper to have it large enough to contain ice for two years consumption, so that if a mild winter should happen, in which little or no ice is to be had, there may be a stock to supply the want. At the bottom of the well there should be a space of about two feet deep, left to receive any moisture that may drain from the ice; over this space should be placed a strong wooden grate, and from thence a small drain should be laid under ground, to carry off the wet. The sides of the well should be built with brick, at least two bricks thick; for the thicker it is, the less danger there will be of the well being affected by any external cause. When the well is brought up within three feet of the surface, there should be another outer-arch or wall begun, which should be carried up to the height of the top of the intended arch of the well; and if there be a second arch turned over this wall, it will add to the goodness of the house: the roof must be high enough above the inner arch to admit of a doorway to get out the ice. If the building is to be covered with slates or tiles, reeds should be laid considerably thick under them, to keep out the sun and external air; and if these reeds are laid the thickness of six or eight inches, and plastered over with lime and hair, there will be no danger of the heat getting thro' them. The external wall may be built in what form the proprietor pleases; and as these ice-houses are placed in gardens, they are sometimes so contrived as to have an handsome alcove-seat in front, with a small door behind it, through which a person might enter to take out the ice; and a large door on the other side, fronting the north, with a porch wide enough for a small cart to back in, in order to shoot down the ice near the mouth of the well, which need not be more than two feet diameter, and a stone so contrived as to shut it up in the exactest manner: all the vacant space above and between this and the large door should be filled up with barley-straw. The building thus finished, should have time to dry before the ice is put into it.

It is to be observed that upon the wooden grate, at the bottom of the well, there should be laid some small faggots, and if upon these a layer of reeds is placed smooth for the ice to lie upon, it will be better than straw, which is commonly used. As to the choice of the ice, the thinner

thinner it is, the easier it may be broken to powder ; for the smaller it is broken, the better it will unite when put into the well. In putting it in, care must be taken to ram it as close as possible ; and also to allow a vacancy of about two inches, all round, next the side of the well, to give passage to any moisture occasioned by the melting of some of the ice. When the ice is put into the well, if a little salt-petre be mixed with it at every ten inches or a foot in thickness, it will cause it to unite more closely into a solid mass. *Miller's Gard. Dict.*

**ICH DIEN**, the motto of the prince of Wales's arms, signifying, in the high dutch, *I serve*.

It was first used by Edward the black prince; to shew his subjection to his father king Edward III.

**ICHNEUMON**, in zoology, the name of the bluish meles, with uniform claws. See the article **MELES**.

This animal is truly of the badger-kind, and indeed very much resembles the common badger in almost every particular. It is about the size of a large cat; the head is of a blue colour, approaching to black, especially about the nose; and all the rest of the body is of a grey colour, like that of our common badger, the under part being darker than the back or sides.

**ICHNEUMON** is also the name of a genus of flies, of the hymenoptera order, with a triple sting at the anus.

**ICHOGRAPHY**, in perspective, the view of any thing cut off by a plane parallel to the horizon, just at the base of it.

Among painters it signifies a description of images, or of antient statues of marble and copper, of busts and semi-busts, of paintings in fresco, mosaic works, and antient pieces of miniature.

**ICHOGRAPHY**, in architecture, a description or draught of the platform or ground-work of a house, or other building. Or it is the geometrical plan or platform of an edifice or house, or the ground-work of a house or building, delineated upon paper, describing the form of the several apartments, rooms, windows, chimnies, &c. See the article **BUILDING**.

The drawing or designing of this is properly the business of the master architect, or surveyor; it being, indeed, the most difficult of any.

**ICHOGRAPHY**, in fortification, denotes the plan or representation of the length and breadth of a fortress, the distinct parts

of which are marked out, either on the ground itself, or on paper.

**ICHOGLANS**, the grand signior's pages, serving in the seraglio.

Those are the children of christian parents, either taken in war, purchased, or presents from the viceroys and governors of distant provinces: they are the most sprightly, beautiful, and well made that can be met with; and are always reviewed and approved of by the grand signior himself, before they are admitted into the seraglios of Pera, Constantinople, or Adrianople, being the three colleges where they are educated, or fitted for employments, according to the opinion the court entertains of them.

**ICHOR**, properly signifies a thin watry humour, like serum; but is sometimes also used for a thicker kind, flowing from ulcers, called also sanies.

**ICHTHYOCOLLA**, **ISINGLASS**, in the materia medica, &c. a preparation from the fish known by the name of huso. See the article **HUSO**.

This is a tough and firm substance, of a whitish colour, and in some degree transparent; it is light, moderately hard, very flexible, and of scarce any smell, and very little taste. We usually receive it in twisted pieces of an oblong and rounded figure, and bent in the shape of a horse-shoe: this our druggists usually beat and pull to pieces, and sell it in thin shreds like skins, which easily dissolve: besides this kind of round isinglass, we meet with some in small thin square cakes, white and very transparent; these are the finest of all. But isinglass, of whatever shape, is to be chosen clean, whitish, and pellucid.

The method of preparing the ichthyocolle is this: they cut off all the fins of the huso, close to the flesh, and take out the bladder, stomach, and intestines; they wash these very clean, and then cut them in pieces, and throwing them into a large quantity of water, they let them steep four and twenty hours, and after this they kindle a fire under the vessel, and keep the liquor just boiling till the greater part of the matters are dissolved; they then stir the whole briskly about; then strain it through flannels, and let the liquor by to cool. When there is a large quantity of fat usually formed upon it, which is carefully skimmed off, and the clear liquor is poured off from the grosser parts which subside, it is put over the fire again, and gently evaporated and skim-

ed afresh, all the time, till by trials they find, that, on letting a spoonful of it cool, it will harden into the consistence of glue. Great care is taken to keep the fire very gentle, to prevent burning towards the end of this evaporation. They then pour it out upon a large, smooth, wooden table; and as it cools, form it into the masses we meet with it in, by cutting and rolling it up.

The greatest quantity of isinglass is made in Russia. We have it principally from Holland, the Dutch contracting for the most of it, before it is made.

It is an excellent agglutinant and strengthener, and is often prescribed in jellies and broth, but rarely enters any compositions of the regular medicinal form. It is the most efficacious as well as the most safe and innocent of all the ingredients used for cleaning wines, upon which account the wine-coopers use a much greater quantity of it than the apothecaries.

A very valuable glue is also made of this drug, which is a proper form to keep it for the wine-coopers use.

**ICHTHYOLOGY**, *ἰχθυολογία*, the science of fishes, or that branch of zoology which treats of fishes. See the article **FISH**. Artedi defines ichthyology to be the science or art of distinguishing all the parts of fishes, and calling them by their proper names; also of giving every fish its generic and specific name; and lastly, to commemorate some of its remarkable qualities. See plate CXLIII.

We have already, under the article **FISH**, given the general distribution of fishes into the classes of plagiuri, chondropterygious, branchiostegious, acanthopterygious, and malacopterygious fishes, with the peculiar characters of each class; and in the annexed Plate of Ichthyology, there is delineated a fish of each class, in the order above mentioned.

As to the plagiuri, or cetaceous fishes, they agree in many particulars with hairy quadrupeds, and are distinguished into genera by much the same characters, especially the teeth; but besides these, the number of fins is also of use in arranging them into distinct genera.

The chondropterygious or cartilaginous fishes differ from each other in the figure of their whole body, the number of foramina or apertures of the gills, &c. by which they are most commodiously subdivided into genera; since the characters of

the first class are here so various as to differ in the different species of the same genus. The characters by which these two classes of fishes may be subdivided into distinct genera, are simple and obvious: but it is a matter of greater difficulty to fix upon invariable characters, by which the other classes may be subdivided in the same manner. The multitude of genera contained under each of them, added to the great resemblance to be found between really distinct genera, make it no easy task to distinguish these genera from each other, which is best done by establishing the generical characters upon such external parts as are most constant and uniform in the same genus, and least common to other genera.

From many instances produced by Artedi, it appears, 1. That the figure of the fins and tail is of no use in determining the genera of these fishes. 2. That the figure of the back, breast, and belly, and even of the whole body, with respect to length and breadth, is of no service for establishing generical distinctions. 3. That the figure of the head, mouth, eyes, nostrils, and other parts belonging to the head, is indeed of the utmost consequence in distinguishing the different genera; but as this figure is common to several otherwise distinct genera, it is rather serviceable in establishing the orders, than genera of fishes. 4. The same may be observed of the figure of the scales, and the situation of the several external parts of fishes, as the mouth, nostrils, eyes, fins, &c. these, though of great use in the description of fishes, afford no distinctive characters of the genera, as being common to several. 5. Neither is the number of fins or teeth to be reckoned a generical character; since this varies in fishes undoubtedly of the same genus.

Having thus shewn what properties of fishes are not, he next considers those which are sufficient generical characters; and observes, that of all the external parts, the only ones to be found in all the spinose fishes, and yet different in each genus, are the little bones of the membrana branchiostega, or membrane of the gills. These bones are found in almost all fishes that have bones, though more conspicuous in some than in others, by reason of the different thickness of the membrane; and the number of them is more constant in the same genus, than that of the fins: thus, all the gadi have constantly

ICHTHYOLOGY.

Order 1. Plagiuri

2. Chondropterygii

3. Branchioptegii

4. Acanthopterygii

5. Malacopterygii

constantly seven of these little bones in the branchiostege membrane of each side; all the species of perch have likewise seven; the cyprini, three; the cotti, six; the clupeæ, eight; the efoces, fourteen; and so of others. There are only two known genera of spinose fish, wherein the number of these bones is not the same in all the species of the same genus, *viz.* the salmon and coregonus; these bones in different species of salmon being ten, eleven, and twelve; and in the different species of coregonus, seven, eight, nine, and ten: and it is very remarkable, that this difference only takes place in fishes, the species of which are so very like each other, as to be known to belong to the same genus at first sight.

Hence it follows, that the number of these little bones in the branchiostege membrane affords the first and most essential character for distinguishing the genera of cateturous and osteopterygious fishes. This however is not sufficient alone; it being also necessary, besides the same number of these bones in the membrane of the gills, 1. That the fishes belonging to each genus, should have the same external figure. 2. That the situation, no less than the number of their fins, be the same. 3. The teeth should also have the same situation. 4. The disposition of the scales should also be the same. 5. The figure and disposition of the other external and internal parts, particularly of the stomach and its appendices, the intestines, air-bladder, &c. should also agree.

If these characters are found to correspond, there can be no doubt but the genus founded on them is just and natural. However, it must be observed, that these characters are not to be expected in full perfection in all the fishes belonging to one and the same genus. But three of these, *viz.* the same number of bones in the branchiostege membrane, the same external figure, and the same disposition of the fins, are essential to the sameness of the genus; the other characters being only additional to these.

**ICHTHYOLOGIST**, an author who has written professedly of fishes.

Ichthyologists are very numerous; but those who have treated this subject with most accuracy and judgment, are Aristotle, Bellonius, Rondeletius, Salvian, Gesner, Willughby, Ray, and Artedi; especially this last author, who is universally acknowledged to be the best on this

subject; and next to him come Willughby and Ray.

**ICHTHYPERIA**, in natural history, a name given by Dr. Hill to the bony palates and mouths of fishes, usually met with either fossil, in single pieces, or in fragments. They are of the same substance with the bufontæ, and are of very various figures, some broad and short, others longer and slender; some very gibbous, and others plainly arched. They are likewise of various sizes, from the tenth of an inch to two inches in length, and an inch in breadth. See **BUFONITÆ**.

**ICHTHYS**, *ἰχθυς*, in antiquity, a celebrated acrostic of the erythræan sibyl, the first words of each verse of which were, *Ἰησὺ Χριστὸς Θεοῦ υἱὸς σωτὴρ*, that is, *Jesus Christus Dei filius servator*; and the initial greek letters form the word *ἰχθυς*, whence the name.

**ICKWORTH**, a town of Suffolk, six miles east of St. Edmundsbury.

**ICONIUM**, the same with Cogni. See the article **COGNI**.

**ICONOCLASTS**, *εικονοκλασταί*, in church-history, an appellation given to those persons, who, in the VIIIth century, opposed image-worship; and is still given by the church of Rome, to all christians who reject the use of images in religious matters. See the article **IMAGE**.

**ICOSAHEDRON**, in geometry, a regular solid, consisting of twenty triangular pyramids, whose vertexes meet in the center of a sphere, supposed to circumscribe it; and, therefore, have their height and bases equal: wherefore the solidity of one of those pyramids multiplied by 20, the number of bases, gives the solid content of the icosahedron.

If fig. 1. n<sup>o</sup> 1. plate CXLIV. be nicely drawn on pasteboard, cut half through, and then folded up neatly together, it will represent an icosahedron. *ibid.* n<sup>o</sup> 2.

**ICOSANDRIA**, in the linnæan system of botany, a class of plants, the twelfth in order, the characters of which, in so far as it differs from the *polyandria*, are these; the cup of the flower is monophyllous and hollow, with the corolla affixed by the unguis to its sides, and about twenty stamina inserted either into the side of the cup, or corolla. See the article **BOTANY**.

The term *icosandria* is here taken in a lax and indeterminate sense, so as to comprehend all plants with more than twelve stamina, and for the most part not

much exceeding twenty. However, the characteristic of the class is rather to be taken from the manner of insertion, than number of the stamina.

To this class belong the cactus or torch-thistle, the amygdalus or almond-tree, the cerasus, or cherry, &c. See the articles CACTUS, ALMOND, &c.

**ICTERIC DISEASE**, the same with the jaundice. See the article JAUNDICE.

**ICTIAR**, in the turkish affairs, an officer who has gone through all the degrees of preferment in his respective body, and consequently has a right to a seat in the divan. See the article DIVAN.

**IDA**, a mountain in the island of Candia or Crete; also another in Natolia, or lesser Asia, celebrated by the poets for the judgment of Paris on the beauty of the three goddesses, Minerva, Juno, and Venus, to the last of whom he gave the preference.

**IDANHA VELHA**, a city of Portugal, in the province of Estremadura, forty-six miles north-east of Portalegre.

**IDEA**, in general, the image or resemblance of a thing, which, though not seen, is conceived by the mind. See the article IMAGE.

In logic, idea denotes the immediate object about which the mind is employed, when we perceive or think of any thing.

To account for the formation of our ideas, it is obvious, that the first thing we perceive, in taking a view of what passes within us, is, that we receive impressions from a variety of external objects; that distinct notices are thereby conveyed into the understanding, and that we are conscious of their being there. This attention of the mind to the object's acting upon it, is by logicians called simple apprehension. It is therefore by this means that we come to be furnished with all those ideas about which our thoughts are employed. For when we look at the sun, moon, a man, a tree, or any other object without us, the image or appearance thereof is immediately conveyed to the soul by the organ of sight; and these images the mind has a power or faculty of renewing or calling up again to its view at pleasure, even when the objects that first produced them are removed. Now our ideas are nothing else than these renewed representations of what we have at any time perceived or felt, by means of which things are again brought under the view of the mind; and by variously

combining these ideas together, the mind can upon many occasions form to itself representations even of things that never perhaps had any real existence in nature, as mountains of gold, &c.

As to the origin or source of our ideas, it is to be observed, that they all have their first rise, and are derived into the understanding, either from the senses, or reflecting upon what passes within ourselves; or, to speak in the language of logicians, from sensation or reflection. From these two great inlets of knowledge the understanding is supplied with all the materials of thinking. For outward objects acting upon our senses, rouse in us a variety of perceptions, according to the different manner in which they affect us; and it is thus that we come by the ideas of light and darkness, heat and cold, sweet and bitter, rough and smooth, and all other impressions which are termed sensible qualities, and which are wholly derived to us from without, and are as numerous as the outward objects that produced them, and the different ways in which our senses are affected by them. This inlet to knowledge, as comprehending all the notices conveyed into the mind by the impulses of external objects upon the organs of sense, is called sensation. But there is yet another source of impressions arising from the attention of the mind to its own acts, when it takes a view of the perceptions lodged there, that were originally furnished by the senses. For these giving the mind an opportunity of exerting its several powers, when we turn the eye of the soul inwards upon them, and take a view of the various ways in which it employs itself about them, we find all our thoughts under whatever form they appear, are attended with consciousness, and that the understanding is enriched with a new set of perceptions no less distinct than those conveyed in by the senses. It is thus that we come by the ideas of perceiving, thinking, doubting, remembering, willing, &c. which are the different acts and workings of the mind itself, represented to us by our own consciousness of what passeth within us. This second source of ideas is called reflection, and presupposes sensation. Besides these two sources there are other ideas derived into our understandings by all the ways of sensation and reflection, as the ideas of pleasure, pain, power, existence, unity, succession, &c. See SENSATION and REFLECTION.

From

From these simple beginnings, all our knowledge, all our discoveries, take their rise ; for we can have no perception of the operations of our minds, until they are exerted ; nor can they be exerted before the understanding is furnished by the senses with the ideas about which to employ them ; as therefore these ideas that give the first employment to our faculties are evidently the perceptions of sense, it is plain that all our knowledge must begin here. Nor shall we among all our discoveries, or that infinite variety of conceptions whereof they consist, be able to point out one original idea, which is not derived from sensation or reflection, or one complex idea that is not made up of those original ones. This will appear more obvious, if it is considered, that to such as are destitute of any of the inlets by which the perceptions of sense are usually admitted, all the ideas thence arising are absolutely lost ; for a blind man can have no idea of light or colours, nor a deaf man form any conception of sound ; and the same may be said of the other senses. Hence it follows, that the mind in the reception of all ideas by sensation is wholly passive, and the perceptions produced correspond to the impressions made upon it, are just as nature furnished them, and have no dependence on our will. For when we see a tree, a house, a man, or any other object, they necessarily appear each under its proper form, nor is it in our power to receive from them other ideas than they are fitted to produce.

In tracing the progress of the mind further, we find by experience, that being thus provided with its original characters and notices of things, it has a power of combining, modifying, comparing and examining them in an infinite variety of lights ; by which means it is enabled to enlarge the objects of its perception, and thereby to acquire an inexhaustible treasure of other ideas, distinct from the former, though resulting from them ; and by the various comparison of its ideas according to such combinations of them as best suits its ends, to exert itself in acts of judging and reasoning, and to push on its views of things from one discovery to another ; and thus we see the progress of the soul in its advances to knowledge from the first dawning of perception. See KNOWLEDGE. Ideas are variously divided by logicians, but the most natural as well as most use-

ful division of them is into simple and complex ideas ; as this division not only comprehends our ideas in all their varieties, but suggests and represents to us the manner and order in which they are introduced into the mind.

Simple ideas, are such of our perceptions, or original notices of things, as are conveyed into or exist in the mind under one uniform appearance, without variety or composition, and are not distinguishable into different ideas. Under this head are included all those ideas that come into the mind by sensation ; for tho' external objects convey at once into the understanding many different ideas all united together, and making as it were one whole, and tho' the qualities of bodies that affect our senses are in the things themselves so mixed and united, that there is no separation between them ; yet the ideas they produce in the mind are simple and unmixed, and are conceived each under a form peculiar to itself, which cannot be divided into two or more different ideas. Thus the ideas of colour, extension and motion, may be taken in at one and the same time, from the same body ; yet these three perceptions are as distinct in themselves, as if all proceeded from different objects, or were exhibited to our notice at different times. Again, some of our simple ideas we acquire purely by means of one sense ; as the ideas of colours and sounds, by the eyes and ears ; of tastes and smells, by the palate and nose ; rough and smooth, by the touch : others we gain by several senses, as space, extension, figure, &c. others again of our simple ideas are suggested to us by the attention of the mind to what passeth within itself, or reflection only, as our ideas of consciousness, perception, volition ; others by sensation and reflection jointly, as those of pain, pleasure, power, existence, unity, &c.

Of simple ideas, it is proper to observe, 1. That they are such as can only be conveyed into the mind, by the proper channels or avenues provided by nature for that purpose. 2. That many of our simple ideas are not images or resemblances of any thing inherent in the objects that produced them, as is usually thought. In order to comprehend this aright, we must distinguish between the primary and secondary qualities of bodies that produce these ideas. Primary qualities are such as are inseparable from the body in what state soever it be, and such

as our senses constantly find in every particle of matter, as solidity, extension, figure, &c. Secondary qualities are such as are, in reality, nothing in the objects themselves, but only powers to produce various sensations in us by means of their primary qualities, that is, by the figure, bulk, texture, &c. of their particles, as colours, sounds, taste, smell, &c.—Now the ideas of primary qualities are in some sense resemblances of them, and their patterns do really exist in the bodies themselves; but the ideas produced in us by those secondary qualities, have no resemblance of them at all; for there is nothing like our ideas existing in the bodies themselves that occasion them; and what we call blue, red, sweet, hot, &c. are in the bodies we denominate from them, no other than a power to produce these sensations in us.

Complex ideas, are those notions or conceptions of things that result from the various combinations and union of our simple ideas. These are of two principal kinds, namely, such as are derived from without, and represent those combinations of simple ideas, that have a real existence in nature, and are conceived to coexist in any particular subject without us; and such as are formed by the mind itself, arbitrarily uniting and putting together its ideas. Of the first kind are all our ideas of particular substances, as gold, silver, iron, a tree, a man, a horse, &c. in which the confused idea of substance, such as it is, is always the chief. And it is to be observed, that the mind in the reception of these, as well as of simple ideas, is wholly passive. Of the second kind of complex ideas are all those arbitrary collections of different ideas, which the mind by its own powers occasionally puts together, by compounding, comparing, diversifying and uniting its original notions, either for use in the commerce of life, or in its pursuit for further knowledge; such are our ideas of stated lengths, whether of duration or space, of numbers, and of many human actions; of which it is to be observed, that they are manifestly the creatures of the mind: for as in the perception of our other ideas, the mind was passive; in the formation of these, it is active.

This last class of our complex ideas, may again be subdivided, according to the different acts of the mind exerted in framing them, into compound

ideas, abstract ideas, and ideas of relations.

Compound idea, is an assemblage of many simple ideas united together by the mind, and considered by it as one picture or representation, and these may be considered as of two kinds. 1. Such as are only variations, or different combinations of the same simple idea without the mixture of any other, as a dozen, a score, which are no more than different assemblages of so many units, &c. 2. Such as are compounded of simple ideas of several sorts put together to make one complex one, as beauty, ingratitude, treason, &c. See *MODE*.

Abstract or general idea, the idea of some general quality, or property considered simply in itself, without any respect to a particular subject. Abstract ideas are formed by the mind by separating from any of its conceptions, all those circumstances that render it particular, or the representative of any simple determinate object: by which means, ideas taken from particular things become general, and in place of standing for individuals, are each made to denote or represent a whole class of things. Thus, for instance, upon seeing a triangle, or circle, the mind by leaving out the consideration of their particular dimension, and every thing else peculiar to them as they immediately affect the sight, and retaining only the notion of what is common to all triangles or circles, such as their figure or shape, formeth a general or abstract idea applicable to every triangle or circle. And the mind proceeding still further by excluding the consideration of their particular configuration, and whatever is peculiar to them, as figures of a particular form, and retaining only the notion of what is common to all geometrical figures, formeth an idea that is still more abstracted or general, applicable to every geometrical figure whatever.

In the same manner does the mind form the notion of whiteness in general, by leaving out the consideration of snow, milk, and every particular substance from which we have at any time received that idea. See the articles *ABSTRACT IDEA*, *ABSTRACTION* and *GENERAL TERMS*. Ideas of relations are a kind of complex ideas arising from the consideration or comparison of one idea with another, by examining their mutual respects, con-

nections,

nections, and correspondencies. It is thus that we acquire the ideas of greater and less, older and younger, father and son, superior and inferior, and innumerable others. See RELATION.

Ideas are also divided by logicians into adequate and inadequate, clear and obscure, real and fantastical.

Adequate ideas are such as perfectly represent those arch-types that the mind supposes them taken from, in all their parts and properties. The idea of a circle, which represents it as a round figure bounded by a curve line, whose parts are all equally distant from a point in the center, is an adequate idea thereof. Inadequate ideas are such as do but partially, or imperfectly, represent those arch-types to which they are referred. See the article ADEQUATE, &c.

Clear or distinct ideas are such as represent the objects to us so, as that when they occur to us again, we can not only readily know them, but easily distinguish them from all others; the contrary whereof is what are called obscure or confused ideas. For instance, the most illiterate, upon seeing the sun or moon, have so clear an idea of them, as easily to know and distinguish them again from any other planet or fixed star; but have not so distinct or clear an idea of jupiter, mars, or the other planets when once pointed out to them, as to know them again from one another, or from the fixed stars.

Real ideas are such as have a foundation in nature, or a conformity with the real being or existence of things.

Fantastical ideas are such as have no foundation in nature, or a conformity with the real being or existence of things, nor any arch-types to which they have a conformity.

**IDENTITATE NOMINIS**, in law, a writ that lies where a person is imprisoned instead of another of the same name, commanding the sheriff to enquire whether the prisoner be the person, against whom the action was brought, or not; and if not, to discharge him.

**IDENTITY**, SAMENESS, denotes that by which a thing is itself, and not any thing else; in which sense, identity differs from similitude as well as diversity. The idea of identity we owe to that power which the mind has of comparing the very being and existence of things, whereby considering any thing as existing at any certain time and place, and comparing it with itself as existing at any other time

and place, we accordingly pronounce it the same, or different. Thus when we see a man at any time and place, and compare him with himself when we see him again at any other time or place, we pronounce him to be the same we saw before. See the article SIMILITUDE and DIVERSITY.

To understand identity aright, we ought to consider the essence and existence, and the ideas these words stand for; it being one thing to be the same substance; another, the same man; and a third, the same person. For, suppose an atom existing at a determined time and place, it is the same with itself, and will continue so to be at any other instant as long as its existence continues; and the same may be said of two or any number of atoms, whilst they continue together; the mass will be the same; but if one atom be taken away, it is not the same mass. In animated beings it is otherwise, for the identity does not depend on the cohesion of its constituent particles, any how united in one mass; but on such a disposition and organization of parts, as is fit to receive and distribute life and nourishment to the whole frame. Man therefore, who hath such an organization of parts partaking of one common life, continues to be the same man, tho' that life be communicated to new succeeding particles of matter vitally united to the same organized body; and in this consists the identity of man, considered as an animal only. But personal identity, or the sameness of an intelligent being, consists in a continued consciousness of its being a thinking being, endowed with reason and reflection, capable of pain or pleasure, happiness or misery, that considers itself the same thing in different times and places. By this consciousness every one is to himself, what he calls *self*, without considering, whether that *self* be continued in the same or divers substances; and so far as this consciousness extends backward to any past action, or thought, so far extends the identity of that person, and makes it the object of reward and punishment. Hence it follows, that if the consciousness went with the hand, or any other limb when sever'd from the body, it would be the same self that was just before concerned for the whole. And if it were possible for the same man to have a distinct incommunicable consciousness at different times, he would without doubt at different times make different

ferent persons ; which we see is the sense of mankind as to madmen, for human laws do not punish the madman for the sober man's actions, nor the sober man for what the madman did, thereby considering them as two persons.

**IDEOT, or IDIOT.** See **IDIOR.**

**IDES, idus,** in the antient roman calendar, were eight days in each month ; the first of which fell on the 15th of March, May, July, and October ; and on the 13th day of the other months.

They were reckoned backwards, in the manner already explained under the article **CALENDS.**

Thus they called the 14th day of March, May, July and October ; and the 12th of the other months, the *pridie idus*, or the day before the ides ; the next preceding day, they called the *tertio idus* ; and so on, reckoning always backwards, till they came to the nones. See **NONES.** This method of reckoning time is still retained in the chancery of Rome, and in the calendar of the breviary.

**IDIOM, ἰδιωμα,** among grammarians, properly signifies the peculiar genius of each language, but is often used in a synonymous sense with dialect. See the articles **LANGUAGE** and **DIALECT.**

**IDIOPATHY,** in physic, a disorder peculiar to a certain part of the body, and not arising from any preceding disease ; in which sense, it is opposed to sympathetic. Thus, an epilepsy is idiopathic, when it happens merely thro' some fault in the brain ; and sympathetic, when it is the consequence of some other disorder.

**IDIOSYNCRASY,** among physicians, denotes a peculiar temperament of body, whereby it is rendered more liable to certain disorders, than persons of a different constitution usually are. See the article **TEMPERAMENT.**

**IDIOT, or IDEOT,** a person that is born a natural fool.

Such a person is not to be prosecuted for any crime, as not having knowledge to distinguish good from evil ; yet it is said, that if a man has so much knowledge as to measure a yard of cloth, tell or number twenty-pence in small money, or regularly to name the days of the week, or to beget a child, he shall not, by our laws, be accounted an ideot.

The king has a right to the custody of an ideot's lands, and to receive the profits of the same during his life, without committing waste ; and finding him and his family, if he have any, necessaries.

**IDOLATRY, εἰδωλολατρεία,** a word of greek original, compounded of εἰδωλον an image, and λατρεύειν, to worship or serve. Idolatry, or the worship of idols, may be distinguished into two sorts. By the first, men adore the works of Gods, the sun, the moon, the stars, angels, dæmons, men and animals : by the second, men worship the work of their own hands, as statues, pictures, and the like : and to these may be added a third, that by which men have worshipped the true God under sensible figures and representations. This indeed may have been the case with respect to each of the above kinds of idolatry ; and thus the Israelites adored God under the figure of a calf.

Some authors make idolatry to be more antient than the deluge, and believe that it began in the time of Enos ; for which they cite the last verse of the fourth chapter of Genesis, where, according to our version, it is said, " Then began men to call upon the name of the Lord ; " but which these authors render, " Then began men to profane the name of the Lord ; " that is, to corrupt the worship of God by idolatry. " At this time, says Maimonides, men began to study the motions of the heavenly bodies, and from thence were led to think, that they were the ministers of God in the government of the world. This induced them to praise, honour and adore the stars, as his officers or substitutes, and upon this foundation, they erected temples, and offered sacrifices to the heavenly bodies."

Others are of opinion, that idolatry did not begin till after the deluge, and that it had its rise in Babylon ; where divine honours were first paid to Jupiter Belus. If this be the truth of the case, it may not be improbable that the idolatry and polytheism which prevailed after the deluge, might spring from the impiety and atheism before the deluge : for it being natural for men to pass from one extreme to another, those who lived immediately after the deluge, and had been, as it were, witnesses of the punishment inflicted on atheism, and impiety, might by ignorance be led to superstition ; and for fear of relapsing into atheism, which had destroyed the world, might set up the worship of an infinite number of gods. This is not to be understood of Noah himself, or his sons, who must be supposed to have had the knowledge of the

the true god ; but of their descendants, upon the division of tongues and dispersion of the people.

However this be, it seems clear, that the stars were the first objects of idolatrous worship ; and that on account of their beauty, their influence on the productions of the earth, and the regularity of their motions, particularly the sun and moon, which were considered as the most glorious and resplendent images of the deity : afterwards, as their sentiments became more corrupted, they began to form images, and to entertain the opinion, that by virtue of consecration, the gods were called down, to inhabit or dwell in their statues. Hence Arnobius takes occasion to rally the pagans for guarding so carefully the statues of their gods, who, if they were really present in their images, might save their worshippers the trouble of securing them from thieves and robbers. For the pagan gods; see the article GODS.

As to the adoration which the antient pagans paid to the statues of their gods ; it is certain, that the wiser and more sensible heathens considered them only as simple representations or figures designed to recal to their minds the memory of their gods. This was the opinion of Varro and Seneca : and the same sentiment is clearly laid down in Plato, who maintains, that images are inanimate, and that all the honour paid to them has respect to the gods whom they represent. But as to the vulgar, they were stupid enough to believe the statues themselves to be gods, and to pay divine worship to flocks and stones.

Soon after the flood, idolatry seems to have been the prevailing religion of all the world; for wherever we cast our eyes at the time of Abraham, we scarcely see any thing but false worship and idolatry. And it appears from scripture, that Abraham's forefathers, and even Abraham himself, were for a time idolaters.

The Hebrews were indeed expressly forbidden to make any representation of God ; they were not so much as to look upon an idol : and from the time of the Maccabees to the destruction of Jerusalem, the Jews extended this precept to the making the figure of any man : by the law of Moses, they were obliged to destroy all the images they found, and were forbidden to apply any of the gold or silver to their own use, that no one might receive the least profit from any

thing belonging to an idol. Of this the Jews, after they had smarted for their idolatry, were so sensible, that they thought it unlawful to use any vessel that had been employed in sacrificing to a false god ; to warm themselves with the wood of a grove, after it was cut down ; or to shelter themselves under its shade.

But the preaching of the christian religion, wherever it prevailed, entirely rooted out idolatry, as did also that of Mahomet, which is built on the worship of one God. It must not, however, be forgotten, that the protestant christians charge those of the church of Rome with paying an idolatrous kind of worship to the pictures or images of saints and martyrs : before these, they burn lamps and wax-candles ; before these, they burn incense, and kneeling offer up their vows and petitions : they, like the pagans, believe that the saint to whom the image is dedicated, presides in a particular manner about its shrine, and works miracles by the intervention of its image ; and that if the image was destroyed or taken away, the saint would no longer perform any miracle in that place.

IDYLLION, *εἰδύλλιον*, in antient poetry, is only a diminutive of the word *εἶδος*, and properly signifies any poem of moderate extent, without considering the subject.

But as the collection of Theocritus's poems, were called idyllia, and the pastoral pieces being by far the best in that collection, the term idyllion seems to be now appropriated to pastoral pieces. See the article PASTORAL POETRY.

So very different are our modern idyllions from those of the antients, by introducing none but allegorical shepherds, that a literal translation of Theocritus's idyllions, however well executed, would be relished only by people of taste, and those too well acquainted with the simplicity and manners of the antients.

JEALOUSY, in general, denotes the fear of a rival ; but is more especially understood of the suspicion, which married people entertain of each others fidelity and affection.

*Bitter-waters of JEALOUSY*, in jewish antiquity, certain consecrated waters, which a woman was obliged to drink, in order to clear herself of the crime of adultery, whereof her jealous husband accused her ; the consequence of which draught was, that if innocent she suffered no harm, but if guilty her belly swelled, &c.

**JEAN DE ANGELI**, a town of Guienne, in France, thirty-five miles south-east of Rochelle.

**JEAN DE LUZ**, a port of France, in the province of Gascony, situated near the frontiers of Spain: west long.  $1^{\circ} 32'$ , north lat.  $43^{\circ} 30'$ .

**JEAN DE MAURIENNE**, a city in the dutchy of Savoy, thirty miles south-east of Chamberry: east long.  $6^{\circ} 8'$ , north lat.  $45^{\circ} 16'$ .

**JEAN PIED DE PORT**, a town of the province of Navarre, in France, situated on the river Nive, on the frontiers of Spain: west long.  $1^{\circ} 25'$  north lat.  $43^{\circ} 16'$ .

**JECORINUS**, in ichthyology, a fish, otherwise called hepatus. See **HEPATUS**.

**JECUR**, the **LIVER**, in anatomy. See the article **LIVER**.

**JECUR MARINUM**, or **JECORINUS**. See **JECORINUS**.

**JECUR UTERINUM**, in anatomy, a name by which some call the placenta. See the article **PLACENTA**.

**JEDBURGH**, the capital of Tiviotdale or Roxburgh, in Scotland, thirty-six miles south-east of Edinburgh: west long.  $2^{\circ} 15'$ , north lat.  $55^{\circ} 25'$ .

**JEDDO**, the capital city of Japan Proper, situated on the east side of the island: east long.  $141^{\circ}$  north lat.  $36^{\circ}$ .

The splendor of the royal palace and public buildings of this city, in the opinion of those Europeans who have seen it, is no where to be equalled. The emperor's palace and gardens, which are in the middle of the city, are five miles in circumference. All the houses are built upon one floor, and the rooms are only divided by folding screens.

**JEER**, or **JEER-ROPE**, in a ship, is a large rope reeved thro' double or treble blocks, lashed at the mast head, and on the yard, in order to hoist or lower the yards.

**JEERS**, or, being brought to the jeers, in the sea-language, signifies, a person's being punished at the jeer-captain, by having his arms extended cross-wise, and tied to the captain-bar when thrust thro' the barrel, and standing thus, with a heavy weight about his neck. In this posture he is obliged to continue till he is either brought to confess some crime of which he is accused, or has suffered the punishment which the captain has sentenced him to undergo.

**JEHOVAH**, one of the scripture names of God, signifying the Being who is self-existent, and gives existence to others. See the article **GOD**.

So great a veneration had the Jews for this name, that they left off the custom of pronouncing it, whereby its true pronunciation was forgotten. They call it tetragrammaton, or the name with four letters; and believe, that whoever knows the true pronunciation of it cannot fail to be heard by God.

**JEJUNUM**, in anatomy, the second of the small guts, so called because it is usually found empty. This is owing to the fluidity of the chyle, the greater stimulus of the bile in it, and the abundance of the lacteal vessels with which it is furnished. Its situation is in the region above the navel; it has a great many connivent glands. Its beginning is where the duodenum ends; and it terminates, where these valves are obliterated: Its length is different in various subjects; but is usually between thirteen and sixteen spans. See **INTESTINES**.

**JEKYL**, a small island in the mouth of the river Alatamaha, in Georgia, fortified by Mr. Oglethorpe.

**JEMPTERLAND**, *Jemptia*, a province of Sweden, bounded by Angermania on the north; by Medelpadia on the east, by Helplingia on the south, and by Norway on the west.

**JENA**, a city of Germany, in the circle of Upper Saxony, and the Landgraviate of Thuringia: east long.  $11^{\circ} 44'$ , north lat.  $51^{\circ}$ .

**JENDE**, a great lake, in the province of Finland, in Sweden.

**JENISA**, a large river of Russia, that runs from south to north thro' Siberia, and falls into the frozen ocean in  $72^{\circ}$  of east longitude, and  $70^{\circ}$  of north lat.

**JENKOPING**, a city of Sweden, in the province of Gothland, situated ninety miles south east of Gottenburg: east long.  $14^{\circ} 30'$ , north  $57^{\circ} 30'$ .

**JENNET**, or **GENET**, in the manege. See the article **GENET**.

**JENNY-WREN**, a name sometimes given to the wren. See the article **WREN**.

**JENO**, or **GENO**, a town of upper Hungary, twenty miles south of Great Waradin, and subject to the house of Austria.

**JENTLING**, in ichthyology, the blue chub, a fish caught in the Danube, and larger than the common chub. See the article **CHUB**.

**JEOPFAILE**, or **JEOPFAYLE**, in law, a term used for an oversight in pleading, or other proceedings at law.

The shewing of these defects or oversights, was formerly often practised by the

the counsel; and when the jury came into court, in order to try the issue, they said, this inquest you ought not to take; and after verdict they would say to the court, to judgment you ought not to go: but several statutes have been made to avoid the delays occasioned by such suggestions; and a judgment is not to be stayed after verdict for mistaking the christian or surname of either of the parties, or in a sum of money, or in the day, month, year, &c. where the same are rightly named in any preceding record.

**JERSEY**, an island in the english channel, fifteen miles west of the coast of Normandy, and eighty miles south of Portland in Dorsetshire: west long.  $2^{\circ} 20'$ , north lat.  $49^{\circ} 20'$ .

It is about 30 miles in circumference, and contains twelve parishes, the chief town is St. Hillary. Though the island is subject to England, the inhabitants are still governed by norman laws, and the courts of England have no jurisdiction there.

**New JERSEY**, a province in North America, which may be bounded on the north by a line drawn from the river Delaware to Hudson's river, which divides it from New-York; by the Atlantic Ocean, on the east; by the same ocean on the south, and by Delaware bay and river, which separates it from Pensilvania, on the west. It lies between  $74^{\circ}$  and  $76^{\circ}$  of west long. and between  $39^{\circ}$  and  $41^{\circ}$  of north lat. and is about 140 miles in length, and 60 in breadth. It is subject to England. The chief towns are Burlington, Perth-Amboy, and Elizabeth Town. It produces corn, black-cattle, furs, and pipe-staves.

**JERUSALEM**, the capital city of Judea, or Palestine, in Asiatic Turkey, situated thirty miles east of the Levant, or Mediterranean Sea, and ninety miles south of Damascus: east long.  $36^{\circ}$ , north lat.  $32^{\circ}$ .

It stands on a high rock, with steep ascents on every side, except on the north, and is surrounded with a deep valley, which is again incompassd with hills. The city is at present three miles in circumference, and has a little altered its situation; for Mount Calvary, which was formerly without the walls, stands now in the middle of the city, and Mount Sion, which stood near the center, is now without the walls.

**JESI**, a city of Italy, in the province of Ancona, and territory of the pope: east long.  $14^{\circ} 40'$ , north lat.  $43^{\circ} 45'$ .

**JESSE**, a branched candlestick, or sconce; an useful ornament, first introduced into our churches about the year 1100.

**JESSELMERE**, the capital of the province of the same name in the East-Indies, subject to the Mogul: east long.  $73^{\circ} 20'$ , north lat.  $27^{\circ}$ .

**JESSO**, or **YEDSO**, a country of Asia, which lies north of Japan, and is said to extend north-east to the continent of America: east long.  $140^{\circ}$ , north lat.  $40^{\circ}$ .

**JESUAT**, a province of India, bounded by Patan on the north, and by Bengal on the south; subject to the mogul.

**JESUITES**, or the society of Jesus, a most famous religious order in the romish church, founded by Ignatius Loyola, a native of Guipuscoa in Spain, who in the year 1538, assembled ten of his companions at Rome, principally chosen out of the university of Paris, and made a proposal to them to form a new order; when, after many deliberations, it was agreed to add to the three ordinary vows of chastity, poverty, and obedience, a fourth; which was, to go into all countries whither the pope should please to send them, in order to make converts to the romish church. Two years after, pope Paul III. gave them a bull, by which he approved this new order, giving them a power to make such statutes as they should judge convenient: on which, Ignatius was created general of the order; which in a short time spread over all the countries of the world, to which Ignatius sent his companions, while he staid at Rome, from whence he governed the whole society.

The entire society is composed of four sorts of members; novices, scholars, spiritual and temporal coadjutors, and professed members. The novices continue so two years, after which they are admitted to make the three simple vows, of chastity, poverty and obedience, in the presence of their superiors: the scholars add some spiritual exercises to their studies. The spiritual coadjutors assist the professed members, and also make the three simple vows: the temporal coadjutors, or lay-brothers, take care of the temporal affairs of the society; and the professed members, which compose the body of the society, besides the three simple vows, add a special vow of obedience to the head of the church in every thing relating to missions among idolaters and heretics. They have professed houses for their professed members

and their coadjutors ; colleges, in which the sciences are taught to strangers ; and seminaries, in which the young jesuits go thro' a course of philosophy and theology. They are governed by a general, who has four assistants, and who appoints rectors, superiors of houses, provincials, visitors, and commissaries. The discipline of these houses, and especially of the colleges, was regulated by Ignatius himself.

**JET**, *gagates*, in natural history, a solid, dry, opaque, inflammable substance, found in large detached masses, of a fine and regular structure, having a grain like that of wood, splitting more easily horizontally than in any other direction, very light, moderately hard, not fusible, but readily inflammable, and burning a long time with a fine greenish flame.

It is of a fine deep black colour, very glossy and shining, except upon its surface, where it has been fouled by accident. When examined by the microscope, it is found to be composed of a number of parallel plates, very thin, and laid closely upon one another. It is not soluble in, nor makes any effervescence with acids. It should be chosen of the deepest black, of a moderate hardness, very light, and such as will split most evenly in an horizontal direction ; this being its great characteristic, by which it is distinguished from the cannel-coal, which breaks equally easy any way.

Jet is of great use to perfumers, and is sometimes prescribed in medicine. Dioscorides tells us, that it is an excellent emollient and discutient, and recommends a fumigation of it for diseases of the womb ; and among the eastern nations, it is still in high repute as a cordial, a strengthener, and prolonger of life.

Every pound of jet pays on importation a duty of 7<sup>7</sup>/<sub>10</sub>d. and draws back 6<sup>7</sup>/<sub>10</sub>d. on exportation.

**JET D'EAU**, a french term, frequently also used with us, for a fountain that casts up water to a considerable height in the air. See **FOUNTAIN**.

**JETSON**, **JETSEN**, or **JETSAM**, in law, is used for any thing thrown out of a ship or vessel that is in danger of being a wreck, and which is driven by the waves on shore. See **FLOTSON**.

**JEVER**, a town of Germany, in the circle of Westphalia, sixteen miles north-east of Embden : east long. 7° 5', north lat. 53° 30'.

**JEWEL**, any precious stone, or ornament beset with them. See the articles **DIAMOND**, **RUBY**, &c.

**JEWEL-OFFICE**, an office belonging to the crown, that has the charge of fashioning and weighing the king's plate, and delivering it out by warrants from the lord chamberlain.

The principal officer is the master of the jewel-office, who has a salary of 450l. per annum.

**JEWS**, those who profess obedience to the laws and religion of Moses, before whom every man worshipped God according to the inclination of his own heart.

How far the religious ceremonies of the Jews were copied from those of the Egyptians, among whom they had so long sojourned, or how far they were typical of something future, are questions which we leave to be discussed by divines. But as to the religion of the modern Jews, it is a manifest absurdity ; since being without a temple, sacrifices, &c. it cannot be considered as subsisting any longer.

Be this as it will, we shall subjoin a few of their miscellaneous customs, as related by Leo of Modena, an author of their own.

When a Jew builds an house, he must leave part of it unfurnished, in remembrance that the temple and Jerusalem now lie desolate. They lay great stress upon frequent washings. They abstain from meats prohibited by the levitical law ; for which reason, whatever they eat must be dressed by Jews, and after a manner peculiar to themselves. Every Jew is obliged to marry, and a man who lives to twenty unmarried, is accounted as actually living in sin.

The Jews, it is said, were formerly at the disposal of the chief lord where they lived, and likewise all their goods. A Jew may be a witness by our law, being sworn on the Old Testament, and taking the oaths to the government.

For a farther account of the Jews, see the articles **CARAITES**, **CIRCUMCISION**, **LEVITES**, **PASSOVER**, **PHARISEES**, **RABBINS**, **SADDUCEES**, **SANHEDRIM**, **SYNAGOGUE**, **TALMUD**, &c.

**JEW'S EARS**, *auricula judæ*, in botany. See **AURICULA**.

This fungus is seldom found unless on the lower parts of the trunks of elder-trees ; whence it is called sambucus. It is not much used by physicians ; but

is in great repute among the common people, who cure themselves of sore throats with a decoction of its milk. This, tho' by no means a pleasant medicine, is however a very efficacious one.

**JEW'S STONE**, *lapis judaicus*, in the materia medica, an extraneous fossil, being nothing but the petrified spine of a large echinus marinus. It is of the figure of an olive, and is furrowed and ridged alternately in a longitudinal direction. It is solid, considerably heavy, and difficult to break; being, indeed, a petrefaction solely composed of spar, and that tolerably pure. Hence, it is said to be a great diuretic and lithontriptic; and that it possesses the former of these virtues is very certain, but it is not equally sure that it has any thing of the other. It acts in this case as mere spar, all the spar in the world, whether in its solid form, or in a natural state of solution in water, being diuretic. The lapis judaicus is given in an impalpable powder, and the dose is from one scruple to a dram.

**JEWISH HOURS**, in chronology. See the article **HOURL**.

**JEZIDES**, among the mahometans, a term of similar import with heretics among christians.

The jezides are a numerous sect inhabiting Turkey and Persia, so called from their head Jezid, an arabian prince, who slew the sons of Ali, Mahomet's father-in-law, for which reason he is reckoned a parricide, and his followers heretics. There are about 200,000 jezides in Turkey and Persia; who are of two sorts, black and white. The white are clad like Turks, and distinguished only by their shirts, which are not slit at the neck like those of others, but have only a round hole to thrust their heads thro'. This is in memory of a golden ring, or circle of light, which descended from heaven upon the neck of their cheq, the head of their religion, after his undergoing a fast of forty days. The black jezides, tho' married, are the monks or religious of the order; and these are called Fakirs.

The Turks exact excessive taxes from the Jezides, who hate the Turks as their mortal enemies, and when, in their wrath, they curse any creature, they call it mussulman: but they are great lovers of the christians, being more fond of Jesus Christ than of Mahomet, and are never circumcised but when forced it.

They are extremely ignorant, and believe both the bible and the koran without reading either of them; they make vows and pilgrimages, but have no places of religious worship.

All the adoration they pay to God consists of some songs in honour of Jesus Christ, the Virgin, Moses, and sometimes Mahomet; and it is a principal point of their religion never to speak ill of the devil, lest he should resent the injury, if ever he should come to be in favour with God again, which they think possible: whenever they speak of him, they call him the Angel Peacock. They bury their dead in the first place they come at, rejoicing as at a festival, and celebrating the entry of the deceased into heaven. They go in companies like the Arabians, and change their habitations every fifteen days. When they get wine, they drink it to excess, and it is said, that they sometimes do this with a religious purpose, calling it the blood of Christ. They buy their wives, and the market-price is two hundred crowns for all women, handsome or not, without distinction.

**IGLAW**, a town of Germany, in the province of Moravia, situated on the river Igl, on the frontiers of Bohemia; subject to the house of Austria: east long. 15° 7', north lat. 49° 16'.

**IGNATIUS'S BEAN**, *faba St. Ignatii*, in the materia medica. See **FABA**.

**IGNAVUS**, in zoology, an animal called in english the sloath, and by authors bradypus. See **BRADYPUS** and **SLOATH**.

**IGNIS**, FIRE, in physiology, chemistry, &c. See the article **FIRE**.

**IGNIS-AQUA**, Helmont's name for the alkalest. See **ALKAHEST**.

**IGNIS-FATUUS**, in meteorology, a meteor otherwise called, will-with-a-wisp. See the article **WILL-with-a-wisp**.

**IGNIS GEHENNÆ**, the same with the universal dissolvent, or alkalest. See the article **ALKAHEST**.

**IGNIS JUDICII**, in our old customs, a purification by fire. See **ORDEAL**.

**IGNISPICIUM**, in antiquity, a species of pyromancy, wherein predictions were drawn from the fire used in sacrifices. See **PYROMANCY** and **DIVINATION**.

**IGNITION**, in chemistry, the heating metals red-hot, without melting them. Lead and tin are too soft, to bear ignition; which takes effect only in the harder metals, as gold and silver, but especially iron.

**IGNORAMUS**, in law, a term which signifies we are ignorant. This is used when the grand jury impanelled on the inquisition of criminal causes, reject the evidence as too weak to make good the presentment or indictment brought against a person, so as to bring him upon his trial by a petty jury; in which case, they indorse this word on the back of the bill of indictment. In consequence of which, all further proceedings against the party accused are stopped, and the supposed offender is delivered without further answer.

**IGNORANCE**, *ignorantia*, the privation or absence of knowledge. See the article **KNOWLEDGE**.

The causes of ignorance, according to Locke, are chiefly these three. 1. Want of ideas. 2. Want of a discoverable connection between the ideas we have. 3. Want of tracing and examining our ideas. See the article **IDEA**.

As to the first of these causes, he observes, that all the simple ideas we have, are confined to the observation of our senses, and the operations of our own mind, which we are conscious of in ourselves. What other ideas it is possible other creatures may have, by the assistance of other senses and faculties, more or perfecter than we have, or different from ours, it is not for us to determine; but to say or think there are no such, because we conceive nothing of them, is no better an argument than if a blind man should be positive, that there was no such thing as sight and colours, because he had no manner of idea of any such thing. What faculties, therefore, other species of creatures have to penetrate into the nature and inmost constitutions of things, we know not. This we know, and certainly find, that we want other views of them besides those we have, to make discoveries of them more perfect. The intellectual and sensible world are in this perfectly alike, that the parts which we see of either of them, hold no proportion with that we do not see; and whatsoever we can reach with our eyes, or our thoughts, of either of them, is but a point, and almost nothing in comparison of the rest.

Another great cause of ignorance, is the want of those ideas we are capable of. This keeps us in ignorance of things which we conceive capable of being known. We have ideas of bulk, figure, and motion; yet not knowing what is

the particular bulk, motion, and figure of the greatest part of the bodies of the universe, we are ignorant of the several powers, efficacies, and ways of operation, by which the effects we daily see are produced. These are hid from us, in some things, by being too remote; in others, by being too minute.

When we consider the vast distance of the known and visible parts of the world, and the reason we have to think, that what lies within our ken, is but a small part of the immense universe, we shall then discover an huge abyss of ignorance. What are the particular fabrics of the great masses of matter which make up the whole stupendous frame of corporeal beings, how far they are extended, and what is their motion, and how continued, and what influence they have upon one another, are contemplations in which at the first glimpse our thoughts are lost. If we confine our thoughts to this little canton, I mean this system of our sun, and the grosser masses of matter that visibly move about it; what several sorts of vegetables, animals, and intellectual corporeal beings, infinitely different from those of our little spot of the earth, may probably be in other planets, to the knowledge of which, even of their outward figures and parts, we can no way attain while we are confined to this earth, there being no natural means, either by sensation or reflection, to convey their certain ideas into our minds?

There are other bodies in the universe no less concealed from us by their minuteness. These insensible corpuscles being the active parts of matter, and the great instruments of nature, on which depend all their secondary qualities and operations, our want of precise distinct ideas of their primary qualities, keeps us in incurable ignorance of what we desire to know about them. Did we know the mechanical affections of rhubarb or opium, we might as easily account for their operations of purging and causing sleep, as a watchmaker can for the motions of his watch. The dissolving of silver in aqua fortis, or gold in aqua regia, and not *vice versa*, would be then perhaps no more difficult to know, than it is to a smith to understand why the turning of one key will open a lock, and not the turning of another. But while we are destitute of senses, acute enough to discover the minute particles of bodies, and to give us ideas of their mecha-

mechanical affections, we must be content to be ignorant of their properties and operations; nor can we be assured about them any farther, than some few trials we make, are able to reach: but whether they will succeed again another time, we cannot be certain. This hinders our certain knowledge of universal truths concerning natural bodies: and herein our reason carries us very little beyond particular matters of fact. And therefore I am apt to doubt, that how far soever human industry may advance useful and experimental philosophy in physical things, yet the scientific will still be out of our reach; because we want perfect and adequate ideas of those very bodies which are nearest to us, and most under our command.

This, at first sight, shews us how disproportionate our knowledge is to the whole extent even of material beings: to which if we add the consideration of that infinite number of spirits that may be, and probably are, which are yet more remote from our knowledge, of which we have no cognizance, we shall find this cause of ignorance, conceal in an impenetrable obscurity, almost the whole intellectual world; a greater certainly, and a more beautiful world than the material. For bating some very few ideas of spirit, which we get from our own minds by reflection, and from thence the best we can collect of the father of all spirits, the author of them and us, and all things, we have no certain information, so much as of the existence of other spirits, but by revelation; much less have we distinct ideas of their different natures, states, powers, and several constitutions, in which they either agree or differ one from another, and from us. And therefore in what concerns their different species and properties, we are under an absolute ignorance.

The second cause of ignorance is the want of a discoverable connection between those ideas we have: where we want that, we are utterly incapable of universal and certain knowledge; and are, as in the former case, left only to observation and experiment. Thus the mechanical affections of bodies, having no affinity at all with the ideas they produce in us, we can have no distinct knowledge of such operations beyond our experience; and can reason no otherwise about them, than as the effects or appointment of an infinitely wise agent,

which perfectly surpasses our comprehensions.

The operation of our minds upon our bodies is as inconceivable. How any thought should produce a motion in body, is as remote from the nature of our ideas, as how any body should produce any thought in the mind. If experience did not convince us that it is so, the consideration of the things themselves would never be able, in the least, to discover it to us.

In some of our ideas there are certain relations, habitudes and connections so visibly included in the nature of the ideas themselves, that we cannot conceive them separable from them by any power whatsoever: in these only, we are capable of certain and universal knowledge. Thus the idea of a right-lined triangle, necessarily carries with it an equality of its angles to two right ones. But the coherence and continuity of the parts of matter, the production of sensation in us, of colours and sounds, &c. by impulse and motion, being such in which we can discover no natural connection with any ideas we have, we cannot but ascribe them to the arbitrary will and good pleasure of the wise architect.

The things which we observe always proceed regularly, we may conclude, act by a law that is set them, but yet by a law that we know not; by which, tho' causes work steadily, and effects constantly flow from them, yet their connections and dependencies not being discoverable in our ideas, we can only have an experimental knowledge of them. Several effects come every day within the notice of our senses, of which we have so far sensible knowledge; but of the causes, manner, and certainty of their production, we must for the foregoing reasons be content to be ignorant. In these we can go no farther than particular experience informs us of matter of fact, and by analogy, guess what effects the like bodies are, upon other trials, like to produce.

The third cause of ignorance is our want of tracing those ideas we have, or may have, and finding out those intermediate ideas which may shew us what habitude of agreement or disagreement they may have one with another. Thus many are ignorant of mathematical truths, for want of application in enquiring, examining, and by due ways comparing those ideas.

IGNORANCE,

**IGNORANCE**, in law, is a want of knowledge of the laws, which will not excuse a person from suffering the penalty inflicted on the breach of them: for every one is obliged, at his peril, to know the laws of the land. An infant who is just arrived at the age of discretion, and who may therefore be supposed to be ignorant of the law, is punishable for crimes; but at the same time infants of tender age, who are naturally ignorant, are excused. This is also the case with respect to persons who are non compos mentis. See **INFANT**, **LUNATIC**, &c.

**IGUANA**, in zoology, an american species of lizard, with a long round tail, five toes on each foot, and the crest of the throat and the dorsal suture dentated. See the article **LIZARD**.

**IHOR**, the capital of the province of Ihor, in Malacca, near the south cape of the further peninsula of India, subject to the Dutch: east long.  $103^{\circ}$ , north lat.  $3^{\circ}$ .

**JIG**, or **GIGG**, in music. See **GIGG**.

**ILCHESTER**, a borough-town of Somersetshire, fourteen miles south of Wells. It sends two members to parliament.

**ILDEFONSO**, a palace belonging to the king of Spain.

**ILEX**, the **HOLM-OAK**, or **EVER-GREEN-OAK**, in botany, a genus of the *tetrandria-tetragynia* class of plants, the flower of which consists of one plain petal, divided into four roundish, hollow, and open segments, cohering only at their bottoms: the fruit is a roundish berry, with four cells, each of which contains a single hard, oblong, and obtuse seed, gibbous on one side, and angular on the other.

The wood of these trees is accounted very good for many sorts of tools and utensils, as mallet-heads, mallet-balls, chairs, wedges, beetles, pins, &c. as also for palisadoes. It likewise affords the most durable charcoal in the world.

The kermes, or species known by the name of the holm-oak, is of a much lower stature than the other species of ever-green oaks; seldom growing to the height of a tree. See **KERMES**.

**ILHEOS**, or **RIO DE ILHEOS**, a province of Brazil in south America, subject to Portugal. It is bounded by the bay of All-saints on the north, and by the Atlantic ocean on the east.

**ILIAC PASSION**, in medicine, a pain in the small intestines, apt to turn to an inflammation, in which their peristaltic motion is inverted, and their contents, and even the excrements themselves, are

voided by the mouth in vomiting. Nothing will pass down, not so much as a flatus. It is often attended with fatal symptoms.

This disease, according to Hoffman, is preceded with costiveness, which is soon followed with most sharp and violent pains, with an inflation, distension, and a tumour of the umbilical region, which feels hard to the touch; the body is so hard bound, that neither wind nor excrements can pass downwards: soon after the wind first makes its way upward, there comes on a nausea, and a frequent vomiting of a bilious and pituitous matter; the breathing grows difficult, and whatever is eaten or drank is soon thrown up again; reddish fæces, with a stinking smell, are afterward forced up by vomiting: this is succeeded by loss of strength, a preternatural heat, a hard and contracted pulse, with great thirst: the urine is red, and is voided with difficulty. When the case becomes desperate, a hiccoughing and delirium appear; the nerves are distended, the body is all in a cold sweat, and violent convulsions and fainting fits put an end to the patient.

This disease may proceed from a rupture, either of the scrotum or the groin; from poisons, from any thing that stops up the passage thro' the small guts, such as hard, dry food, chestnuts, sea-biscuits, quinces, pears, unripe acerb fruit, when eaten in large quantities; to which drinking little, a sedentary life, and a melancholy disposition of mind, will greatly contribute: these all tend to harden the fæces; the gross intestines may also be plugged up with scybals, especially if a person, either through shame, or want of convenience, does not listen to the calls of nature.

As to the cure, Sydenham thinks it necessary first of all to bleed in the arm, and afterwards, in an hour or two, exhibit a powerful clyster; the smoke of tobacco blown into the bowels through an inverted pipe, he recommends as the most efficacious remedy: this may be repeated some time after, unless the effect of the first renders it unnecessary. If the disease will not yield to this, a pretty strong cathartic is advisable: thus, take of the pill of simple colocynth, half a dram; of calomel, one scruple; and as much as is sufficient of the balsam of peru. Make the whole into four pills to be taken out of a spoonful of syrup of violets, taking no liquor upon them less they

they cannot be retained : or, take resin of scammony, or instead of it, resin of jalap, twelve grains ; calomel, one scruple ; reduce them into powder, taking this out of a spoonful of cow's milk : take one or two spoonfuls of the same milk after swallowing them. If the patient cannot retain this, let him take twenty-five drops of the thebaic tincture in half an ounce of spirituous cinnamon-water ; and when the vomiting and pain remit, let the cathartic be repeated ; and if the pain returns, give the anodyne again, and repeat it every fourth or sixth hour till the intestines are easy, and the cathartic begins to pass downwards. When it has done working, give the following draught : take of spirituous water of cinnamon, two ounces ; of thebaic tincture, twenty-five drops ; of which make a draught, which is to be repeated twice or thrice a day, till the vomiting and pains quite cease : afterwards it will be advisable to give a paregoric, at bedtime, for several nights.

Hoffman advises, after the pains are mitigated by anodynes, that a cataplasin should be applied to the hypogastric region, to stop the vomiting and hiccupping, which may be composed of equal parts of old venice-treacle, and expressed oil of nutmegs, with the addition of oil of mint and camphire. This done, a gentle laxative of manna, cream of tartar, and oil of sweet almonds may be given with a more happy success, if the excrements have been long retained. When there is an inflammation, nothing is better than six or eight grains of purified nitre, and half a grain of camphire mixed with some antispasmodic powder, and then taken in a convenient vehicle. Outwardly apply a liniment of axungia-humana, or any other penetrating fat, and a dram of camphire.

But when other things fail in the cure of the iliac passion, recourse must be had to quicksilver ; half a pound or a pound at most is sufficient, with fat broth or oil ; and the patient should lie on his right side, or walk gently about the room, that its descent may be easier ; but if there is an actual inflammation, the quicksilver should not be used. Opiates may be used to mitigate the pain, provided they are exhibited in the beginning after bleeding, or before there is any signs of a mortification. Clysters are generally very advantageous, for they relax the spasm of the gross intestines,

and for this purpose warm water with spirit of marshmallows will be sufficient : they should be given very soon after the first attack. When the iliac passion proceeds from an incarcerated hernia, then Heister recommends bleeding as of the greatest advantage. See HERNIA.

**ILIACUS MUSCULUS**, in anatomy, a broad, thick muscle, lying on the inside of the os ilium. It is fixed by fleshy fibres to the internal labium of the crest of the os ilium, to that of the slope between the two anterior spines, to the insides of these spines, to the superior half of the inside of this bone, and to the adjacent lateral part of the os sacrum. All these fibres, contracting by degrees, run obliquely towards the lower part of the musculus psoas, uniting with it ; and being fixed by a kind of aponeurosis to the outside of its tendon, all the way to the little trochanter.

**ILIAD**, *Ἰλιάς*, in literary history, the name of an antient epic poem, the first and finest of those composed by Homer.

The poet's design in the *iliad* was to shew the Greeks, who were divided into several little states, how much it was their interest to preserve a harmony and good understanding among themselves : for which end, he sets before them the calamities that befel their ancestors from the wrath of Achilles, and his misunderstanding with Agamemnon ; and the advantages that afterwards accrued to them from their union. The *iliad* is divided into twenty-four books, or rhapsodies, which are marked with the letters of the alphabet.

The critics maintain the *iliad* to be the first, and yet the best epic poem that ever appeared in the world. Aristotle's poeticks are almost wholly taken up about it, forming precepts from that poet's practice. Some authors tell us, that Homer invented not only poetry, but all other arts and sciences ; and that there are visible marks of a perfect knowledge of every one of them to be seen in the *iliad*. There is a translation of this noble poem into our language, by the late ingenious Mr. Pope ; being, perhaps, the most elegant, and most in imitation of the original, of any attempt that way in any language whatever.

**ILIUM**, in anatomy, the third and last of the small guts, is situated principally below the navel, near the ossa ili ; whence its name. Its length is various : sometimes not more than fifteen, sometimes

twenty spans or more. Its beginning is where the valves of the jejunum cease to be conspicuous, and its end is where the larger intestines begin; in which place it is, in a very singular manner, inserted into the left side of the colon. It has no other valves except that great one at the end, which is called, by many, *valvula coli Bauhini*: its glands are, in general, more numerous towards the end than in any other part.

**ILIUM OS.** See **INNOMINATA OSSA**.

**ILL**, a river which rising near Basil, in Switzerland, runs north through Alsace, and having passed by Colmar, Schellstat, and Straßburgh, falls into the Rhine a little below the last city.

**ILLEGITIMATE.** See **LEGITIMATE**.

**ILLENOIS**, the inhabitants of a country contiguous to the illinois-lake, in Canada, in north America, which is situated between 88° and 93° of west long. and between 41° and 46° of north lat.

**ILLER**, a river of Germany, which rising in the mountains of Tyrol, runs north through Swabia, and falls into the Danube at Ulm.

**ILLEVIABLE**, in law, signifies any debt or duty that cannot be levied.

**ILLUSTRIOUS**, was antiently a title of honour in the roman empire, first given to the most distinguished among the knights who had a right to bear the *latus clavus*. Afterwards it was given to the first rank of the *honorati*, that is, to the *præfeti prætorii*, treasurers, *comites*, &c. There were, however different degrees among the illustrious; and as in Spain there are *grandees* of the first and second class, so in Rome they had their *illustres majores* and *minores*. The novels of Valentinian distinguish five classes of the illustrious, among whom the *illustres administratores* bore the first rank.

**ILMEN**, a lake in the province of Great Novogrod, in Russia, in 34° east long. and 58° north lat.

**ILMINSTER**, a market-town of Somersetshire, twenty-four miles south-west of Wells.

**ILOCK**, a town of Sclavonia, situated on the Danube, and subject to the house of Austria: east long. 20° 32', north lat. 45° 33'.

**ILS**, a river of Germany, which rising in the mountains of Bohemia, runs south and falls into the Danube at Passau.

**ILSLEY**, a market-town of Berkshire, ten miles north-west of Reading.

**IMAGE**, in a religious sense, is an artificial representation or similitude of some person or thing, used either by way of decoration and ornament, or as an object of religious worship and veneration; in which last sense, it is used indifferently with the word *idol*. See **IDOL**.

There is no doubt but that these images, or idols, were at first of the plainest and most simple materials; and as in the early ages people had but little skill in sculpture, it is probable that they made choice of such materials as were most easily wrought and fashioned into the intended figure; from hence it is not unlikely that the first images were made of earth, and that to give them some beauty, they were painted with different colours. Thus Pliny tells us, that Tarquinius Priscus caused a statue of Jupiter Capitolinus to be made of earth and painted red. Next to earth, wood seems to have been the most common material for images; but in length of time they were made of brass, silver, and gold. For the worship of images, see the articles **GODS** and **IDOLATRY**.

The worship of images among the christians, occasioned great contests both in the eastern and western churches; but at length this worship, in spite of all opposition made against it, was allowed and enjoined.

The roman catholics boast of the miraculous effects of the images of their saints. The image of Jesus Christ, which feeling itself wounded with a dagger by an impious wretch, laid its hand upon the wound, is famous at Naples. It is pretended that the image of St. Catherine of Sienna, has often driven out devils, and wrought other miracles: and that the lady of Lucca, when insolently assaulted by a soldier, who threw a stone at her, and had like to have broken the head of the child Jesus, whom she held on her right arm, immediately set him on her left, and the child liked sitting on that arm so well, that since that accident, he has never changed his situation.

As to the greek church, tho' they reject the use of graven images and statues, they pay a boundless veneration to pictures, and upon solemn festivals plant the picture of the saint to whom the church is dedicated in the center of the church; and every person present salutes it not by kneeling or prostration, but by giving it a kiss. If the picture represents

our

our blessed Lord, they kiss its feet; if the virgin Mary, its hands; but if it be any other saint, they approach it with more familiarity, and kiss its cheek. Before these pictures they also address their prayers.

**IMAGINATION**, a power or faculty of the mind, whereby it conceives and forms ideas of things communicated to it by the outward organs of sense.

Lord Bacon, having divided the doctrine of the mental faculties into logics and ethics, considers the imagination as performing the office of an agent or ambassador on both sides, and assisting alike in the judicial and ministerial capacity. Sense, according to him, commits all sorts of notions to the imagination, and reason afterwards judges of them. In like manner, reason transmits select and approved notions to the imagination before the decree is executed; for imagination always precedes and excites voluntary motion, and is therefore a common instrument both to the reason and the will; only it has two faces, that turned towards reason bearing the effigy of truth, but that towards action, the effigy of goodness, yet so as to appear the effigies of sisters.

Mr. Boyle says, that there are many instances in physic-books of diseases arising from imagination, particularly where the disease is excessively dreaded; adding, that he knew a lady who had the small-pox by this means: nor is it only in women that imagination has these effects, for he tells us of a man whose hair was suddenly changed from a fear of his going to be put to death. The remembrance of a loathsome potion will often produce a horror, attended with a sensible commotion of the whole body, and a kind of convulsion about the stomach. Shame, we see, occasions the blood to be plentifully thrown up into the face, as will also great and sudden joy. Longing in women may be supposed to create great alteration in the body of the mother, since it will leave such lasting and strong impressions upon that of the infant. And Mr. Boyle tells us of a young lady who washing in St. Winifrid's well, and fixing her eyes very attentively upon the red pebble-stones which in a scattered order made a large part of those that appeared through the water, a while afterwards grew big, went her time, and was delivered of a child, whose skin was plentifully speckled with spots of

the colour and magnitude of these stones. We have had lately an ingenious poem, in English, upon the pleasures of the imagination; and Addison's essays upon that subject in the *Spectator*, as well as Hutchinson's treatise on beauty and virtue, deserve the attention of such as desire to be informed in this branch of philosophy.

**IMAM**, a name applied by the mahometans to him who is head of the congregations in their mosques; and by way of eminence to him who has the supreme authority both in respect to spirituals and temporals.

There are subordinate imams in each town who represent the chief imam, but only with respect to religion. When the imam of the musfulman religion is mentioned without distinction, it is always restricted to the rightful and lawful successor of Mahomet, the fountain both of secular and sacred jurisdiction. The mahometans are not perfectly agreed concerning the dignity of some of the circumstances of this office: some hold the imamate to be settled by divine right, like the aaronical priesthood, in one family: others think it not so unalterably tied to genealogy and descent, as to hinder its passing from one family to another; and they say that an imam may be deposed for vicious conduct, and his office conferred on another.

The schiites, or disciples of Ali, maintain, that this privilege belongs to the family of Ali exclusive of all others; Ali being sole heir to Mahomet: hence, they own no person for the head of religion, who cannot prove his descent in a right line from this first imam. There are imams belonging to particular mosques, who are in the nature of our parish-priests.

**IMBARGO**, or **EMBARGO**, in naval affairs. See the article **EMBARGO**.

**IMBECILITY**, a languid, infirm state of body; which, being greatly impaired, is not able to perform its usual exercises and functions.

**IMBEZLE**, signifies to steal, pilfer, or purloin, and also to waste or diminish goods, &c. entrusted to a person's charge and care. Imbezlers of wool forfeit double damages, and may be committed to the house of correction till paid; and servants embezling their master's goods to the value of 40s. are deemed guilty of felony without benefit of clergy.

**IMBIBING**, the action of a dry porous body, that absorbs or takes up a moist or fluid

fluid one : thus, sugar imbibes water ; a sponge, the moisture of the air, &c. See **MOISTURE**, **HYGROMETER**, &c.

**IMBRICATED**, among botanists, an appellation given to such leaves of plants, as are placed over one another like the tiles of a house.

The term imbricated is likewise applied to some of the heart shells, from their being ridged transversely in the same manner.

**IMENSAT**, a town of Germany, in the circle of Swabia, situated in east long.  $10^{\circ} 8'$ , north lat.  $47^{\circ} 25'$ .

**IMITATION**, in literary matters, the act of doing or striving to copy after, or become like to, another person or thing.

Du Bos observes, that the principal merit of poems and pictures, consists in the imitation of such objects as would have excited real passions ; and that the passions which these imitations give rise to, are only superficial, and not so strong as that of the object imitated, and are therefore soon effaced. He also maintains, that the imitation of tragic objects in poems and pictures, afford most pleasure : we listen, therefore, with pleasure to those unhappy men who make a recital of their misfortunes by means of a painter's pencil, or of a poet's verses ; but, as Diogenes Laertius observes, it would afflict us extremely, were we to hear them bewailing their sad disasters in person. The too great impressions these imitations make upon man, was the reason of Plato's excluding them from his republic. Poets and painters cannot choose too engaging a subject for their imitation, since the principal charm of these two arts, as Du Bos observes, proceeds from the imitation of objects capable of engaging us.

Imitation, says he, ought not to be servile, but like that which Horace, Virgil, and many other good writers made use of, who preceded them ; that is, by following the genius of the language in which they composed, and taking nature for their first model.

**IMITATION**, in music, a particular way of composition wherein each part is made to imitate the other, either throughout the whole piece, which is one of the kinds of canon ; or only during some measures, which is a simple imitation. Sometimes the motion or figure of the notes is only imitated, and that often by a contrary motion, which makes what they call a retrograde imitation.

Imitation differs from a fugue, says Mr Brossard, in regard in the former the repetition must be a second, third, sixth seventh, or ninth, either above or below the first voice or guide ; to which it may be added, that it may be at any interval, and differs properly from fugue, in that in imitation the intervals may not be precisely the same ; whereas were the repetition to an unison, fourth, fifth, or octave, higher or lower, and the intervals exactly the same in the comes and guide, it would be a fugue.

**IMMACULATE**, something without stain, chiefly applied to the conception of the holy virgin. See **CONCEPTION**.

**IMMANENT**, in logic. The schoolmen distinguish two kinds of actions, the one transient, which pass from the agent to the patient, the other immanent, which continue in the agent. See **ACT**.

**IMMATERIAL**, something devoid of matter, or that is pure spirit : thus God, angels, and the human soul are immaterial beings. See the articles **GOD**, **ANGEL**, and **SOUL**.

**IMMEDIATE**, whatever is capable of producing an effect without the intervention of external means ; thus we say, an immediate cause, in opposition to a mediate or remote one. See **CAUSE**.

**IMMEDIATE MODE**. See **MODE**.

**IMMEMORIAL**, in law, an epithet given to the time or duration of any thing, whose beginning we know nothing of.

In a legal sense, a thing is said to be of time immemorial, or time out of mind, that was before the reign of king Edw. II.

**IMMENSITY**, an unlimited extension, or which no finite and determinate space, repeated ever so often, can equal. See the article **INFINITY**.

**IMMERETTA**, a province of asiatic Turkey, situated between Georgia and the Euxine sea.

**IMMERSION**, that act by which any thing is plunged into water, or other fluid. See the article **FLUID**.

It is used in chemistry for a species of calcination, when any body is immersed in a fluid to be corroded ; or it is a species of lotion, as when a substance is plunged into any fluid in order to deprive it of a bad quality, or communicate to it a good one.

**IMMERSION**, in astronomy, is when a star or planet is so near the sun with regard to our observations, that we cannot see it ; being, as it were, enveloped and hid in the rays of that luminary. It also denotes

denotes the beginning of an eclipse of the moon, or that moment when the moon begins to be darkened, and to enter into the shadow of the earth; and the same term is also used with regard to an eclipse of the sun, when the disk of the moon begins to cover it. In this sense emerſion ſtands oppoſed to immerſion, and ſignifies the moment wherein the moon begins to come out of the ſhadow of the earth, or the ſun begins to ſhew the parts of his diſk which were hid before. See the article ECLIPSE.

Immersion is frequently applied to the ſatellites of Jupiter, and eſpecially to the firſt ſatellite; the obſervation whereof is of ſo much uſe for diſcovering the longitude. The immerſion of that ſatellite is the moment in which it appears to enter within the diſk of jupiter, and its emerſion the moment when it appears to come out.

The immerſions are obſerved from the time of the conjunction of jupiter with the ſun, to the time of his oppoſition; and the emerſions from the time of his oppoſition to his conjunction.

The peculiar advantage of theſe obſervations is, that during eleven months of the year, they may be made at leaſt every other day. The perfection of this theory and the praxis thereon, we owe to Mr. Caſſini.

**IMMORTAL**, that which will laſt to all eternity; as having in it no principle of alteration or corruption: thus God and the human ſoul are immortal. See the articles GOD and SOUL.

**IMMUNITY**, a privilege or exemption from ſome office, duty, or impoſition, as an exemption from tolls, &c.

Immunity is more particularly underſtood of the liberties granted to cities and communities.

**IMMUTABILITY**, one of the divine attributes, founded on the abſolute perfection of the deity. See GOD.

The immutability of God is two-fold, physical and moral. The firſt conſiſts in this, that the divine eſſence does not, nor poſſibly can, receive any alteration; and the moral immutability is founded on the perfection of his nature, whereby he always wills the ſame things, or ſuch as are beſt on the whole.

**IMOLA**, a city of Italy, ſeventeen miles eaſt of Bologna, ſubject to the pope.

**IMPALED**, in heraldry; when the coats of a man and his wife who is not an heiress are borne in the ſame eſcutcheon,

they muſt be marſhalled in pale; the huſband's on the right ſide, and the wife's on the left: and this the heralds call baron and feme, two coats impaled.

If a man has had two wives, he may impale his coat in the middle between theirs; and if he has had more than two, they are to be marſhalled on each ſide of his in their proper order.

**IMPALPABLE**, that whoſe parts are ſo extremely minute that they cannot be diſtinguiſhed by the ſenſes, particularly by that of feeling.

**IMPANATION**, a term uſed by divines, to ſignify the opinion of the lutherans with regard to the eucharift, who believe that the ſpecies of bread and wine remain together with the body of our Saviour after conſecration.

**IMPANELLING**, in law, ſignifies the writing down or entering into a parchment, liſt or ſchedule, the names of a jury ſummoned by the ſheriff to appear for ſuch public ſervices as juries are employed in. See the article PANNEL.

**IMPARLANCE**, in law, a petition in court for a day to conſider or adviſe what answer the defendant ſhall make to the plaintiff's action; and is the continuance of the cauſe till another day, or a longer time given by the court.

An imparlance is general or ſpecial; general is when it is entered in general terms, without any ſpecial claule therein; ſpecial is where the defendant deſires a further day to answer. And this laſt imparlance is of uſe to plead ſome matters, which cannot be pleaded after a general imparlance.

It is ſaid that imparlance was formerly from day to day, but now it is from one term to another. In caſe the plaintiff amends his declaration after the ſame is delivered or filed, the defendant may in courſe imparl to the next term afterwards, unleſs the plaintiff pays coſts; but if he does, and they are accepted, the defendant may not have an imparlance. Likewise the not delivering a declaration in time, is ſometimes the cauſe of imparlance; and when the plaintiff declares, yet does not proceed in three terms after, in ſuch caſe the defendant may imparl to the next ſucceeding term. But there are divers caſes wherein imparlances are not to be given, as where a perſon is ſued by an attorney or any other privileged perſon of the court in an aſſiſe, one may not imparl except good cauſe be given, nor ſhall there be impar.

imparlancei n action of special claufum fregit, &c.

**IMPARSONNEE**, or a parfon imparfonee, in law. See the article **PARSON**.

**IMPASSIBLE**, that which is exempt from fuffering, or cannot undergo pain or alteration.

The ftoics place the foul of their wife man in an impaffible, or imperturbable ftate. See the article **STOIC**.

**IMPASTATION**, the mixtion of various materials of different colours and confiftencies, baked or bound together with fome cement, and hardened either by the air or by fire.

**IMPASTATION**, in mafonry, a term ufed for a work made of ftucco, or ftone, beaten and wrought up in manner of a paffe.

Some authors are of opinion, that the obelifks and the huge antique columns ftill remaining, were made by impaftation.

**IMPASTING**, or **EMPASTING**, in painting. See the article **EMPASTING**.

**IMPATIENS**, **TOUCH-ME-NOT**, in botany, a genus of plants otherwife called **balsamina**. See **BALSAMINA**.

This plant is faid to be fo ftrong a diuretic, as to bring on a diabetes.

**IMPEACHMENT**, an accusation and profecution for treason and other crimes and mifdemaneors. Any member of the lower houfe of parliament may impeach any one belonging either to that body, or to the houfe of lords. The method of proceeding, is to exhibit articles on the behalf of the commons, by whom managers are appointed to make good their charge. Thefe articles are carried to the lords, by whom every perfon impeached by the commons is always tried; and if they find him guilty, no pardon under the great feal can be pleaded to fuch an impeachment. 12 Will. III. cap. ii.

**IMPEACHMENT of waffe**, is a prohibition or refraint from committing of waffe upon lands or tenements. This term alfo fignifies a demand of fatisfaction for waffe committed by a tenant, who has only a particular eftate in the land granted, as for life or years. Yet a perfon that holds lands on leafe containing this claufe, *viz.* to hold without impeachment of waffe, has thereby fuch an intereft in the lands, &c. that he may commit waffe without being impeached or queftioned for it.

**IMPEDIMENTS**, in law, are fuch hindrances as put a ftop, or ftay, to a perfon's seeking for his right by due courfe of law.

Perfons under impediments are thofe that are either under age, or under cover, that are non compos mentis, in prifon, beyond fea, &c. who by our ftatutes are allowed time to claim and profecute their rights, after fuch impediments are removed, efpecially in cafe of fines levied.

**IMPENETRABILITY**, in philofophy, that property of body, whereby it cannot be pierced by another: thus, a body, which fo fills a fpace as to exclude all others, is faid to be impenetrable. See the articles **BODY**, **EXTENSION**, &c.

**IMPERATIVE**, one of the moods of a verb, ufed when we would command, entreat or advife: thus, *go, read, take pity, be advifed*, are imperatives in our language; but in the learned languages, this mood has a peculiar termination to diftinguifh it from others, as *i*, or *ito*, *ge*; *lege*, or *legito*, *read*, &c. and not only fo, but the termination varies, according as you addrefs one or more perfons, as *audi* and *audite*; *αυείλω*, *αυείλων*, *αυείλωσαν*, &c.

**IMPERATOR**, in roman antiquity, a title of honour conferred on victorious generals, by their armies, and afterwards confirmed by the fenate.

**IMPERATORIA**, **MASTER-WORT**, in botany, a genus of the *pentandria digynia* clafs of plants, the general corolla of which is uniform; the fingle flowers are compofed each of five inflexo-cordate and nearly equal petals; the fruit is naked, round, compreffed, and feparable into two parts; the feeds are two, oval, furrowed with two lines on one fide, and furrounded with a broad margin.

The root of this plant is cordial and fudorific, and is an ingredient in many compofitions.

**IMPERATRIX**, in botany, the fame with meum, or fpignel. See the article **MEUM**.

**IMPERFECT**, fomething that is defective, or that wants fome of the properties found in other beings of the fame kind: thus moifes are called imperfect plants, becaufe almofl all the parts of fructification are wanting in them; and for the like reafon, is the appellation imperfect given to the fungi and submarine plants. See **MOSS**, **FUNGI**, and **SUBMARINE**.

**IMPERFECT FLOWERS**, thofe otherwife called ftamineous. See the article **STAMINEOUS**.

**IMPERFECT NUMBERS**, fuch whole aliquot parts taken together, do either exceed or fall fhort of that whole number of which they are parts; they are either abundant

abundant or deficient. See the articles **ABUNDANT** and **DEFICIENT**.

**IMPERFECT TENSE**, in grammar, a tense that regards some præterite tense, or denotes the thing to be at that time present, and not quite finished; as *scribebam, I was writing*.

**IMPERIAL**, something belonging to an emperor or empire, as imperial crown, imperial chamber, imperial cities, imperial diet, &c. See **CROWN**, **CHAMBER**, **CITY**, **DIET**, &c.

**IMPERIAL** is also a city and port-town of the province of Chili, in south America, situated in west lon. 80°, north lat. 39°.

**IMPERSONAL VERB**, in grammar, a verb to which the nominative of any certain person cannot be prefixed; or, as others define it, a verb destitute of the two first and primary persons, as *decet, oportet*, &c. The impersonal verbs of the active voice end in *t*, and those of the passive in *tur*; they are conjugated thro' the third person singular of almost all the tenses and moods: they want the imperative, instead of which we use the present of the subjunctive; as *pœniteat, pugnetur*; nor, but a few excepted, are they to be met with in the supines, participles, or gerunds.

**IMPERVIOUS**, a thing not to be pervaded, nor passed through, either by reason of the closeness of its pores, or the particular configuration of its parts.

**IMPETIGO**, in medicine, a name by which the leprosy of the Greeks is sometimes called. See **LEPROSY**.

**IMPETIGO** is also a species of itch, attended with dry scales or scurf, and an uneasy pruriginous itching. See **ITCH**.

**IMPETRATION**, in law, the obtaining any thing by request or prayer: but in our old statutes, it is taken for the pre-obtaining of church benefices in this realm, from the court of Rome, which lie in the disposition and gift of the king and other lay-patrons of this land.

**IMPETUS**, in mechanics, the force with which one body impels or strikes another. See **MOMENTUM**, **GUNNERY**, &c.

**IMPING**, in falconry, the inserting of a feather in the wing of an hawk, in the place of one that is broken.

**IMPLANTATION**, the same with transplantation. See **TRANSPLANTATION**.

**IMPLEAD** signifies to sue or prosecute by due course of law.

**IMPLEMENTS** is used for all things necessary for a trade, or the furniture of an household; in which sense, it is frequent-

ly used in wills, conveyances of moveables, &c.

**IMPLICITE**, something tacitly comprised or understood; that is, contained in a discourse, clause, or proposition, not in express terms, but only by induction and consequence.

**IMPLICATION**, in law, is where something is implied, that is not expressed by the parties themselves in their deeds, contracts, and agreements.

In this case, the want of words may be supplied by implication. Thus, where a husband by will devises all the goods in his house, to his wife; and after her decease, bequeaths his house and those goods to his son, it is implied, in law, that the widow is to have the house for life; because though the son might have had it, he is not mentioned by will to have any thing till after the decease of the mother. But it is otherwise, where a person devises part of his lands to his wife for life, and the part so devised, with all the rest of his lands to the youngest son, and his heirs, after the wife's decease: in this case, as there is no express devise of the rest of the lands to the wife, she cannot have them by implication; for since the eldest son, who is heir at law, is not excluded, he shall have them during his mother's life, and till the devise to the youngest son takes effect.

**IMPORTATION**, in commerce, the bringing merchandize into a kingdom from foreign countries; in contradistinction to exportation. See **EXPORTATION**.

We shall here give some of the principal laws relating to the importation of goods into this kingdom. Goods imported without entry, or paying customs, are forfeited; and the lord-treasurer, the barons of the exchequer, or chief magistrates of the place where the offence was committed, or next adjoining to it, may grant a warrant to any person, who, with the assistance of a constable, may break open doors, chests, &c. and take thence any prohibited or unaccustomed goods; but this is to be done, within one month after the offence was committed. But if false information is given, the person wrongfully accused, may recover costs and damages. See the article **DUTY**.

No ship or vessel arriving from beyond sea is to be above three days in sailing from Gravesend to the place of discharge on the river Thames, unless hindered by contrary winds or other impediment. And no ship bound for the port of London is

to touch or stay at any place adjoining to any shore, between Gravesend and Chester-quay. True entries are to be made of all such ships lading, upon oath of the master or purser for that voyage; also where she took in her lading, where she was built, how manned, who were the owners, and who the master during the voyage. In all out-ports, ships are to come directly to the place of unloading, and make true entries as aforesaid, upon penalty of the forfeiture of 100*l*.

After any ship is cleared, and the watchmen and tidefmen discharged from their attendance, if there be found on board any concealed goods that have not paid the duty inwards, the master, or other person taking charge of the ship, shall forfeit 100*l*.

Porters, carmen, watermen, &c. assisting in landing unaccustomed goods, shall, on conviction, for the first offence, be committed to the next jail till they find security for their good behaviour; and for their second offence, they are to be committed to prison for two months, without bail or mainprize, or till they are discharged by the court of exchequer, or each of them pay 5*l*. to the sheriff of the county.

No merchant-denizen shall cover a stranger's goods, but shall, by himself or agent, sign one of his bills of every entry, with the mark, number, and contents of every parcel of goods, without which no entry shall pass. And no children of aliens under the age of twenty-one years, shall have entry made in their names, nor be permitted to trade.

Merchants, trading into the port of London, shall have free liberty to lade and unlade their goods at any of the lawful quays between the Tower and London-bridge, from sun-rising to sun-setting, from September 10, to March 10; and between six o' clock in the morning and six in the evening, from March 10, to September 10; giving notice thereof to the respective officers, appointed to attend the lading and unlading of goods. And such officers as shall refuse to be present, shall forfeit 5*l*. for every default.

To prevent combination between importers, and seizers of goods unlawfully imported or exported, none shall seize them but the officers of the customs, or such as shall be authorised so to do by the lord treasurer, under-treasurer, or a special commission from his majesty, under the great or privy seal.

If any seizer of prohibited or unaccustomed goods does not make due prosecution thereof, it is lawful for the custom-house officers, or others deputed thereto, to make seizure of such goods, and they shall be, in law, adjudged the first true informers and seizers, and have the benefit thereof, notwithstanding any law and statute to the contrary.

All foreign goods permitted to be landed by bills at sight, bills at view or suffrance, shall be landed at the most convenient quays and wharfs, as the officers of the customs shall direct; and there, or at the king's storehouse of the respective ports, shall be measured, weighed, numbered, &c. by the officers appointed, who shall perfect the entry, and subscribe their names to it, and the next day make their report to the customer, collector, or comptroller; or in default thereof, shall forfeit 100*l*.

Any merchant who shall import goods, shall have liberty to break bulk in any lawful port or quay, the master or purser first making oath of the true contents of the ship's lading. No english merchant shall put on shore in Scotland or Ireland, any merchandize of the growth or produce of any of his majesty's plantations, unless the same have been first landed in England, Wales, or Berwick, and paid the duties with which they are chargeable, under the penalty of forfeiting the ship and goods, three fourths to the king, and one fourth to the informer, or he that shall sue for the same: but if a ship be disabled, or driven into any port of Ireland, and unable to proceed on her voyage, her goods may be put on shore, under the hands of the principal officers of the customs there residing, till the goods can be put on board some other vessel, to be transported to some part of England or Wales.

Natives of England or Ireland may import into England, directly from Ireland, any hemp, flax, thread, yarn, and linnen, of the growth and manufacture of Ireland, custom-free; the chief officer so importing bringing a certificate from the chief office in Ireland, expressing the particulars of the goods, with the names and places of abode of the exporters thence, and of such as have sworn that the said goods are, bona fide, of the growth and manufacture of that kingdom, and who they are assigned to in England; and the chief officer shall make oath, that the said goods are the same that are on board, by virtue of that certificate.

**IMPOSITION** of hands, a religious ceremony, in which a bishop lays his hand upon the head of a person, in ordination, confirmation, or in uttering a blessing. This practice is also generally observed by the dissenters at the ordination of their ministers, when all the ministers present place their hands upon the head of him whom they are ordaining, while one of the body prays for a blessing on him and his future labours.

Imposition of hands was a jewish ceremony, introduced not by any divine authority, but by custom; it being the practice of those people, whenever they prayed for any person, to lay their hands on his head. Our Saviour observed the same ceremony both when he conferred his blessing on the children, and when he cured the sick: the apostles also laid hands on those, upon whom they conferred the Holy Ghost. In the antient church, imposition of hands was even practised in marriage, which custom is still observed by the Abyssinians.

However, the use of this term, which in its original signification was general, is now restrained, by custom, to the laying on of hands practised in ordination.

**IMPOSSIBLE**, that which cannot be done or effected.

A proposition is said to be impossible, when it contains two ideas, which mutually destroy each other, and which can neither be conceived nor united together in the mind: thus, it is impossible, that a circle should be a square, because we conceive clearly that squareness and roundness destroy each other by the contrariety of their figure.

Impossibilities are of three kinds, *viz.* metaphysical, physical, and moral. A thing is metaphysically impossible, when it cannot be done even by divine power; as that a square should be round, &c. those ideas, as was already observed, destroy each other, imply a contradiction, and are, strictly speaking, nothing at all, in regard that what is affirmed, is at the same time denied: this impossibility is otherwise termed absolutely impossible.

A thing is said to be physically impossible, that cannot be done by any natural powers, as the resurrection of the dead: this is otherwise termed *impossibile creaturae*, or impossible with regard to the creature.

A thing is morally impossible, when, of its own nature, it is possible; but yet is attended with such difficulties, as that,

all things considered, it appears impossible: thus, it is morally impossible that all men should be virtuous, or that a man should throw the same number with three dice an hundred times successively.

But with greater propriety a thing is said to be morally impossible, when it is repugnant to good sense and decency, or contrary to the laws of nature: thus the lawyers say, *omne turpe est impossibile*: these conditions are impossible, therefore, which sense and decorum do not allow to be performed, though in themselves very possible to those who have no regard to good sense, &c.

**IMPOST**, in law, signifies in general a tribute or custom, but is more particularly applied to signify that tax which the crown receives for merchandizes imported into any port or haven. See **DUTY**. Some, notwithstanding, distinguish imposts from customs, which last are rather the profits arising to the king from goods exported. See the article **CUSTOMS**.

**IMPOSTS**, in architecture, the capitals of pilars, or pilasters, which support arches.

An impost, sometimes called chaprel, is a sort of plinth, or little cornice, which crowns a pier, and supports the first stone whence an arch or vault commences. The imposts are conformable to their proper orders. The tuscan has only a plinth; the doric has two faces crowned; the ionic, a larmier, or crown over the two faces, and its mouldings may be carved; the corinthian and composite have a larmier, frieze, and other mouldings. See the articles **TUSCAN**, **DORIC**, &c.

The projectures of the imposts must not exceed the naked of the pilaster: sometimes the entablature of the order serves for the impost of the arch, and this has a very grand and stately appearance. The impost is a thing very essential to the composition of the ordonnances, inasmuch that without it, in the place where the curve-line of the arch meets with the perpendicular line of the pillar, there always seems a kind of elbow.

**IMPOSTHUME**, in surgery, &c. the same with abscess. See **ABSCESS**.

**IMPOTEENCE**, or **IMPOTENCY**, in general, denotes want of strength, power, or means to perform any thing.

Divines and philosophers distinguish two sorts of impotency, natural and moral; the first is a want of some physical principle, necessary to an action; or where a being is absolutely defective, or not free  
and

and at liberty to act : the second only imports a great difficulty, as a strong habit to the contrary, a violent passion, or the like.

Impotency is, more particularly, used for a natural inability to coition. Impotence with respect to men, is the same as sterility in women; that is, an inability of propagating the species. There are many causes of impotence, as a natural defect in the organs of generation, which seldom admits of a cure: accidents, or diseases; and in such cases the impotence may, or may not be remedied, according as these are curable or otherwise. But there is reason to believe that the most frequent causes of impotence are preposterous methods of venery, and too often repeated venereal injuries. See the article GONORRHOEA.

Dr. James thinks that a sudden impotence happening to a man not accustomed to any disorders of that kind, and not accountable for from any preceding accidents, is a fore-runner of some great disorder; and that, in such cases, provocatives are very dangerous, because it is possible they may increase the disorder which causes the impotence, and make it fatal. Hippocrates advises a man who has a mind to get children, not to get drunk, nor drink white-wine, but that which is strong and unmixed, nor to use the warm bath.

Another principal cause of impotence is the vicious habit of drinking spirits, that is, drams and the like.

**IMPRACTICABLE CASE**, in algebra, that otherwise called irreducible. See the article IRREDUCIBLE.

**IMPRECATION**, a curse, or wish that evil may befall any one. See the article EXECRATION.

**IMPREGNATION**, the getting a woman with-child. See PREGNANCY.

The term impregnation is also used, in pharmacy, for communicating the virtues of one medicine to another, whether by mixture, coction, digestion, &c. See the articles MIXTURE, COCTON, &c.

**IMPRESSION** is applied to the species of objects, which are supposed to make some mark or impression on the senses, the mind, and the memory.

The peripatetics assert, that bodies emit species resembling them, which are conveyed to the common sensorium, and there are rendered intelligible by the active intellect; and when thus spiritualized, are called expressions, or expi-  
often

species, as being expressed from the others.

**IMPRESSION** also denotes the edition of a book, regarding the mechanical part only; whereas edition, besides this, takes in the care of the editor, who corrected or augmented the copy, adding notes, &c. to render the work more useful. See the article EDITOR.

**Privilege for IMPRESSION**. See the article PRIVILEGE.

**IMPREST, Auditors of**. See the article AUDITOR.

**IMPREST-MONEY**, the money paid at the enlisting of soldiers.

**IMPRISONMENT**, the state of a person restrained of his liberty, and detained under the custody of another.

No person is to be imprisoned but as the law directs, either by the command or order of a court of record, or by lawful warrant; or the king's process, on which one may be lawfully detained. And at common law, a person could not be imprisoned unless he were guilty of some force and violence, for which his body was subject to imprisonment, as one of the highest executions. Where the law gives power to imprison, in such case it is justifiable, provided he that does it in pursuance of a statute, exactly pursues the statute in the manner of doing it, for otherwise it will be deemed false imprisonment, and of consequence it is unjustifiable. Every warrant of commitment for imprisoning a person, ought to run, "Till delivered by due course of law," and not "Until farther order;" which has been held ill, and thus it also is, where one is imprisoned on a warrant not mentioning any cause for which he is committed.

A person being sent to prison by a warrant from a secretary of state, without assigning any cause, &c. it was adjudged, that he ought to be discharged for that reason. Persons may also, by bail or habeas corpus, be discharged from their imprisonment in any case bailable. See the articles HABEAS CORPUS, BAIL, PRISON, and PRISONER.

**IMPROPER FRACTIONS**, in arithmetic. See the article FRACTION.

**IMPROPRIATION**, a parsonage or ecclesiastical living, the profits of which are in the hands of a layman; in which sense, it stands distinguished from appropriation, which is where the profits of a benefice are in the hands of a bishop, college, &c. though these terms are now

often used promiscuously. See the article **APPROPRIATION**.

**IMPULSE**, or **IMPULSIVE FORCE**, in mechanics, the same with impetus. See the article **IMPETUS**.

**IMPURITY**, in the law of Moses, is any legal defilement. Of these there were several sorts; some were voluntary, as the touching a dead body, or any animal that died of itself, or any creature that was esteemed unclean; or the touching things holy, by one who was not clean, or was not a priest; the touching one who had a leprosy, one who had a gonorrhœa, or who was polluted by a dead carcass, &c. Sometimes these impurities were involuntary, as when any one inadvertently touched bones, or a sepulchre, or any thing polluted; or fell into such diseases as pollute, as the leprosy, &c.

The beds, cloaths, and moveables which had touched any thing unclean, contracted also a kind of impurity, and in some cases communicated it to others.

These legal pollutions were generally removed by bathing, and lasted no longer than the evening. The person polluted plunged over head in the water, and either had his cloaths on when he did so, or washed himself and his cloaths separately. Other pollutions continued seven days, as that which was contracted by touching a dead body. That of women in their monthly courses lasted till this was over with them. Other impurities lasted forty or fifty days, as that of women who were lately delivered, who were unclean forty days after the birth of a boy, and fifty after the birth of a girl. Others again lasted till the person was cured. Many of these pollutions were expiated by sacrifices; and others by a certain water or lye, made with the ashes of a red heifer, sacrificed on the great day of expiation. When the leper was cured, he went to the temple, and offered a sacrifice of two birds, one of which was killed, and the other set at liberty. He who had touched a dead body, or had been present at a funeral, was to be purified with the water of expiation, and this upon pain of death. The woman who had been delivered, offered a turtle and a lamb for her expiation; or if she was poor, two turtles or two young pigeons.

These impurities, which the law of Moses has expressed with the greatest accuracy and care, were only figures of other more important impurities, such as the sins and

iniquities committed against God, or faults committed against our neighbour. The saints and prophets of the Old Testament were sensible of this; and our Saviour, in the gospel, has strongly inculcated, that they are not outward and corporeal pollutions which render us unacceptable to God, but such inward pollutions as infect the soul, and are violations of justice, truth, and charity.

**IMPUTATION**, in general, the charging something to the account of one, which belonged to another: thus, the assertors of original sin maintain, that Adam's sin is imputed to all his posterity. See the article **ORIGINAL SIN**.

In the same sense, the righteousness and merits of Christ are imputed to true believers. See the article **JUSTIFICATION**.

**INACCESSIBLE**, something that cannot be come at, or approached, by reason of intervening obstacles, as a river, rock, &c. It is chiefly used in speaking of heights and distances. See the articles **HEIGHT** and **DISTANCE**.

**INACTIVITY** of matter. See **INERTIA**.

**INADEQUATE IDEA**. See **IDEA**.

**INALIENABLE**, that which cannot be legally alienated or made over to another: thus the dominions of the king, the revenues of the church, the estates of a minor, &c. are inalienable, otherwise than with a reserve of the right of redemption.

**INAMELLING**, or **ENAMELLING**. See the article **ENAMELLING**.

**INANIMATE**, a body that has either lost its soul, or that is not of a nature capable of having any.

**INANITION**, among physicians, denotes the state of the stomach when empty, in opposition to repletion.

**INARCHING**, in gardening, is a method of grafting, commonly called grafting by approach, and is used when the stock intended to graft on, and the tree from which the graft is to be taken, stand so near, or can be brought so near, that they may be joined together. The method of performing it, is as follows: take the branch you would inarch, and having fitted it to that part of the stock where you intend to join it, pare away the rind and wood on one side, about three inches in length. After the same manner cut the stock or branch in the place where the graft is to be united, so that the rind of both may join equally together; then cut a little tongue upwards in the graft, and make a notch in the stock to admit it; so that when they are

joined, the tongue will prevent their slipping, and the graft will more closely unite with the stock. Having thus placed them exactly together, tie them with some bays, or other soft tying; then cover the place with grafting clay, to prevent the air from entering to dry the wound, or the wet from getting in to rot the stock: you should also fix a stake in the ground, to which that part of the stock, together with the graft, should be fastened, to prevent the wind from breaking them asunder, which is often the case, when this precaution is not observed. In this manner they are to remain about four months, in which time they will be sufficiently united, and the graft may then be cut from the mother tree, observing to slope it off close to the stock; and if at this time you cover the joined parts with fresh grafting-clay, it will be of great service to the graft.

This operation is always performed in April or May, and is commonly practised upon myrtles, jasmynes, walnuts, firs, pines, and several other trees that will not succeed by common grafting, or budding.

**INAUGURATION**, the coronation of an emperor or king, or the consecration of a prelate: so called from the ceremonies used by the Romans, when they were received into the college of augurs. See **CORONATION**, **CONSECRATION**, &c.

**INCA**, or **YNCA**, a name given by the natives of Peru to their kings, and the princes of the blood. Pedro de Cieza, in his Chronicle of Peru, gives the origin of the incas, and says, that that country was, for a long time, the theatre of all manner of crimes, of war, dissention, and the most dreadful disorders, till at last two brothers appeared, one of whom was called Mangocapa; of this person, the Peruvians relate many wonderful stories. He built the city of Cusco, made laws, established order and harmony by his wise regulations, and he and his descendants took the name of inca, which signifies king or great lord. These incas became so powerful, that they rendered themselves masters of all the country from Paito to Chili, and from the river Maule on the south, to the river Augasfinago on the north; these two rivers forming the bounds of their empire, which extended above thirteen hundred leagues in length. This they enjoyed till the divisions between inca Guascar and Atabalipa, which the Spaniards laying hold of, made them-

selves masters of the country, and destroyed the empire of the incas.

**INCAMERATION**, a term used in the chancery of Rome, for the uniting of lands, revenues, or other rights, to the pope's domain.

**INCANTATION**, denotes certain ceremonies, accompanied with a formula of words, and supposed to be capable of railing devils, spirits, &c. See the articles **CHARM**, **CARMEN**, &c.

**INCAPACITY**, in the canon-law, is of two kinds: 1. The want of a dispensation for age in a minor, for legitimization in a bastard, and the like: this renders the provision of a benefice void in its original. 2. Crimes and heinous offences, which annul provisions at first valid.

**INCARNATION**, in theology, the act whereby the second person of the holy Trinity assumed the human nature, viz. a true body and reasonable soul, in order to accomplish the redemption of fallen mankind. See **TRINITY** and **REDEMPTION**. This fundamental doctrine of christianity is very expressly taught in scripture: thus, in Gal. iv. 4. it is said, "God sent forth his son, made of a woman:" and 1 John iv. 14. "And we have seen and do testify, that the Father sent the Son to be the saviour of the world."

The generation of Christ was miraculous, as being conceived by the power of the Holy Ghost, and born of the Virgin Mary; from the time of which blessed nativity, the christian æra commences. See the article **EPOCHA**.

**INCARNATIVES**, in surgery, medicines which assist nature in filling up wounds or ulcers with flesh; or rather remove the obstructions thereto. See **VULNERARY**. Internal incarnatives are aliments which supply a balsamic chyle, and consequently generate flesh, and produce a full or plump habit.

**INCARNATIVE**, or **UNITING BANDAGE**, is a bandage of the head, so called from its being used to unite the lips of a wound. It is about two inches broad, having a longitudinal slit in its middle, about the length of three or four fingers breadth. See plate XXV. fig. 3. n° 6.

The chief use of this bandage is to retain the lips of a rectilinear wound close together, whether in the head, eye-lids, or other parts of the body. For the method of applying it, roll up each end, and after the wound has been dressed with proper balsams, and a plaster and two narrow compresses laid on each side, the slit

slit of the bandage is to be fixed near the wound, in such a manner, that one of its ends being carried round the head, and the roller being passed through the slit, both of the rollers are drawn tight, so as to bring the lips of the wound close together. The two rollers in each hand being then exchanged, and crossed upon the forehead, and the like being done under the chin, as long as the bandage will permit, each end of it is to be fastened by pins or suture. This bandage is not to be taken off till the lips of the wound may be supposed to be united; unless any urgent symptoms should require its removal.

**INCARTATION**, among chemists, the same with depart. See **DEPART**.

**INCENSE**, or **FRANK-INCENSE**, in the materia medica, &c. a dry resinous substance, known among authors by the names thus and **olibanum**. See the article **OLIBANUM**.

Incense is a rich perfume, with which the ancient pagans, and the roman catholics still, perfume their temples, altars, &c.

The burning of incense made part of the daily service of the antient jewish church. The priests drew lots to know who should offer it; the destined person took a large silver dish, in which was a centur full of incense; and being accompanied by another priest, carrying some live coals from the altar, went into the temple. There, in order to give notice to the people, they struck upon an instrument of brass placed between the temple and the altar; and being returned to the altar, he who brought the fire left it there, and went away. Then the offerer of incense having said a prayer or two, waited the signal, which was the burning of the holocaust; immediately upon which he set fire to the incense, the whole multitude continuing all the time in prayer. The quantity of incense offered each day, was half a pound in the morning, and as much at night.

One reason of this continual burning of incense might be, that the multitude of victims that were continually offered up, would have made the temple smell like a slaughter-house, and consequently have inspired the comers rather with disgust and aversion than awe and reverence, had it not been overpowered by the agreeable fragrance of those perfumes.

**INCEPTIVE**, a term used by Dr. Wallis to express such moments, or first prin-

ciples, which, though of no magnitude themselves, are notwithstanding capable of producing it. Thus, a point is inceptive of a line, and a line inceptive of surface, &c.

**INCEST**, the crime of venereal commerce between persons who are related in a degree wherein marriage is prohibited by the law of the country.

Some are of opinion that marriage ought to be permitted between kinsfolks, to the end that the affection so necessary in marriage might be heightened by this double tie, and yet the rules of the church have formerly extended this prohibition even to the seventh degree; but time has now brought it down to the third or fourth degree.

Most nations look on incest with horror, Persia and Egypt alone excepted. In the history of the antient kings of those countries we meet with instances of the brother's marrying the sister; the reason was, because they thought it too mean to join in alliance with their own subjects, and still more so to have married into any foreign family.

**INCEST SPIRITUAL**, a crime committed in like manner between persons who have a spiritual alliance by means of baptism or confirmation.

Spiritual incest is also understood of a vicar or other beneficiary, who enjoys both the mother and the daughter, that is, holds two benefices, the one whereof depends upon the collation of the other.

Such a spiritual incest renders both the one and the other of these benefices vacant.

**INCH**, a well known measure of length; being the twelfth part of a foot, and equal to three barley-corns in length. See **FOOT** and **MEASURE**.

**INCH OF CANDLE**, or sale by inch of candle. See the article **CANDLE**.

**INCHASING**, or **ENCHASING**. See the article **ENCHASING**.

**INCIDENCE**, in mechanics, denotes the direction in which one body strikes on another.

In optics, the angle **ACP**, (pl. **CXLIV**. fig. 2. n<sup>o</sup> 1.) made by the ray **AC**, and the perpendicular **PC**, is called the angle of incidence; but Dr. Barrow, and some others, call it the angle of inclination; and by the angle of incidence understand its complement **ECA**.

Mr. Molyneux, in his *Dioptrics*, uses the words inclination and incidence promiscuously, and by the angle of inci-

dence or inclination, always intends the angle ACP.

The angle PCB, is called the angle of reflection, and is always equal to the angle of incidence ACP; which is thus proved :

Every ray of light goes the shortest way that possibly it can : thus, if you suppose the ray AC. (*ibid.*) to fall on the plain glass or surface EG, and thence to be reflected to B, so that the angle ACE be equal to BCG; then will AC and CB, be the two shortest lines that can possibly be drawn from the points A and B, to the point of incidence C in the plane EG: for instance, they will be shorter than AD + DB, or any others.

For produce CB to F, and draw DF, because the vertical angles ECF and BCG are equal, the arch EF is equal to BG, equal to AE by the supposition; but it is plain, that  $FC = AC = CB$ ; wherefore  $FB (= AC + CB)$  is less than  $DF + DB = AD + DB$ : and so it will be in every case. Wherefore, since the ray must go the nearest way, the angle of incidence will always be equal to that of reflection: For the two angles ECA, and BCG, being thus equal, their compliments ACP and PCB must also be equal, and may be thus proved. Produce the ray AC directly till it meet with the perpendicular GH in H: then make GK equal GH, and produce CB to K: I say CK is the reflected ray, and that the angle PCK is equal to PCA: for PC being drawn perpendicular to the plane EG, the angle ECA + ACP are equal to the angles GCB + KCP; because they are both equal to a right angle. But ECA is equal to GCH, which is equal to GCK by construction; and therefore the angle of incidence, ACP, is equal to the angle of reflection, PCK. Q.E.D.

It is likewise demonstrated in optics, that the sines of the angles of incidence, and refraction, are to each other reciprocally as the resistances of the mediums. And Sir Isaac Newton, in his Optics, says, the sine of incidence is either accurately, or very nearly in a given ratio to the sine of refraction. And that the angles of reflection, and refraction, lie in one and the same plane with the angle of incidence. Whence, if that proportion be known in any inclination of the incident ray, 'tis known in all the inclinations, and thereby the refractions in

all cases of incidence on the same refracting body may be determined. Thus, if the refraction be made out of air into water, the sine of incidence of the red light is to the sine of its refraction as 4 to 3. If out of air into glass, the sines are as 17 to 11. In light of other colours, the sines have other proportions; but the difference is so little, that it need seldom be considered.

Suppose therefore, that RS. (*ibid.* n<sup>o</sup> 2.) represents the surface of stagnating water, and that C is the point of incidence in which any ray coming in the air from A in the line AC, is reflected or refracted, and I would know whether this ray shall go after reflection or refraction: I erect upon the surface of the water, from the point of incidence, the perpendicular CP, and produce it downwards to Q, and conclude from what has been said, that the ray after reflection and refraction, shall be found somewhere in the plane of the angle of incidence, ACP, produced. I let fall therefore, upon the perpendicular CP, the sine of incidence AD; and if the reflected ray be desired, I produce AD to B, so that DB be equal to AD, and draw CB. For this line CB shall be the reflected ray, the angle of reflection BCP, and its sine BD, being equal to the angle and sine of incidence. But if the refracted ray be desired, I produce AD to H, so that DH may be to AD as the sine of refraction to the sine of incidence, that is, (if the light be red) as 3 to 4; and about the center C, and in the plane ACP, with the radius CA, describing a circle ABE, I draw parallel to the perpendicular CPQ, the line HE cutting the circumference in E, and joining CE, this line CE shall be the line of the refracted ray. For if EF be let fall perpendicularly on the line PQ, this line EF shall be the sine of refraction of the ray CE, the angle of refraction being ECQ; and this line EF is equal to DH, and consequently in proportion to the sine of incidence AD as 3 to 4.

INCIDENT, in law, something that inseparably belongs to another: thus, a court baron is incident to a manor.

INCIDENT, in poetry, denotes much the same with episode. See EPISODE.

INCISIVE, an appellation given to whatever cuts or divides: thus, the fore-teeth are called dentes incisivi, or cutters; and medicines of an attenuating nature, incidents, or incisive medicines. See the articles TEETH and ATTENUANTS.

Fig. 1. ICOSA HEDRON.

Fig. 2. INCIDENCE.

Fig. 3. INCLINATION.

Fig. 5. IRIS, the *FLOWER DE LUCE*.

Fig. 4 IPOMÆA.

**INCLE**, a kind of tape made of linnen-yarn, which on importation pays for every dozen pounds, a duty of 1l. 5s. 8  $\frac{8}{100}$  d. and draws back 1l. 1s. 11  $\frac{2}{100}$  d. on exportation; for the dozen pieces in rolls, containing thirty-six yards each, 19s. 3  $\frac{6}{100}$  d. and draws back 16s. 5  $\frac{4}{100}$  d. and for every pound weight of whitened or bleached linnen-yarn, known by the name of unwrought incle, or short spinnel, 3d.

**INCLINATION**, is a word frequently used by mathematicians, and signifies the mutual approach, tendency or leaning of two lines, or two planes towards each other, so as to make an angle.

Inclination of a right line to a plane, is the acute angle, which that line makes with another right line drawn in the plane through the point where the inclined line intersects it, and through the point where it is also cut by a perpendicular drawn from any point of the inclined plane.

Inclination of the axis of the earth, is the angle which it makes with the plane of the ecliptic; or the angle, contained between the planes of the equator and ecliptic.

Inclination of a planet, is an arch of the circle of inclination, comprehended between the ecliptic and the plane of a planet in its orbit.

The greatest inclination of saturn, according to Kepler, is  $2^{\circ} 32'$ ; of jupiter,  $1^{\circ} 20'$ ; of mars,  $1^{\circ} 50' 30''$ ; of venus,  $3^{\circ} 22'$ ; of mercury,  $6^{\circ} 54'$ . According to de la Hire, the greatest inclination of saturn is  $2^{\circ} 33' 30''$ ; of jupiter,  $1^{\circ} 19' 20''$ ; of mars,  $1^{\circ} 51' 00''$ ; of venus,  $3^{\circ} 25' 5''$ ; of mercury,  $6^{\circ} 52' 00''$ .

Inclination of a plane, in dialling, is the arch of a vertical circle, perpendicular both to the plane, and the horizon, and intercepted between them. To find this, Let AB (plate CXLIV. fig. 3.) be a plane inclined to the horizon HR; apply to the plane AB a quadrant DCF, so as the plummet CE may cut off any number of degrees on the limb as EF: I lay the arch DE is the measure of the angle of inclination ABH; for draw BG perpendicular to HR, then because CE is parallel to BG, the angle ECF is equal to CBG; but DCF is equal to GBH, being both right angles, therefore the angle DCF—ECF, is equal to the angle GBH—CBG; that is, DCE is equal ABH.Q.E.D.

**INCLINED PLANE**, in mechanics, one

that makes an oblique angle with the horizon.

If a force, with a given direction, supports a height upon an inclined plane; that force is to the weight, as the sine of the inclination of the plane to the sine of the angle which is made by the line in which the force acts, and the line perpendicular to the plane. Thus, let AB (plate CXLV. fig. 1. n<sup>o</sup> 1.) be the inclined plane, P the weight supported, and DPV the direction of the force which supports the weight. Let PC be drawn perpendicular to AB; and from the point C, let CB be drawn parallel to the horizon, and perpendicular to the common section of the plane and the horizon, meeting the plane in B; and CA perpendicular to the horizon and also to CB, meeting the plane in A, and the line in which the force acts in V.

Now P may be conceived to be held unmoved by three forces acting together, one of which is the force of the weight itself tending downwards in a line parallel to VC, viz. PH; the second is the force acting in the line DPV, and the third is the resistance of the plane itself, acting in the line CP, perpendicular to the plane: but these three forces are to each other as the sides of the triangle VPC, as will be evident by drawing a line thro' P parallel to VC, and completing the parallelogram H $\nu$ . The force, therefore, is to the weight which it sustains, as PV to VC; that is, as the sine of the angle VCP, or ABC, to the sine of the angle CPV, or CPD. Q.E.D. Therefore the force by which any heavy body would descend on any inclined plane, to the force of the descent on the perpendicular, is as the sine of the angle of the plane's inclination to the radius. For practice therefore, let the weight of any body be W, and P the power wanted to sustain it on an inclined plane. I say, by this theorem. R : W :: sine incli. : P. The three first of which are given, wherefore the fourth is found by trigonometrical calculation, thus. Let a body weigh 9999 pounds; what power will sustain it from descending on a plane inclined to the horizon with an angle of 34 degrees? Answer, 5592 pounds. See the work.

Weight 9999. 3.999957

S. L. incl. =  $34^{\circ} 9.747562$

13.747519

Radius 10.000000

5592 =  $3.747519$  = the power

If the points V and A coincide, that is, if the force acts according to the direction BA, the angle CPD, will be a right angle; and therefore, in that case, the force is to the weight as the sine of the inclination of the plane to the radius, or as the height AC to its length AB. And in this case, the force which is required to support a given weight is least of all; because the proportion of the sine of the inclination of the plane to the radius, is less than its proportion to any other sine whatever. If the point V falls above A; the greater the angle APV is, so much the more force is necessary to support the given weight upon the plane AB. Infomuch, that by increasing the angle APV, the proportion of the sine of the angle ABC, to the sine of the angle CPD, is also increased, till PV, AV, becoming parallel, and the angles VCP, CPD for that reason equal, the force and the weight will also become equal. So likewise if the point V falls below A, as at v, the force required to support the given weight, is again increased; the angle APv being increased, till P $\omega$ , vC become equal, and then the force and the weight will become equal again. Further, when the lines P $\omega$ , PC coincide, and the angle vPC by that means vanishes, the sine of the angle ABC will bear an infinite proportion to the sine of that; that is, no finite force whatsoever, acting in a line perpendicular to the plane, will be able to support the weight upon the plane. If the line in which the force acts be parallel to the base of the plane, the weight is to the force which supports it, as BC to CA, or as the base of the plane to the height of it. If from the point P, (*ibid.* n<sup>o</sup> 2.) PF be let fall perpendicular to BC; and from the point C, CG perpendicular to VP; it will easily appear, that PV is to VC (that is, the force is to the weight) as CF to CG. Wherefore the force and the weight will then support one another upon an inclined plane, when they are to each other reciprocally as perpendiculars drawn from the point C to the lines in which they act; (or, if GCF be looked upon as an angular ballance moveable about the center C) reciprocally as the velocities of the Points G and F reckoned upon the lines in which the forces act. If it should be required to lift up a very heavy body, as W or w (*ibid.* n<sup>o</sup> 3.) the height CB, it would be impracticable to raise it up in the line CB without a power

whose intensity is equal to that of the weight; and even in that case very inconvenient to do it, especially in building. But if an inclined plane AB be laid arising from the horizontal line AC, from whence the weight is to be raised, a less power than the weight will serve for that purpose, unless it pushes the body directly against the plane (as in the direction WT) or draws the body away from the plane (as from W towards e, t, or L) or in any direction on that side of the line Ee.

The direction in which the body can most easily be drawn or pushed up the plane is the line W $\omega$  M, parallel to the plane, and passing thro' the center of the weight; for whether the power divides a plane  $\angle$  K (in a direction perpendicular to it) along the line WM, or the power P (by its descent to p) draws it in the same line, the velocity of the power will be equal to the line W $\omega$ , the space described by the center of gravity of the weight, whilst the same weight rises only the perpendicular height ZB (= nW) or has the said line properly to express its velocity. If the body was a cylinder, as a rolling stone, and the plane Tt were to pass thro' the gudgeons or axis of the said stone, it is evident that the case would be same; and as the weight P has its rope running over the roller (or upper pulley) M, the line Pp will be the velocity of the power. Therefore in this case the weight (if kept in æquilibrium) will be to the power as W $\omega$  (=TB) to wY (=BZ) or as the hypothenuse AB is to the perpendicular BC, which (by Eucl. 4. 6.) are in the same proportion; and consequently, if the power be never so little increased, it will draw the weight up the plane.

That the power acts with the greatest advantage, whilst it draws in the line of direction W $\omega$  (parallel to the plane) is evident, because if, one end of the said plane of direction remaining fixed at W, the other should move towards B, or beyond it, then the body would be partly drawn against the plane, and therefore the power must be increased in proportion to the greatest difficulty of traction: And if the end w of the line above-mentioned should be carried to D, or beyond it, the power must be also increased, inasmuch as it endeavours to lift the body off from the plane.

If the power draws in a line of direction WB (*ibid.*) parallel to the base of the plane;

*Fig. 1.* INCLINED PLANE.

Fig. 2 INCLINED TOWER.

*Fig. 4* INDIVISIBLES

Fig. 3.  
INDENTED

Fig. 5.  
INVESTED

plane; then, in order to keep the weight  $W$  in æquilibrium by the power  $\pi$ , the said power must be to the weight, as  $ZB$  to  $ZT$ , or as the perpendicular  $BC$  to the base  $AC$  of the triangle  $ACB$ . For if we suppose the pulley  $R$  at so great a distance from  $W$ , that the line of direction  $WR$  may not sensibly alter its horizontal position, whilst the body  $W$  rises the height  $BZ$ , in such manner that  $\pi \pi (=WY$ , and not  $Ww)$  will be the velocity of the power. So that the velocity of the power to that of the weight will not be as the hypothenuse to the perpendicular, as in the former case, but as the base to the perpendicular in the triangle  $ACB$ . If the powers be increased just enough to overcome the friction of the plane, and draw up the body  $W$ , let the pulley  $R$  be lifted up gradually to  $r$ , so as to keep the line  $WR$  parallel to itself till it comes to  $wr$ , and the power will be descended to  $\pi$ , when the weight is come to  $wB$ . But  $\pi \pi$ , together with the distance  $Rr$ , is equal to  $\pi w$ , or  $WY$ , &c. And this traction, being constantly made in the angle  $WBT$ , is the case. For the motion of the loaded cylinder upon an inclined plane, see **CYLINDER**.

**INCLINED TOWERS**; those whose tops hang so far over, as to appear dangerous to people walking below.

Such is that represented in plate **CXLV**. fig. 2. where  $PP$  is the perpendicular let fall from the top of the tower to  $TT$  the horizontal plane. Now the reason why such towers do not fall, is owing to their centers of gravity being supported: thus  $C$ , the center of gravity of the tower here represented, is supported by the perpendicular  $CO$ , so that it cannot fall; but had the tower been built higher to  $A$ , so as to transfer the center of gravity from  $C$  to  $c$ , the tower must have fallen, since the perpendicular  $co$  is not supported, as falling without the foundation of the tower.

**INCLINERS**, or **INCLINING DIALS**. See the article **DIAL**.

**INCLOSURE**, in husbandry, the fence or hedge made to inclose lands. See the articles **FENCE** and **HEDGE**.

A very good inclosure may be made of elder-sticks, or truncheons, cut ten or twelve feet long, and stuck into the bank slope-wise, so as to make a chequer-work. These make the speediest shelter of any; and when the trees are grown up, they are valuable for the turner's use. They succeed extremely well in

watery places; and when planted on the banks of rivers, they prevent them from being undermined by the current.

The throwing down inclosures is an offence punishable by our antient statutes; yet if the lord of a manor incloses part of the waste, and does not leave sufficient room for the commoners, they may break down such inclosure, or have a writ of assize.

**INCOGNITO**, or **INCOG**, is applied to a person that is in any place, where he would not be known: but it is more particularly applied to princes, or great men, who enter towns, or walk the streets without their ordinary train, or the usual marks of their distinction and quality.

**INCOMBUSTIBLE**, something that cannot be burnt, or consumed by fire.

Authors talk much of a combustible cloth, made of the asbestus. See **ASBESTUS**. In the Philosophical Transactions, n<sup>o</sup> 276, we have an account of an incom-bustible lint, which is a peculiar species of asbestus, or earth-flax, which is never formed into compact masses as the other species are, but is always found in loose filaments, very fit to be wrought into cloth. It is found only, so far as yet known, in the county of Aberdeen in Scotland. The antient Romans spun their asbestus into cloths, in which they wrapped up the dead bodies, before committing them to the funeral pile, in order to preserve their ashes distinct from those of the wood. What they had for this purpose, seems, by all accounts, to have been very short; but this species would be much more proper, as being seven or eight inches long.

**INCOMMENSURABLE**, a term in geometry, used where two lines, when compared to each other, have no common measure, how small soever, that will exactly measure them both. And in general, two quantities are said to be incommensurable, when no third quantity can be found that is an aliquot part of both.

Such are the diagonal and side of a square; for tho' each of those lines have infinite aliquot parts, as the half, the third, &c. yet not any part of the one, be it ever so little, can possibly measure the other, as is demonstrated in prop. 117. lib. x. of Euclid.

Rappus, lib. iv. prop. 17. speaks also of incommensurable angles. As to surfaces which cannot be measured by a common surface, they are said to be incommensurable in power.

**INCOMMENSURABLE NUMBERS** are such as have no common divisor, that will divide them both equally.

**INCOMPATIBLE**, that which cannot subsist with another, without destroying it: thus cold and heat are incompatible in the same subject, the strongest overcoming and expelling the weakest.

**INCORPORATION**, in pharmacy, is much the same as impastation, being a reduction of dry substances to the consistence of a paste, by the admixture of some fluid; thus pills, boles, troches, and plasters are made by incorporation. Another incorporation is, when things of different consistences, are by digestion reduced to one common consistence.

**INCORPOREAL**, a thing, or substance, which has no body; as God, angels, and the soul of man.

**INCORRUPTIBLE**, that which cannot be corrupted. See **CORRUPTION**.

**INCORRUPTIBLES**, or **INCORRUPTIBLES**, in church-history, heretics which had their original at Alexandria, in the time of the emperor Justinian. Their distinguishing tenet was, that the body of Jesus Christ was incorruptible from his conception, by which they meant that after and from the time he was formed in the womb of his holy mother, he was not susceptible of any change or alteration, not even of any natural and innocent passions, as hunger, thirst, &c. so that he eat without any occasion before his death, as well as after his resurrection.

**INCRASSATING**, in pharmacy, &c. the rendering fluids thicker by the mixture of other substances less fluid; or by the evaporation of the thinner parts.

Incrassating medicines are such as reduce the too fluid blood and juices to a proper consistence, and a due condensation.

**INCRUSTATION**, in surgery, the induction of a crust or eschar upon any part.

Among maçons, incrustation signifies the lining or coating of a wall, either with glossy stones, rustics, marble, pottery, or stucco-work, and that either equally or in panels and compartments.

**INCRUSTED**, or **INCRUSTATED COLUMN**, is a column consisting of several pieces, or slips of some precious marble massicated or cemented round a mould of brick, or other matter.

**INCUBATION**, the action of a hen, or other fowl brooding on her eggs.

**INCUBUS**, or **NIGHT MARE**, in medicine,

the name of a disease which consists in a spasmodic contraction of the muscles of the breast, usually happening in the night, and attended with a very painful difficulty of respiration and great anxiety. The most obvious symptom of this disease is a sensation like that of some great weight laid upon the breast: this is attended with so violent a prohibition of respiration, that the person becomes unable to move any part of his body, or to utter any distinct or articulate sound. This whole complaint goes off as soon as any one limb is moved, but there is oftentimes an universal lassitude of the whole body left behind it, which remains for some space of time.

This disease attacks people in the nighttime, in a sort of middle state, between sleeping and waking; and commonly, as Willis observes, when the stomach is oppressed with aliment of a hard digestion, especially if the patient lies on his back. Those of a plethoric habit are most subject to it; and among them, such particularly as have a great thickness of the blood; as also persons who are subject to hypochondriac complaints, and to disorders of the spleen.

Hence the causes of this disease are a stagnation of the blood in plethoric habits, where it is thick about the vena portæ, which nature is endeavouring to throw off by means of those spasmodic motions which constitute this disease, and very often crudities in the primæ viæ become additional causes, and exasperate the complaint. Physicians esteem this disease of no danger; but Junker thinks it is much to be suspected, that many of those people, who are found dead in their beds, perish by it.

When this distemper returns so often as to call for the advice of a physician, the method is to give gentle purges, three or four times, with the digestive medicines: such as gum ammoniacum, or the tartarum vitriolatum: on the intermediate days after this, bleeding in the foot is proper; and when this has been done, powders of nitre and cinnabar usually complete the cure. If they fail, the common method in hypochondriac cases is to be used. When there are crudities in the primæ viæ which exasperate this disease, then, after the purges, gentle bitters and other medicines are to be given, which will restore the tone of the stomach. Gentian-root and orange-peel in infusion, are very good for this purpose.

When

When it happens wholly from a load on the stomach, a gentle vomit alone will perform the cure. To prevent returns of this disease, the patient should eat light suppers, and must accustom himself to lie on one or the other side, never on the back, nor with his head very low.

Heister observes, that those who have troubled dreams, or walk in their sleep, are to be cured in the same manner, as proceeding from the same causes.

**INCUMBENT**, a clerk, or minister who is resident on his benefice: he is called incumbent, because he does, or at least ought, to bend his whole study to discharge the cure of his church.

**INCUMBRAVIT**, or **QUARE INCUMBRAVIT**, in law. See **QUARE**.

**INCURVATION** of the rays of light, their bending out of a rectilinear or straight course, occasioned by refraction. See the article **REFRACTION**.

**INCUS**, in anatomy, a bone of the internal ear, somewhat resembling one of the anterior dentes molares.

In the incus, we are chiefly to observe its body, its fovea, or hollow, serving for its articulation with the malleus, and its two crura, or legs; to the longer of which, there is joined another bone called the stapes. See **EAR**.

**INDECIMABLE**, something not chargeable with tithes. See **TITHES**.

**INDEFEISIBLE**, or **INDEFEAZABLE**, a term in law, for what cannot be defeated or made void; as an indefeisible estate of inheritance, &c.

**INDEFINITE**, or **INDETERMINATE**, that which has no certain bounds; or to which the human mind cannot affix any. Descartes makes use of this word in his philosophy instead of infinite, both in numbers and quantities, to signify an unconceivable number, or a number so great that an unit cannot be added to it; and a quantity so great as not to be capable of any addition. Thus, he says, the stars visible and invisible are in number indefinite; and not as the ancients held infinite; and that quantity may be divided into an indefinite number of parts, not an infinite number.

**INDEFINITE** is also used in the schools to signify a thing that has but one extreme; for instance, a line drawn from any point and extended infinitely. Thus what they call eternity *a parte ante*, or eternity, *a parte post*, are indefinite durations.

**INDEFINITE PROPOSITION**. See the article **PROPOSITION**.

**INDEFINITE**, in grammar, is understood of nouns, pronouns, verbs, participles, articles, &c. which are left in an uncertain indeterminate sense, and not fixed to any particular time, thing, or other circumstance.

**INDELIBLE**, something that cannot be cancelled, or effaced. Thus baptism and ordination, according to the church of Rome, are sacraments which convey indelible characters to the persons baptized and ordained.

**INDEMNIFY**, in law, the saving harms; or, a writing to secure one from all damage and danger that may ensue from any act. An indemnity in regard to estates, is called a warranty. See the article **WARRANTY**.

*Act of INDEMNITY*, the same with *act of grace*. See *Act of GRACE*.

**INDENTED**, in heraldry, is when the out-line of an ordinary is notched like the teeth of a saw. See plate **CXLV**. fig. 3.

**INDENTED LINE**, in fortification, the same with what the french engineers call redent; being a trench and parapet running out and in, like the teeth of a saw; and is much used in irregular fortification. See the article **FORTIFICATION**.

**INDENTED LEAF**, among botanists, is one notched round its verge. See **SERRATED**.

**INDEPENDENTS**, a sect of protestants in England and Holland, so called from their independency on other churches, and their maintaining that each church or congregation has sufficient power to act and perform every thing relating to religious government within itself, and is no way subject or accountable to other churches or their deputies.

They therefore disallow parochial and provincial subordination, and form all their congregations upon a scheme of co-ordinancy. But tho' they do not think it necessary to assemble synods; yet if any be held, they look on their resolutions, as prudential councils; but not as decisions, to which they are obliged to conform.

As to their service, they pray publicly for kings, and all in authority: they read and expound the scripture, and administer the sacraments of baptism and the Lord's Supper. Their public officers are pastors, teachers, ruling elders, and deacons. Their church censures lie all within the compass of admonition and excommunication.

The present independents differ from the  
to N  
presbyterians

presbyterians only in their church government, in being generally more attached to the doctrines distinguished by the term orthodoxy, such as original sin, election, reprobation, &c. and in administering the Lord's Supper at the close of the afternoon's service. See PRESBYTERIANS.

The several sects of baptists are all independents with respect to church government; and, like them, administer the Lord's Supper in the evening, whereas the presbyterians administer it after the forenoon's service. See ANABAPTISTS.

**INDETERMINATE**, in general, an appellation given to whatever is not certain, fixed, and limited; in which sense, it is the same with indefinite.

**INDETERMINATE PROBLEM**, in algebra, one which is capable of an indefinite number of solutions. See EQUATION.

**INDEX**, in anatomy, the same with the fore-finger. See FINGER.

**INDEX**, in arithmetic and algebra, shews to what power any quantity is involved, and is otherwise called exponent. See the article EXPONENT.

**INDEX of a logarithm**, that which shews of how many places the absolute number, belonging to a logarithm, doth consist; and of what nature it is, whether an integer or fraction. Thus, in this logarithm 2.523421, the number 2 standing on the left hand of the point is called the index; because it shews that the absolute number, answering to the above logarithm, consists of three places: for the number is always one more than the index.

If the absolute number be a fraction, then the index of the logarithm hath a negative sign, marked thus 2.523421. See the article LOGARITHM.

**INDEX of a globe**, the little style or gnomon, which being fixed on the pole of the globe, and turning round with it, points out the hours upon the hour circle. See the article GLOBE.

**Expurgatory INDEX**, a catalogue of prohibited books in the church of Rome.

The first catalogues of this kind were made by the inquisitors, and these were afterwards approved of by the council of Trent, after some alteration was made in them by way of retrenchment, or addition. Thus an index of heretical books being formed, it was confirmed by a bull of Clement VIII. in 1595, and printed with several introductory rules; by the fourth of which, the use of the scriptures in the vulgar tongue is forbidden to all

persons, without a particular licence; and by the tenth rule it is ordained, that no book shall be printed at Rome, without the approbation of the pope's vicar, or some person delegated by the pope; nor in any other places, unless allowed by the bishop of the diocese, or some person deputed by him, or by the inquisitor of heretical pravity.

The Trent index being thus published, Philip II. of Spain ordered another to be printed at Antwerp, in 1571, with considerable enlargements. Another index was published in Spain, in 1584, a copy of which was snatched out of the fire when the English plundered Cadiz. Afterwards there were several expurgatory indexes, printed at Rome and Naples, and particularly in Spain.

**INDIA PROPER**, or **HITHER INDIA**, a large peninsula in Asia, bounded on the north by Ubec Tartary, and Thibet; on the east, by another part of Thibet, the kingdom of Afem, Ava, and Pegu; on the south by the bay of Bengal, and the Indian ocean; and by the same ocean and Persia on the west: situated between  $66^{\circ}$  and  $92^{\circ}$  of east longitude, and between  $7^{\circ}$  and  $40^{\circ}$  of north latitude; being about 2000 miles in length from north to south, and 1500 miles in breadth from east to west, where broadest; tho' the southern part of the peninsula is not 300 miles broad. All the country within these limits is either subject or tributary to the great Mogul. It is frequently called *Indostan*, a name supposed to be derived from the river Indus, on its western frontiers: it is also called the *Mogulistan*, from the imperial family now upon the throne, who trace their pedigree from Tamerlane, a Mogul Tartar.

The produce of this country, and what the Europeans import from thence, is chiefly chints, calicoes, muslins, some silk, pepper, and diamonds, which are purchased by most nations with silver; but the Dutch frequently barter spices for them, which makes the India trade doubly advantageous to them.

**INDIA beyond the Ganges**, is a country bounded by Thibet and Boutan on the north; by China, Tonquin, and Cochinchina on the east; by the Indian Ocean on the south; and by the hither India, the bay of Bengal, and the Straits of Malacca on the west: it is situated between  $92^{\circ}$  and  $104^{\circ}$  of east longitude, and between the equator and  $30^{\circ}$  degrees of north latitude: being near 2000 miles

in length from north to south ; but of a very unequal breadth ; in which limits are comprehended the kingdoms of Afem, Ava, Pegu, Laos, Siam, Cambodia and Malacca, governed by as many indian princes ; only the Dutch have usurped the dominion of Malacca. In this country there are a vast number of elephants, and consequently a great deal of ivory ; our merchants also meet with gold and precious stones, canes, opium, and such other articles as are usually found within the tropics.

**INDIAN BERRY**, *coccus indicus*, in commerce, &c. See **COCCULUS**.

It is as little used in the shops, being esteemed poisonous. Fishermen have a way of mixing it in paste, which when eaten greedily by the fish, intoxicate them to such a degree as to make them for a time appear lifeless, and float upon the water ; and the good women use it, mixed with stavesacre, for destroying vermin in children's heads.

**INDIAN LEAF**, the leaf of a large and lofty tree, called malabathrum, which grows in Malabar, principally upon the mountains.

The antients have said much of the virtues of the malabathrum ; they call it stomachic, sudorific and cephalic. Dioscorides ascribes to it all the virtues of the indian spikenard, and says, that it possesses them in a superior degree: but at present it is utterly disregarded, and only kept in the shops as an ingredient in the theriaca, mithridate, and some other compositions.

**INDICATION**, in physic, whatever serves to direct the physician how to act.

There are four sorts of indications, 1. The prophylactic or preservative, which directs what is necessary to be done, in order to preserve health, and avert threatened diseases. 2. Curative, shewing how to remove diseases actually formed. 3. Palliative, or mitigatory, which relates to the mitigation of the symptoms, when too violent to be neglected till the termination of the disease. 4. Vital, which relates to the immediate preservation of life.

**INDICATIVE**, in grammar, the first mood, or manner, of conjugating a verb, by which we simply affirm, deny, or ask something ; as, *amant*, they love ; *non amant*, they do not love ; *amantne*, do they love ?

**INDICATIVE COLUMN**. See **COLUMN**.

**INDICAVIT**, in law, a writ or prohibition that lies for a patron of a church, whose clerk is sued in a spiritual court by another clerk for tythes, amounting to a fourth part of the profits of an advowson ; for then the suit belongs to the king's court.

This writ cannot be had before the defendant is libelled in the ecclesiastical court, a copy of which must be produced in the court of chancery, before the writ is granted ; and brought before judgment is given in the spiritual court, otherwise the indicative will be void.

**INDICTION**, in chronology, a cycle of fifteen years. See **CYCLE**.

The roman or papal indiction, which is that used in the pope's bulls, begins on the first of January ; and by it the popes have dated their acts ever since Charlemain made them sovereigns. But besides this, there are other two kinds of indiction mentioned by authors, *viz.* that of Constantinople, beginning on the first of September ; and the imperial or cesarian indiction, which commenced on the 14th of September.

**INDICTION** is also used for the convoking an ecclesiastical council or assemble. See the article **COUNCIL**.

**INDICTIVE FEAST DAYS**, *indictive ferie*, the same with those called conceptive. See the article **FERIÆ**.

**INDICTMENT**, in law, is a bill or declaration of complaint, at the suit of the king, drawn up in form of law, and exhibited against a person, and afterwards preferred to the grand jury or inquest, who are to find whether the complaint be true or not. An indictment differs from an accusation only in this, that the preferrer of the bill is not tied to the proof thereof, under any penalty, except there appear to be a conspiracy.

As indictments are purely for the good and quiet of the common-wealth, they are to be preferred for criminal, not civil matters. They are used in cases of high treason, and petit treason, felony, and trespasses of all kinds, and in all pleas of the crown ; though they cannot be used for injuries of a private nature, that neither concern the king nor the public : and therefore all indictments ought to be brought for offences committed against the common-law, or against statutes ; and not for every slight misdemeanor. A person cannot be indicted of suspicion of felony, but of the very crime itself ;

and then if he be not in custody, the sheriff is commanded to attach his body by a *capias*, &c. A person indicted for felony may have counsel allowed to speak for him, as to matter of law only: but such as are indicted for treason may have a copy of their indictment before trial, in order to advise with counsel; and such indictments are to be found within three years after the offence committed, unless the treason be directly against the king's person.

Indictments must be certain in every point, and charge some particular offence; also goods stolen must be particularly set down, and the offence laid positively, and not by way of recital. There must also be expressed the christian name, surname, and addition of the offender, with the day, year, and place in which the offence was committed, as also the nature of the offence. In an indictment for murder, the length, depth, or other dimension of the wound must be expressed, that a judgment may be formed whether it was mortal: and in felony, the value of the things stolen is to be particularly mentioned, in order that it may appear whether the offender has been guilty of grand or petit larceny. A mistake in spelling the defendant's surname is not a sufficient cause for abating the indictment, provided it sounds like it. If a word of consequence be omitted in an indictment, it renders the whole naught; but the case is not the same, where a word of form is omitted, or where there is an omission of a synonymous word, if the sense is not injured. In case one part of an indictment is inconsistent with another part of it, the indictment becomes void; tho' where the sense is plain, the court will dispense with a small inconsistency. Indictments are amendable the same term they are brought into court, but not afterwards; and in criminal prosecutions, the amendment must be only such as is permitted by the common law. Indictments for crimes committed, ought to be laid in the county where they were done; for otherwise, upon pleading the general issue, not guilty, if it appears that the offence was committed in another county or place different from that in the indictment, the defendant will be acquitted. An offender is subject to indictment, for a felony committed against a person unknown; yet some body must be proved to be the proprietor upon the trial, or else the property

will be presumed to be in the prisoner, he having pleaded not guilty. An indictment being at the king's suit, the prosecutor is a good witness to prove the charge contained in it; and no damage can be given to the party aggrieved, except it be particularly grounded on some statute. Indictments before justices of the peace may be removed by *certiorari* into the king's-bench.

INDIES, east and west. See INDIA and AMERICA.

INDIGESTION, in medicine, a crudity, or want of due coction, either in the food, an humour of the body, or an excrement. See CRUDITY and DIGESTION.

INDIGETES, a name which the antients gave to some of their gods.

There are various opinions about the signification of this word; some maintaining it was given to all the gods, in general; and others only to the semi-gods, or great men deified. Others say, it was given to such gods as were originally of the country, or rather such as were the gods of the country that bore this name. Others again, hold, that it was ascribed to such gods as were patrons and protectors of particular cities.

INDIGNATORIUS MUSCULUS, a muscle of the eye, otherwise called *abducens*, and *rectus exterior*: it has this appellation from its drawing the eye outwards, thereby occasioning the appearance of scorn. See the article EYE.

INDIGO, in commerce, a preparation of the juice of a plant, called by some anil, the characters of which are these: the cup is plane; the alæ of the flower are connivent at their upper edges, and are of the same figure with the vexillum. It is one of the *diadelphia decandria* class of Linnæus.

This plant grows to about two feet high, with roundish leaves; and is a native of both the East and West-Indies.

As to the indigo blue, it is a *fecula*, or settling, made by means of water and oil olive out of the leaves of the anil, or indigo plant: there is a difference between that made by the leaves only, and that which is made of the leaves and small branches. The choicest of the former sort is that which bears the surname of *Serquisse*, from a village of that name some leagues from Surat in the East-Indies. It is made also about Biana and Coffa near Agra; and also in the kingdom of Golconda. In making the *fecula* of anil, in order to make indigo

of it, they cut the herb with a sickle, when the leaves begin to fall upon touching them; and after they have stripped them from the branches, they put them into a sufficient quantity of water in a vessel called the steeping vat; and let them infuse there thirty or thirty-five hours; after which they turn the cock, in order to let the water run off, which is become of a green colour inclining towards blue, into a vessel of the nature of a churn, where it is worked by means of a roller or turner of wood, the ends of which are pointed and faced with iron: this they work till the water abounds with a lather; then they cast into it a little oil of olive, that is, one pound into such a quantity of the liquor, as will yield seventy pounds of indigo, such as is saleable; and as soon as the said oil is thrown in, the lather separates into two parts, so that you may observe a quantity curdled as milk is when ready to break: then they cease working, and let it stand to settle; which when it has done some time, they open the pipe or cock of the vessel, in order to let the water clear off, that the feculæ which is subsided may remain behind at the bottom of the vessel like the lees of wine. Then taking it out, they put it into straining bags of cloth, to separate what water was left: after which they convey it into chests or boxes that are shallow, to dry it; and being dried, it is what we call indigo.

Choose the indigo of Serquisse in flat cakes, of a moderate thickness, neither too soft nor too hard, of a deep violet colour, light, and such as swims on water; and when broken, has no white spots in it; and, lastly, such as is copperish or reddish on being rubbed with one's nail, and has the least dust and broken pieces in it.

The other sort of indigo is also the feculæ made from the anil, and differs nothing from the former, but as it is made of the whole plant, stalk and leaf; the best of which kind is that which bears the name Guatimala, that comes from the West Indies. In choosing this indigo, it should be as near the other kind as can be; but the surest proof of its goodness is its burning upon the fire like wax, and leaving only a little ashes behind. The second sort of indigo is that of St. Domingo, differing nothing from the Guatimala, only that it is not of so lively a colour; the third is the Jamaica indigo;

the fourth is that of the Leeward islands; all which are better or worse, according as they are more or less neat and pure.

The use of the indigo is for the dyer and landrasses, serving the last to put among their linnen. The painters use it to grind with white for painting in blue; for if it is used alone and neat, it turns black; ground with yellow, it makes a green: some confectioners and apothecaries preposterously use this to colour sugars, with which to make conserves and syrup of violets, by adding some orrice.

From and after the 25<sup>th</sup> of March 1749, all persons who shall import into Great Britain, from any of the british colonies in America, in vessels trading and manned as by law directed, any good and merchantable indigo, free from any false mixtures and fit for dyers use, being the product of the colony from whence the same was imported, shall be intitled to six-pence for every pound thereof, to be paid out of the customs upon demand by the collector of the port where the same is imported. If any person make entry of foreign-made indigo under the name of british plantation made, or shall mix any foreign indigo or any false mixture with that made in the british plantations, in order to claim the premium, he shall forfeit the said indigo; and in case of such mixture, the quantity so mixed, both foreign and british plantation made, and double the value thereof, shall be forfeited by the person making such mixture.

Indigo of Turkey, of the West Indies, or rich indigo, as also dust indigo, and that of the british plantations, pay no duty on importation, and consequently have no draw-back on exportation.

INDIRECT *modes of syllogisms*, in logic, are the five modes of the fourth figure, expressed by the barbarous words *baralipli*, *celantes*, *dabitis*, *fapesmo*, *frisesom*. See MODE and FIGURE.

It is the conversion of the conclusion which renders the modes indirect; for instance, a syllogism in *darii*, and another in *dabitis*, would be perfectly alike were it not for that conversion; the propositions having the same quantity and the same quality, and the middle term being the subject in the major and the attribute in the minor, in both; it remains then that to make a distinction, that which is the subject of the conclusion in *darii*, be the attribute in the conclusion

of *debitis*; and that which is the attribute in the first, the subject in the last.

DA- Every thing that promotes salvation is advantageous:

RI- There are afflictions which promote salvation:

I. Therefore, there are afflictions which are advantageous.

DA- Every thing that promotes salvation is advantageous:

BI- There are afflictions which promote salvation:

TIS. Therefore, some things promoting salvation are afflictions.

**INDIVIDUAL**, *individuum*, in logic, a particular being of any species, or that which cannot be divided into two or more beings equal or alike.

The usual division in logic is made into genera or genus's, those genera into species, and those species into individuals. See the articles **GENUS** and **SPECIES**.

The schoolmen make a four-fold distinction of individuals, *viz.*

*Individuum vagum*, that which, tho' it signifies but one thing, yet may be any of that kind: as when we say a man, a certain person, or one said so and so; tho' but one person is meant, yet that one person, for aught that appears to the contrary, may be any body.

*Individuum determinatum*, is when the thing is named and determined, as Plato, Socrates, mount Atlas: this is also called *individuum signatum*.

*Individuum demonstrativum*, is when some demonstrative pronoun is used in the expression, as this man, that woman. *Individuum ex hypothesi*, or by supposition, is when an universal name or term is restrained by the supposition to a particular thing; as when we say the son of Mary, instead of Christ; the writer of the trojan war, instead of Homer.

**INDIVISIBLE**, among metaphysicians. A thing is said to be indivisible absolute, absolutely indivisible, that is a simple being, and consists of no parts into which it may be divided. Thus God is indivisible in all respects, as is also the human mind, not having extension or other properties of body.

**INDIVISIBLE** *secundum quid est*, indivisible with respect to what it now is, a substance which, though it consists of parts into which it may be divided, yet never can be so divided as to remain the same: thus a measure or number is said to be indivisible, for if from a foot-line, for

example, any thing is deducted, it is no more a foot-line; and if from the number three any thing is subtracted, it is no longer the same number. See the next article.

**INDIVISIBLES**, in geometry, the elements or principles into which any body or figure may be ultimately resolved; which elements are supposed infinitely small: thus a line may be said to consist of points, a surface of parallel lines, and a solid of parallel and similar surfaces; and then, because each of these elements is supposed indivisible, if in any figure a line be drawn through the elements perpendicularly, the number of points in that line will be the same as the number of the elements; whence we may see that a parallelogram, prism, or cylinder, is resolvable into elements or indivisibles, all equal to each other, parallel and like to the base; a triangle into lines parallel to the base, but decreasing in arithmetical proportion, and so are the circles which constitute the parabolic conoid, and those which constitute, the plane of a circle, or surface of an isosceles-cone. See the article **INFINITESIMALS**.

A cylinder may be resolved into cylindrical curve surfaces, having all the same height, and continually decreasing inwards, as the circles of the base do-on which they insit.

The method of indivisibles is only the antient method of exhaustions, a little disguised and contracted. It is found of great use in shortening mathematical demonstrations, of which take the following instance in the famous proposition of Archimedes, *viz.* that a sphere is two thirds of a cylinder circumscribing it.

Suppose a cylinder, an hemisphere, and an inverted cone, (plate CXLV. fig. 4.) to have the same base and altitude, and to be cut by infinite planes all parallel to the base, of which *dg* is one. It is plain the square of *db* will be every where equal to the square of *kc* (the radius of the sphere) the square *bc* = *eb* square; and consequently, since circles are to one another as the squares of the radii, all the circles of the hemisphere will be equal to all those of the cylinder, deducting thence all those of the cone: wherefore the cylinder, deducting the cone, is equal to the hemisphere: but it is known, that the cone is one third of the cylinder, and consequently the sphere must be two thirds of it. Q. E. D.

INDORSE-

**INDORSEMENT**, in law, any thing written on the back of a deed, as a receipt for money received.

There is likewise an indorsement, by way of assignment, on bills of exchange and notes of hand; which is done, by writing a person's name on the back thereof. See the article **BILL**.

**INDRAPORE**, a dutch settlement on the west coast of Sumatra, in the East Indies.

**INDUCEMENT**, in law, signifies what may be alledged as a motive; and, in our law, it is used specially in several cases; as, there is an inducement to actions, to a traverse in pleading, and to an offence committed, &c. It has been held that a general indebitus is insufficient, where it is the ground of an action; but where it is only the inducement to it, as in consideration of forbearing a debt till a certain day, this being a collateral promise, is good without shewing how the debt became due. A person ought to induce his traverse, when he denies the title of another; for this reason, because he should not deny it, till he shews some colourable title in himself; and because, if the title traversed should be found naught, and no colour appear for him who traversed, in that case no judgment can be given.

**INDUCTION**, in law, is putting a clerk or clergyman in possession of a benefice or living to which he is collated, or presented. See **PRESENTATION**.

After the bishop has granted institution, which is a kind of approbation of the choice made of the person, he issues out his mandate to the archdeacon to induct him; who either does it personally, or commissions some other person to do it for him. This is analogous to livery and seisin in temporal estates, and puts the clergyman inducted into possession of the church, glebe-land, tythes, &c.

Induction is performed in the following manner: the clergyman commissioned takes the minister to be inducted by the hand, lays it upon the key of the church, the ring of the door, the latch of the church-gate, or on the church-wall, and pronounces these words, "By virtue of this commission, I induct you into the real and actual possession of the rectory of, &c. with all its appurtenances." Then he opens the church door, and puts the parson in possession, who commonly tolls a bell, to give notice to the people that he has taken possession of the church.

Induction may also be made by delivery of a clod or turf of the glebe.

**INDULGENCES**, in the romish church, are a remission of the punishment due to sins, granted by the church, and supposed to save the sinner from purgatory. Clement VI. in his decretal, which is generally received by the church of Rome, declares, that our Saviour has left an infinite treasure of merits, arising from his own sufferings, besides those of the blessed virgin and the saints; and that the pastors and guides of the church, and more especially the popes, who are the sovereign disposers of this treasure, have authority to apply it to the living, by virtue of the keys, and to the dead, by way of suffrage, to discharge them from their respective proportions of punishment, by taking just so much merit out of this general treasure, as they conceive the debt requires, and offering it to God.

The power of granting indulgences has been greatly abused in the church of Rome. It was one of the chief things which the council of Constance laid to the charge of John XXIII. in 1415, that he impowered his legates to absolve penitents from all sorts of crimes, upon the payment of sums proportionable to their guilt. Pope Leo X. in order to carry on the magnificent structure of St. Peter's at Rome, published indulgences, and a plenary remission to all such as should contribute money towards it. Finding the project take, he gave his sister, the princess of Cibo, the benefit of the indulgencies of Saxony, and the neighbouring parts, and farmed out those of other countries to the highest bidders, who, to make the best of their bargains, procured the ablest preachers to cry up the value of the ware. "Happy times for sinners! says a modern writer, their crimes were rated, and the remission of them set up by auction. The apostolic chancery taxed sins at a pretty reasonable rate. It cost but ninety livres, and a few ducats, for crimes which people on this side the Alps punished with death."

It was this great abuse of indulgences that contributed not a little to the first reformation of religion, in Germany, where Martin Luther began first to declaim against the preachers of indulgences, and afterwards against indulgences themselves: but since that time the popes have been more sparing in the exercise

of this power: however, they still carry on a great trade with them to the Indies, where they are purchased at two reals a piece, and sometimes more.

The pope likewise grants indulgences to persons at the point of death, that is, he grants them, by a brief, power to choose what confessor they please, who is authorized thereby to absolve them from all their sins in general.

**INDULT**, in the church of Rome, the power of presenting to benefices granted to certain persons by the pope. Of this kind is the indult of kings and sovereign princes, in the romish communion, and that of the parliament of Paris granted by several popes. By the concordat for the abolition of the pragmatic sanction, made between Francis I. and Leo X. in 1516, the french king has the power of nominating to bishoprics, and other consistorial benefices, within his realm. At the same time, by a particular bull, the pope granted him the privilege of nominating to the churches of Britany and Provence. In 1648, pope Alexander VIII. and in 1668, Clement IX. granted the king an indult for the bishoprics of Metz, Toul, and Verdun, which had been yielded to him by the treaty of Munster; and in 1668, the same pope Clement IX. granted him an indult for the benefices in the counties of Roussillon, Artois, and the Netherlands. The cardinals likewise have an indult granted them by agreement between pope Paul IV. and the sacred college in 1555, which is always confirmed by the popes at the time of their election. By this treaty the cardinals have the free disposal of all the benefices depending on them, and are empowered likewise to bestow a benefice in commendam.

**INDULTO**, a duty, tax, or custom paid to the king of Spain, for all such commodities as are imported from the West Indies in the galleons. See **GALLEONS**.

**INDUS**, a large river of Asia, which rises in the mountains which separate Tartary from India, and discharges itself into the Indian ocean.

**INERTIA of matter**, in philosophy, is defined by Sir Isaac Newton to be a passive principle by which bodies persist in their motion or rest, receive motion in proportion to the force impressing it, and resist as much as they are resisted. It is also defined by the same author to be a power implanted in all matter, whereby

it resists any change endeavoured to be made in its state.

This power then coincides with the vis resistendi, or power of resisting, whereby every body endeavours, as much as it can, to persevere in its own state, whether of rest or uniform rectilinear motion; which power is still proportionable to the quantity of matter in any body: for since natural bodies consist of a mass of matter, that, of itself, is not able to induce any change in its state, if bodies were once at rest, it is necessary that they should always remain in that state of rest, unless there is applied a new force to produce motion in them: but if they were in motion, the same energy or force would always preserve the motion; and therefore bodies would always retain their motion, and would always proceed forward in the same right line with the same tenour, since they cannot of themselves acquire either rest or a retardation, or a change of their direction to turn on one side or the other.

There are some philosophers who readily enough acknowledge, that no body can move of itself, that is, pass from rest to motion of itself; but then they are not as willing to grant, that bodies once moved cannot of themselves arrive at rest, by reason they see the motions of projectiles languish by degrees, and at last the moving bodies themselves come to rest. See **PROJECTILES**.

But as no mode or accident can of its own accord, or by itself, be destroyed, and as all effects produced by transient causes do remain always, unless there be some new and extraneous cause that destroys them; so likewise motion once commenced, will be continued always, unless it be hindered by some external cause: nor is it more in the power of a body once moved, to lay aside its motion or energy to move, and return of itself to rest, than it can put off the figure that it has been once formed into, and acquire a new one, without some extrinsic cause. Therefore, as there is in all bodies a certain force, or rather inactivity, whereby they oppose every change; from which cause it proceeds, that they are very difficultly put out of their state, whatever it is: but that inactivity is the same in moving bodies as in those at rest, nor do bodies less resist the action, whereby they are brought from motion

to rest, than that whereby they pass from rest to motion; that is, there is not required a less force to put a stop to the motion of any body, than was before necessary to impress that motion on the same body. Whence since the vis inertiae, or inactivity of matter, always equally resists equal changes, it will not be less powerful to continue a body in motion, which has begun to move, than to preserve a quiescent body in the same state of rest.

There are some philosophers who suppose body of its own nature to be as indifferent to motion as to rest; but by this indifference they do not, we suppose, mean such a disposition in bodies, whereby they do not in the least resist rest or motion: for on this supposition it would follow, that any body, however great, and moved with the swiftest velocity, might be stopped by any the smallest force; or if the great body was at rest, it might be moved by any body, however small, without the least loss of velocity in the impelling body: that is, any small body impinging on a greater one, would carry that greater body along with it, without the least loss of its motion; and each body after the impulse, would be jointly carried along with that celerity that the small body had at first, which we all know is absurd. This indifference, therefore, is not placed in a non-resistance to motion from a state of rest, or to rest from a state of motion; but in this only, that a body of its own nature is not more propense to motion than to rest, nor more resists to pass from a state of rest to motion, than to return again from that motion to the same state of rest: besides, any quiescent body may be moved by any force; and an equal force, acting in a contrary direction, will be able to destroy that motion; and in this, this indifference consists.

Since, according to this law, a body once in motion always continues in that motion, the philosophers ask, Why all projectiles lose by degrees their motion? Why do they not proceed in infinitum? If motion did not of its own nature decay, a stone thrown at the beginning of the world, would by this time have gone through an immense and almost infinite space. And so indeed it would, if its motion had been in vacuo, or in free spaces, and without any gravity. But since all projectiles are carried either thro' the air, or on the rough surfaces of other

bodies, they must be necessarily retarded: for since all bodies in motion must drive and thrust out of its place the resisting air, or overcome the roughness of the superficies upon which they are moved, they will lose all that force and motion that is constantly employed in overcoming these obstacles, and consequently the motion of projectiles will be continually diminished: but if there was no resistance in the medium, no roughness in the superficies on which they were moved, no gravity that continually forces the bodies towards the earth, motion would always continue the same, without any retardation at all. So in the heavens, where the medium is exceedingly rare, the planets do continue their motions for a very long time; and upon ice, or any other very smooth surface without any roughness, heavy bodies in motion are not soon brought to rest.

**INFALLIBLE**, something that cannot err, or be deceived. See **ERROR**.

One of the great controversies between the protestants and papists, is the infallibility which the latter attribute to the pope; though, in fact, they themselves are not agreed on that head, some placing this pretended infallibility in the pope and a general council. See the articles **COUNCIL** and **POPE**.

**INFAMY**, in law, is a term which extends to forgery, perjury, gross cheats, &c. by which a person is rendered incapable of being a witness or juror, even tho' he is pardoned for his crimes. See the articles **FORGERY**, **PERJURY**, &c.

**INFANT**, *infans*, in medicine, denotes a young child. See the articles **CHILD** and **DELIVERY**.

It being a matter of great importance how tender infants are treated, we shall lay down some rules for the direction of the diet, regimen, and other non-naturals, as well with regard to the infant as the nurse.

As soon, therefore, as the child is brought into the world, it ought, immediately after the ligature and cutting off the umbilical vessels, to be washed in a warm bath, prepared of water alone, or a mixture of wine and water. The midwife too should be allowed a convenient place and time to examine the child, and set to rights any parts that may be ill-formed by the birth. She should likewise stroke the belly with the hollow of her hand, in order to excite a discharge of the feces. If the new-born infant is

found to be weakly, it should be refreshed by washing it with warm wine, rubbing it gently, anointing the breast, back, and crown of the head with some analeptic spirits; or by breathing strongly into its mouth, after chewing cloves and other aromatics; or giving it a small quantity of rhenish wine, or cinnamon-water. Great caution is also necessary in swaddling the infant, lest out of negligence or ignorance, it receive any injury by this means: for besides that infants frequently become hump-backed from too great a stricture of the breast by bandage, by thus obstructing the circulation, they fall into a consumption, and are subject to ruptures and many other disorders.

The next care is, that infants, who for want of a discharge by stool in the mother's womb, always come into the world with their intestines replete with excrements, be seasonably purged. But in case the weak nature of the infant should not be sufficient of itself, providence has kindly furnished the mother at first with thin serous milk, whose detarging and diluting quality opens the body much better and with greater safety than the most select evacuants, and no danger is to be dreaded from it, unless that milky liquor flows from an impure spring; or the mother, from the difficulty of the birth, be agitated by convulsive motions; or unless any other circumstances concur which forbid the use of a medicine elaborated by nature in the breasts of women: in which case, if the infant has not a stool within twenty four hours, it may be proper to give it a very small quantity of solutive syrup of roses, or a clyster of whey and honey.

As to a proper diet, milk deservedly constitutes the principal, and the universal aliment; because it supplies both meat and drink at the same time, is grateful to the stomach, and for this purpose it was wisely ordered by the Creator, that women, immediately after their delivery, should accumulate a sufficient quantity of it in their breasts. As infants are nourished by the breasts either of the mother or a hired nurse, it is certainly the duty of parents, and those entrusted with the health of children, to take care that they generate pure and temperate milk. This is best obtained by their observing an exact method of diet, and avoiding all those

things which communicate any taste to the milk, even imperceptible to the senses, and especially such as are capable of producing distempers. Particularly let the nurse, if there be a necessity for one, be healthy, in the flower of her age, from twenty to thirty, rather lean than fat, of good morals, composed in mind, neither melancholy, passionate, nor a drunkard; nor let her milk be too stale; but her diet be regular, and great care must be taken that she does not all at once pass from a hard and sparing diet, to one that is delicate and plentiful. But nothing less than an absolute necessity should prevail on a mother to suffer her tender progeny to be delivered up to a mercenary nurse; since this is a barbarity exceeding every thing to be met with in the brute creation: for not only all the disorders incident to the body, but even those of the mind itself, are communicated to the sucking child.

It often happens that the milk is corrupted by various sudden causes, by which either the mother or the nurse may be affected: and here precautions are necessary to prevent impending danger: the milk is extremely vitiated by the terror of the woman who gives suck; and consequently the best preservative against the injury arising from it, is not to give the breast immediately after a fright. The same holds true with respect to anger; and since the injury done to the milk by violent passions, upon its long continuance in the breasts, endangers both the child and the nurse, to prevent this, the milk should be seasonably extracted.

It sometimes happens that either the infant is incapable of sucking the milk out of the breasts, or the nurse, from illness, or some other cause, is incapable of affording it: In this case, other proper aliments are to be provided, among which are sweet whey, barley-broth, water-gruel, emulsions of almonds, barley boiled to the consistence of a pulp, with the addition of the yolk of an egg; several kinds of pap, made of flour, or crums of bread boiled in water, given with or without milk: but chewing victuals and giving it to a child, ought by no means to be allowed; because by such mastication, not only the most subtle part of the pap is sucked out, but any infection of the saliva and corrupted teeth are easily communicated to infants. When children arrive at such an habit

as to be capable of digesting other aliments, care should be taken not to give them food of a hard consistence; they ought not to eat salt meat in great quantities, unripe fruit, bread not duly fermented, or too new; nor ought they to eat much of any kind of sweet meats.

As to the prevention of the diseases in infants, nothing is more useful both for the nurse and the child, than infusions of such herbs as sweeten the blood, made in water: and here an infusion of betony, root of liquorice, fennel-seed, and the like, are highly proper. Nor do they act amiss who sometimes, after a meal, eat a quantity of fennel or annise-seed, which increases the milk, and prevents gripes in the infant.

Since milk stagnating in the stomach and duodenum soon grows acid and coagulated, and thus excites a thousand dangerous symptoms, the greatest care ought to be taken to prevent what is attended with such dangerous consequences; for which purpose those powders are extremely efficacious which contain crabs-eyes, egg-shells, the root of florentine orris, saffron, the seeds or oil of annise, &c. of which a dose may be given twice or three times a week. And since the health of infants greatly depends upon a due and sufficient discharge of the excrements by stool, and the preservation of the tone of the stomach and intestines, gentle laxatives, if necessary, should be sometimes interposed; but strong and acrid purges, as resin of jalap, scammony, black heliobore, and the like, are improper and pernicious. They ought not to take aloes on account of the heat it occasions, nor the leaves of senna because of the costiveness it produces: nor are these prejudicial only when given to children, but also when given to the nurses; for being mixed with the milk, they often throw the tender infants into convulsions. Sydenham rightly observes, that children, in the first month, are often seized with the epilepsy from too frequent stools; and Galen justly asserted, that the bodies of children ought not to be excicated with purgatives, which would prevent their growing. And, really, it is inexpressible how much the tender and weak stomachs of new born infants are prejudiced by purgatives.

*Diseases of INFANTS* may be reduced to the following heads. 1. Retention of the meconium, or first stools, already taken notice of. 2. Aphthæ, or thrush, which

affect the whole mouth, and even intestines: for this Heister advises a grain or two of mercurius dulcis, given in two drams of solutive syrup of roses: he would have the nurse, likewise, take rhubarb, and the absorbent powders; and externally, Shaw would have the ulcers touched frequently with a mixture of honey of roses, and oil of vitriol. 3. Chaffing, or galling, of the flesh, already treated of under the article EXCORIATION.

4. Costiveness, for which Heister recommends two or three grains of rhubarb in solutive syrup of roses, or a solution of manna, till the child's belly is opened; and afterwards the testaceous powders. 5. Coughs of infants seldom prove obstinate, usually giving way to pectoral syrups, or a little spermaceti; relaxing the bowels at the same time with rhubarb, given in solutive syrup of roses. In very bad cases, a few drops of spirit of sal-armoniac, given pretty often, has a very good effect; and if the child be almost choked, a quarter of a grain of tartar emetic, taken as a vomit, will snatch it from the jaws of death. Oil of sweet almonds is likewise very good; as are flowers of sulphur, in phlegmatic habits. 6. Crusta Lactea, or scabby eruptions, otherwise called achores, already treated of under the articles ACHOR and CRUSTA. 7. Atrophy, or consumption, for the cure of which, the crudities of the bowels should be evacuated by gentle laxatives, now and then repeated, to which a few grains of mercurius dulcis must always be added; or even the purgative salts may be prescribed. Externally, baths of soft-water, with aromatic herbs, with friction of the joints while in the bath, and frequent motion, are recommended. 8. Convulsion, if owing to acrimonious humours in the bowels, is cured by gentle doses of syrup of rhubarb, with the absorbent powders; but when epileptic, cinnabar is to be given freely in powders; and when owing to worms, mercurius dulcis is the best of all medicines. 9. Diarrhœa of infants is already treated of under its proper article. 10. Stoppage of the nose sometimes happens, inasmuch that they can scarce breathe, suck, or swallow; for the cure of which, after a suitable purge, dissolve two or three grains of white vitriol in half an ounce of marjoram-water; then filtre it, and apply it now and then to the nostrils with a linen-rag. Or you may apply oil of sweet almonds, impregnated with oil of mar-

poram, to the bottom and sides of the nostrils, which will resolve the filth. 11. Running of the eyes and ears is a very common complaint, which is cured by small doses of the decoction of pimpernel-root, saffras, and gentle laxatives, in which a grain or two of calomel is mixed. 12. Vomiting is rather accounted salutary than otherwise; but when too violent, it may be remedied by gentle clysters. 13. Suppression of urine is cured by giving half a scruple of some neutral salt, as vitriolated tartar, arcanum duplicatum, and the like; but if these fail, a catheter must be introduced into the bladder, which is much easier in girls than boys. 14. Fevers of children, see FEVER. 15. Difficulty of teething, see DENTITION. 16. Imperforations of the necessary parts, so that there is no passage for the stools or urine; in which the assistance of the surgeon must be speedily called in, or the infant is lost. 17. Jaundice, or a yellowness of the skin, see JAUNDICE. 18. Worms in children, see WORMS. 19. Rickets seldom attack children before they are nine months old, see RICKETS. 20. Gripes, and other disorders of the bowels, are generally owing to corrupted milk; the cure of which consists in the use of antacids, mild cathartics, and clysters of the same intention, with gentle carminatives. Sometimes, indeed, the gripes are so violent as not to be cured without two drops of the thebaic tincture in a little syrup of roses. Absorbents are also deemed excellent in these disorders, as they cure the gripes, restlessness, and watching in infants, as certainly as opium eases pain in adults.

*Hare-Lip* in INFANTS. See LIP.

INFANT, in law, signifies a person under the age of one and twenty.

An infant may bind himself apprentice, and if he serve seven years, may have the benefit of his trade; but if he be guilty of misbehaviour, the master may give him gentle correction, or complain to a justice of peace and have him punished. He may also bind himself for the payment of necessities, such as meat, drink, washing, apparel and learning, though not by bond with a penalty: infants are not obliged to pay for cloaths, unless it be proved that they were for their own wearing, and convenient and necessary for them to wear according to their degree and estate; and though an infant may buy necessities, he cannot borrow

money to do it; for the law will not trust him with money, except at the peril of the lender, who must either see it thus laid out, or take care to lay it out himself in such necessities. If an infant is the defendant in an action, the plaintiff has six years to commence his action in after the infant comes of age; and an infant who is a plaintiff, has also six years, after he comes of age, to sue, by the statute of limitations. If an infant grants leases for a term of years, he may, at his full age, either confirm the lease, or bring trespass against the lessee for the occupation. Also a lease granted to an infant may be avoided by waving the land before the rent day expressed therein. An infant may purchase lands, where such purchase is intended for his benefit, though at his full age he may either avoid or confirm such purchase; and, in case an infant sell lands by deeds indented and enrolled, he may avoid the same. However, infants are bound by all acts of necessity, as in presentations to benefices, admittances and grants of copyhold estates, assenting to legacies, and conditions annexed to lands, whether an estate comes by grant or by descent.

INFANTE and INFANTA, all the sons and daughters of the kings of Spain and Portugal, except the eldest; the princes being called *infantes*, and the princesses *infantas*.

INFANTRY, in military affairs, denotes the whole body of foot-soldiers. See the articles FOOT and SOLDIERS.

INFECTION, among physicians, the same with contagion. See CONTAGION.

INFERNAL-STONE, *lapis infernalis*. See the article LAPIS.

INFINITE, that which has neither beginning nor end: in which sense God alone is infinite. See the article GOD.

Infinite is also used to signify that which has had a beginning, but will have no end, as angels and human souls. This makes what the schoolmen call *infinitum a parte post*; as, on the contrary, by *infinitum a parte ante*, they mean that which has an end but had no beginning.

INFINITE, or INFINITELY GREAT LINE, in geometry, denotes only an indefinite or indeterminate line, to which no certain bounds, or limits, are prescribed.

INFINITE QUANTITIES. The very idea of magnitudes infinitely great, or such as exceed any assignable quantities, does include a negation of limits: yet if we nearly examine this notion, we shall find that

that such magnitudes are not equal among themselves, but that there are really besides infinite length and infinite area, three several sorts of infinite solidity; all of which are *quantitates sui generis*, and that those of each species are in given proportions.

Infinite length, or a line infinitely long, is to be considered either as beginning at a point, and so infinitely extended one way, or else both ways from the same point; in which case the one, which is a beginning infinity, is the one half of the whole, which is the sum of the beginning and ceasing infinity; or, as may be said, of infinity *a parte ante* and *a parte post*, which is analogous to eternity in time and duration, in which there is always as much to follow as is past, from any point or moment of time: nor doth the addition or subtraction of finite length, or space of time, alter the case either in infinity or eternity, since both the one or the other cannot be any part of the whole.

As to infinite surface, or area, any right line, infinitely extended both ways on an infinite plane, does divide that infinite plane into equal parts, the one to the right, and the other to the left of the said line; but if from any point, in such a plane, two right lines be infinitely extended, so as to make an angle, the infinite area, intercepted between those infinite right lines, is to the whole infinite plane as the arch of a circle, on the point of concurrence of those lines as a center, intercepted between the said lines, is to the circumference of the circle; or, as the degrees of the angle to the 360 degrees of a circle: for example, right lines meeting at a right angle do include, on an infinite plane, a quarter part of the whole infinite area of such a plane.

But if two parallel infinite lines be supposed drawn on such an infinite plane, the area intercepted between them will be likewise infinite; but at the same time will be infinitely less than that space, which is intercepted between two infinite lines that are inclined, though with never so small an angle; for that, in the one case, the given finite distance of the parallel lines diminishes the infinity in one degree of dimension; whereas, in a sector there is infinity in both dimensions: and consequently the quantities are the one infinitely greater than the other, and there is no proportion between them.

From the same consideration arise the three several species of infinite space or

solidity; for a parallelopiped, or a cylinder, infinitely long, is greater than any finite magnitude, how great soever; and all such solids, supposed to be formed on given bases, are as those bases in proportion to one another. But if two of these three dimensions are wanting, as in the space intercepted between two parallel planes infinitely extended, and at a finite distance, or with infinite length and breadth, with a finite thickness, all such solids shall be as the given finite distances one to another; but these quantities, though infinitely greater than the other, are yet infinitely less than any of those wherein all the three dimensions are infinite. Such are the spaces intercepted between two inclined planes infinitely extended; the space intercepted by the surface of a cone, or the sides of a pyramid, likewise infinitely continued, &c. of all which notwithstanding, the proportions one to another, and to the *vacuum*, or vast abyss of infinite space (wherein is the locus of all things that are or can be; or to the solid of infinite length, breadth and thickness taken all manner of ways) are easily assignable; for the space between two planes is to the whole as the angle of those planes to the 360 degrees of the circle. As for cones and pyramids, they are as the spherical surface intercepted by them is to the surface of the sphere, and therefore cones are as the versed lines of half their angles to the diameter of the circle: these three sorts of infinite quantity are analogous to a line, surface, and solid; and, after the same manner, cannot be compared, or have no proportion the one to the other.

INFINITESIMALS, among mathematicians, are defined to be infinitely small quantities.

In the method of infinitesimals, the element, by which any quantity increases or decreases, is supposed to be infinitely small, and is generally expressed by two or more terms, some of which are infinitely less than the rest, which being neglected as of no importance, the remaining terms form what is called the difference of the proposed quantity. The terms that are neglected in this manner, as infinitely less than the other terms of the element, are the very same which arise in consequence of the acceleration, or retardation, of the generating motion, during the infinitely small time in which the element is generated; so that the remaining terms express the elements that would

would have been produced in that time, if the generating motion had continued uniform : therefore those differences are accurately in the same ratio to each other as the generating motions or fluxions. And hence, though in this method infinitesimal parts of the elements are neglected, the conclusions are accurately true without even an infinitely small error, and agree precisely with those that are deduced by the method by fluxions.

For example, (pl. CXLVI. fig. 1.  $n^{\circ} 1$ .) when DG, the increment of the base AD, of the triangle ADE, is supposed to become infinitely little, the trapezium DGHE (the simultaneous increment of the triangle) consists of two parts, the parallelogram EG, and the triangle EIH; the latter of which is infinitely less than the former, their ratio being that of one half DG to AD: therefore, according to this method in fluxions, the part EIH is neglected, and the remaining part, viz. the parallelogram EG is the difference of the triangle ADE. Now it was shown, (see the article FLUXIONS,) that EG is precisely that part of the increment of the triangle ADE which is generated by the motion with which this triangle flows, and that EIH is the part of the same increment which is generated in consequence of the acceleration of this motion, while the base, by flowing uniformly, acquires the augment DG, whether DG be supposed finite or infinitely little.

Example 2. The increment DELM HG (*ibid.*  $n^{\circ} 2$ .) of the rectangle AE, consists of the parallelograms EG, EM, and Ib; the last of which, Ib, becomes infinitely less than EG or EM, when DG and LM, the increments of the sides, are supposed infinitely small; because Ib is supposed to EG as LM to AL, and to EM as DG to AD; therefore, Ib being neglected, the sum of the parallelograms EG and EM is the difference of the rectangle AE: and the sum of EG and EM is the space that would have been generated by the motion with which the rectangle AE flows continued uniformly, but that Ib is the part of the increment of the rectangle which is generated in consequence of the acceleration of this motion, in the time that AD and AL, by flowing uniformly, acquire the augments DG and LM. The same may be observed in propositions wherein the fluxions of quantities are determined; and thus the man-

ner of investigating the differences, or fluxions of quantities, in the method of infinitesimals, may be deduced from the principles of the method of fluxions. For instead of neglecting EIH because it is infinitely less than EG,  $n^{\circ} 1$ . (according to the usual manner of reasoning in that method) we may reject it; because we may thence conclude, that it is not produced in consequence of the generating motion DG, but of the subsequent variations of this motion. And it appears why the conclusions in the method of infinitesimals are not to be represented as if they were only near the truth, but are to be held as accurately true.

In order to render the application of this method easy, some analogous principles are admitted, as that the infinitely small elements of a curve are right lines, or that a curve is a polygon of an infinite number of sides, which being produced, give the tangents of the curve; and by their inclination to each other measure the curvature. This is as if we should suppose, when the base flows uniformly, the ordinate flows with a motion which is uniform for every infinitely small part of time, and increases or decreases by infinitely small differences at the end of every such time.

But however convenient this principle may be, it must be applied with caution and art on various occasions. It is usual therefore, in many cases, to resolve the element of the curve into two or more infinitely small right lines; and sometimes it is necessary, if we would avoid error, to resolve it into an infinite number of such right lines, which are infinitesimals of the second order. In general, it is a postulatam in this method, that we may descend to the infinitesimals of any order whatever, as we find it necessary; by which means, any error that might arise in the application of it may be discovered and corrected by a proper use of this method itself. For an example of this, see Maclaurin's Fluxions, article 498.

It is likewise to be observed, when the value of a quantity that is required in a philosophical problem becomes, in certain particular cases, infinitely great or infinitely little, the solution would not be always just though such magnitudes were admitted. As when it is required to find by what centripetal force a curve could be described about a fixed point that is either in the curve, or is so situated,

ated, that a tangent may be drawn from it to the curve, the value of the force is found infinite at the center of the forces in the former case, and at the point of contact in the latter; yet it is obvious, that an infinite force could not deflect the line described by a body that should proceed from either of these points, into a curve; because the direction of its motion in either case passes thro' the center of the forces, and no force, how great soever, that tends towards the center could cause it to change that direction. But it is to be observed; that the geometrical magnitude by which the force is measured, is no more imaginary in this than in other cases, where it becomes infinite; and philosophical problems have limitations that enter not always into the general solution given by geometry.

But to obviate these scruples, which the brief manner of proceeding in the method of infinitesimals is apt to suggest to such as enter on the higher parts of geometry, after having been accustomed to a more strict and rigid kind of demonstration in the elementary parts. To such it may seem not to be consistent with the perfect accuracy that is required in geometrical demonstration, that, in determining the first differences, any part of the element of the variable quantity should be rejected, merely because it is infinitely less than the rest, and that the same part should be afterwards employed for determining the second and higher differences, and resolving some of the most important problems. Nor can we suppose that their scruples will be removed, but rather confirmed, when they come to consider what has been advanced by some of the most celebrated writers on this method, who have expressed their sentiments concerning infinitely small quantities in the precise terms; while some of them deny their reality, and consider them only as incomparably less than finite quantities, in the same manner as a grain of sand is incomparably less than the whole earth; and others represent them, in all their orders, as no less real than finite quantities. From what has been said, it will appear that a satisfactory account may be given for the more brief way of reasoning used in the method of infinitesimals; and that when we investigate the first differences, we may reject the infinitesimal part of the element, not merely because they are infinitely less than the other parts; but because the quantities

generated, and their mutual relations, depend upon the generating motions, and are discovered by them. The same infinitesimal parts of the element, however, may serve for measuring the acceleration or retardation of those motions from that term, or the powers which may be conceived to accelerate or retard them at that term: and here the infinitely small parts of the element that are of the third order, are neglected for a similar reason, being generated only in consequence of the variation of those powers from that term of the time. In this manner we presume some satisfaction may be given to the scrupulous (who may be apt to demur at the usual way of reasoning in this method) while nothing is neglected without accounting for it; and thus the harmony may appear to be more perfect betwixt the method of fluxions and that of infinitesimals.

But, however safe and convenient this method may be, some will always scruple to admit infinitely little quantities, and infinite orders of infinitesimals, into a science that boasts of the most evident and accurate principles, as well as of the most rigid demonstrations; and therefore in this article, more unexceptionable postulate have been used. In order to avoid such suppositions, Sir Isaac Newton considers the simultaneous increments of the flowing quantities as finite, and then investigates the ratio, which is the limit of the various proportions, which those increments bear to each other, while he supposes them to decrease together, till they vanish; which ratio is the same with the ratio of fluxions.

**INFIRMARY**, a kind of hospital, where the weak and sickly are properly taken care of. See **HOSPITAL**.

**INFLAMMABILITY**, that property of bodies, which disposes them to kindle, or catch fire. See the articles **FIRE**, **FLAME**, **HEAT**, &c.

According to Dr. Shaw, the oil, contained in bodies, is the sole principle of their inflammability. See **FUEL**.

From many experiments Boerhaave found, that all those parts of vegetables, which are capable by fire of making a true flame, are easily miscible among each other, when pure, simple, and inflammable. Thus alcohol, which is the only known body perfectly inflammable, however prepared, provided it be pure, may be intimately mixed with any other alcohol prepared in any other manner, without

without the least alteration thence arising. So also all pure oils, when rightly purged of other parts, will mix thoroughly with each other. Nay, all the purest oils, and even alcohol itself, may be so accurately mixed together, as to form one homogeneous fluid, in which the best microscopes shall not be able to discern the least diversity of parts; which, however, is to be understood with this restriction, that there be not the smallest drop of water in such oil or alcohol. So also camphor, which may be reckoned among the vegetable solids, burns wholly away, dissolves and mixes intimately, not only in alcohol, but in any pure oil: and the like holds of other perfectly inflammable vegetables, which mix in oils or alcohol the more thoroughly, as they are more entirely inflammable. The same holds of resins, balsams, and gum-resins, which, when mixed under the conditions above specified, may be liquified even by a small degree of heat, or even run spontaneously. Nor must it be omitted, that all perfectly inflammable bodies contain certain viscid parts, which produce a brisk cohesion; and that many of them are incapable of being frozen by any degree of cold hitherto known, as appears in linseed oil. See COLD, FROST, FREEZING, OIL, and ALCOHOL. But what appears most wonderful in regard to the inflammability of bodies, is the production of actual flame by the mixture of two cold liquors. The mixture which most constantly and happily produces this effect, is oil of turpentine with an aqua fortis, made in the following manner: take two pounds of dried and powdered nitre, which mix with one pound of concentrated oil of vitriol, or of common oil of vitriol of a sufficient strength: distil this mixture in a retort with a reverberatory fire, and the liquor thereby raised will be an aqua fortis, capable of producing fire and flame with oil of turpentine without any farther assistance. But without being at the trouble of making an aqua fortis on purpose, if well dephlegmated spirit of nitre be mixed with a sufficient quantity of well rectified oil of vitriol, this mixture will give fire very readily with oil of turpentine, or any other aromatic oil. The proportions are an ounce of the spirit of nitre, half an ounce of the oil of vitriol, and an ounce of oil of turpentine; tho' Mr. Geoffroy tells us, he has succeeded very well with a dram of

spirit of nitre, a dram of oil of vitriol, and three drams of oil of turpentine. This experiment, performed with turpentine instead of its oil, is extremely diverting, as the flame not only continues longer, but there are a great many successive explosions.

**INFLAMMATION**, in surgery and medicine, is defined to be a pressure and attrition of the red arterial blood, stagnating in the smallest canals, produced by the motion of the rest of the blood, thrown into a violent and forcible commotion, by means of a fever. See the article FEVER.

This definition of an inflammation is taken from its causes. Others define it from its symptoms to be a species of tumour attended with a burning heat, pain, redness, resistance, and a continual pulsation and pricking. See TUMOUR.

Inflammations are either external, being such as fall properly under the business of surgery, and are cured by manual operations and topical remedies; or internal, being such whose cure is to be expected chiefly from the use of internal remedies.

*General division of external INFLAMMATIONS.* External inflammations, seated in the common integuments, are generally termed phlegmons but when slighter, they are called furuncles. The inflammation which is not fixed deep, but only spreads superficially on the skin, is usually distinguished by the name of an erysipelas; and the inflammatory tumour that arises at the finger-ends, is termed paronychia; when the inflammation fixes in the groin or armpits, the tumour is called a bubo; when under the ears, parotis. If an inflammation seizes the hands and feet from extreme cold, chilblains arise: other inflammations have also particular names, according to the particular part of the body they possess.

*General causes of external INFLAMMATIONS.* The cause of a phlegmon, or an external inflammation, arises generally from too thick or viscid a state of the blood, stagnating in the anastomoses of the smallest arteries and veins; so that the blood being sent in larger quantities than it can pass thro' those vessels, must of consequence excite the fore-mentioned general symptoms of an inflammation, and must occasion great disorders at every part where such stagnation is made. And tho' no part of the body, whether

external

external or internal, nor the bones themselves are exempt from this kind of inflammation, yet it more frequently happens in the fat and glands than any where else.

With regard to the cause whence that inspissation and stagnation in those vessels proceeds, they are, according to Heister, of two kinds, of which the first may be called external, and the latter internal. Among the external causes are placed in the first rank all wounds, fractures, luxations, contusions, punctures by thorns and splinters, with a too great compression of the vessels, whether by too strict a bandage, or otherwise. To these causes may be added burns of all sorts, extreme cold, too violent a motion of the body, the external or internal application of too sharp and stimulating substances, sticking plasters, oily and fat things, with abundance of the like nature, which stop up the pores of the skin, and impede the free course of the blood. Amongst the internal causes, the same author reckons any thing acrimonious in the fluids, as in the scurvy; as also from the blood's abounding in too great quantities, or being of too thick a consistence; or lastly, when it circulates in the body with too violent a motion: for by this means the grosser particles of the blood are drove, and, as it were, wedg'd into smaller vessels, than they can readily find a passage through, and this, more especially, when a sudden cold is spread over a body that is in a great heat. In short, every thing will produce an obstruction which makes the parts of the blood too gross and bulky, or too much contracts the mouths of the small vessels.

*General crises and cure of* INFLAMMATIONS. Inflammations terminate variously, according to their different degrees of violence, the causes from whence they arise, the parts which they affect, and the particular constitution of the patient, with several other circumstances which also presage to us what shall be the end of the inflammation. But the several ways wherein an inflammation terminates are chiefly four. It is either, 1. so dispersed and resolved as to vanish without leaving any considerable injury in the part affected, and which afterwards recovers its former vigour, and is of all others, the best course it can take; or else, 2. the inflammation suppurates, and degenerates into an abscess, so as to leave ever after some damage in the organ; or else, 3.

the inflammation degenerates into a gangrene, or sphacelus; or lastly, into a hard tumour, commonly called a scirrhus, which grows more compact in the part affected, as the inflammation remits or goes off.

As to the resolution and dispersion of an inflammation, that is usually practicable, when it is only of a milder kind, in a sound habit of body, when the blood is not yet too viscid nor vehement in its motion; and this treatment we have delivered already under the article DISPERSION.

But suppuration follows, when the inflammation is more violent, the circulation more rapid, but yet the mass of blood somewhat temperate, and without much acrimony: the treatment of an inflammation that terminates in a suppuration, the reader will find delivered under the articles SUPPURATION, ABSCESS, &c.

When the forementioned symptoms are much more violent, and when the blood is at the same time more acrimonious and rapid than it ought to be, the inflammation generally terminates in a gangrene, the nature and treatment of which see under the article GANGRENE. But if the inflamed part be full of glands, and the blood very thick, glutinous, and inspissated, the small blood-vessels are then so strongly stuffed up with the glutinous blood, that they are compacted together, the parts lose their sensation, and are converted into a hard tumour, which is thence called a scirrhus. See the article SCIRRHUS.

INFLAMMATION *in the breasts*, a disorder most incident to child-bearing women, and almost constantly happens in a few days after their delivery.

If the milk should be propelled too plentifully and forcibly into the breast, which at such times frequently happens; and if the mother should then be seized with cold, fear, anger, or a sudden perturbation of mind, the sanguiferous and lactiferous vessels being thence obstructed, the breasts must then become inevitably tumid, which will be attended with great heat, redness, resistance, and violent pain. The same accident often happens to women that give suck even a long time after their lying in, and is sometimes the case of those who have no milk, all proceeding from the causes already mentioned; and Heister gives us an instance of a man's breast being in-

flamed by means of a great fright. These inflammations do not, according to that author, always happen to be equally intense and violent; for sometimes it seizes the whole breast; sometimes only one side; and at other times occupies only a small part of the breast: sometimes the inflammation lies very near the skin; at other times very deep; and at one time it has urgent symptoms, and at another, it sits easy on the part.

This disorder may be speedily removed in women of condition, and such as do not suckle their children, if some of the plaster of *Sperma ceti* spread on linnen be applied warm all round the breast soon after parturition; being perforated in the middle, to transmit the papilla or nipple; the accession of the milk being also repelled by a very strait bandage. Among the internal remedies, the most proper are such as bring down the lochia puerperarum, when they do not flow in sufficient plenty of themselves: the principal remedies for this purpose are the essence of myrrh, amber, the essence of saffron, elixir proprietatis, &c. Lastly, with respect to the proper drink, it must be carefully observed to diminish the quantity of milk by smallness and poverty of the meat and drink, upon which account the patient should be recommended to drink small broth, tea, or the like watry liquors: and if the mother be desirous of suckling the infant, there can be no better preservative against the inflammations of the breasts. But when the inflammation is fixed, the cure must be attempted either by dispersion or suppuration, for the method of which see **DISPERSION, and SUPPURATION.**

But if it happens that the tumour will neither yield to dispersion nor suppuration, and is in danger of turning to a scirrhus, or cancer, the patient must be kept in good spirits, and the plaster of *Sperma ceti* be constantly retained on the tumour, by which means it will probably either grow less, or else vanish.

For other kinds of external inflammations, see the articles **FURUNCLE, ERYSIPELAS, PARONYCHIA, BUBO, PAROTIS, &c.**

But internal inflammations, or such whose cure is to be expected chiefly from the use of internal remedies, are in particular as follow.

**INFLAMMATION of the bladder**, that attended with an acute, burning, pressing pain, in the region of the pubes, a fever,

and a continual tenesmus, or desire of going to stool, and a perpetual striving to make water.

Other symptoms of this disease are a rumbling of the bowels, griping pains, great anxiety of the precordia, difficult breathing, want of appetite, and vomiting, coldness of the extreme parts, a hard, quick, unequal, contracted pulse, inquietude, and sometimes convulsions.

There is another kind which is more superficial, and is either rheumatic or erysipetulous, in which the fever is more easily and speedily cured, by promoting a diaphoresis; and persons in years, who are affected with the scurvy, gout, rheumatism, or violent head-achs, are most subject to it, especially if they catch cold from a north wind. The former arises commonly from the stoppage of the menses, bleeding, piles, or other usual sanguinary evacuations, and not seldom from a virulent gonorrhœa, unskillfully suppressed by astringents; or when treated by medicines of too sharp and hot a nature.

This disease is mortal, if it terminates in an ulcer, or mortification: the latter is immediate death.

The cure must be attempted, says Hoffman, with bleeding in the foot, if a suppression of the menses or hæmorrhoidal flux be the cause. If it proceeds from the scurvy, &c. recourse must be had to gentle diaphoretics, diluents, and remedies which obtund the acrimony of the humours, such as decoctions of the root of scorzonera, china, skirrets, and fennel. Also infusions in the manner of tea of the tops of yarrow, flowers of mallows, winter cherries, and seed of daucus made with milk, and sweetened with syrup of marsh-mallows. To these may be added emulsions of the four cold seeds. If the patient is costive, manna will be proper with antimoniated nitre, to which rhubarb may be joined, as occasion requires. If the disease is violent, diaphoretic powders with nitre, in a larger proportion than ordinary, as also five grains of saffron, and two of camphire, with the emulsions aforesaid. Externally antispasmodics and gentle discutients will be proper; for which purpose it was Hoffman's method to apply bladders, filled with a decoction of emollient flowers. If the tenesmus and difficulty of urine arise from spasms, there is nothing better than the vapours of a decoction in milk of the flowers of melilot, elder, chamomile,

chamomile and mallows, and the tops of yarrow. This decoction may be put into a close-stool, and the patient sit over it.

**INFLAMMATION of the brain.** See the article PHRENSY.

**INFLAMMATION of the diaphragm.** See the article PARAPHRENITIS.

**INFLAMMATION of the eyes.** See the article OPHTHALMIA.

**INFLAMMATION of the fauces.** See the article QUINSEY.

**INFLAMMATION of the intestines,** according to Boerhaave, is an inflammation contracting the intestines, and stopping up the passage thro' them ; attended with a vehement fixed, burning pain, which is irritated by things taken inwardly. When the inflammation is in the upper part of the intestines, the stomach will be greatly distended with wind. When the pain is exasperated, it produces convulsions of the diaphragm and abdominal muscles, vomiting, and painful inflations, with rumblings and sharp griping pains, which may bring on the iliac passion, or twisting of the guts. Hoffman says, that when there is a burning pain in the abdomen, with a preternatural heat of the whole body, as also a quick pulse, loss of strength, anxiety and inquietude, the seat of the disease may justly be suspected to be in the intestines. If the pain is above the navel, and below the stomach, attended with a fever, nausea, and reaching, it is a sign that that part of the colon is affected, which lies beneath the stomach, and is extended from the right to the left side. If the pain lies in the right hypochondrium, under the spurious ribs, it shews that part of the colon to be inflamed where it joins with the ilium. When the complaint is on the left side, under the loins, where the psoas muscle is placed, it is a sign that the colon, and that part of the mesentery joined thereto, is the seat of the disease, especially when it adheres to the peritonæum : but when the pain is in the middle of the abdomen about the navel, it shews the small guts are certainly affected. In all which cases the pain is supposed to be attended with a fever.

Arbuthnot advises, that this disease be carefully distinguished from a colic, proceeding from a cold cause, because what is good for the latter is poison in the former. It must have a speedy remedy, or it will soon, according to that writer, end in the iliac passion, or a mortifi-

cation. Besides copious bleeding, he thinks, there is scarcely any other method of cure than fomenting and relaxing the bowels with emollient liquids taken warm, both by the mouth and in clysters, and this every hour. Warm fomentations, or young, vigorous, and sound animals applied to the body are extremely beneficial.

Boerhaave directs, that the patient should only be nourished with broth, in which gently detergent roots have been boiled.

After bleeding and clysters, if the pain continues violent, Hoffman is of opinion that there will be no manner of danger in giving opiates, by which means the excruciating pain will be alleviated, and the spasms appeased, and a breathing sweat will follow. When this is done, and the fever abated, there will be no occasion to continue the dilating, relaxing and moistening medicines, but rather the nervous and corroborating ; such as the preparations of amber, especially the salt and tincture ; the former of which may be given in a bolus from six to sixteen grains, and the latter from twenty to eighty drops, in any convenient vehicle.

If the patient survives three days, and the acuteness of the pain abates with a chillness and shivering throughout the body, it is a sign of a suppuration, and within fourteen days the imposthume will break, and if it falls into the cavity of the abdomen, it will corrupt the whole mass of fluids, putrify the viscera, and turn to an ascites, whence the patient will die of a consumption. In this case, Boerhaave and Arbuthnot recommend whey and chalybeat waters, as likely to prove most beneficial. The imposthume may also turn either to a gangrene or scirrhus, both which are mortal.

**INFLAMMATION of the kidneys.** See the article NEPHRITIS.

**INFLAMMATION of the liver.** When the liver is inflamed, it compresses the stomach, diaphragm, and the neighbouring viscera of the abdomen ; it stops the circulation of the fluids, hinders the generation and excretion of the gall, and all digestion ; it produces a great many bad symptoms, as the jaundice, with all the diseases depending thereon. See the article HEPATITIS.

A fever, an inflammation, and pungent pain on the region of the liver, and diaphragm, a tension of the hypochondria, yellowness of the skin and eyes, and a

saffron-coloured urine, are signs of an inflammatory disposition of the liver. See the article JAUNDICE.

This disease terminates as other inflammations ; being cured by resolution, concoction, and excretion, of the morbid matter ; or it terminates in an abscess, icterhus, or gangrene. See ABSCESS, &c. During the first state, Arbuthnot tells us, that a warm regimen and saffron, which some reckon a specific, are improper. On the other hand, that cooling, resolving liquors, taken inwardly, as whey and sorrel boiled in it, outward fomentations, and frequent injections of clysters, bathing and frictions, relax and render the matter fluid. Honey, with a little rhenish wine and vinegar, the juices and jellies of some ripe garden-fruits, and those of some lactescent plants, as endive, dandelion, and lettuce, are resolvent. Violent purging hurts ; gently relaxing the belly relieves, diluents with nitrous salts are beneficial, or tamarinds boiled in warm water, or whey. The feverish matter is often carried off by urine, and therefore diuretics not highly stimulating are proper.

If the inflammation be recent, extremely violent, and without any signs or hopes of resolution, concoction, and excretion, Boerhaave advises, that the case be treated with the same cautions and remedies as is directed in pleuritis, and other similar inflammatory disorders ; such remedies only excepted, as the situation of the part affected cannot admit of, except only, that all antiphlogistic fluids, either drank or injected by clysters, are particularly serviceable in the case before us.

*INFLAMMATION of the lungs.* See the article PERIPNEUMONY.

*INFLAMMATION of the pleura.* See the article PLEURISY.

*INFLAMMATION of the stomach* is known by a burning, fixed, and pungent pain in the stomach, which is exasperated at the instant any thing is taken into it, and is succeeded by a most painful vomiting and hiccough. There is, besides, an inward heat, anxiety, and a tensile pain about the precordia, an acute continual fever, great thirst, difficult breathing, inquietude, tossing of the body, coldness of the extreme parts, a hard, contracted, quick, and sometimes, unequal pulse. In the medical essays, we have an instance of this disease being attended with a hydrophobia. See HYDROPHOBIA.

Boerhaave says, that this disease, if not suddenly cured, is generally mortal : therefore, that as soon as it is discovered, plentiful bleeding is necessary, that the patient's drink should be very soft, antiphlogistic, and emollient ; and also that clysters of the same kind should be administered to him.

Arbuthnot advises, that the patient should totally abstain from every thing that has acrimony in it ; even the cooling nitrous salts, which are beneficial in other inflammations, irritate too much. Vomits, cordials, and spirituous liquors, are little better than poison : milk generally curdles. Aliments must be given frequently, and by a spoonful at a time, for any distension increases the inflammation. A thin gruel of barley, oatmeal, whey, with a very little sugar, or honey, or chicken broths, are proper aliments : whey-emulsions, barley-water, and emollient decoctions are proper drinks. If poisons of the caustic kind or metallic medicines ill prepared cause the inflammation, oily fat things are proper, as new milk, cream, oil of sweet almonds, or oil of olives taken often and plentifully, according to Hoffman. If in the cholera morbus an inflammation is apprehended, he advises absorbents and burnt hart's horn, with gelatinous decoctions of calves and neats feet, or hartshorn-gellies, and water-gruel. Outwardly he recommends the following liniment as useful in all cases ; take oil of sweet almonds, two ounces ; camphire, one dram ; make a liniment, with which anoint frequently the precordia, applying a hot linnen-cloth over it. The following epithem he recommends as an excellent discutient and sudorific. Take of the vinegar of roses, two ounces ; spirit of wine camphorated, two drams ; tincture of saffron, and tincture of castor, of each one dram ; nitre, half a dram : let this epithem be applied warm to the region of the stomach.

If there happens an imposthume, honey, and even honey of roses, taken inwardly, is, according to Arbuthnot, a good cleanser ; and decoctions of comfrey-roots, healing.

*INFLAMMATION of the womb or uterus,* appears from extraordinary heat and a fixed pain in the groin, with an acute fever, a pain in the loins and belly, an inflation of the abdomen, a stimulus to make water and to go to stool, heat, and a difficulty of urine.

Other

Other symptoms, according to Astruc, are a tumour, pain, heat, and tension of the hypogastric region, redness of the os uteri, and great heat of the vagina. If the fore-part of the uterus is affected, there is a dysury; if the back part, a tenesmus; frequent faintings and cardialgia, a burning fever; or, if the inflammation is violent, a lypiria, in which the external parts or extremities are cold, and the internal burn, and the pulse is imperceptible; a delirium and phrensy; the breasts swell, in proportion as the inflamed uterus.

Hoffman distinguishes this disease into the superficial and more profound. He says, that it is easily formed in child-bed women, and frequently accompanies the milk-fever, and may be cured in a few days if rightly managed. But that when it is more intense, and attended with grievous symptoms without remission, it kills on the seventh, ninth, or eleventh day; a white miliary fever generally supervenes, which is the worst omen, as it shews a mortification of the uterus. See the article MILIARY FEVER.

If the inflammation is not resolved, it generally ends in a mortification, ulcer, cancer, or scirrhus. See the article MORTIFICATION, &c.

Women in childbed sometimes have the womb inflamed, from the fault of an unskilful midwife, or hard labour; or the lochia being stopped by pains or hysterical spasms, dread or cold: wherefore proper precautions should be taken to prevent it, for which purpose Hoffman advises to keep them under a gentle diaphoretic regimen, and to allay the almost febrile heat; to which end oil of almonds alone is very proper, or with a fourth part of sperma ceti given daily to half an ounce in chicken-broth: externally the whole abdomen should be anointed with oil of dill, camomile and white lillies, of each an ounce; oil of caraways, a dram; or a dram of camphire; laying a warm napkin doubled over the same. The tumult being thus appeased, the lochia are to be promoted with pills made of bitter extracts, temperate resinous gums and aloes well corrected, of which fifteen grains is a dose, morning and evening, to be continued from five to eight days: these are also good when the after-birth, or part of it is retained. If there is a fever, the belly is distended with wind, the lochia are retained, and the spasms tend to the upper parts; then

the last-mentioned author directs the patient to be bled in the foot, and to render the stagnating blood fluxile by the following mixture. Take chervil-water, the carduus benedict. scordium, elder-flowers, acacia, and distilled vinegar, each an ounce and half; crabs-eyes, a dram and a half; powder of antimony, half a dram; spirit of nitre dulcified, twenty drops; syrup of card. benedict. two drams; let the patient take two or three spoonfuls every two hours. The drink may be chicken-broth with scorzonera-root, succory and shavings of hartshorn boiled therein.

In women out of child-bed, the inflammation generally happens in the neck of the uterus and the vagina, and then besides the foregoing things, the same author recommends the application of epithems to the pubes, uterine injections, pessaries, and suppositories: the epithem may be of arquebuse water, four ounces; essence of saffron, camphorated spirit of wine, of each two ounces; nitre, a dram, dissolved in elder-flower water; and, as circumstances require, mixt with vinegar of rue, or scordium, and applied with a double cloth. The injection may consist of asses-milk with flowers of elder, myrrh, and saffron, and a little nitre may be added to the decoction. The tenesmus may be appeased with emollient half baths, or with one ounce of oil of sweet almonds, and twelve grains of saffron, injected into the anus. These remedies are useful in case of a suppuration.

If it proceeds from external causes, and there is a fever, pain in the groin, difficulty of urine, and costiveness, bleed first in the arm, and then in the foot; give a clyster, and apply melilot-plaster, two ounces; sperma ceti, half an ounce; gum ammoniac, two drams; saffron, one dram; camphire, half a dram, mixt together; not omitting gentle diaphoretics and discutients.

**INFLAMMATORY DISEASES.** To these may be referred the several diseases mentioned in the preceding article, either attended with a fever, as well as lesser inflammations without a fever; besides all chronic disorders arising from inflammations, the chief whereof are old coughs, consumptions and the rheumatism, without a fever. See COUGH, &c.

Hoffman lays down this as an axiom, for all practitioners to observe; that in all inflammatory diseases of the nervous and membranaceous

membranaceous parts, as in the phrenzy, pleurisy, in the inflammation of the liver, stomach, intestines, and bladder, nothing is more pernicious, or brings on death more suddenly, than opiates taken inwardly.

**INFLAMMATORY FEVERS** are distinguished into two stages; the first, whilst the pulse continues hard, in which it is proper to bleed; the second, when the inflammatory symptoms still remaining, the pulse is too low for that evacuation; in this state blisters are the chief remedy, and which, except in a few singular cases, are not to be used sooner. If the blisters are large, it is better to apply them gradually, than many at a time. See the articles **FEVER** and **INFLAMMATION**.

**INFLECTION**, or *Point of INFLECTION*, in the higher geometry, is the point where a curve begins to bend a contrary way. See the article **FLEXURE**.

To determine the point of inflection in curves, whose semi-ordinates  $CM$ ,  $Cm$  (pl. CXLVI. fig. 2. n<sup>o</sup> 1. and 2.) are drawn from the fixed point  $C$ ; suppose  $CM$  to be infinitely near  $Cm$ , and make  $mH = Mm$ ; let  $Tm$  touch the curve in  $M$ . Now the angles  $CmT$ ,  $CMm$ , are equal; and so the angle  $CmH$ , while the semi-ordinates increase, does decrease, if the curve is concave towards the center  $C$ , and increases if the convexity turns towards it. Whence this angle, or, which is the same, its measure will be a minimum or maximum, if the curve has a point of inflection or retrogression; and so may be found, if the arch  $TH$ , or fluxion of it, be made equal to 0, or infinity. And in order to find the arch  $TH$ , draw  $mL$ , so that the angle  $TmL$  be equal to  $mCL$ ; then if  $Cm = y$ ,  $mr = x$ ,  $mT = t$ , we shall have  $y : \dot{x} ::$

$t : \frac{tx}{y}$ . Again, draw the arch  $HO$  to

the radius  $CH$ ; then the small right lines  $mr$ ,  $OH$ , are parallel; and so the triangles  $OLH$ ,  $mLr$ , are similar; but because  $HI$  is also perpendicular to  $mL$ , the triangles  $LHI$ ,  $mLr$ , are also similar:

whence  $t : \dot{x} :: y : \frac{xy}{t}$ ; that is, the

quantities  $mT$ ,  $mL$ , are equal. But  $HL$  is the fluxion of  $Hr$ , which is the distance of  $Cm = y$ ; and  $HL$  is a negative quantity, because while the ordinate  $CM$  increases, their difference  $rH$  decreases; whence  $\dot{x}x + \dot{y}y - \dot{y}\dot{y} = 0$ , which

is a general equation for finding the point of inflection, or retrogradation.

**INFLECTION**, in grammar, the variation of nouns and verbs, by declension and conjugation. See **DECLENSION** and **CONJUGATION**.

**INFLEX LEAF**, among botanists, one whose point bends inward, towards the stem of the plant. See the article **LEAF**.

**INFLUENCE**, a quality supposed to flow from the heavenly bodies, either with their light or heat; to which astrologers idly ascribe all sublunary events.

**INFLUENT FEVER**, the same with a nervous one. See the article **FEVER**.

**INFORCED**, and **INFORCEMENT**. See **REINFORCED** and **REINFORCEMENT**.

**IN FORMA PAUPERIS**, in law. See the articles **FORMA**.

**INFORMATION**, in law, is nearly the same in the crown-office, as what in our other courts is called a declaration. It is sometimes brought by the king, or his attorney-general, or the clerk of the crown-office; and at other times by a private person, who informs or sues, as well for the king as himself, upon the breach of some popular statute, in which a penalty is given to the party that will sue for it. It differs from an indictment, which must be found by the oaths of ten men at least; for an information is only the allegation of the person that brings it. An information lies for offences at common-law, as batteries, conspiracies, nuisances, contempts, libels, seditious words, &c. and in many cases by statute, on which the offender is rendered liable to a fine, or other penalty: an information also lies against the inhabitants of a town, for not repairing the highways, for going armed in affray of the peace, &c. and in general for any offence against the public good, or the principles of justice: but where an information brought is only for vexation, the defendant may bring an information against such vexatious informer. All informations brought by informers on penal statutes, where a certain sum is allowed him, must be brought in the county where the offence was committed, and within a year after the fact was done; but a party aggrieved, not being a common informer, is not obliged to bring his information in the proper county; for he may lay it in what county he pleases. If an informer, without leave of the court, compounds with the defendant, he forfeits 10*l*. and may be set in the pillory.

Where

Where an information is exhibited for trespass, battery, &c. to which the defendant appears and pleads to issue, and the prosecutor does not bring on the trial within a year after the issue joined; or if a verdict pass for the defendant, the court is to allow the defendant costs, unless it appears that there was reasonable cause for the information. 4 & 5 Will. & Mar. cap. xviii. After a plea is put in to an information for any offence, the defendant may be so far indulged by the court, as to appear by his attorney. A replication to an information on a special plea in the courts of Westminster, must be made by the attorney-general; but if it be before the justices of assize, is must be made by the clerk of assize: yet the replication to a general issue on an information *qui tam* (that is, at the suit both of the king and the party) in the courts of Westminster, may be made in the name of the attorney-general only; and in such actions, most of the precedents are for the replication to be made by the plaintiff, and a demurrer may be made to an information *qui tam*, without the attorney-general.

**INFORMER**, a person that informs against or prosecutes another, upon any penal statute. See the preceding article.

**INFORMATUS NON SUM**, in law. See the article **NON SUM INFORMATUS**.

**INFORMIS**, something irregular in its form, or figure. See the article **FIGURE** and **FORM**.

Hence, *stellæ informes*, in astronomy, are such of the fixed stars as are not reduced into any constellation. See the articles **CONSTELLATION** and **STAR**.

**INFRACTION**, a term chiefly used to signify the violation of a treaty. See the article **TREATY**.

**INFRALAPSARIANS**, in church-history, an appellation given to such predestinarians, as think the decrees of God, in regard to the salvation and damnation of mankind, were formed in consequence of Adam's fall. See **PREDESTINATION**.

**INFRASCAPULARIS**, in anatomy, one of the depressor-muscles of the arm, which has its origin from the whole internal surface of the scapula, and its termination in the interior part of the humerus. See the article **DEPRESSOR**.

**INFRASPINATUS**, in anatomy, one of the abductor-muscles of the arm, which has its origin in the cavity below the spine of the scapula. See **ABDUCTOR**.

**INFULA**, in antiquity, a broad kind of fillet, made of white wool, which the priests used to tie round their heads. Hence Virgil, *Æn.* x. 538.

*Infula cui sacra redimibat tempora vittæ.*

**INFUNDIBULIFORM**, in botany, an appellation given to such monopetalous or one-leaved flowers, as resemble a funnel in shape, or which have a narrow tube at one end, and gradually widen towards the limb or mouth. There are two kinds of infundibuliform, or funnel-fashioned flowers; one of which is like an inverted hollow cone, and the other somewhat like a faucer, and thence called hypocrateriform. See **FLOWER**.

**INFUSION**, in pharmacy, a method of obtaining the virtues of plants, roots, &c. by steeping them in a hot or cold liquid.

Hot infusions are made by pouring boiling water, or any other menstruum, on the drugs whose virtues we would extract: thus, in order to obtain the common infusion of senna, take the leaves of senna, an ounce and a half; of crystals of tartar, three drams; of the lesser cardamom-seeds husked, two drams: boil the crystals of tartar in a pint of water till they are dissolved, then pour the water, while boiling hot, upon the senna and the rest; and when the liquor is cold, strain it off.

But all tinctures and infusions of ingredients, whose principal virtues depend upon their lighter or more subtil and spirituous parts should not be made by steeping them in a hot, but in a cold menstruum; and if such infusions be required rich and strong, they are to be made so, not by suffering the menstruum to be heated, or to remain long upon the ingredients, but by adding fresh ingredients several times to the same liquor, infusing them quick, and each time keeping out the ingredients that have been once used: by this means we shall procure the full virtues of simples, unaltered in their nature, yet exalted or concentrated to such a degree, that a few spoonfuls of the liquor shall contain the spirit or quintessence of a pound of the plant. This is an effect not to be expected from fire, which almost constantly alters the nature of things committed to it; nor could a valuable essence of violets, jacinth, lilies, borage-flowers, or any flower or plant of an extremely fine odoriferous spirit, be procured by heat, as it readily  
may

may by steeping these flowers in cold water, cold vinegar, cold wine, and the like; and frequently pouring the tincture upon fresh flowers, till the liquor becomes strongly impregnated.

**INGANNO**, in music, is when having done every thing proper for ending a cadence, a mark of silence is placed instead of the final, which the ear naturally expects, and is deceived. See **CADENCE**.

**INGELSHEIM**, a town of Germany, in the palatinate of the Rhine, eight miles south-west of Mentz: east longit.  $7^{\circ} 40'$ , north lat.  $50^{\circ}$ .

**INGENUITAS REGNI**, antiently signified the commonalty of the realm; and it is said, that this title was likewise given to the barons and lords of the king's council.

**INGENUOUS**, *ingenuus*, in roman antiquity, an appellation given to persons born of free parents, who had never been slaves: for the children of the liberti, or persons who had obtained their liberty, were called libertini, not ingenui; this appellation of ingenuous being reserved for their children, or the third generation.

**ENGINEER**, or **ENGINEER**. See the articles **ENGINEER** and **GUNNERY**.

**INGLUVIES**, the crop or craw of granivorous birds, serving for the immediate reception of the food, where it is macerated for some time, before it is transmitted to the true stomach.

**INGOLSTAT**, a town of Germany, in the circle of Bavaria, situated on the river Danube, thirty miles west of Ratisbon: east lon.  $11^{\circ} 30'$ , and north lat.  $48^{\circ} 45'$ .

**INGOT**, a mass of gold or silver, melted down and cast in a mould, but not coined or wrought. See **GOLD** and **SILVER**.

**INGRAFTING**, or **GRAFTING**, in gardening. See **GRAFTING**.

**INGRAILED**, or **ENGRAILED**, in heraldry. See the article **ENGRAILED**.

**INGRAVING**, or **ENGRAVING**. See the article **ENGRAVING**.

**INGREDIENTS**, in pharmacy, whatever simple medicines enter the composition of a compound one.

**INGRESS**, in astronomy, signifies the sun's entering the first scruple of one of the four cardinal signs, especially aries.

**INGRESS**, **EGRESS**, and **REGRESS**, in law, words frequently used in leases of lands, which signify a free entry into, a going out of, and returning from some part of the premises leased to another.

**INGRESSU**, in law, a writ of entry, termed also a *præcipe quod reddat*. See the articles **ENTRY** and **PRÆCIPE**.

**INGRIA**, a province of Russia, bounded by the lake Ladoga, the river Nieva, and the gulph of Finland on the north, by Novogorod on the east and south, and by Livonia on the west.

**INGROSSER**, one who buys up great quantities of any commodity, before it comes to market, in order to raise the price.

If a person gets into his hands, otherwise than upon a demise or grant of lands, any corn growing, butter, cheese, fish, or other victuals, within the kingdom, with intent to sell the same again at a high price, he shall be deemed an unlawful ingrosser. But the buying of corn to be ground into meal, or for making of starch, in order to sell it again; or barley and oats to make malt and oatmeal, are not included in this statute. Foreign corn and victuals, except fish, are also exempted; as are licensed badgers, fishmongers, butchers, poulterers, &c. that buy in their own ways of dealing, and are not guilty of forestalling, or selling the same again at unreasonable prices by retail. A merchant who imports victuals or merchandize into this kingdom, may dispose of the same in gross; yet the person who purchases them of him, may not do so, since by that means the price would be enhanced. If this was allowed, a monied man might ingross into his hands a whole commodity, with an intent to sell it again at what price he thought proper: but the ingrossing the whole of any commodity is indictable, and the offender, whether he sell any part of them or not, is subject both to a penalty and to corporal punishment, by common law.

**INGROSSER** also signifies a clerk or person who copies records, deeds, or other instruments of law, on skins of parchment.

**INGROSSING** of a fine, is the chirographer's making the indentures of a fine, and also the delivery of it to him on whom it is levied. See the article **CHIROGRAPHER**.

**INGUEN**, in anatomy, the same with what is otherwise called groin, or pubes. See the article **PUBES**.

**INGUINAL**, in anatomy, &c. any thing belonging to the groin. Hence, **INGUINAL HERNIA** is a hernia in that part called by surgeons bubonocoele. See the article **BUBONOCOELE**.

**INHARMONICAL**

**INHARMONICAL RELATION**, in music, is much the same with discord. See the articles **DISCORD** and **RELATION**.

**INHERENCE**, in philosophy, a term sometimes used to denote the connection of an accident with its substratum, or substance. See the articles **ACCIDENT** and **SUBSTANCE**.

**INHERITANCE**, a perpetual right or interest in lands, invested in a person and his heirs.

The term inheritance is used, not only where a person has lands or tenements by descent; but where he becomes seized in fee-simple, or fee-tail, by purchase. The inheritances mentioned in our law are either corporeal or incorporeal: the corporeal relate to lands, tenements, &c. that may be touched or handled; and the incorporeal, to such rights as are annexed to corporeal inheritances, as advowsons, tithes, annuities, offices, &c. There is likewise another inheritance, which is termed several, that is, where two or more hold lands or tenements severally; as when two persons hold to them and the heirs of their two bodies; in which case these two have a joint estate during their lives, but their heirs have several inheritances.

According to the law of inheritances, the first child is always preferred, and the male before the female; and he that has the whole blood, before another that has only a part of the blood of his ancestor.

As to goods and chattels, they cannot be turned into an inheritance.

**INHIBITION**, a writ to forbid a judge's proceeding in a cause that lies before him.

This writ generally issues out of an higher court-christian to an inferior, and is of much the same nature as a prohibition. See the article **PROHIBITION**.

**INHUMATION**, in chemistry, a method of digesting substances by burying the vessel, in which they are contained, in horse-dung or earth. See the article **DIGESTION**.

**INJECTION**, in surgery, the forcibly throwing certain liquid medicines into the body, by means of a syringe, tube, clyster-pipe, or the like.

Many disorders are very difficultly, if at all curable, unless some proper liquor be injected into the parts affected; which is performed by drawing the liquor into the syringe, and forcing it out again into the disordered parts. In doing this, one caution is extremely necessary, *viz.* to apply the instrument very carefully, and to

be mindful that the liquor you inject be not too hot or cold.

As for injections in the gonorrhoea, disorders of the uterus, &c. See the articles **GONORRHOEA**, **FLUOR ALBUS**, **SYRINGE**, &c.

Surgeons also describe the manner of injecting liquors into the veins of living men, or other animals. A vein being opened, usually in the arm, as in bleeding, the small pipe of the syringe is introduced, and the liquor is injected or forced into the vein upwards, towards the heart; which being done, the orifice is to be dressed in the same manner as after bleeding.

Though this practice is at present disused, on account of the bad consequences attending it; yet the injection of proper medicines in apoplexies, quinzies, the hydrophobia, &c. wherein no medicine at all can be taken by the mouth, deserves to be tried.

**Anatomical INJECTION**, the filling the vessels with some coloured substance, in order to make their figures and ramifications visible.

For this purpose, a fine red injection is prepared thus: pour a pint of oil of turpentine on three ounces of vermilion, stir them well together, and then strain all through a fine linnen-cloth. If a green injection is wanted, distilled verdigrease may be used instead of the vermilion.

A coarse injection may be made of one pound of tallow, five ounces of white-wax, three ounces of oil of olives, melted together, and adding two ounces of venice-turpentine; and when this is dissolved, three ounces of vermilion or verdigrease, are to be thoroughly mixed with the other ingredients, and the whole strained through a linnen-cloth.

For the manner of preparing bodies to be injected, see the article **PREPARATION**.

**INITIATED**, in antiquity, a term chiefly used in speaking of persons who were admitted to a participation of the sacred mysteries among the heathens. See the article **MYSTERY**.

**INJUNCTION**, in law, is a writ or kind of prohibition granted in several cases; and for the most part grounded on an interlocutory order or decree, made in the court of chancery or exchequer, for staying proceedings either in courts of law, or ecclesiastical courts. An injunction is obtained either for not appearing and putting in an answer in due time, upon equity confessed, or upon matter that ap-

pears on record. If it be for staying suits in other courts, it is grantable on suggestion of some matter, by which the plaintiff is rendered incapable of making his defence there, either for want of witnesses, from his being sued at law for what in equity he ought not to pay, or because the court, in which he is sued at law, acts erroneously, or denies him the benefit of the law, &c. Sometimes it issues on the defendant's non-appearance, to give a complainant possession of lands, &c. and sometimes for staying waste, in which last case an affidavit must be first made, of waste committed in lands, &c. This writ is directed not only to the party himself, but to all and singular his counsellors, attorneys, and solicitors; and, therefore, if any attorney, after having been served with an injunction, proceeds against the party that obtained it, the court, out of which it issued, will commit him to the fleet-prison for contempt: but as an injunction ought not to be granted in a criminal case, so whenever this happens, the court of king's bench may break it, and protect those that proceed in contempt of it.

**INJURY**, any wrong done to a man's person, reputation, or goods. See the articles **ASSAULT**, **TRESPASS**, &c.

**INK**, *atramentum*, a black liquor generally made of an infusion of galls, copperas and a little gum arabic. See the article **GALLS**, **COPPERAS**, &c.

To make a very good ink for writing: take three ounces of good galls, reduced to powder, which infuse in three pints of river or rain-water, setting it in the sun or a gentle heat, for two days; then take common copperas, or green vitriol, three ounces, powder it, put it into the infusion, and set it in the sun for two days more; lastly, shake it well, and add an ounce of good gum arabic.

To make the London powder-ink: take ten ounces of the clearest nut-galls, which reduce to a fine powder; then add two ounces of white copperas, four ounces of roman vitriol, and of gum arabic or sandarach an ounce; pound and sift them very fine. This powder, though whitish itself, will, when put into water, turn it to a good black ink: an ounce of the powder serves to make a pint of ink.

To make a shining ink: take gum arabic and roman vitriol, of each an ounce; galls well bruised, a pound; put them into rape-vinegar, or vinegar made of clear small beer; set them in a warm

place, stir them often till the liquor becomes black, and then add to a gallon of this preparation an ounce of ivory-black, and a quarter of a pint of seed-lac-varnish.

To make a shining japan or china ink: take an ounce of lamp-black, and clarify it in an earthen pipkin, to take out the dross; two drams of indigo; half a dram of peach-black; one dram of black endive, burnt; reduce them to a very fine powder, and then take a moiety of fig-leaf-water, another part of milk, and a very little gum arabic, and mixing all the ingredients well together, make them up for use.

**Printing Ink** is made by boiling or burning linseed-oil till it is pretty thick, adding a little rosin to it, while hot, and then mixing this varnish with lamp-black.

Printing-ink, on its being imported from abroad, pays 7s. 8  $\frac{4}{10}$ d. the hundred weight, of which 6s. 9d. is repaid on its exportation.

**INK** is also an appellation given to any coloured liquor, used in the same manner as the atramentum, or black ink; as red, green, blue, yellow, &c. inks.

Red ink is made thus: take wine-vinegar a pint; rasings of brazil, one ounce; alum, half an ounce; boil them gently, and add five drams of gum arabic: dissolve the gum, strain the ingredients, and keep the liquid for use.

Green ink is made by boiling verdigrease with argol, in fair water, and adding a little gum arabic.

Blue ink is made by grinding indigo with honey and the white of eggs, and making it fluid with water.

Yellow ink is made by an infusion of saffron in water, with a little alum and gum arabic.

**Sympathetic Ink**, a liquor with which a person may write, without the letters appearing, till some means be taken to render them legible.

Of this kind are the glutinous juices of plants, or any other thick and viscid fluids, provided they have no remarkable colours themselves; for being written on white paper, nothing will appear, till some fine powder of any coloured earth is thrown over the paper, whereby the letters become legible: the reason of this is evident, as the powder sticks only to the letters formed by the invisible but viscid liquor.

Another sort of sympathetic inks are made of infusions, the matter of which easily

easily burns to a charcoal: thus, if a scruple of sal armoniac be dissolved in two ounces of fair water, letters written therewith will be invisible till held before the fire; for the sal armoniac being burnt to a charcoal, by a heat not strong enough to scorch the paper, the letters are thereby rendered visible.

Another sort of sympathetic inks are made of a solution of lead in vinegar, and a lixivium of lime and orpiment; for if a letter be written with the former, nothing will appear: but to conceal the affair still more, some different subject may be written above it, with a black ink made of burnt cork and gum-water; then, if a piece of cotton, wetted with the said lixivium, be rubbed over the paper, the sentence that was visible will disappear, and the invisible one, before written with the solution of lead, will be seen in its place very black and strong.

**INLAGATION**, the restoring an outlawed person. See **OUTLAWRY**.

**INLAND bills of exchange**, those payable in distant parts of this kingdom.

If any such bills be lost, or miscarry, within the time limited for payment, the drawer is obliged to give other bills of the same tenor; security being given, if demanded, in case the lost bill be found again. In case the party on whom an inland bill of exchange shall be drawn, shall refuse to accept the same, the party to whom payable shall cause such bill to be protested for non-acceptance, as in case of foreign bills; for which protest he shall pay two shillings, and no more. See **BILL**, **ACCEPTANCE**, **PROTEST**, &c.

**INLAYING**, the art of marquetry. See the article **MARQUETRY**.

**INN**, a place appointed for the entertainment and relief of travellers.

Inns are licensed and regulated by justices of the peace, who oblige the landlord to enter into recognizances for keeping good order. If a person who keeps a common inn, refuses to receive a traveller into his house as a guest, or to find him victuals and lodging, on his tendering a reasonable price for them, he is liable to an action of damages, and may be indicted and fined at the king's suit. The rates of all commodities sold by inn-keepers, according to our antient laws, may be assessed: and inn-keepers not selling their hay, oats, beans, &c. and all manner of victuals, at reasonable prices, without taking any thing for litter, may be fined and imprisoned, &c.

by 21 Jac. I. cap. xxi. Where an inn-keeper harbours thieves, persons of an infamous character, or suffers any disorders in his house, or sets up a new inn where there is no need of one, to the hindrance of antient and well governed inns, he is indictable and fineable; and by statute, such inn may be suppressed. Action upon the case lies against any inn-keeper, if a theft be committed on his guest, by a servant of the inn, or any other person not belonging to the guest; though it is otherwise where the guest is not a traveller, but one of the same town or village, for there the inn-keeper is not chargeable; nor is the master of a private tavern answerable for a robbery committed on his guest: it is said, that even though the travelling guest does not deliver his goods, &c. into the inn-keeper's possession, yet if they are stolen, he is chargeable. An inn-keeper is not answerable for any thing out of his inn, but only for such as are within it; yet where he, of his own accord, puts the guest's horse to grass, and the horse is stolen, he is answerable, he not having the guest's orders for putting such horse to grass. The inn-keeper may justify the stopping of the horse, or other thing of his guest, for his reckoning, and may detain the same till it be paid. Where a person brings his horse to an inn, and leaves him in the stable, the inn-keeper may detain him till such time as the owner pays for his keeping; and if the horse eats out as much as he is worth, after a reasonable appraisement made, he may sell the horse, and pay himself: but when a guest brings several horses to an inn, and afterwards takes them all away except one, this horse so left may not be sold for payment of the debt for the others; for every horse is to be sold, only to make satisfaction for what is due for his own meat.

**INNS of court**, are colleges in London, for the study of the laws of England, with all conveniencies for the lodging and entertainment of the professors and students.

In these colleges, there are not only such students as study the laws of this kingdom, in order to render themselves capable of practising in the courts of law at Westminster; but also such other gentlemen of fortune as apply themselves to this study, in order to know and vindicate their rights, and to render themselves more serviceable to their country.

Our inns of court, which are numerous, and justly famed for the production of men of learning, are governed by masters, principals, benchers, stewards, and other officers, and have public halls for exercises, readings, &c. which the students are obliged to attend and perform for a certain number of years, before they can be admitted to plead at the bar. These societies have not, however, any judicial authority over their members; but instead of this they have certain orders among themselves, which have, by consent, the force of laws: for lighter offences, persons are only excommunicated, or put out of commons; for greater, they lose their chambers, and are expelled the college; and when once expelled out of one society, they are never received by any of the others. The gentlemen in these societies may be divided into benchers, outer-barristers, inner-barristers, and students.

The four principal inns of court are the Inner-temple, Middle-temple, Lincoln's inn, and Gray's inn; the other inns are the two serjeant's inns; and the others, which are less considerable, are Clifford's inn, Symond's inn, Clement's inn, Lion's inn, Furnival's inn, Staple's inn, Thavies inn, Barnard's inn, and New-inn. These are mostly taken up by attorneys, solicitors, &c. but they belong to the inns of court, who send yearly some of their barristers, to read to them.

**INN-AND-INN**, a game on dice, very much practised at an ordinary, may be played by two or three, each having a box in his hand. There are four dice, and you may drop what you please, six-pences, shillings, &c. or guineas. Every inn, you drop; and every inn-and inn, you sweep all: likewise, if you throw out, if but two play, your adversary wins all; but if three play, the stake may be divided between the other two, or played for.

Here you are to observe, that out, is when you have thrown no doublets on the four dice; inn, is when you have thrown two doublets of any sort; and inn-and-inn, is when you throw all doublets, whether of any sort, or otherwise; as four aces, &c. or two aces, &c. and two of any other denomination. The battle may be for as much or as little as you please, and is not ended till every penny of that money be won: this seems just, since in a battle of ten pounds, a gentleman hath

been reduced to five shillings, and yet hath won the battle at last.

Like all other games, this too has its tricks; we shall only mention one instance by way of example: a gentleman who had spent the greater part of his patrimony, bethought himself how he should retrieve it; and having been a considerable loser by gaming, he fixed on this as the basis of his future settlement; accordingly he at length contrived a box, not screwed within as usual, which, nevertheless, was so well painted as to look exactly like a screwed box; it was likewise but half board wide at top, and, narrow at bottom, so that he had the dice wholly under his own management. In short, with this box, and the artful placing of the dice, he won a thousand pounds the first night, at the game of inn-and-inn; next night he won an estate of two hundred a year; on which he forswore all gaming for the future, well knowing how many have been ruined by it.

**INN**, in geography, a large river which rises in a mountain of the Alps, in the country of the Grisons, runs north-east through Tyrol and Bavaria, and discharges itself into the Danube.

**INN**, or **INNER**, in the manege, is applied differently according as the horse works to the right or left, upon the volt; or as he works along by a wall, a hedge, or the like: for in moving by a wall, the leg next the wall is called the outer leg, and the other the inner leg: and upon volts, if a horse works to the right, the right heel is the inner heel, and the right leg the inner leg; but if he works to the left, the left heel is the inner heel, &c. At present, riding-masters, in order to be more easily understood, generally use the terms right and left, instead of outer and inner.

**INNATE IDEAS**, those supposed to be stamped on the mind, from the first moment of its existence, and which it constantly brings into the world with it: a doctrine, which Mr. Locke has abundantly refuted. See the article **IDEA**.

**INNERKEITHING**, a port-town of Scotland, in the county of Fife, situated on the north shore of the frith of Forth, ten miles north-west of Edinburgh.

**INNERLOCHY**, or **FORT WILLIAM**, a fortress erected in the highlands of Scotland, at the mouth of a bay or lake in the county of Lochaber, twenty-eight miles

miles south-west of Lochness: west lon.  $5^{\circ} 15'$ , and north lat.  $56^{\circ} 55'$ .

**INNISKILLING**, a strong town of Ireland, in the province of Ulster, and county of Fermanagh: west lon.  $7^{\circ} 50'$ , and north lat.  $54^{\circ} 20'$ .

**INNOCENTS-DAY**, a festival of the christian church, observed on December 28, in memory of the massacre of the innocent children by the command of Herod, king of Judea; who being alarmed at hearing that an infant was born king of the Jews, and imagining that his own kingdom was in danger, sent orders to have all the children slain that were in Bethlehem, and the adjacent country. The greek church in their calendar, and the abyssinians of Ethiopia in their offices, commemorate fourteen thousand infants on this occasion.

**INNOMINATA OSSA**, in anatomy, three bones, which compose the extreme part of the trunk of a human body. These, though single in adults, are in infants three perfectly distinct bones, each of which has its peculiar name; the upper one is called the ileum; the anterior one, the os pubis, or os pectinis; and the posterior one, the os ischium. These are joined by the intervention of a cartilage, as it were in the middle of that singular cavity called the acetabulum, and continue visibly distinct to the age of puberty; after which they coalesce, and form one entire bone so perfectly, that there is not the least vestige remaining that they ever were separate. The innominata ossa are joined on each side, in the hinder part, to the os sacrum, by ligaments and cartilages, and form a very firm and strong, though somewhat moveable articulation with it; and with this bone they also form the cavity called the pelvis; they also cohere with the os sacrum on each side, by means of two peculiar and very robust ligaments, each being a finger's breadth broad, and two or three finger's breadth long.

The use of these bones are to support and sustain the spina dorsi, and indeed all the parts above themselves; to make a firm and proper juncture of the other parts of the body with the thighs; to serve for the place of origin to several muscles; to form the cavity of the pelvis, and to defend its contents from external injuries.

**INNOVATION, or NOVATION.** See the article NOVATION.

**INNUENDO**, a word that was frequently used in declarations of slander, and law-

pleadings, when these were in latin, in order to ascertain a person or thing before mentioned; but now, instead of the word innuendo, we say, meaning so and so.

The practice of stretching innuendos, it is observed, has of late years, in some particular cases, too much prevailed amongst us: however, it has been held, that an innuendo cannot make that certain which was uncertain before; nor will the law allow words to be enlarged by an innuendo, so as to support an action on the case for uttering them. In slander, the person and words should both of them be distinctly specified, and not want an innuendo to make them out; and therefore an innuendo will not render an action for a libel good, where the preceding matter imports no scandal.

**INOCULATION**, in medicine, the art of transplanting a distemper from one subject to another, by incision, particularly used for engrafting the small pox. See the article POX.

The design of this operation is to communicate by art a milder species of the small pox to the infant or adult patient, than that received by the natural infection; and this by engrafting some of the variolous matter, in order to which a small incision is to be first made, with a scalpel or lancet, through the skin of the arm, and having inserted a small particle of the purulent matter, taken from a mild kind of the pox, the little wound is then to be dressed with some dry lint, and covered with a plaster. After the operation, the patient must constantly keep his chamber, the air of which should be moderately warm, and his diet regulated by some prudent physician, by which means this disorder will shew itself in seven or eight days, without any malignant symptoms, and if assisted by a proper regimen, and a moderate warmth, it usually runs gently through its several stages. When the patient has once had the disorder this way, though ever so mild, it is certain from experience, that they never have it again; and therefore the opinion of those seems to be well grounded, who think that the propagation of the small pox by inoculation might be of general use and benefit to mankind, in preserving the lives of some, and the most important members of others, as the face, eyes, hearing, viscera, &c. History informs us, that the disorder was this way propagated many hundred years ago, among the Greeks, Turks, and Chinese,

Chinese, whereas it is but of late years that the European nations have come into it, among which the English seem to have approved and followed it most. The experiment succeeded so well in the hands of the British physicians, that king George I. countenanced the same in all his dominions, and from thence the practice prevailed with success in Germany, particularly in the dominions of Hanover.

It must, however, be confessed, that there were many, both among the French and English, who endeavoured to suppress and vilify the practice in their writings; but it is thought by Heister, that all their objections have been sufficiently answered and obviated by Dr. Jurin and other able physicians.

Heister declares himself of opinion, that so far from thinking the practice fatal or mischievous, he rather firmly believes it might, under a proper management, be of the greatest use and benefit to the lives and healths of mankind; for, as he judges, the small pox arise from a pestilential virus or matter lodged in the blood, from the very first day of the birth, which breaks out almost in every person, sooner or later, and the more early usually the better, as it is seldom we observe the pox favourable in those more advanced in years; so that the matter seems to multiply itself in the blood, and augment with the patient's age. If, therefore, the disorder be procured of a mild kind by this operation, and the blood cleared of its latent virus, while small in quantity, and the infant young, he doubts not but many might by this means be not only preserved from death, but even conducted safely through the several stages of the disease, without the insults of its most malignant symptoms. We are convinced from experience, as well as reason, that, the disorder which breaks out from a natural infection, is generally more severe and fatal than that produced by art; and no wonder it should be so, since in the last, the physician has the opportunity of choosing the most favourable season, and of preparing his patient before-hand, by a proper regimen, diet, and medicines.

In the Phil. Trans. vol. xlvii. we have a new method of inoculation, discovered by Mr. Brooke, and communicated by him, in a letter, read before the Royal Society, May 14, 1752, to Dr. Parsons, secretary to the society for foreign corre-

spondence, shewing by experiments, that the pock may be engrafted without making any incision, only by the application of a little lint impregnated with variolous matter, and confining it with an adhesive plaster. Mr. Brooke tried the experiment upon several patients, and always with success; the absorbent vessels, he believes, in young subjects especially, will always take in a sufficient quantity of the matter to contaminate the whole mass of the circulating fluids; and though the density of the pores, or scaly insipifications of the materia perspirabilis, in adults, may in some measure prevent the disorder from being communicated by contact, yet friction will easily remove that obstacle; for by this means the cuticle is made as thin as is required, and the warmth induced by friction will dilute the mouths of the absorbent vessels, and draw a moderate flux of juices to that part, so that they may take in a sufficient quantity of variolous matter, to bring on the disorder.

In the same volume of the Transactions, we have an extract of a letter to Dr. Maty, from Geneva, read June 18, following, concerning the introduction and success of inoculation in that city. Their first method of doing it was generally the same as is now practised in England, whence instructions were sent to Geneva, when they began to inoculate: yet three persons were inoculated in a new manner: these were blistered slightly by means of a small vesicatory applied to that part of the arm where the incision is usually made. The blister occasioned by this plaster was opened, and a pledgit, dipped in the pocky matter was applied to the excoriated part: some pocky matter was made use of, which was kept three weeks; and some that had even been kept four months, without any apparent difference in the effects from that which was fresh. The experience which they have hitherto had in Geneva, has suggested to them a conjecture, that the incision ought to have been made deeper, where the matter, which is used, has been kept some time. All who had been inoculated by that time at Geneva, had recovered; and the far greater part of them had but an inconsiderable number of pustules.

INOCULATION, or BUDDING, in gardening, is commonly practised upon all sorts of stone-fruit, as nectarines, peaches, apricots, plumbs, cherries, as also upon oranges and jasmines; and, indeed, this

is preferable to any sort of grafting for most sorts of fruit. The method of performing it is as follows: you must be provided with a sharp penknife with a flat haft, which is to raise the bark of the stock to admit the bud; and some found bals-mat, which should be soaked in water, to increase its strength, and render it more pliable; then having taken off the cuttings from the trees you would propagate, you must choose a smooth part of the stock about five or six inches above the surface of the ground, if designed for dwarfs; but if for standards, they should be budded six feet above ground. Then with your knife make an horizontal cut across the rind of the stock, and from the middle of that cut make a slit downwards, about two inches in length, so that it may be in the form of a T; but you must be careful not to cut too deep, lest you wound the stock; then having cut off the leaf from the bud, leaving the foot-stalk remaining, you should make a cross cut, about half an inch below the eye, and with your knife slit off the bud, with part of the wood to it: this done, you must with your knife pull off that part of the wood which was taken with the bud, observing whether the eye of the bud be left to it or not; for all those buds which lose their eyes in stripping, are good for nothing: then having gently raised the bark of the stock with the flat haft of your penknife clear to the wood, thrust the bud therein, observing to place it smooth between the rind and wood of the stock, cutting off any part of the rind belonging to the bud, that may be too long for the slit made in the stock; and so having exactly fitted the bud to the stock, tie them closely round with bals-mat, beginning at the under part of the slit, and so proceeding to the top, taking care not to bind round the eye of the bud, which should be left open: When your buds have been inoculated three weeks or a month, those which are fresh and plump, you may be sure are joined; and at this time you should loosen the bandage, which if it be not done in time, will injure if not destroy the bud. The March following cut off the stock sloping, about three inches above the bud, and to what is left fasten the shoot which proceeds from the bud: but this must continue no longer than one year; after which the stock must be cut off close above the bud. The time

for inoculating is from the middle of June to the middle of August: but the most general rule is, when you observe the buds formed at the extremity of the same year's shoot, which is a sign of their having finished their spring growth. The first sort commonly inoculated is the apricot, and the last the orange-tree, which should never be done till the latter end of August. And in doing this work, you should always make choice of cloudy weather; for if it be done in the middle of the day, when the weather is hot, the shoots will perspire so fast, as to leave the buds destitute of moisture.

**INORDINATE PROPORTION**, is where there are three magnitudes in one rank, and three others proportional to them in another, and you compare them in a different order. Thus suppose the numbers in one rank to be 2, 3, 9; and those of the other rank 8, 24, 36; which are compared in a different order, *viz.* 2:3::24:36; and 3:9::8:24. Then rejecting the mean terms of each rank, you conclude 2:9::8:36.

**INOSULATION**, in anatomy, the same with anastomasis. See **ANASTOMASIS**.

**INQUEST**, in law, signifies an inquiry made by a jury, in a civil or criminal cause, by examining witnesses. See the article **JURY**.

There is also an inquest of office, used for the satisfaction of the judges, and sometimes to make inquiry whether a criminal be a lunatic or not; upon which inquest, if it be found that the criminal only feigns himself to be a lunatic, and at the same time refuses to plead, he may be dealt with as one standing mute. See the article **MUTE**.

Where a person is attainted of felony and escapes, and afterwards on being re-taken denies that he is the same man, inquest must be made into the identity of the person by a jury, before he can be executed.

**INQUIRENDO**, in law, an authority given to one or more persons, to inquire into something for the advantage of the king.

**INQUISITION**, in law, a manner of proceeding by way of search or examination used on the king's behalf, in cases of out-lawry, treason, felony, self-murder, &c. to discover lands, goods, and the like, forfeited to the crown. Inquisition is also had upon extents of lands, tenements, &c. writs of elegit, and where

where judgment being had by default, damages and costs are recovered.

**INQUISITION**, in the church of Rome, a tribunal in several roman-catholic countries, erected by the popes for the examination and punishment of heretics.

This court was founded in the twelfth century by father Dominic and his followers, who were sent by pope Innocent III. with orders to excite the catholic princes and people to extirpate heretics, to search into their number and quality, and to transmit a faithful account thereof to Rome. Hence they were called inquisitors; and this gave birth to the formidable tribunal of the inquisition, which was received in all Italy, and the dominions of Spain, except the kingdom of Naples and the Low Countries.

This diabolical tribunal takes cognizance of heresy, judaism, mahometanism, sodomy, and polygamy; and the people stand in so much fear of it, that parents deliver up their children, husbands their wives, and masters their servants, to its officers, without daring in the least to murmur. The prisoners are kept for a long time, till they themselves turn their own accusers, and declare the cause of their imprisonment; for they are neither told their crime, nor confronted with witnesses. As soon as they are imprisoned their friends go into mourning, and speak of them as dead, not daring to solicit their pardon, lest they should be brought in as accomplices. When there is no shadow of proof against the pretended criminal, he is discharged, after suffering the most cruel tortures, a tedious and dreadful imprisonment, and the loss of the greatest part of his effects. The sentence against the prisoners is pronounced publicly, and with extraordinary solemnity. In Portugal they erect a theatre capable of holding three thousand persons, in which they place a rich altar, and raise seats on each side in the form of an amphitheatre. There the prisoners are placed, and over-against them is a high chair, whither they are called, one by one, to hear their doom, from one of the inquisitors.

These unhappy people know what they are to suffer, by the cloaths they wear that day. Those who appear in their own cloaths, are discharged upon payment of a fine; those who have a *santo benito*, or strait yellow coat without sleeves, charged with St. Andrew's cross,

have their lives, but forfeit all their effects: those who have the resemblance of flames, made of red serge, sewed upon their *santo benito*, without any cross, are pardoned, but threatened to be burnt if ever they relapse: but those who, besides these flames, have on their *santo benito*, their own picture, surrounded with figures of devils, are condemned to expire in the flames. The inquisitors, who are ecclesiastics, do not pronounce the sentence of death; but form and read an act, in which they say, that the criminal being convicted of such a crime, by his own confession, is with much reluctance delivered to the secular power to be punished according to his demerits: and this writing they give to the seven judges, who attend at the right side of the altar, who immediately pass sentence. For the conclusion of this horrid scene, see the article *ACT of faith*.

**INQUISITORS**, in law, persons who have power by their office to make inquiry in certain cases; as sheriffs, and coroners on view of the body, &c.

**INROLLMENT**, in law, is registering any lawful act, as a statute or recognizance acknowledged, a deed of bargain and sale, &c. in the rolls of chancery, king's bench, common pleas, or exchequer, at the hustings of Guildhall, London, or at the quarter-sessions.

Inrollments of deeds must be recorded in court, and for the sake of perpetuity ingrossed on parchment: yet it is said that inrolling a deed does not make it a record, which is an entry on parchment of judicial matters controverted in a court of record; and of which the court is to take notice: but the inrollment of a deed, is only a private act of the parties concerned, of which the court takes no notice at the time when it is done, tho' the court gives way and accedes to it. All deeds may be inrolled at common law, and tho' by accident a seal is broke off, it will not hinder it. A deed when inrolled must be acknowledged before a master in chancery, or a judge of the court where it is inrolled; which being the officer's warrant for its inrollment, such inrollment will be allowed as good proof of the existence of the deed itself.

*Clerk of INROLLMENTS.* See the article *CLERK of inrollments*.

**INSCONCED**, in the military art, part of an army that have fortified themselves with a sconce or small fort, in order to defend some pass, &c.

**INSCRIBED**,

**INSCRIBED**, in geometry. A figure is said to be inscribed in another, when all its angles touch the sides or planes of the other figure. See the articles **HEXAGON**, **PENTAGON**, &c.

**INSCRIPTION**, a title or writing carved, engraved, or affixed to any thing, to give a more distinct knowledge of it, or to transmit some important truth to posterity.

The inscriptions mentioned by Herodotus and Diodorus Siculus, sufficiently shew that this was the first method of conveying instruction to mankind, and transmitting the knowledge of history and sciences to posterity: thus the antients engraved upon pillars both the principles of sciences, and the history of the world. Pisistratus carved precepts of husbandry on pillars of stone; and the treaties of confederacy between the Romans and Jews, were engraved on plates of brass. Hence, antiquarians have been very curious in examining the inscriptions on antient ruins, coins, medals, &c.

**INSECTS**, in zoology, a numerous class of animals, whose bodies are neither regularly covered with hair, feathers, or scales, as in the generality of other animals; but either with a hard, and as it were horny substance, or with a soft and tender skin; and of which the far greater part, that is, all the insects with a hard covering to their bodies, have on their heads antennæ, otherwise called horns and feelers.

The most general sub-division of insects is into two series, *viz.* the winged and naked ones; each of which comprehends several subordinate orders of genera, each containing numerous species.

The several orders of the first series are the coleoptera, hemiptera, neuroptera, lepidoptera, hymenoptera, and diptera; and those of the second series, are the aptera, reptilia, zoophyta, testacea, and lithophyta: of all which we have treated under their respective articles. See the articles **COLEOPTERA**, **HEMIPTERA**, **NEUROPTERA**, &c.

**Generation of INSECTS.** See the article **GENERATION**.

**Transformation of INSECTS.** See the article **TRANSFORMATION**.

**INSERTION**, in anatomy, the close conjunction of the vessels, tendons, fibres, and membranes of the body with some other parts. See the articles **TENDON**, **MUSCLE**, &c.

**INSIDIANT DISEASES**, those which shew no evident symptom, but lie concealed in the body, ready to break forth on the least provocation, as it were by surprise.

**INSINUATION**, in our law, a clandestine creeping into a person's mind, or favour; but, among the civilians, it bears a different signification; as the insinuation of a will is the first production of it, *viz.* the leaving it in the hands of the register, in order to the procuring a probate thereof.

**INSIPID**, an appellation given to things without taste. See the article **TASTE**.

**INSITION**, in gardening, the same with grafting. See the article **GRAFTING**.

**INSOLATION**, in chemistry, the suffering matters to stand and digest in the heat of the sun, instead of that of a furnace. See **FIRE** and **HEAT**.

**INSOLVENT**, a term applied to persons unable to pay their debts. See the articles **DEBT** and **DEBTOR**.

**INSPICIENDO VENTRE**, in law. See the article **VENTRE**.

**INSPIRATION**, among divines, implies the conveying of certain extraordinary and supernatural notices or motions into the soul.

In discoursing upon the argument concerning the inspiration of the scripture, the learned Du Pin alledges the testimony of the Jews, the authority of our Saviour and his apostles, and the universal consent of the christian church.

1. It cannot be in the least doubted, but that the antient Jews were thoroughly persuaded that the books in their canon were written by prophets divinely inspired: they looked upon the law of Moses as the law of God himself, and on the pentateuch as the foundation of their religion: they had even the evidence of their senses, that Moses was sent by God, that he conversed familiarly with him, and was assisted by him in an extraordinary manner; witness the many miracles which God wrought by him, and his divine providence and protection being vouchsafed to him in an unusual manner; so that, upon the whole, they had all imaginable evidence that the laws and historical narrations of Moses were all of them penned by inspiration from heaven. As to the other canonical books collected by Ezra, it cannot be questioned, with any colour of reason, but that Ezra, in drawing up his canon and sacred books, made choice of those which had the character of divinely in-

spired writings, and had been always acknowledged as such by the universal consent of the jewish nation ; and the synagogue looked upon this canonical system as prophetic and divinely inspired. See **CANON** and **BIBLE**.

2. From the unexceptionable testimony of the Jews, M. Du Pin proceeds to alledge the authority of our Saviour and his apostles. It is upon the evidence of these books that our Saviour proves himself to be the messias, and by them that he confutes the Jews. The apostles followed their master's doctrine in this as well as in all other things : these books they made use of to authorise the gospel they preached, and to prove that the prophecies concerning the messias, were fulfilled in the person of Jesus Christ.

3. From these authorities he proceeds to the testimony of the primitive church : those who were instructed by our Saviour and his apostles, had not only the same regard for the books of the Old Testament as the Jews themselves had, but likewise by universal consent received the gospels and epistles of the apostles as writings penned by the inspiration of the holy ghost. The primitive christians being fully persuaded of this truth, received the apostles doctrine with intire submission, and looked upon it as no other than the instruction of Jesus Christ and of God himself. See the article **CHRISTIAN RELIGION**.

**INSPISSATING**, in pharmacy, an operation whereby a liquor is brought to a thicker consistence, by evaporating the thicker parts. See **INCRASSATING**.

**INSPRUCK**, a city of Germany, in the circle of Austria, capital of the county of Tyrol, situated on the river Inn, in east long.  $11^{\circ} 26'$ , north lat.  $47^{\circ} 12'$ .

**INSTALLMENT**, the instating or establishing a person in some dignity.

This word is chiefly used for the induction of a dean, prebendary, or other ecclesiastical dignitary, into the possession of his stall, or other proper seat in the cathedral to which he belongs. It is also used for the ceremony whereby the knights of the garter are placed in their rank in the chapel of St. George at Windsor, and on many other like occasions. It is sometimes termed installation. See **GARIER**.

**INSTANT**, such a part of duration wherein we perceive no succession ; or it is that which takes up the time only of one idea in our minds.

The schoolmen distinguish three kinds of instants ; a temporary, a natural, and a rational instant.

Temporary instant is a part of time immediately preceding another : thus the last instant of a day precedes, immediately and really, the first instant of the following day.

Natural instant is what we otherwise call a priority of nature, which obtains in things that are subordinated in acting, as first and second causes, or causes and their effects : for the nature of things requires, that if there be a second cause there must be a first ; and that there must be a cause, if there be an effect. See the article **CAUSE**.

Rational instant is not any real instant, but a point which the understanding conceives to have been before some other instant, founded on the nature of the thing which occasioned it to be conceived : for instance, if God made several things voluntarily, which he could otherwise have let alone, there is a reasonable foundation to conceive God such as he is in himself, before he had made any of these voluntary determinations : but as there was no real instant when God had not formed any determination, this instant is called a rational instant, by way of opposition to an instant of time.

**INSTAURATION**, the re-establishment or restauration of a religion, a church, or the like, to its former state.

**INSTEP**, in the manege, is that part of a horse's hind leg which reaches from the ham to the pattern-joint ; and which, when the horse is in his natural posture of standing, should be large, flat, and in a perpendicular line with the ground : for when the insteps do not stand perpendicularly, it is a certain sign of weakness either in the reins or hinder quarters.

**INSTINCT**, an appellation given to the sagacity and natural inclinations of brutes, which supplies the place of reason in mankind. See **REASON** and **BRUTE**.

**INSTITUTES**, in literary history, a book containing the elements of the roman law, and constitutes the last part of the civil-law. See **CIVIL-LAW**.

The institutes are divided into four books, and contain an abridgment of the whole body of the civil-law ; being designed for the use of students.

**INSTITUTION**, in general, signifies the establishing or founding something.

In the canon and common law, it signifies

fies the investing a clerk with the spiritualities of a rectory, &c. which is done by the bishop, who uses the formula, "I institute you rector of such a church, with cure of souls, and receive your care and mine." This makes him a complete parson as to spirituality, but not as to temporality, which depends on induction. See the article **INDUCTION**. The term institutions is also used, in a literary sense, for a book containing the elements of any art or science: such are institutions of medicine, institutions of rhetoric, &c.

**INSTRUCTIVE COLUMN**, in architecture. See the article **COLUMN**.

**INSTRUMENT**, in general, whatever is subservient to a cause in producing any effect. See **CAUSE** and **EFFECT**.

A common case of mathematical instruments contains several compasses, a sector, scale, drawing-pen, and protractor. See the articles **COMPASSES**, **SECTOR**, **SCALE**, &c.

A case of pocket instruments for surgeons, which they ought always to carry about with them, contains lancets of different sizes; scissars, fit for several uses; forceps, plain and furnished with teeth; incision-knives, straight and crooked; a spatula, probes, needles, &c. See the articles **LANCET**, **SCISSARS**, **FORCEPS**, &c.

The following instruments used by surgeons, pay on their importation according to these rates. Trepanns, the dozen pay 1s. 11 $\frac{1}{10}$ d. and draw back on exportation, 1s. 8 $\frac{2}{10}$ d. Bullet-knives, the dozen, pay 9 $\frac{2}{10}$ d. and draw back 8 $\frac{1}{10}$ d. Incision-sheers, paices, or tooth-drawers and pulicanes, the dozen pay 11 $\frac{5}{10}$ d.

and draw back 10 $\frac{12\frac{1}{2}}{100}$ d. Setts, the bundle, containing sixteen, pay 4 $\frac{6\frac{2}{10}}{100}$ d. and draw back 4 $\frac{5}{100}$ d. More if made of iron, for every 112 pounds, 4s. 8 $\frac{2\frac{5}{10}}{100}$ d. and draw back 4s. 8 $\frac{2\frac{5}{10}}{100}$ d. if made of

steel, the 112 pounds pay 5s. 1 $\frac{8\frac{7}{10}}{100}$ d. the

whole of which is returned on exportation: but if they are made of silver, they are to pay as plate. See **PLATE**.

**INSTRUMENT**, in law, some public act, or authentic deed, by which any truth is made apparent, or any right or title established in a court of justice. See **DEED**.

**INSTRUMENTS**, in music, are either played on by means of wind, as the organ,

flute, hautboy, &c. or of strings, as the harpsichord, violin, &c. See the articles **ORGAN**, **FLUTE**, **HARPSICHORD**, &c.

**INSULATED**, *insulatus*, in architecture, an appellation given to such columns as stand alone, or free from any contiguous wall, &c. like an island in the sea; whence the name. See **COLUMN**.

**INSULT**, *insultus*, in medicine, signifies the access of the paroxysm of intermitting diseases. See the articles **INTERMITTING** and **PAROXYSM**.

**INSULT**, in the art of war, the same with assault. See the article **ASSAULT**.

**INSUPER**, over and above, a term used by the auditors of the exchequer in their accounts; thus, where a certain sum is charged to a person's account, they say, so much remains, insuper, to the accountant.

**INSURANCE**, or **ASSURANCE**, in law and commerce, a contract or agreement whereby one or more persons, called insurers, assurers, &c. oblige themselves to answer for the loss of a ship, house, goods, &c. in consideration of a premium paid by the proprietors of the things insured.

Insurances are of various kinds, as on ships or parts of ships, on merchandize singly, and on ships and goods jointly; and these are again branched out to run either for a time stipulated, or to one single port, or out and home, with liberty to touch at the different places mentioned in the policy. Insurances may likewise be made on goods sent by land, or by hoys, &c. on rivers; and this is frequently done, more especially on jewels, and other things of great value. They may likewise be made on ships and goods, lost or not lost, which is commonly done when a ship has been long missing; and those words being inserted in the policy, oblige the under-writers to pay, though the ship was lost at the time of making such insurance, except the assured had then certain knowledge of the ship's being wrecked; in which case the subscription shall not oblige, as this is accounted a mere fraud. So likewise if a person get more insured than the ship is worth, with a villanous design to destroy her, this fraudulent act will not oblige the insurers, but expose the proprietors to suffer death for their knavery. If a ship is insured from the port of London to any foreign port, and before she breaks ground is burnt, the insurers are not liable; unless the words of the in-

insurance are, at and from the port of London; but if she has once broke ground, and after being driven back, takes fire, the insurers are answerable. An insurance made on prohibited goods is not binding, unless they were not prohibited till after the insurance was made. Where the policy expressly mentions that the ship is to depart with convoy, it is intended that she shall, if possible, keep with the convoy during the voyage, and if she depart wilfully from the convoy, it is a fraud; but if having departed with convoy, she by stress of weather loses the convoy, and is taken, the insurers are liable. If there be thieves on board among themselves, the master of the ship is to answer for that, and not the insurers; for tho' the words of the policy insure against losses by thieves, yet assailing thieves are only here intended. An insurance made in a foreign country, may be sued in England by the common law, if the insurers come here. Where the policy is against restraint of princes, that does not extend to a navigation carried on against the law of nations, or where there shall be a seizure for not paying of customs, or the like. If goods be insured as the goods of an ally, when they are the goods of an enemy, it is a fraud, and the insurance not good. If a man pays money on a policy of insurance, supposing a loss where there was none, this shall be money received for the use of the insurer, for which he may maintain an action. Damages happening to goods in their own nature perishable, are not to be borne by the insurer. A suppression of the truth, or a false allegation, is sufficient to discharge the policy; for it is a general rule, that the insured ought to inform the insurer of all material circumstances that were come to his knowledge, at the time of making the policy, in order that the contract may be fairly adjusted; which being a contract upon chance, cannot be done, if one party knows more than the other; for equality in contracts, by the law-merchant, is essential; but a proof of an intention to make a deviation, will not avoid the policy before the deviation is actually made.

By an act made in 19 Geo. II. it is determined, that after the first day of August, 1746, no assurance shall be made on ships or lading by way of gaming or wagering, or without benefit of salvage to the insurer: that it shall

not be lawful to make re-assurance, unless the assurer shall become insolvent, become a bankrupt, or die; in which cases such assurer, or his executors, &c. may make re-assurance to the amount of the sum before assured, provided it be expressed in the policy to be a re-assurance. That all sums of money lent on bottomry or at respondentia, upon any ships belonging to his majesty's subjects, bound to or from the East Indies, shall be lent only on the ship or merchandize, laden, or to be laden, on board such ship, and shall be so expressed in the condition of the bond; and the benefit of salvage shall be allowed to the lender, his agents or assigns, who alone shall have a right to make assurance on the money so lent; and no borrower of money on bottomry, &c. shall recover more on any assurance, than the value of his interest in the ship or merchandize, exclusively of the money so borrowed; and in case it shall appear, that the value of his share in the ship or merchandize does not amount to the full sum borrowed, such borrower shall be responsible to the lender for so much of the money borrowed, as he hath not laid out on the ship or merchandize, with lawful interest for the same, together with the insurance and all other charges, to the proportion which the money not laid out shall bear to the whole money lent, notwithstanding the ship and merchandize be totally lost.

Whenever advice is received of the loss of a ship or goods insured, application is to be made to the insurers, and the vouchers produced; and if they are satisfied they will pay the money; but if they have cause to scruple the doing it, the insured must stay till the insurers can obtain a more satisfactory account; but if nothing be heard of the ship in any reasonable time, the insurers will be obliged to pay the money agreed upon. The policies made of insurances are to be stamped within three days after the ship is insured, on the penalty of paying 100l.

The principal offices for the insurance of ships and merchandize in London, are the Royal-exchange assurance, and the London-assurance, both of which are established by act of parliament. These offices also insure houses and other buildings, goods, wares, and merchandize, from loss or damage by fire; and the former of them also assure lives.

The Royal-exchange insurance, on a brick

brick or stone building, insures any sum not exceeding 200*l.* at 5*s.* *per ann.* and any larger sum not exceeding 1000*l.* after the rate of 2*s.* 6*d.* *per cent.* *per ann.* Above 1000*l.* and not exceeding 2000*l.* at 3*s.* *per cent.* Above 2000*l.* and not exceeding 3000*l.* at 4*s.* *per cent.* On goods and merchandize, the property of the assured, within any brick or stone building, or on the goods and building together, this office insures any sum not exceeding 300*l.* for 7*s.* 6*d.* *per ann.* and larger sums after the rates above-mentioned: but timber or plaster-buildings, or goods or merchandize therein, pay 8*s.* *per ann.* for 200*l.* and after the rate of 4*s.* *per cent.* for any greater sum not exceeding 1000*l.* and 5*s.* *per cent.* for all insurances above 1000*l.* and not

exceeding 2000*l.* On a timber or plaster building with goods and merchandize together, any sum, not exceeding 300*l.* may be insured for 12*s.* *per ann.* and larger sums at the above rates. The goods belonging to hazardous trades, as distillers, chemists, apothecaries, colourmen, tallow-chandlers, oilmen, innholders, &c. deposited in brick houses, pay 8*s.* *per ann.* for insuring 200*l.* and after the rate of 4*s.* *per cent.* for any greater sum not exceeding 1000*l.*; and above 1000*l.* and not exceeding 2000*l.* 5*s.* *per cent.* but when the houses and goods are put together, the price of insurance is 4*s.* *per cent.* *per ann.* without any other charge except the policies.

The London insurance has the following annual premiums.

Sums assured.	Common insurances.	Hazardous insurances.	Double hazardous insurances.
Any sum			
Not exceeding 200 <i>l.</i>	4 <i>s.</i> <i>per annum.</i>	6 <i>s.</i> <i>per annum.</i>	10 <i>s.</i> <i>per annum.</i>
From 200 <i>l.</i> to 1000 <i>l.</i>	2 <i>s.</i> <i>per cent.</i>	3 <i>s.</i> <i>per cent.</i>	5 <i>s.</i> <i>per cent.</i>
From 1000 <i>l.</i> to 2000 <i>l.</i>	2 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>	4 <i>s.</i> <i>per cent.</i>	7 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>
From 2000 <i>l.</i> to 3000 <i>l.</i>	4 <i>s.</i> <i>per cent.</i>	6 <i>s.</i> <i>per cent.</i>	7 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>

The hand-in-hand office insure for seven years at 12*s.* *per cent.* on brick, and double that sum for timber-houses.

The sun-fire office, besides 7*s.* 6*d.* for the policy and mark, has the following annual premiums.

Sums insured.	Common insurances.	Hazardous insurances.	Double hazardous insurances.
Any sum			
Not exceeding 200 <i>l.</i>	4 <i>s.</i> <i>per annum.</i>	6 <i>s.</i> <i>per annum.</i>	10 <i>s.</i> <i>per annum.</i>
From 200 <i>l.</i> to 1000 <i>l.</i>	2 <i>s.</i> <i>per cent.</i>	3 <i>s.</i> <i>per cent.</i>	5 <i>s.</i> <i>per cent.</i>
From 1000 <i>l.</i> to 2000 <i>l.</i>	2 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>	4 <i>s.</i> <i>per cent.</i>	7 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>
From 2000 <i>l.</i> to 3000 <i>l.</i>	3 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>	5 <i>s.</i> <i>per cent.</i>	7 <i>s.</i> 6 <i>d.</i> <i>per ct.</i>

The friendly society insurance, has some very extraordinary regulations, the principal of which is, that every one of the assured becomes a member of the society; and when any loss happens, contributes in proportion to the sum he has insured, to make good the damage; on which account he pays only 1*s.* 4*d.* *per cent.* *per ann.* premium, and 6*s.* 8*d.* *per cent.* as a caution; but what is unexpended of the 6*s.* 8*d.* is returned to the party insured at the end of seven years.

We have also insurances for lives, in virtue of which, when the person insured dies, a sum of money becomes payable to the person on whose behalf the policy of insurance was granted. The principal insurance office of this kind, is that of the amicable society for a perpetual

assurance, kept in Serjeant's inn, Fleetstreet, London.

In this office, after paying the charges of the policy, and 10*s.* entrance-money, each person pays 5*l.* *per annum*, by quarterly payments, and from these payments, the dividends, which usually amount to 100*l.* and upwards, are to arise. All persons admitted are to be between the ages of twelve and forty-five, and in a good state of health. Any person is allowed to have two or three insurances or numbers on the same life, whereby such person will be intitled to a claim on each number so insured; and every claimant is empowered to put in a new life, in the room of one deceased, within twelve kalendar months next after the end of the current year. By becoming

coming members of this society, clergymen, physicians, lawyers, tradesmen, and all whose income ceases at the time of their death, may, in all probability, leave to their families a claim of not less than 100*l.* for every 5*l.* annually paid in.

The value of insurances upon lives, depends upon the probability of the continuance of any proposed life or lives, during any proposed term. Any questions of this kind may be determined from Dr. Halley's table, and from the principles of the Doctrine of Chances. But, as far as we can learn of the practice on such occasions, the premiums paid to insurers are generally higher than any computation founded on observations concerning the probabilities of human life, will warrant. Thus it is not unusual to make a person pay 5 *per cent.* for the insurance of his life for a twelvemonth, that is, in case the person dies within the year, the insurer is to pay 100*l.* for every 5*l.* received. Now it appears from Dr. Halley's table, which estimates the probability of life low enough, that 5 *per cent.* is an adequate value only for a life of an advanced age, such as sixty-four. See the article LIFE.

**INTACTÆ**, in conics, an appellation sometimes given to the asymptotes. See the article ASYMPTOTES.

**INTAGLIOS**, precious stones on which are engraved the heads of great men, inscriptions, and the like; such as we frequently see set in rings, seals, &c.

**INTAKERS**, a sort of robbers in the north of England, who formerly received the booty which their confederates the out partners, brought from the borders of Scotland.

**INTEGER**, in arithmetic, a whole number, in contradistinction to a fraction. See NUMBER and FRACTION.

**INTEGRAL**, or **INTEGRANT**, in philosophy, appellations given to parts of bodies which are of a similar nature with the whole: thus filings of iron have the same nature and properties as bars of iron.

Bodies may be reduced into their integrant parts by triture or grinding, limation or filing, solution, amalgamation, &c. See GRINDING, &c.

**INTENDMENT**, in law, is the intention, design, or true meaning of a person or thing, which frequently supplies what is not fully expressed: but tho' the intent of

parties in deeds and contracts is much regarded by the law, yet it cannot take place against the rules of law.

**INTENDMENT of crimes**; this, in case of treason, where the intention is proved by circumstances, is punishable in the same manner as if it was put in execution. So if a person enter a house in the night-time, with an intent to commit burglary, it is felony; also an assault, with an intent to commit a robbery on the highway, is made felony, and punished with transportation. 7 Geo. II. c. 23.

**INTERCALARY**, *intercalaris*, in chronology, an appellation given to the odd day inserted in leap-year; which was so called from *calo*, *calare*, to proclaim, it being proclaimed by the priests with a loud voice. See the articles **BISSEXTILE** and **LEAP-YEAR**.

**INTERCEPTED AXIS**, in conic sections, the same with **ABSCISS**. See **ABSCISS**.

**INTERCESSION**, in roman antiquity, the act of a tribune of the people, or other magistrate, whereby he inhibited the act of another magistrate.

The tribunes had an unlimited power to interceed or controul the acts of every other magistrate, who could only inhibit the acts of inferior magistrates. See the article **TRIBUNE**.

**INTERCOLUMNIATION**, in architecture, denotes the space between two columns, which is always to be proportioned to the height and bulk of the columns.

Some authors have laid down the following proportions for the intercolumniations, at a medium, *viz.* in the tuscan order, it must be equal to four diameters of the column below; in the doric, to three; in the ionic, to two; in the corinthian, to two and a quarter; and in the composite, to one and an half.

**INTERCOMMONING**, in law, is when the commons of two manors lie together, and the inhabitants of both have, time out of mind, caused their cattle to feed promiscuously on them.

**INTERCOSTAL**, in anatomy, an appellation given to such muscles, nerves, arteries and veins as lie between the ribs. See the article **RIB**.

The intercostal muscles are thin fleshy plates, two between each two ribs, one external and the other internal. The intercostal nerves are branches of the fifth and sixth pair; the intercostal arteries are branches of the two subclavians; and the

the intercostal veins arise from the vena azygos. See the articles **MUSCLE**, **NERVE**, **ARTERY**, &c.

**INTERDICT**, an ecclesiastical censure, by which the church of Rome forbids the performance of divine service in a kingdom, province, town, &c. This censure has been frequently executed in France, Italy and Germany; and in the year 1170, pope Alexander III. put all England under an interdict, forbidding the clergy to perform any part of divine service, except baptizing of infants, taking confessions, and giving absolution to dying penitents. But this censure being liable to the ill consequences of promoting libertinism and a neglect of religion, the succeeding popes have very seldom made use of it.

There was also an interdict of persons, who were deprived of the benefit of attending on divine service. Particular persons were also antiently interdicted of fire and water, which signified a banishment for some particular offence: by this censure no person was allowed to receive them, or allow them fire or water; and being thus wholly deprived of the two necessary elements of life, they were doubtless under a kind of civil death.

**INTEREST**, is the premium or money paid for the loan or use of money; and is distinguished into two kinds, simple and compound.

Simple interest is that which is paid for the principal, or sum lent, at a certain rate or allowance made by law, or agreement of parties, whereby so much as 5*l.* or 6*l.* or any other sum, is paid for 100*l.* lent out for one year; and more or less proportionally for greater or lesser sums, and for more or less time. For example, if it is 5*l.* to 100*l.* for one year, it is 2*l.* 10*s.* for half a year, and 10*l.* for two years: also 10*l.* for one year of 200*l.* and 5*l.* for half a year; and so on, for other sums and times. Thus, as the law, or agreement of parties, fixes a certain ratio, or, as we call it, rate of interest, which is so much on the 100*l.* for one year; from this we can easily find the proportional interest on 1*l.* for one year, being plainly the  $\frac{1}{100}$  part of the interest of 100*l.* so if this is 5*l.* that is .05*l.* if this is 6*l.* that is .06*l.* and if this is 5*l.* 10*s.* or 5.5*l.* that is .055*l.* Wherefore, if we understand the rate of interest to be the interest of 1*l.* for one year, the more common questions about simple in-

terest will relate to these four things, viz. any principal sum, its interest, the time in which it gives that interest, and the rate, or interest of 1*l.* for one year, according to which that principal, interest and time are adjusted to one another.

From which we have four problems; in the rules whereof we suppose the principal and interest expressed in the denomination of pounds, by reducing what is less than 1*l.* to a decimal of 1*l.* and the time to be expressed in years, and decimal parts of one year.

**Prob. I.** Having any principal sum, and time, with the rates of interest given, to find the interest of that sum for that time and rate.

**Rule:** Multiply the principal rate and time continually into one another, the product is the interest sought.

Observe, if we express the principal by *p*, the interest by *i*, the time by *t*, and the rate by *r*, then this rule is thus represented,  $i = p t r$ .

**Example:** The rate of interest being .05*l.* what is the interest of 85*l.* for 4 years and 3 quarters, or 4.75 years?

**Answer.** 20*l.* 3*s.* 9*d.* = 20.1875*l.* = 85 × 4.75 × .05.

Which is thus performed:

$$\begin{array}{r} 85 = p \\ 4.75 = t \\ \hline 425 \\ 595 \\ \hline 340 \\ 403.75 \\ \hline .05 = r \\ \hline 20.1875 \text{ pounds.} \end{array}$$

Which decimal is reduced by multiplying it by 20, 12, and 4: thus,

$$\begin{array}{r} .1875 \\ \hline 20 \\ \hline 3.7500 \text{ shillings} \\ \hline 12 \\ \hline 15000 \\ \hline 4 \\ \hline 7500 \end{array}$$

9.0000 pence

**Prob. II.** Having the rate, principal and interest, to find the time.

**Rule:** Divide the interest by the product of the rate and principal, the quote is the time: thus,  $t = \frac{i}{rp}$ .

**Example:** The rate .05*l.* principal 85*l.* interest 20*l.* 3*s.* 9*d.* or 20.1875*l.* the time is 4.75 years, or 4  $\frac{3}{4}$  years.

Thus,  $4.75 = \frac{20.1875}{85 \times .05}$ , or  $\frac{20.1875}{4.25}$ .

Demonstration:

Demonstration: This rule is deduced from the former; thus, since  $n = trp$ , then dividing both sides by  $rp$ , it is  $\frac{n}{rp} = t$ .

Prob. III. Having the principal, interest, and time, to find the rate.

Rule: Divide the interest by the product of principal and time, the quote is the rate: thus,  $\frac{n}{tp} = r$ .

Example:  $n = 20.1875$  l.  $t = 4.75$  years,  $p = 85$  l. then is  $r = .05$  l.  $= \frac{20.1875}{4.75 \times 85}$ , or  $\frac{20.1875}{403.75}$ .

Demonstration: Since  $n = trp$ , divide both by  $tp$ ; it is  $\frac{n}{tp} = r$ .

Prob. IV. Having the rate, time and interest, to find the principal.

Rule: Divide the interest by the product of rate and time, the quote is the principal; thus,  $\frac{n}{tr} = p$ .

Example:  $n = 20.1875$  l.  $t = 4.75$  years,  $r = .05$  l. then is  $p = 85$  l.  $= \frac{20.1875}{4.75 \times .05}$ , or  $\frac{20.1875}{.2375}$ .

Demonstration: Since  $n = trp$ , divide both sides by  $tr$ , the quote is  $\frac{n}{tr} = p$ .

Scholium: If the interest of any sum for any time is added to the principal, this total or sum is called the amount, (*viz.* of the principal and its interest for that time.) And then from these four things, *viz.* the amount, which we call  $a$ , the principal, the time and rate, arise four problems; for having any three of these the fourth may always be found. Thus,

Prob. V. Having the principal, time and rate, to find the amount.

Rule: Find the interest by prob. I. add it to the principal, the sum is the amount. Thus, by prob. I. the interest is  $p tr$ ; therefore the amount is  $a = p tr + p$ . The reason is evident.

Note: Because  $p tr = rt \times p$ , and  $p = 1 \times p$ ; therefore  $rt p + p = rt + 1 \times p = a$ . And so the rule may be expressed thus; to the product of the rate and time add unity, and multiply the sum by the principal, the product is the amount.

Example: What is the amount of 246 l. principal in 2 years and  $\frac{1}{2}$ , or 2.5 years,

the rate of interest being .05 l? Answer 246 l. + 30.75 l. = 276 l. 15 s. for the interest is  $= 246 \times .05 \times 2.5 = 30.75$  l. Or thus;  $.05 \times 2.5 = .125$  l. to which add 1, it is  $1 + .125$  l. which multiplied by 276, produces 276.75 l.

Prob. VI. Given the principal, amount and time, to find the rate.

Rule: Take the difference betwixt the principal and amount, and divide it by the product of the time and principal, the quote is the rate: thus,  $r = \frac{a-p}{tp}$ .

Example: Suppose  $a = 276.75$  l.  $p = 246$ ,  $t = 2.5$  years; then is  $r = .05$  l.  $= \frac{276.75 - 246}{2.5 \times 246} = \frac{30.75}{615}$ .

Demonstration: Since by prob. V.  $a = trp + p$ , take  $p$  from both sides, it is  $a - p = trp$ ; then divide both by  $tp$ , it is  $\frac{a-p}{tp} = r$ .

Prob. VII. Given the amount, principal and rate, to find the time.

Rule: Take the difference of the amount and principal, and divide it by the product of the principal and rate, the quote is the time: thus  $t = \frac{a-p}{rp}$ .

Example: Suppose  $a = 276.75$  l.  $p = 246$  l.  $r = .05$ ; then is  $t = 2.5$  years  $= \frac{276.75 - 246}{246 \times .05} = \frac{30.75}{12.3}$ .

Demonstration: In the last problem,  $a - p$  was equal to  $trp$ ; and dividing both by  $rp$ , it is  $\frac{a-p}{rp} = t$ .

Prob. VIII. Given the amount, rate, and time, to find the principal.

Rule: Add 1 to the product of the rate and time, and by that sum divide the amount, the quote is the principal: thus,  $p = \frac{a}{rt+1}$ .

Example:  $a = 276.75$  l.  $r = .05$  l.  $t = 2.5$  years; then is  $p = 246 = \frac{276.75}{2.5 \times .05 + 1} = \frac{276.75}{1.125}$ .

Demonstration: By prob. V. it is  $a = rt + 1 \times p$ ; therefore dividing both sides by  $rt + 1$ , it is  $\frac{a}{rt+1} = p$ .

Compound INTEREST, is that which is paid for any principal sum, and the simple interest due upon it for any time, accumulated into one principal sum. Example:

ple: if 100l. is lent out for one year at 6l. and if at the end of that year the 6l. due of interest be added to the principal, and the sum 106l. be considered as a new principal bearing interest for the next year (or whatever less time it remains unpaid) this is called compound interest, because there is interest upon interest, which may go on by adding this second year's interest of 106l. to the principal 106l. and making the whole a principal for the next year.

Now, although it be not lawful to let out money at compound interest, yet in purchasing of annuities or pensions, &c. and taking leases in reversion, it is very usual to allow compound interest to the purchaser for his ready money; and, therefore, it is very necessary to understand it.

Let therefore, as before,  $p$  = the principal put to interest;  $t$  = the time of its continuance;  $a$  = the amount of the principal and interest;  $R$  = the amount of 1l. and its interest for one year, at any given rate, which may be thus found.

*Viz.* 100:106::1:1,06 = the amount of 1l. at 6 per cent. Or 100:105::1:1,05 = the amount of 1l. at 5 per cent. And so on, for any other assigned rate of interest.

Then if

$R$  = amount of 1l. for 1 year, at any rate.

$R^2$  = amount of 1l. for 2 years,

$R^3$  = amount of 1l. for 3 years,

$R^4$  = amount of 1l. for 4 years,

$R^5$  = amount of 1l. for 5 years,

Here  $t = 5$ . For 1:R::R:RR::RR:RRR::RRR:R<sup>4</sup>::R<sup>4</sup>:R<sup>5</sup>:&c. in a geometrical progression continued; that is, as 1l. is to the amount of 1l. at 1 year's end: so is that amount: to the amount of 1l. at 2 years end, &c. Whence it is plain, that compound interest is grounded upon a series of terms, increasing in geometrical proportion continued; wherein  $t$  (*viz.* the number of years) does always assign the index of the last and highest term, *viz.* the power of  $R$ , which is  $R^t$ .

Again, as 1:R<sup>t</sup>:: $p$ : $pR^t = a$  the amount of  $p$  for the time, that  $R^t$  = the amount of 1l. That is, as 1l. is to the amount of 1l. for any given time:: so is any proposed principal, or sum: to its amount for the same time.

From what has been said, we presume, the reason of the following theorems will be very easily understood.

Theorem I.  $pR^t = a$ , as above.

From hence the two following theorems are easily deduced.

Theorem II.  $\frac{a}{R^t} = p$ .

Theorem III.  $\frac{a}{p} = R^t$ .

By these three theorems, all questions about compound interest may be truly resolved by the pen only, *viz.* without tables: though not so readily as by the help of tables calculated on purpose.

Example I. What will 256l. 10s. amount to in 7 years, at 5 per cent. *per annum*, compound interest?

Here is given  $p = 256.5$ ,  $t = 7$ , and  $R = 1.05$ , which being involted until its index =  $t$  (*viz.* 7) will become  $R^7 = 1.40710$ . Then  $1.40710 \times 256.5 = 360.92115 = a = 360l. 18s. 5d.$  which is the answer required.

Example II. What principal or sum of money must be put out to raise a stock of 360l. 18s. 5d. in seven years, at 5 per cent. *per annum*, compound interest?

Here is given  $a = 360.92115$ ,  $R = 1.05$  and  $t = 7$  to find  $p$  by theorem II. Thus  $R^7 = 1.40710$  ( $360.92115 = a$ )  $256.5 = p$ . That is,  $p = 256l. 10s.$  which is the sum or principal required.

Example III. In what time will 256l. 10s. raise a stock of (or amount to) 360l. 18s. 5d. allowing 5 per cent. *per annum*, compound interest?

Here is given  $p = 256.5$ ,  $a = 360.92115$ ,  $R = 1.05$ . To find  $t$  by theorem III.

$R^t = \frac{a}{p} = \frac{360.92115}{256.5} = 1.40710$ , which

being continually divided by  $R = 1.05$  until nothing remain, the number of those divisions will be  $t = 7$ .

Thus 1.05)1.40710(1.3400, and 1.05) (1.3400)1.2762, and 1.05(1.2762)1.2155, and so on until it become 1.05)1.05(1. which will be at the seventh division.

Therefore it will be  $t = 7$ , the number of years required by the question.

Example IV. If 261. 10s. will amount to, or raise a stock of 360l. 18s. 5d. in 7 years time, what must the rate of interest be, *per cent. per annum*.

Here is given  $p = 261.5$ ,  $a = 360.92115$ , and  $t = 7$ ; quere  $R$ . By theorem III.

$\frac{a}{p} = R^t = 1.40710$ ; as before in the last

example. And if  $R^7 = 1.40710$ , then  $R = \sqrt[7]{1.40710}$ , which may be thus extracted.

10 S

Put

$$\begin{array}{l|l}
 \text{Put} & 1 \quad r + e = R, \text{ then} \\
 1 \odot 7 & 2 \quad r^7 + 7r^6e + 21r^5ee, \&c. = R^7 = 1.40710 = G \\
 2 - r^7 & 3 \quad 7r^6e + 21r^5ee, \&c. = G - r^7 \\
 3 \div 7r^5 & 4 \quad re + 3ee = \frac{G - r^7}{7r^5} = D \\
 4 \div r + 3e & 5 \quad e = \frac{D}{r + 3e}
 \end{array}$$

Let  $r = 1$ , then  $D = 0.0575$ .

$$\begin{array}{r}
 \text{Operation.} \quad r = 1.00 \quad 0.0575 \quad (0.05 \\
 \quad \quad \quad + 3e = .15 \quad 575 \\
 \text{Divisor } 1.15
 \end{array}$$

$$\begin{array}{l}
 \text{First } r = 1.00 \quad \} = 1.05 = R. \\
 \quad \quad \quad + e = 0.05 \quad \}
 \end{array}$$

Then  $1 : 0.05 :: 100 : 5$  the rate *per cent.* required.

**INTEREST**, in law, is generally taken for a chattel real, or a lease for years, &c. but more for a future term.

An estate in lands, &c. is better than a bare interest therein; yet, according to the legal sense of the word, an interest extends to estates and titles which a person has in or out of lands, &c. for by grant of a person's whole interest in land, a reversion, as well as possession, in simple fee, passes.

**INTERJECTION**, in grammar, an indeclinable part of speech, signifying some passion or emotion of the mind.

As the greatest part of the expressions used on these occasions are taken from nature alone, the real interjections, in most languages, are monosyllables; and as all nations agree in these natural passions, so do they agree in the signs and indications of them, as of love, mirth, &c.

The greeks confound their interjections with adverbs, and the hebrews confound them with their adverbs and prepositions, calling them all by the general name particle.

**INTERIM**, a name given to a formulary, or kind of confession of the articles of faith, obtruded upon the protestants after Luther's death by the emperor Charles V. when he had defeated their forces; so called because it was only to take place in the interim (mean time) till a general council should have decided all points in dispute between the protestants and the romanists. It retained most of the doctrines and ceremonies of the romanists, excepting that of marriage, which was allowed to priests, and communion to the laity under both kinds. Most of the protestants rejected it. There were two other interims, one of Leipzig, the other of Franconia.

**INTERLOCUTORY ORDER**, in law, an order that does not decide the cause, but only some matter incident thereto, which happens between the beginning and end of a cause; as when, in chancery or exchequer, the plaintiff obtains an order for an injunction until the hearing of the cause; which order, not being final, is called interlocutory.

**INTERLOPERS**, are properly those who, without due authority, hinder the trade of a company or corporation lawfully established, by dealing in the same way.

**INTERLUDE**, an entertainment exhibited on the theatre between the acts of a play, to amuse the spectators while the actors take breath and shift their dress, or to give time of changing the scenes and decorations.

In the ancient tragedy, the chorus sung the interludes, to shew the intervals between the acts. In after times, they made use of the pantomimes to relieve the audience, that they might not grow weary of the play; a practice which can never be mentioned to their honour: for it is certain evidence of a bad taste, when the audience cannot bear to sit out a dramatic entertainment, without being relieved by such low diversions. But we have not the least reason to wonder at this, who have seen, in our own time and nation, rope and ladder-dancers, and other notable artists of this class, not only admitted upon the stage, but received there with the utmost applause. Interludes now are generally songs, dances, or concerts of music. Aristotle and Horace give it for a rule, that interludes should consist of songs founded on the principal parts of the drama.

**INTERLUNUS MORBUS**, the same with the epilepsy. See **EPILEPSY**.

**INTERMEDIATE**, is usually understood of the space of time elapsed from any certain point to any other.

**INTERMEWING**, in falconry, is a hawk's mewwing, from the first change of her coat, till she turn white.

**INTERMITTENT**, or **INTERMITTING FEVERS**, such fevers as go off and soon return again, in opposition to those which

which are continual. See the article **FEVER**.

These fevers are distinguished into various classes, according to the interval of time between the relapse into them, as tertian fever, quartan fever, &c. See the articles **TERTIAN**, **QUARTAN**, &c.

It may be observed, that intermittents in general are either vernal, and rage from February till August; or autumnal, and rage from August to February. Fevers of this kind begin with an oscitation, pandiculation, weariness, weakness, cold, horror, rigor, tremor, and paleness of the extremities, a difficult respiration, an anxiety, a nausea, a vomiting, a quick, weak, and slow pulse. The more violent and numerous these symptoms are, the worse the fever is; and afterwards, the heat and other symptoms are the worse. This is the first stage of intermittent fevers, which corresponds to the increase of continual fevers, and is of all other stages the most dangerous: for in this condition, the urine is generally crude and thin. This stage of intermittent fevers is succeeded by another, which begins with heat, redness, a strong, large, and free respiration, a small anxiety, a large and strong pulse, an excessive thirst, a pain in the limbs and head, generally a redness of the urine: this stage corresponds to the state and height of continual fevers. Then last of all, there generally appears a profuse sweat, a remission of all the symptoms, a thick urine, with a sediment resembling black dust, sleep, a total absence of the fever, lassitude, and weakness.

Intermittent fevers frequently terminate in those of the acute and dangerous kind, which is generally owing to an excessive heat, and too brisk a motion of the fluids. The cure requires that we should use aperient, saline, alkaline, aromatic, mineral, diluting, mild, and oleaginous substances, heat, motion, fomentation, and friction, during the intermission, or in the first stage; the medicines of this kind are all Tachenius's salts of herbs: the most considerable of which are obtained from wormwood, *carduus benedictus*, and stalks of beans, nitre, antimoniated nitre, diaphoretic antimony unwashed, sal ammoniac, sal prunella, and sal polychrestus, tartarus regeneratus, tartarus tartarizatus, salt of tartar, reduced to a saponaceous mass with oil of turpentine, and all the parts of all the aromatic herbs, especially of those which are re-

solvent. In order to purge the *primæ viæ* from the redundant sordes, a purge or a vomit is often beneficial, exhibited so long before the paroxysm that its operation may be over before the fit comes on. That an intermitting fever, says Dr. Mead, is not carried off by the peruvian bark with a proper degree of certainty, without promising a vomit, or a purge, or both, is not unknown to physicians; but to join some mild cathartic to this remedy will perhaps appear new in practice. For it is commonly thought among us, that this medicine has little or no effect, unless the patient be costive while he takes it; but long experience has taught me, continues the doctor, that it is quite necessary to add a small quantity of rhubarb to this febrifuge, so as to procure two stools at least every day; nor have I ever observed that this procedure has lessened its virtue, but rather rendered it more efficacious.

However, the doctor observes, that it sometimes happens that this febrifuge fails in true intermittents, which failure he ascribes generally to a bad habit of body, in which case the physician should use his best endeavours to discover in what part the fault lies; and it will be commonly found to be in the viscera and glands of the abdomen. Upon this account, he thinks it necessary to prescribe some purges, and sometimes vomits; and in the intermediate days, deobstruents and stomachics; the best of which are aromatic bitters, and preparations of steel.

**INTERNAL**, in general, signifies whatever is within a thing.

Euclid (lib. 1. prop. 32.) proves, that the sum of the three angles of every triangle is equal to two right angles; whence he deduces several useful corollaries. See the article **TRIANGLE**.

He likewise deduces, from the same proposition, this theorem, *viz.* that the sum of the angles of every rectilinear figure, is equal to twice as many right angles, as the figure hath sides, excepting or subtracting four.

**INTERNODIUM**, among botanists, denotes the space between two knots or joints of the stalks of barley, oats, and the like plants.

**INTEROSSEUS**, in anatomy, an appellation given to the muscles which move the fingers and toes, from their being situated between the bones of those parts. See the articles **MUSCLE**, **FLEXOR**, &c.

**INTERPOLATION**, among critics, denotes a spurious passage, inserted into the writings of some ancient author.

One great rule with regard to the expunging interpolations, is, that the restitution be perfectly agreeable to the rest of the work.

**INTERPRETER**, in general, denotes a person who explains the words or writings of another, so as to make them intelligible to those who did not understand them before.

**INTERREGNUM**, the time during which the throne is vacant, in elective kingdoms; for in such as are hereditary, like ours, there is no such thing as an interregnum.

**INTERREX**, the magistrate who governs during an interregnum.

In ancient Rome, this magistrate was continued even after the expulsion of their kings.

**INTERMENT**, the act of burying the dead. See the article **BURIAL**.

**INTERROGATION**, or *point of INTERROGATION*, in grammar, a character of this form (?) serving to denote a question.

**INTERROGATION**, in rhetoric, is a figure, whereby the orator proposes something by way of question; which, it must be owned, greatly enlivens the discourse.

**INTERROGATORIES**, in law, are questions wrote down, and demanded of the witnesses examined in a cause, more especially in the court of chancery. These interrogatories must relate only to the necessary point, and be either drawn up or perused, and also signed by counsel: but care must be taken, that they are not calculated to lead a person in what he has to say, by putting words as it were into his mouth, as, did you not see such a thing done? the depositions taken upon such interrogatories will be suppressed; for they ought not to lean to one side more than another, and therefore should be expressed after this manner, did you see or not see? The examiners, and also the commissioners who examine the witnesses produced on interrogatories, must examine only one interrogatory at a time, and not ask any idle questions, or set down impertinent answers.

**INTERRUPTION**, in matters of proportion, signifies the same with disjunction, or disjunct proportion. See the article **DISCRETE**.

Interruption is noted thus, (:) and intimates the breaking off the ratio in the middle of four disjunct or discrete pro-

portionals; as,  $A : B :: C : D$ , that is as  $A$  is to  $B$ , so is  $C$  to  $D$ . See the articles **PROPORTION**, **RATIO**, &c.

**INTERRUPTION** is likewise a figure in rhetoric, wherein a person, to shew his passion, breaks off his discourse suddenly and abruptly.

**INTERSECTION**, in the mathematics, signifies the cutting of one line or plane by another: thus, we say, that the mutual intersection of two planes is a right line. See **LINE** and **PLANE**.

**INTERSOILING**, in husbandry, is laying one kind of soil or mould upon another, as clay on sand, sand on earth, &c.

**INTERSPINALES colli**, in anatomy, small fleshy muscles of the neck, arising from the superior parts of each double spinal process of the neck, except of the second vertebra; and inserted into the inferior parts of all the double spines. When these muscles act, they draw the spines of the vertebrae of the neck nearer each other.

**INTERSTELLAR**, a word used by some authors to express those parts of the universe that are without and beyond our solar system.

In the interstellar regions are supposed to be several other planetary systems moving round each fixed star as the center of their motion, as the sun is that of ours. And if it be true, as is not improbable, that each fixed star may be thus a sun to some habitable orbs that may move round it, the interstellar world will be infinitely the greater part of the universe.

**INTERTIES**, in architecture, those small pieces of timber that lie horizontally between the sommers, or between them and the fell, or refon.

**INTERTRANSVERSALES colli**, in anatomy, certain muscles situated among the transverse apophyses of the vertebrae: they arise from the lower vertebra, and are inserted into that next above: they are of the same size and figure with the interspinales.

**INTERVAL**, in music, the difference between two sounds, in respect of acute and grave; or, that imaginary space terminated by two sounds, differing in acuteness or gravity.

When two or more sounds are compared in this relation, they are either equal or unequal in the degree of time: such as are equal are called unisons, with regard to each other, as having one tune; the other, being at a distance from each other, constitute what we call an interval in music.

music ; which is properly the distance in time between two sounds.

Intervals are distinguished into simple and compound.

A simple interval, is without parts or divisions. Such are the octave, and all that are within it ; as the second, third,

fourth, fifth, sixth, and seventh, with their varieties.

A compound interval, consists of several lesser intervals : such are all those greater than the octave ; as the ninth, tenth, eleventh, twelfth, &c. with their varieties.

Table of intervals, simple and compound.

1	2	3	4	5	6	7	Simple
8	9	10	11	12	13	14	Double
15	16	17	18	19	20	21	Triple
22	23	24	25	26	27	28	Quadruple
29	30	31					

Intervals } Compound  
Intervals.

Those in the upper line are the simple intervals, the other three the compound ones, *i. e.* such as are either doubled, tripled, or quadrupled.

To reduce a compound interval to a simple one, Mr. Broffard gives this rule : From the denominator thereof take seven, and what remains is the simple interval ; as from a thirteenth take seven, there remains six, which shews the thirteenth to be the sixth doubled : again, from twenty-six take seven three times, which are twenty-one, and five remains ; therefore, says he, the twenty-sixth appears to be the fifth quadrupled.

But this distinction, into simple and compound, regards practice only, because there is really no such thing as a least interval. Besides by a simple interval here, is not meant the least practised, but such as tho' it were equal to two or more lesser, which are in use ; yet, when we would make a sound move so far up and down, we always pass immediately from one of its terms to the other.

What is meant then by a compound interval, will be very plain ; it is such whose terms are in practice, taken either in immediate succession, or such where the sound is made to rise and fall from the one to the other, by touching some intermediate degrees ; so that the whole becomes a composition of all the intervals from one extreme to the other.

What we now call a simple interval, the antients called *diastem* ; and our compound one, they called *sytem*. Each of these has differences ; even of the simple, there are some greater and some lesser, but they are always discord ; but of the compound or *sytem*, some are concord, and others discord. Unisons, 'tis plain, cannot possibly have any variety ; for when there is no difference, as in uniso-

nance, which flows from a relation of of equality, 'tis evident there can be no distinction : unisons therefore are often called concords, (tho' they may not properly be so called). But an interval depending on a difference of time, or a relation of inequality, admits of variety ; and so the terms of every interval, according to their particular relation or difference, make either concord or discord. Some indeed have restrained the word concord to interval, making it include a difference of tune : But this is precarious ; for as the word concord signifies an agreement of sounds, it is certainly applicable to unisons in the first degree. Intervals, 'tis plain, may differ in magnitude, and there may be an infinite variety, according to the possible degrees of tune ; for there is no difference so great or so little, but a greater or lesser may possibly be conceived : 'tis true, with regard to practice, there are limits which are the greatest and least intervals our ears can judge of, and which may actually be produced by voice or instrument.

The degrees of tune are proportionable to the number of vibrations of the sonorous body, in a given time ; or the velocity of their courses and recourses. Now these differences in tune constitute, as has been already said, the intervals in music ; these therefore must be greater or lesser, as the differences are ; and 'tis the quantity of these, which is the subject of the mathematical part of music.

These intervals are measured, not in the simple differences or arithmetical ratios of the numbers expressing their vibrations or lengths ; but in their geometric ratios, and vice versa : it is however to be observed, that in comparing the equality of the intervals, the ratios expressing them, must be all of one species, otherwise

wife this absurdity would follow, that the same two sounds may make different intervals. To determine in general, which of two or more intervals is the greatest, take all the ratios as proper fractions, and the least fraction will be the greatest interval.

The antients were extremely divided about the measuring of intervals. Pythagoras and his followers measured them by the ratios of numbers. They supposed the differences of gravity and acuteness to depend on the different velocities of the motions that cause sound; and thought therefore, that they could only be accurately measured by the ratios of those velocities; which ratios were first investigated by Pythagoras, on occasion of his passing by a smith's shop, and observing a concord between the sound of the hammers striking on the anvil. Aristoxenus opposed this: he thought reason and mathematics had nothing to do in the case, and that sense was the only judge in the dispute; the other being too subtle, to be of any use. He therefore determined the octave, fifth, and fourth, which are the most simple concords, by the ear; and by the difference of the fourth and fifth, he found out the tone, which he settled as an interval the ear could judge of; he also measured every interval by various additions and subtractions, made of those mentioned one with another. Ptolemy keeps a middle way between the two; he finds fault with one for despising reason, and with the other for excluding sense; and shews how these two might mutually assist each other in this matter. Aristoxenus says, there are two principal differences in intervals; the first is that of magnitude, and the other as being concord and discord; for, says he, every concord differs in magnitude from every discord; which may be interpreted, that every interval is of a different compass or extent from another. As concords and discords, intervals have many differences; but of these, magnitude is the principal. But Euclid reckons five differences of intervals, first in magnitude; second, in kind; third, in being either concord or discord; fourth, in being simple or compounded; and lastly, rational or irrational. First then, intervals differ in magnitude, in which respect some are called minor, such as ditonus, trieminitonium, tonus, heminitonium, and diesis;

others major, as diatessaron, diapente, and diapasen. In the genus or kind, intervals differ, as being either diatonic, chromatic, or enharmonic, *i. e.* divided as each of these require. As concords and discords they differ; the concords are diatessaron, diapente, diapasen, and the like; and all intervals less than a fourth or diatessaron, are dissonant, as well as those situated between the concords. And lastly, they differ as to rational and irrational: rational intervals are such as we can distinguish by numbers, as the tone, heminitonium, ditonus, tritone, &c. The irrational are such whose magnitudes vary in an irrational manner, *i. e.* so that we cannot fix a certain proportion between their two extremes in numbers.

But in the modern system of music, intervals are founded on certain ratios or proportions expressible in numbers, which may all be analysed into the prime numbers 2, 3, and 5. And all intervals may be found from the octave, fifth, and third major, which respectively correspond to those numbers. These are the musician's elements, from the various combinations of which, all the agreeable variety of relations of sounds result. And Dr. Pepusch, in the *Phil. Trans.* n° 481, assures us, it may be looked on as the standard of truth; and that every interval that occurs in music is good or bad, as it approaches to, or deviates from what it ought to be on these principles. Mr. Euler, in his *Nov. Theor. Mus.* defines an interval, the measure of the difference of an acute and grave sound: thus, suppose three sounds  $a, b, c$ , of which  $c$  is the most acute,  $a$  the most grave, and  $b$  the intermediate sound. It appears, that the interval between the sounds  $a$  and  $c$ , is the aggregate of the intervals between  $a$  and  $b$ , and between  $b$  and  $c$ . Therefore, if the interval between  $a$  and  $b$ , be equal to that between  $b$  and  $c$ , which happens when  $a : b :: b : c$ ; the interval between  $a$  to  $c$ , will be double the interval  $a$  to  $b$ , or  $b$  to  $c$ . This being considered, it will appear that intervals ought to be expressed by the measures of the ratios, constituting the sounds forming those intervals: but ratios are measured by the logarithms of fractions, the numerators of which denote the acute sounds, and the denominators the grave. Hence the interval between the sounds  $a$  and  $b$ , will be expressed by the logarithm

garithm of the fraction  $\frac{b}{a}$  which is usually denoted by  $L \frac{b}{a}$ ; or, which comes to the same, by  $Lb - La$ . The interval therefore of equal sounds,  $a$  to  $a$ , will be null, as  $La - La = 0$ . The interval called an octave, or diapason, will be expressed by the logarithm of 2; and the interval of the fifth or diapente, will be  $L \frac{1}{2} = L3 - L2$ . From whence it appears, that those intervals are incommensurable; so that no interval, however small, can be an aliquot part, both of the octave and fifth. The like may be said of the intervals  $L \frac{2}{3}$  and  $L \frac{3}{4}$ , and others whose logarithms are dissimilar. But intervals expounded by logarithms of numbers, which are powers of the same root, may be compared. Thus the interval of the sounds 27 : 8, will be the interval of the sounds 9 : 4, as 3 is to 2: for  $L \frac{27}{8} = 3 L \frac{3}{2}$ , and  $L \frac{9}{4} = 2 L \frac{3}{2}$ . Euler. *ibid.* p. 74. But tho' the logarithms of numbers, which are not powers of the same root, be incommensurable, yet an approximating ratio of such may be found. Thus, the measure of the octave is  $L2 = 0.3010300$ , and the measure of the fifth is  $L3 - L2 = 0.1760913$ . Hence the interval of the octave will be to that of the fifth, nearly as 3010300 to 1760913; which ratio being reduced to smaller terms, will give us these simpler expressions for the ratio of the octave and fifth, 2 : 1, 3 : 2, 5 : 3, 7 : 4, 12 : 7, 17 : 10, 29 : 17, 41 : 24, 53 : 31, which last is very near the truth. Euler. *id.* p. 75. In like manner, intervals may be divided into any number of equal parts: for this purpose we need only divide the logarithm of the proposed interval into the same number of parts, and then find its corresponding number by the tables. The ratio of the number so found, to unity, will give the required ratio of the divided interval to its proposed part. Thus let the third part of an octave be required; its logarithm will be  $= 0.1003433 = \frac{1}{3} L2$ : the ratio corresponding nearly to this, will be 53 : 50, or less accurately, 29 : 23, or 5 : 4, which last expresses the third major; and this is by the less knowing taken for the third part of an octave, and seems to be such on our harpsichord and organs, where from C to E is a third, from E to G  $\sharp$  another, and from G  $\sharp$  or A  $\flat$  to c, ano-

ther third. But the more intelligent know, that G  $\sharp$  and A  $\flat$  ought not to be reputed the same sound, since they differ by a diesis enharmonica, which is nearly equal to two commas.

**INTERVALS**, in gardening and husbandry, the spaces left between the several rows of plants sown or set in gardens or fields. See the article **HUSBANDRY**.

**INTESTATE**, in law, a person that dies without making a will; in which case, a distribution of his personal estate, after his debts and funeral charges are paid, is to be made among the wife and children of the deceased, or for want of such, among the next of kin. Here the statute, immediately upon the intestate's death, vests an interest in the persons intitled, so that if one dies before the distribution, his share is to go to his executors and administrators, and not to the survivors of the next akin to the intestate. See the article **ADMINISTRATOR**.

**INTESTINES**, in anatomy, long cylindrical, hollow, and membranaceous bodies; or rather, one such continued body, or tube, reaching from the stomach to the anus.

In these we are to observe, 1. Their length, which is usually six times the height of the person they belong to.

2. Their wonderful circulations, and the uses of them. 3. Their connection by means of the mesentery, with the vertebrae of the loins. 4. Their number, which tho' properly, as already observed, but one, yet is it usually made six, whereof three are called the small intestines, *intestina tenuia*, viz. the omentum, jejunum, and ilium; and the other three, the larger intestines, *intestina crassa*, viz. the caecum, colon, and rectum. See the articles **OMENTUM**, **JEJUNUM**, &c.

The structure and substance of the intestines are membranaceous; being formed, in every part, of five coats or tunics. The first is the common coat, from the peritonæum, and is membranaceous. The second is cellular, and is called by late writers, *tunica cellulosa* Ruyfchii; it is continuous with the mesentery, and is to be discovered by inflating it: this coat, in fat animals, frequently contains abundance of fat. The third is muscular; it is composed of a double series of fibres, in part longitudinal, and in part annular; and these assist the motion of the guts. The fourth coat is nervous: it is furnished with abundance of cellu-

les,

les, vascules, and glands, and is thicker than the others: from this arise the rugæ, and the valves of the intestines. The fifth is the villous coat, which sustains the terminations of the excretory vessels, and the beginnings of the lacteals: hence, when nicely examined, it has the appearance of a sieve: it is the organ of percolation of the chyle.

The intestines have vessels in great abundance, running over every part of their substance. Their arteries are from the meseriæ ones; the upper meseriæ serving for the smaller intestines, the lower for the larger; and these make a multitude of very singular and surprising anastomoses. The veins are meseriæcs, and go off to the vena portæ and the liver. The nerves are sent from the intercostals, and the par vagum. And beside these we are to observe the lacteal vessels. See the article LACTEAL.

The rectum, it is to be observed, receives blood-vessels also from the hypogastrics. There are also, besides the brunnerian glands of the duodenum, other glands in the intestines, called from the name of the person who discovered them, glandulæ Peyerii. These, in the small guts, are usually little, congregate, and miliary; but sometimes they are single. They are larger as they are nearer to the duodenum, and smaller as they approach towards the great guts. Their office is to discharge into the intestines a liquor, which serves for the attenuation of the chyle, and for the lubricating of the intestines. In the larger guts, and in the vermiform appendage, they are single and large, of a lenticular figure; and they are largest of all in the rectum. They have mouths, out of which there is secreted a fluid, which serves to lubricate the sides of the intestines, and to soften the fæces, that they may be evacuated without pain.

The use of the smaller guts is to promote the formation of the chyle, to perfect its secretions, and to propel the remaining fæces to the larger. The office of the larger guts is to receive and collect the matter of the fæces, and at a proper time to expel it. See CHYLE.

In the annexed plate of the intestines, *a, a*, (plate CXLVI. fig. 3. n<sup>o</sup> 1.) represent the liver turned upwards, in order to shew the gall-bladder *b*. The cystic duct, marked *c*, uniting with the hepatic duct *d*, forms the ductus com-

munis choledocus *e*. The vena portæ is marked *f*; some small branches of the hepatic artery, *g*; the umbilical vein, *b*; the stomach, with its coronary vessels, *i, i, i*; the spleen, *k*; a portion of the omentum, with some of the adipose glands, *l, l, l*; the windings of the small intestines, *m, m, m*; part of the colon, *n, n, n*; the muscular fascia of the colon, *o, o, o*; the extremity of the colon, *p*, where it makes a flexure in order to form the rectum, *q*; the extremity of which, marked *r*, is called the anus. The sphincter-muscle of the anus, is marked *s*; and its elevators, *t, t*.

N<sup>o</sup> 2. *ibid.* represents the oesophagus, marked *A*; the stomach, marked *B*; the pancreas, marked *C, C*; the pancreatic duct, marked *D*; and the duodenum, marked *E*.

*Falling out of the INTESTINES.* See the articles HERNIA and RUPTURE.

*Inflammation of the INTESTINES.* See the article INFLAMMATION.

*Wounds of the INTESTINES,* especially of the small guts, admit of little or no hopes of a cure; yet as the great guts sometimes admit of the future to advantage, it is better to use a doubtful remedy than none: besides that, by this means, the discharge of the chyle and fæces into the cavity of the abdomen, which would occasion great mischief, is prevented.

Small wounds of the intestines, not exceeding the size of a goose-quill, should by no means be stitched, but left to nature; as they frequently unite much sooner this way, than if irritated by the suture. But large wounds are to be stitched up with the glover's suture, before the intestine is returned.

To perform this, you are to be provided with a small needle threaded with silk; an assistant should take hold of one part of the gut by a fine piece of linnen well aired, while the surgeon should hold the other part in his left hand, and sew up the whole wound after the glover's manner, leaving very small spaces, not more than the twelfth of an inch each, between each of the stitches. The last stitch should be fastened with a knot, but the other end must hang about a foot out of the abdomen, by means of which the silk may be drawn out when the intestine is healed. After this is performed, the wound of the abdomen is next to be taken care of, and stitched up, keeping the lower or depending part of

the

Fig. 2. INFLECTION.

Fig. 3. I N T E S T I N E S.

the wound open with a tent, till all the preternatural fluids are discharged out of the cavity of the abdomen, and till the union of the wound in the intestine shall give leave to draw away the silk with which the suture was performed on it. See the article *GASTRORAPHY*.

As the modern surgeons, however, have found that few are saved who have received any large wound in the intestines, and that in those few who do recover, the wounded parts, from the fineness of the coat of the gut, do not properly unite, but rather adhere to the inner part of the peritoneum, or to the omentum, or to some other of the intestines, they rather choose now to let alone the operation of the suture of the gut, and substitute a gentler method of cure. They pass a waxed thread through a fine needle, and with this they fasten the wounded part of the intestine to the internal orifice of the wound in the abdomen. The thread that in this case hangs out of the abdomen, is to be so firmly fixed by the application of sticking-plasters to the wound, that the intestine cannot recede from the part to which it was fastened, nor can it evacuate any of its contents into the cavity of the abdomen. When this operation is well performed, the intestine easily adheres to the internal part of the abdomen, and the patient suffers infinitely less pain and hazard, than from the former way of making the suture. The same method of cure also is the proper one for wounds of the stomach, where they are within the reach of the hand, and it is sometimes crowned with success.

Where any part of the intestines is carried away, the case is plainly desperate; yet some of the late eminent surgeons having observed, that the lips of the intestines, so wounded, would sometimes unexpectedly adhere to the wound in the abdomen, took this hint from nature toward a cure in such desperate cases. Whenever, therefore, a surgeon is called in a case of this kind, after diligently examining the state of the upper part of the intestine which has suffered the loss of substance, he should stitch it to the external wound; for by this means the patient may not only be saved from instant death, but there have been instances where the wounded intestine has been so far healed, that the feces which used to be voided by the anus, have been voided by the wound in the abdomen. And

this, tho' from the necessity of wearing a tin or silver pipe, or keeping cloths constantly upon the part to receive the excrement, may seem to be very troublesome; yet it is surely far better to part with one of the conveniencies of life, than to part with life itself; besides, the excrements that are voided by this passage, are not so offensive in smell, as those voided per anum.

The same method of cure may conveniently also be put in practice, where any part of the intestine is mortified, by having been thrust out of the abdomen; for in this case if you tie up the mesenteric arteries, the corrupted or mortified part of the intestine may be cut off, and the remaining sound part made to adhere to the wound of the abdomen. And it is surely better to try this method and save if it be only a few by it, than to leave all in this unhappy situation to perish without help.

**INTESTINAL**, something belonging to, or seated in the intestines. See the preceding article.

Heister gives the name of intestinal fever to a species of fever called by others mesenteric. See *MESENTERIC*.

To this species he also refers the dysenteric, catarrhal, and petechial fevers. See *FEVER*, *DYSENTERY*, *PETECHIAL*, &c.

**INTRADA, ENTRY**, in the Italian music, is much the same with prelude or overture. See the article *PRELUDE*.

**INTRENCHMENT**, or **RETRENCHMENT**, in the art of war. See the article *RETRENCHMENT*.

**INTRIGUE**, or **INTREAGUE**, an assemblage of events or circumstances, occurring in an affair, and perplexing the persons concerned in it.

In this sense, it is used to signify the nodus or plot of a play or romance; or that point wherein the principal characters are most embarrassed, through the artificer and opposition of certain persons, or the unfortunate falling out of certain accidents and circumstances.

In tragedy, comedy, or an epic poem, there are always two designs; the first and principal is that of the hero of the piece.

The second contains the designs of all those who oppose him: these opposite causes produce opposite effects; to wit, the efforts of the hero for the execution of his design, and the efforts of those who thwart it. As those causes and designs are the beginning of the action, so these efforts are the middle, and there form a

knot or difficulty which we call the intrigue, that makes the greatest part of the poem. It lasts as long as the mind of the reader or hearer is suspended about the event of those opposite efforts: the solution or catastrophe commences when the knot begins to unravel, and the difficulties and doubts begin to clear up. The intrigue of the *Iliad* is twofold, the first comprehends three days fighting in Achilles's absence, and consists on the one side in the resistance of Agamemnon and the Greeks, and on the other in the inexorable temper of Achilles. The death of Patroclus unravels this intrigue, and makes the beginning of a second. Achilles resolves to be revenged, but Hector opposes his design; and this forms the second intrigue, which is the last day's battle.

In the *Æneid* there are also two intrigues, the first is taken up in the voyage and landing of Æneas in Italy; the second is his establishment there: the opposition he met with from Juno in both these undertakings, forms the intrigue.

As to the choice of the intrigue, and the manner of unravelling it, it is certain they ought both to spring naturally from the ground and subject of the poem. Bossu gives us three manners of forming the intrigue of a poem; the first is that already mentioned; the second is taken from the fable and design of the poet; in the third the intrigue is so laid, as that the solution follows from it of course.

**INTRINSIC**, a term applied to the inner, real, and genuine values, properties, &c. of any thing, in opposition to their extrinsic or apparent values, &c. See the article **EXTRINSIC**.

**INTRUSION**, in law, obtains where an ancestor dies seised of an estate, or inheritance which is expectant upon an estate for life, and the tenant for life dies; after which a stranger enters before the heir, in which case he is said to intrude. Bracton says, that intrusion signifies any unlawful entry upon lands, &c. by a person who has no right to the same, in prejudice of the person to whom they are legally decended. The difference between an intruder and an abator, according to Fitzherbert, is this, *viz.* that an abator enters into lands, &c. void by the death of a tenant in fee, whilst an intruder enters on lands void by the death of a tenant for life or years. An entry on the king's lands and possessions upon the death of a tenant, &c. is term-

ed intrusion against the king, for which an information may be exhibited; tho' before office is found, he that occupies the land shall not be an intruder, and yet the king is entitled to the profits thereof after the tenant's estate is ended.

**INTRUSION DE GARD**, was a writ formerly in use, where an infant or person within age entered upon his lands, and kept out his lord.

**INTRUSIONE**, is a writ which lies against an intruder at the suit of him that has the fee, &c. If a person has only an estate-tail, he may not have this writ, but is to bring a writ of formedon.

**INTUITION**, among logicians, the act whereby the mind perceives the agreement or disagreement of two ideas, immediately by themselves, without the intervention of any other; in which case, the mind perceives the truth as the eye doth the light, only by being directed towards it. Thus the mind perceives that white is not black, that three are more than two, and equal to one and two. See the article **IDEA**.

This part of knowledge, says Mr. Locke, is irresistible, and, like the sun-shine, forces itself immediately to be perceived as soon as ever the mind turns its view that way. It is on this intuition that all the certainty and evidence of our ether knowledge depends; this certainty every one finds to be so great, that he cannot imagine, and therefore cannot require, a greater. See the articles **JUDGMENT**, **KNOWLEDGE**, **DEMONSTRATION**, &c.

**INVALID**, a person wounded, maimed, or disabled for action by age, &c. For the colleges or hospitals built for the reception and accommodation of invalids, or soldiers and seamen worn out and disabled in the service, see the articles **COLLEGE** and **HOSPITAL**.

**INVECTED**, in heraldry, denotes a thing fluted or furrowed.

Invected is just the reverse of ingrailed, in which the points are turned outward to the field, whereas in invected they are turned inward to the ordinary, and the small semicircles outward to the field. See plate **CXLV**. fig. 5.

**INVECFIVE**, in rhetoric, differs from reproof, as the latter proceeds from a friend, and is intended for the good of the person reproved; whereas the invective is the work of an enemy, and entirely designed to vex and give uneasiness to the person against whom it is directed.

**INVENTION**,

**INVENTION**, denotes the act of finding any thing new, or even the thing thus found.

Invention is, according to lord Bacon, of two very different kinds, the one of arts and sciences, the other of arguments and discourse: the former he sets down as absolutely deficient. That the other part of knowledge is wanting, says he, seems clear; for logic professes not, nor pretends to invent either mechanical or liberal arts; nor to deduce the operations of the one, or the axioms of the other: but only leaves us this instruction, "To believe every artifi in his own art."

His lordship further maintains, that men are hitherto more obliged to brutes than reason for inventions. Whence those who have written concerning the first inventors of things, and origin of sciences, rather celebrate chance than art, and bring in beasts, birds, fishes and serpents, rather than men, as the first teachers of arts. No wonder, therefore, as the manner of antiquity was to consecrate the inventors of useful things, that the Egyptians, to whom many arts owe their rise, had their temples filled with the images of brutes, and but a few human idols amongst them. As to the invention of arts, continues our author, we are rather beholden to the wild goat for chirurgery, to the nightingale for music, to the stork for clysters, to the accidental flying off of a pot's cover for artillery, and, in a word, to chance, or any thing else, rather than logic.

Invention is therefore used for a subtilty of mind, or somewhat peculiar in a man's genius, which leads him to the discovery of things new; whence we say a man of invention.

Invention, according to Du Bos, is that part which constitutes the principal merit of works, and distinguishes the great genius from the simple artifi.

**INVENTION**, in rhetoric, being one of the second divisions of invention, according to Bacon, signifies the finding out and choosing of arguments which the orator is to use for proving his point, or moving his hearers passions.

This invention, in the opinion of that philosopher, cannot properly be called invention, which is the discovery of things not yet known, and not the recollecting things that are known; the only use and office of this rhetorical invention being out of the stock of knowledge already laid up, to select such articles as make

for the purpose. The same author divides the methods of procuring a stock of matter for discourse into two; the first of which is either by marking out and indicating the parts wherein a thing is to be searched after, which he calls the topical way; and the second is by laying up arguments for use that were composed before hand, and which he calls the promptuary way. See the articles **TOPICAL** and **PROMPTUARY**.

Cicero wrote four books upon invention, whereof two only are remaining. Invention, according to this author, is the principal part of oration.

**INVENTION**, in poetry, is applied to whatever the poet adds to the history of the subject he has chosen, as well as to the new turn he gives it.

**INVENTION**, in painting, is the choice which the painter makes of the objects that are to enter the composition of his piece.

M. Felibien gives the general name invention to every thing that depends on the genius of the painter, as the ordonnance, the disposition of the subject, and even the subject itself, when it is new. He also distinguishes invention into two kinds, that which arises immediately from the mind of the painter, and that which he borrows from some other: the first is when he absolutely invents the subject himself; and the second, when he borrows it from history, fable, &c.

Mr. de Piles observes, that invention is different from disposition, and that it is those two things together that form composition; for after having made a good choice of objects proper for the subject, they may be ill disposed, and then, tho' the invention be ever so good, the disposition will be faulty, and the piece will displease.

**INVENTION** is also used for the discovery of a thing hidden. Hence,

**INVENTION** of the holy cross. See the article *Invention of the Cross*.

**INVENTORY** in law, &c. is a schedule containing all the goods and chattles of a deceased person that belonged to him at the time of his death, together with the value of the same, as appraised by two or more indifferent persons.

Executors, as well as administrators, are to deliver in upon oath to the ordinary indented inventories, one part of which is to remain with the ordinary, and the other part with the executor or administrator. This is required for the benefit

of the creditors and legatees, that the executor or administrator may not conceal any part of the personal estate from them. The statute ordains, that the inventory shall be exhibited within three months after the person's decease; yet it may be done afterwards, for the ordinary may dispense with the time, and even with its being ever exhibited, as in cases where the creditors are paid, and the will is executed.

**INVERARY**, a parliament-town of Scotland, in the county of Argyle, of which it is the capital, situated on Lochfin, forty-five miles north-west of Glasgow: west long.  $5^{\circ}$ , north lat.  $56^{\circ} 28'$ .

**INVERNESS**, a parliament and port-town of Scotland, the capital of the county of Inverness, situated at the mouth of the river Ness: west long.  $4^{\circ}$  north lat.  $57^{\circ} 46'$ .

**INVERSE**, is applied to a manner of working the rule of three, or proportion, which seems to go backward, or contrary to the order of the common or direct rule. See the articles *RULE of three* and *PROPORTION*.

**INVERSE** *method of fluxions*. See the article *FLUXIONS*.

**INVERSE** *planting*. See *PLANTING*.

**INVERSION**, the inverting or turning any thing backwards.

**INVERSION**, in grammar, is where the words of a phrase are ranged in a manner not so natural as they might be.

It is a considerable beauty either in verse or prose, when we have it from an able hand; it gives vigour and variety to a sentence, and keeps the mind in an agreeable suspense and expectation of a marvellous turn and conclusion.

**INVERURY**, a parliament-town of Scotland, in the county of Aberdeen, situated on the river Don, ten miles west of Aberdeen.

**INVESTIGATION**, properly denotes the searchi<sup>g</sup> or finding any thing out by the tracts or prints of the feet; whence mathematicians, schoolmen, and grammarians, come to use the term in their respective researches.

Investigation of a theme, in grammar, is the finding out the primitive tense, mood, and person of any verb, far removed from its source. To understand a greek author, it is absolutely necessary to be well acquainted with the method of investigating a theme. This theme, in the greek tongue, is the present tense of the indicative mood.

Clenard was the first who introduced this term into grammar; he gives the title *investigatio thematis* to that part where he teaches the manner of finding whence any person or tense of a verb proceeds, and of reducing it to its primitive word, or finding its indicative.

**INVESTITURE**, in law, a giving livery of seisin or possession. There was anciently a great variety of ceremonies used upon investitures; as at first they were made, by a certain form of words; and afterwards, by such things as had the greatest resemblance to the thing to be transferred: thus where lands were intended to pass, a turf, &c. was delivered by the grantor to the grantee. In the church, it was customary for princes to make investiture of ecclesiastical benefices, by delivering to the persons they had chosen, a pastoral staff and a ring.

**INULA**, in botany, a genus of the *syngenesia-polygamia-superflua* class of plants, with radiated flowers: the receptacle is naked; the down is simple; and the antheræ terminate in setæ at their bases.

**INVOCATION**, in theology, the act of adoring God, and especially of addressing him in prayer for his assistance and protection. See the articles *ADORATION* and *PRAYER*.

The difference between the invocation of God and of the saints, as practised by the papists, is thus explained in the catechism of the council of Trent. "We beg of God, says the catechism, to give us good things, and to deliver us from evil; but we pray to the saints, to intercede with God, and obtain those things which we stand in need of. Hence we use different forms in praying to God, and to the saints: to the former we say, hear us, have mercy on us; to the latter we only say, pray for us." The council of Trent expressly teaches, that the saints who reign with Jesus Christ, offer up their prayers to God for men, and condemn those who maintain the contrary doctrine. The protestants reject and censure this practice as contrary to scripture, deny the truth of the fact, and think it highly unreasonable to suppose that a limited finite being should be in a manner omnipresent, and at one and the same time hear and attend to the prayers that are offered to him in England, China, and Peru; and from thence infer, that if the saints cannot hear their requests, it is inconsistent with common sense

sense to address any kind of prayer to them.

**INVOCATION**, in poetry, an address at the beginning of a poem, wherein the poet calls for the assistance of some divinity, particularly of his muse, or the deity of poetry.

The invocation is said to be absolutely necessary in an epic poem, as the poet relates things which he could not be supposed to know, unless he were inspired by some deity. Besides, it serves his readers as an example of piety, which ought to be the foundation of his whole work. Add to this, that the gods are to have a part in the action, and it is not decent he should set them to work, without first asking them leave.

In the course of an epic poem, it is true, several invocations occur, particularly when any thing extraordinary comes to be related; as when Virgil describes the metamorphosis of Æneas's fleet into sea nymphs: but the first invocation is always the most considerable.

In the invocation, Bossu considers two things; the first is what the poet requests; and the second, to what deity he addresses his request. As to the first, Homer has so closely joined the invocation to the proposition, that he seems to invoke his muse for the whole work. Virgil, on the contrary, only requests his muse to furnish him with a part of his subject: he even mentions the particular part, in which he desires her assistance; and after proposing his matter, in all its extent, he begs the muse to acquaint him with the cause of it.

As to the deity invoked, the same author observes, that it must always be the divinity that presides over poetry in general, or that which presides over the particular subject of the work. Ovid's invocation in his metamorphosis, and likewise Lucretius's, is of this latter kind; those of Homer and Virgil are of the former: they only invoke the muses, and thus distinguish between the divinities who preside over poetry, and those who preside over the actions of the poem, and have parts in it. Lord Shaftsbury observes, that an invocation appears cold from a modern poet.

**INVOICE**, an account in writing of the particulars of merchandise, with their value, custom, charges, &c. transmitted by one merchant to another in a distant country.

One copy of every invoice is to be in-

serted verbatim in the invoice-book, for the merchant's private use; and another copy must, immediately upon shipping off the goods, be dispatched by post, or otherwise, to the correspondent. This copy is commonly drawn out upon a sheet of large post-paper, to the end of which is subjoined a letter of advice.

It must here be observed, that when a merchant ships off goods for his own account, the invoice sent to the factor contains only the quantity of goods, but nothing of the cost and charges; and the letter subjoined consists of instructions signifying in what manner the employer inclines to have his goods disposed of, and returns made.

**INVOICE-BOOK**, this book is paged, and contains copies of the invoices of goods sent to sea: for as a merchant is obliged to send his correspondent an invoice of all the goods he consigns to him, so it is reasonable that he should keep a copy of it for himself. For the further uses of invoice-books, see *BOOK of invoices*.

**INVOLUCRUM**, among botanists, that sort of calyx or cup, which surrounds a number of flowers together, every one of which has, besides this general cup, its own particular perianthium. See the article *CALYX*.

The involucre consists of a number of little leaves, disposed in a radiated manner.

**INVOLUTION**, in algebra, the raising of a quantity from its root to any power assigned. See *QUANTITY* and *POWER*.

Any simple quantity is involved by multiplying the exponent by that of the power required: thus, to raise, any simple quantity to its second, third, fourth, &c. power, is only to multiply its exponent 1, by 2, 3, 4, &c. and, in general, the power expressed by  $m$ , of any quantity, is had by multiplying its exponent by  $m$ . Thus, the second power of  $a$  is  $a^{2 \times 1} = a^2$ ; its third power, or cube, is  $a^{3 \times 1} = a^3$ ; and the  $m$ th power of  $a$  is  $a^{m \times 1} = a^m$ .

Also the square of  $a^4$  is  $a^{2 \times 4} = a^8$ ; the cube of  $a^4$  is  $a^{3 \times 4} = a^{12}$ ; and the  $m$ th power of  $a^4$  is  $a^{4 \times m}$ . The square of  $abc$  is  $a^2 b^2 c^2$ , the cube is  $a^3 b^3 c^3$ , and the  $m$ th power is  $a^m b^m c^m$ .

The coefficients must also be raised to the same power by a continual multiplication of itself by itself, as often as unit is contained in the exponent of the power required. Thus, the square of  $3a$  is  $3 \times$

$3 \times a^2 = 9a^2$ : and the cube of  $3ab$  is  $3 \times 3 \times 3 \times a^3b^3 = 27a^3b^3$ .

As to the signs, when the quantity to be involved is positive, it is obvious that all its powers must be positive too: and when the quantity to be involved is negative, then all its powers whose exponents are even numbers must be positive, and those whose exponents are odd numbers negative; because any number of multiplications of a negative, if that number be even, gives a positive. The

power then can only be negative when its exponent is an odd number, though the quantity to be involved be negative. Thus the powers of  $-a$  are  $+a^2$ ,  $-a^3$ ,  $+a^4$ ,  $-a^5$ ,  $+a^6$ , &c. those powers whose exponent are 2, 4, 6, &c. being positive; but those whose exponents are 1, 3, 5, &c. negative.

The involution of any compound quantity is performed by a continual multiplication of it by itself, as in the binomial  $a+b$ . Thus,

$$\begin{array}{r}
 a+b = \text{root.} \\
 \times a+b \\
 \hline
 a^2+ab \\
 + ab+b^2 \\
 \hline
 a^2+2ab+b^2 = \text{the square, or second power.} \\
 \times a+b \\
 \hline
 a^3+2a^2b+ab^2 \\
 + a^2b+2ab^2+b^3 \\
 \hline
 a^3+3a^2b+3ab^2+b^3 = \text{cube, or third power.} \\
 \times a+b \\
 \hline
 a^4+3a^3b+3a^2b^2+ab^3 \\
 + a^3b+3a^2b^2+3ab^3+b^4 \\
 \hline
 a^4+4a^3b+6a^2b^2+4ab^3+b^4 = \text{biquadratic, or fourth power.} \\
 \times a+b \\
 \hline
 a^5+4a^4b+6a^3b^2+4a^2b^3+ab^4 \\
 + a^4b+4a^3b^2+6a^2b^3+4ab^4+b^5 \\
 \hline
 a^5+5a^4b+10a^3b^2+10a^2b^3+5ab^4+b^5 = \text{the fifth power.} \\
 \times a+b \\
 \hline
 a^6+5a^5b+10a^4b^2+10a^3b^3+5a^2b^4+ab^5 \\
 + a^5b+5a^4b^2+10a^3b^3+10a^2b^4+5ab^5+b^6 \\
 \hline
 a^6+6a^5b+15a^4b^2+20a^3b^3+15a^2b^4+6ab^5+b^6 = \text{sixth power, \&c.}
 \end{array}$$

If the powers of  $a-b$  are required, they will be found the same as the preceding; only the terms, in which the exponent of  $b$  is an odd number, will be negative, because an odd number of multiplications of a negative produces a negative: thus, the cube of  $a-b$  will be found to be  $a^3-3a^2b+3ab^2-b^3$ ; where the second and third term are negative, the exponent of  $b$  being an odd number in these terms. In general, the terms of any power of  $a-b$  are positive and negative by turns. But the reader will find a general theorem, for raising a binomial to any power required, under the article BINOMIAL. If a quantity, consisting of three or more terms, is to be involved, it may be distinguished into two parts, which are to be raised to any power in the same manner as a binomial; and then, by the same rules, you may substitute, instead of the powers of these compound parts,

their values: thus,  $\overline{a+b+c}^2 = \overline{a+b+c}^2$   
 $= a^2 + b^2 + c^2 + 2ac + 2bc + 2ab$   
 $+ b^2 + 2ac + 2bc + c^2$ . And,  $\overline{a+b+c}^3$   
 $= a^3 + 3a^2b + 3a^2c + 3ab^2 + 3ab^2 + 3ac^2 + 3abc$   
 $+ 3b^2c + 3ac^2 + 3bc^2 + c^3$ .  
 In these examples,  $a+b+c$  is considered as composed of the compound part  $a+b$ , and the simple part  $c$ ; and then the powers of  $a+b$ , are formed by the binomial theorem, and substituted for  $\overline{a+b}^3$ , and  $\overline{a+b}^2$ .

The reverse of involution is called evolution, or the extraction of roots; that is, the finding the roots of the powers of any quantity, whether simple or compound. See the article EXTRACTION.

JOACHIMITES, in church-history, the disciples of Joachim a cistercian monk, who was an abbot of Flora in Calabria,

labria, and a great pretender to inspiration.

The joachimites were particularly fond of certain ternaries : the Father, they said, operated from the beginning till the coming of the Son ; the Son, from that time to theirs, which was the year 1260 ; and from that time the Holy Spirit was to operate in his turn. They also divided every thing relating to men, to doctrine, and the manner of living, into three classes, according to the three persons in the Trinity : the first ternary was that of men ; of whom the first class was that of married men, which had lasted during the whole period of the Father ; the second was that of clerks, which had lasted during the time of the Son ; and the last was that of the monks, in which there was to be an uncommon effusion of grace by the Holy Spirit : the second ternary was that of doctrine, *viz.* the Old Testament, the New, and the everlasting Gospel ; the first they ascribed to the Father, the second to the Son, and the third to the Holy Spirit : a third ternary consisted in the manner of living, *viz.* under the Father, men lived according to the flesh ; under the Son, they lived according to the flesh and the spirit ; and under the Holy Ghost, they were to live according to the spirit only.

**JOANNA**, one of the islands of Comoro, situated between the north-west part of Madagascar and Zanguebar, in Africa : east long. 45°, south lat. 12°

**JOB**, or *Book of JOB*, a canonical book of the Old Testament, containing a narrative of a series of misfortunes which happened to a man whose name was Job, as a trial of his virtue and patience ; together with the conferences he had with his cruel friends, on the subject of his misfortunes, and the manner in which he was restored to ease and happiness. This book is filled with those noble, bold, and figurative expressions, which constitute the very soul of poetry.

Many of the jewish rabbins pretend that this relation is altogether a fiction : others think it a simple narrative of a matter of fact, just as it happened : while a third sort of critics acknowledge that the groundwork of the story is true, but that it is wrote in a poetical strain, and decorated with peculiar circumstances, to render the narration more profitable and entertaining.

The time is not set down, in which Job lived. Some have thought that he was much antienter than Moses, because the

law is never cited by Job or his friends, and because it is related that Job himself offered sacrifices. Some imagine that this book was wrote by himself ; others say, that Job wrote it originally in syriac or arabic, and that Moses translated it into hebrew : but the rabbins generally pronounce Moses to be the author of it, and many christian writers are of the same opinion.

The worship of Job is of great antiquity among the greeks and latins : the greeks celebrate his festival on May 6, and the latins keep it on the same month. A great number of churches and chapels are dedicated to this holy man, particularly in Spain and Italy ; and he is invoked principally against the leprosy, the itch, the foul disease, and the like distempers.

**JOBBER**, in law, a person that buys and sells cattle for others. Hence stock-jobbers are persons who buy and sell stocks for other persons.

**IOGUIS**, among the east-indians, a kind of hermits, who generally stand under trees, or near their pagods. Some of them go stark naked, holding their arms across over their heads, and continue in that posture all their lives : others lie on the ground, with one leg higher than the other, and their arms raised above their head ; and these wretched penitents insensibly lose the use of their arms and legs : some confine themselves in cages, set on the top of a thick stake, fixed in the ground, and these cages are so small, that they put the penitent to prodigious torture : some holding a sabre in one hand, and a kind of shield in the other, go up a kind of crane, where hooking themselves to an iron, which runs a considerable way into their backs, they spring forward into the air, flourishing their sabres, and launching out into extravagant praises of their idols : and others plunge into the Ganges, in hopes of being devoured by a crocodile, fancying that by this means they shall obtain the happiness of the next life.

These miserable wretches are considered by the Indians as perfect models of piety and holiness : they are followed by persons of both sexes, who make a vow of devoting themselves to their service, and are wholly employed in soothing their voluntary sufferings by offering them alms and refreshments. They call the pious to their devotions by ringing a little bell ; and when they hold their spiritual conversations, they sit close in a ring, and

set up a banner, made of several pieces of stuff, fastened at the end of a stick.

**JOHN**, or *Gospel of St. JOHN*, a canonical book of the New Testament, containing a recital of the life, actions, doctrine, and death of our Saviour Jesus Christ, written by St. John the apostle and evangelist. See the article **GOSPEL**.

St. John wrote his Gospel at Ephesus, after his return from the isle of Patmos, at the desire of the christians of Asia. St. Jerom says, he would not undertake it, but on condition they should appoint a public fast, to implore the assistance of God; and that the fast being ended, St. John, filled with the Holy Ghost, broke out into these words, "In the beginning was the word," &c. The antients assign two reasons for this undertaking: the first is, because, in the other three Gospels, there was wanting the history of the beginning of Jesus Christ's preaching, till the imprisonment of John the Baptist; which, therefore, he applied himself particularly to relate. The second reason was, in order to remove the errors of the cerinthians, ebionites, and other sects.

**St. JOHN'S DAY**, the name of two christian festivals, one observed on June 24. kept in commemoration of the wonderful circumstances attending the birth of St. John the Baptist; and the other on Dec. 27, in honour of St. John the Evangelist.

*Christians of St. JOHN*. See **CHRISTIANS**.

**St. JOHN'S BREAD**, *ceratonia*, in botany. See the article **CERATONIA**.

**St. JOHN'S WORT**, a plant called by authors hypericum. See **HYPERICUM**.

*Sweet JOHNS*, in botany, a name sometimes given to the pink.

**St. JOHN'S**, in geography, one of the Philippine-islands, situated in 126° east lon. and 7° north lat.

**St. JOHN'S** is also an island in the bay of St. Lawrence, situated north of New Scotland: west lon. 65°, north lat. 47°.

**JOIGNY**, a town of Champagne, in France, thirty miles south-west of Troyes.

**JOINDER**, or **JOYNDER**, in law, signifies a joining of two persons in the same action: as for instance, if there are two joint-possessors of goods, and these are taken from one of them, they may both join in an action to recover them. An action against the owners of a ship, on account of goods damaged, must be brought against all of them: and where there are several partners in trade, and one has the management, actions must be brought against all the partners jointly. In ac-

tions personal, several wrongs may be joined in one writ; yet this cannot be done where some things are founded on a tort, and some on a contract, because they require a different plea and a different process. However, a general action of trespass, and a special action on the case, may be joined in one action; and any actions may be joined, in which the plea, not guilty, goes to all.

**JOINERY**, the art of working in wood, or of fitting various pieces of timber together.

It is called by the French *menuiserie*, *q. d.* small work, to distinguish it from carpentry, which is employed about large and less curious works. See the article **CARPENTRY**.

In the annexed plate (CXLVII.) are represented the tools employed in this art; where A is a work-bench; *b*, the hook; *c*, the screw; *d*, the hold-fast; *a*, *a*, *a*, holes in the legs of the bench; *e*, *e*, mallets; B, B, B, &c. planes of several sorts; where B<sub>1</sub> is called a fore-plane; B<sub>2</sub>, a jointer; B<sub>3</sub>, a strike-block; B<sub>4</sub>, a smoothing-plane; B<sub>5</sub>, a rabbet-plane; B<sub>6</sub>, the plough; C, C, C, chisels of several sorts; C<sub>1</sub> and C<sub>3</sub> being called formers; C<sub>2</sub>, a paring-chisel; C<sub>4</sub>, a skew-former; C<sub>5</sub>, a mortef-chisel; C<sub>6</sub>, a gouge; D is a square, *a* being called the handle; *b*, the tongue; *c*, the outer square; and *d*, the inner square; E, E, hand-saws; F, the bevil, with its tongue moveable upon a center; G, a gage; H, a piercer; *a* being its head; *b*, the pad; *c*, the stock; and *d*, the bit; I, a gimblet; K, an augre; *aa* being its handle; and *b*, its bit; L, a hatchet; M, a frame or bow-saw; N, a whip-saw; O, a tenant-saw; Q, a compass-saw; R, a hammer; and S, a foot-rule, to measure their work with.

**JOINT**, in general, denotes the juncture of two or more things.

The joints of the human body are called by anatomists articulations. See the article **ARTICULATION**.

The term joint is also applied to the separation between the stones or bricks of a building, usually filled with mortar, plaster, or cement: also by carpenters, to the several manners of assembling or fitting pieces of wood together; as a dovetail joint, &c.

*Stiffness of the JOINTS*, in surgery and medicine, sometimes proceeds from the bones being broken, bruised, or wounded, especially about the extreme parts, which being

# Instruments used in JOINERY

being kept in one posture, in order for cure, the synovia of the joints becomes thick, and depraves or quite abolishes its motion ; or it may proceed from the bony juice proceeding from broken bones, and insinuating itself into the joint. Hoffman says, diseases of the joints sometimes proceed from spasms of the ligaments.

If difficulty of motion proceeds from long rest, it is to be treated with emollient and resolving fomentations, ointments, oils, and the hot fat of animals, often rubbed upon the joint ; at the same time using a gentle flexure, till the motion is gradually restored. If these will not do, then warm emollient baths must be used, or hot-bath-waters, till the inspissated liquor is dissolved, and the motion as much as possible restored. If it proceeds from the juice of broken bones, or the nodous gout, it is generally incurable, if the former remedies will not do.

**JOINT-EXECUTORS**, in law, are when two or more persons are appointed such by will ; in which case they are accounted but as one single person, so that the actions done by one of them are taken to be the acts of all, because they all represent the person of the testator : thus, where two joint-executors are possessed of a lease for years, in right of their testator, one of them may sell the term without the others joining ; and in like manner, where one joint-executor gives a release, the other is bound by it, each having an authority over the whole estate : but a joint-executor is not charged with the acts of his companion, any farther than he is actually possessed of the goods of the testator ; however, if joint-executors enter into an agreement, that each shall intermeddle with particular parts of the testator's estate, in that case, each becomes chargeable for the whole, by agreement. It has been held, that two joint-executors cannot plead separate pleas, because their testator, if living, on an action brought against him, could have been allowed but one plea ; and that if all the executors are not named in an action brought by joint-executors, the action will abate. As to legatees, the receipt of one executor charges not the other.

**JOINT-LIVES**, in law, is where any thing is granted or given to two or more during their lives. See the article **LIFE**.

**JOINT-TENANTS**, are such as hold lands or tenements jointly by one title ; as where a man grants lands, &c. to two

persons and their heirs ; such persons, during their joint-tenancy, must jointly plead as well as be jointly sued, which is common to them with coparceners of lands. See the article **COPARCENERS**.

Every joint-tenant in an estate has a right to his own share, and may give lease or forfeit the same ; he may make a lease, but not a deed of feoffment, or grant, to any besides his companion. Joint-tenants cannot singly dispose of more than the part that belongs to them ; for where they join in any gift or grant of lands, in the judgment of the law, each gives but his respective part : therefore, if one joint-tenant grants a rent-charge out of his part, after his death the survivor shall have the whole land discharged, because the land will be his by survivorship : but where a lease for years is made by a joint-tenant, it cannot be avoided by the survivor. Sometimes joint-tenants enter into covenants, not to take advantage of each other by survivorship ; and, indeed, they, as well as tenants in common of inheritance, are bound by statute to make partition, in the same manner as coparceners.

**JOINTURE**, in law, generally signifies a settlement of lands and tenements, made on a woman in consideration of marriage. See the article **MARRIAGE**.

It also signifies a covenant, by which the husband, or some friends of his, assures lands, &c. to his wife for the term of her life. See the article **ANNUITY**.

Here it is observable, that an estate settled in jointure, which comes from the ancestors of the wife, and is not of the purchase of the husband, or some ancestor of his, will not be accounted a good jointure. Where no estate of inheritance is reserved to the husband and his heirs, but the estate is granted to the wife for life, or in tail, the remainder to a stranger ; this will not be a legal jointure, although the same is made by the husband or his ancestor.

In order to make a perfect jointure agreeable to the statute 27 Hen. VIII. cap. x. several things are to be observed : 1. That it be made to take effect for the wife's life, either in possession or profit, presently after the decease of her husband.

2. That it be for the term of her own life, or for a greater estate : it may however be limited to continue no longer than she remains a widow, &c. 3. That it be expressed to be in satisfaction of her whole

whole dower, and not a part thereof.

4. That, though it may be made either before or after marriage, yet, if before, the wife cannot waive it, and claim her dower at common law: but if made afterwards, she may, at the death of her husband. It is here said, that all other settlements in lieu of jointures, that are not pursuant to this statute, are jointures at common law, and no bars to claim of dower. See DOWER.

Upon the husband's death, the wife may enter on her jointure, and is not driven to a real action, as she is to recover dower at common law. Wherefore, on a lawful eviction of her jointure, she shall be endowed according to the rate of her husband's lands, of which she was entitled to dower by the common law; and should she be evicted of part of her jointure, she shall have dower for so much thereof. A husband committing treason shall not occasion a forfeiture of the wife's jointure; yet feme-coverts committing the same, or felony, are liable to forfeit their jointures; and upon conviction of recufancy, they incur the forfeiture of two parts in three of their jointures, as well as dowers.

JOINTURESS, or JOINTRESS, the person on whom a jointure is settled. See the preceding article.

Where an estate, settled on a wife, is a jointure by law, and the jointress makes any alienation thereof, either by fine, feoffment, &c. with another husband, such alienation shall be a forfeiture of the estate so settled, as a jointure: but a jointress may, by lease, demise and grant an estate for forty years, &c. if she live so long, or for life, without incurring a forfeiture. In case the jointress covinously suffers a recovery to bar the heir, he may enter presently upon the lands, &c.

JOINVILLE, a town of Champaign, in France, situated on the river Marne: east longitude  $5^{\circ} 15'$ , and north latitude  $48^{\circ} 27'$ .

JOISTS, or JOYSTS, in architecture, those pieces of timber framed into the girders and summers, on which the boards of the floor are laid.

Joists are from six to eight inches square, and ought seldom to lie at a greater distance from each other than ten, or, at most, twelve inches, nor ought they ever to bear a greater length than ten feet, or to be less into the wall than eight inches. All joists on the back of a chimney ought

to be laid with a trimmer, at six inches distance from the back.

Some carpenters furr their joists, as they call it; that is, they lay two rows of joists, one over another, the undermost of which are framed level with the under side of the girder; and the uppermost, which lie cross the lower ones, lie level with the upper side of the girder.

JONAH, or *Prophecy of JONAH*, a canonical book of the Old Testament, in which it is related, that Jonah was ordered to go and prophecy the destruction of the Ninevites; but that disobediently attempting a voyage another way, he was discovered by the rising of a sudden tempest, and cast into the sea, where he was swallowed up by a whale, which having lodged him three days and three nights in his belly, disgorged him upon the shore; whereupon being sensible of his past danger and surprising deliverance, he betook himself to the journey and embassy, to which he was appointed; and arriving at Nineveh, the metropolis of Assyria, he, according to his commission, boldly laid open to the inhabitants, their sins and misdeeds, and proclaimed their sudden overthrow; upon which the whole city, by prayer and fasting, and a speedy repentance, happily averted the divine vengeance, and escaped the threatened ruin.

IONIA antiently was a province of the lesser Asia, or Natolia, bounded by Etolia on the north, Lydia on the east, Caria on the south, and the Archipelago on the west.

IONIC ORDER, the third of the five orders of architecture, being a kind of mean between the robust and delicate orders. See plate CXLVIII, fig. 1.

The first idea of this order was given by the people of Ionia, who, according to Vitruvius, formed it on the model of a young woman of an elegant shape, dressed in her hair; whereas the doric had been formed on the model of a strong robust man. The ionic order is distinguished from the composite, in that it has none of the acanthus-leaves in its capital; and from the tuscan and doric, by the channels and flutings in its shaft.

The capital of this order is adorned with volutes, and its cornice with dentiles. The proportions of the ionic pillar, as they are taken from the famous one in the temple of Fortuna Virilis at Rome, now the church of St. Mary the Egyptian,

an, are these: 1. The entire order from the superficies of the area to the cornice, are twenty-two modules, or eleven diameters. 2. The column with its base contains eighteen modules. 3. The entablature contains four modules. 4. The volute of the capital is of an oval form. 5. The columns in this order are often hollowed, and furrowed with twenty-four gutters or channels, called flutings: these flutings are not always concave from the top of the shaft to the bottom, but for that third of it next the base, they are filled up with a kind of rods or canes; and in the other two thirds they are left hollow, or friated, in imitation of the folds or plaits of a garment.

When this order was first invented, its height was but sixteen modules; but the antients, to render it still more beautiful than the doric, augmented its height, by adding a base to it.

Mr. Le Clerc makes its entablement four modules and ten minutes, and its pedestal six entire modules; so that the whole order makes twenty-eight modules ten minutes.

This order is at present used properly in churches and religious houses, courts of justice, and other places of tranquility and devotion.

This order has one advantage above any of the rest, which consists in this, that the fore and hind parts of its capital are different from its sides; but this is attended with an inconvenience, when the ordonnance is to turn from the front of the building to the side; to obviate which, the capital may be made angular, as is done in the temple of Fortuna Virilis.

Scamozzi, and some other modern architects, have introduced the upper part of the composite capital, in lieu of the ionic, imitating that of the temple of Concord, whose four sides are alike. To render it a little more beautiful, the volute may be made a little oval and inclining.

For the base, cornice, freeze, and pedestal of this order, see the articles *BASE*, *CORNICHE*, &c.

**IONIC DIALECT**, in grammar, a manner of speaking peculiar to the people of Ionia.

At first it was the same with the antient attic; but passing into Asia, it did not arrive at that delicacy and perfection to which the Athenians attained. The Ionians generally changed the *α* into *η*, as

*σοφία* into *σοφῆ*: they put the *η* and *ι* for *ε*, and *αι* for *η*, as *αγῆσιον* for *αγῆσιον*: *αναγκαῖη* for *αναγκη*: they also change *α* and *ε* into *υ*, *αυ* into *ωυ*, *ει* into *ευ* and *εε*, *ευ* into *ω* and *ηυ*, and *εο* into *ευ*, as *βαλῆ* into *βηῖ*, *αληθεια* into *αληθητη*, *δαυμα* into *δωῦμα*, *αυθ* into *ωυθ*, *ποιεσθαι* into *ποιεασθαι*, *ημεεις* into *ημεεε*, &c. they also intert the *ι* and *υ*, as *εσιν* for *εσιν*, and *πολυς* for *πολυς*.

**IONIC SECT** was the first of the antient sects of philosophers; the others were the italic and eleatic. The founder of this sect was Thales, who being a native of Miletus in Ionia, occasioned his followers to assume the appellation of ionic: Thales was succeeded by Anaximander, and he by Anaximenes, both of Miletus; Anaxagoras Clazomenius succeeded them, and removed his school from Asia to Athens, where Socrates was his scholar. It was the distinguishing tenet of this sect that water was the principle of all natural things.

**IONIC TRANSMIGRATION** was antiently a very celebrated epocha; it took its rise from the retreat of the athenian colonies, who, upon the death of Codrus, put themselves under the command of his son Neleus, and established the twelve cities of Ionia in Asia. These colonies, according to Eratosthenes, were established fifty years after the return of the Heraclidae; and, according to Marham, seventy-seven years after the taking of Troy.

**JOVIAL**, *jovialis*, among chemists, &c. something belonging to tin, as the bezoardicum joviale. See *BEZOARDICUM* and *TIN*.

**JONK**, or *JONQUE*, in naval affairs, is a kind of small ship, very common in the East-indies: these vessels are about the bigness of our fly-boats; and differ in the form of their building, according to the different methods of naval architecture used by the nations to which they belong. Their sails are frequently made of mats, and their anchors are made of wood.

**JONTHLASPI**, in botany, a plant called by Linnæus *clypeola*. See *CLYPEOLA*.

**JOSHUA**, a canonical book of the Old Testament, containing a history of the wars and transactions of the person whose name it bears. This book may be divided into three parts; the first of which is a history of the conquest of the land of Canaan; the second, which begins at the twelfth chapter, is a description of that

country, and the division of it among the tribes; and the third, comprised in the two last chapters, contains the renewal of the covenant he caused the Israelites to make, and the death of their victorious leader and governor. The whole comprehends a term of seventeen, or, according to others, of twenty-seven years.

**JOURNAL**, a day-book, register, or account of what passes daily.

**JOURNAL, or DAY-BOOK**, among merchants, is that wherein the transactions, recorded in the waste-book, are prepared to be carried to the ledger, by having their proper debtors and creditors ascertained and pointed out, for a more distinct account of which, see the article **Book**.

**JOURNAL**, at sea, is a register kept by the pilot and others, wherein notice is taken of every thing that happens to the ship from day to day, with regard to the winds, the rhumbs, the rake, soundings, &c. and in order to enable him to adjust the reckoning, and determine the place where the ship is.

For the method of correcting a journal at sea, by making proper allowances for the lee-way, variation, &c. see the articles **LEE-WAY**, **VARIATION**, **RECKONING**, &c.

The remarkable occurrences of the whole day being finished in the log-book, if the latitude by account agree with the latitude by observation, the ship's place will be truly determined; if not, then the reckoning must be corrected, before it be placed in the journal. See the article **LOG-BOOK**.

The form of the journal, together with an example of two days work, is as follows. **N. B.** To express the days of the week, the seamen commonly use in their books the characters by which the sun and planets are expressed, *viz.* ☉ denoting Sunday, ☿ Monday, ♀ Tuesday, ♁ Wednesday, ♃ Thursday, ♄ Friday, and ♅ Saturday.

**JOURNAL** is also a name common for weekly essays, news-papers, &c. as the *Gray's Inn Journal*, the *Westminster Journal*, &c.

**JOURNEYMAN**, properly one who works by the day only; but it is now used for any one who works under a master, either by the day, the year, or the piece.

**JOURNEYS-ACCOUNTS**, in law, signifies as soon as possible: thus, when a writ is rendered void by the death of the defend-

A Journal from the Lizard towards Jamaica, in the ship Neptune, J. M. commander.

Week Days.	Months.	Days.	Winds.	Direct Course.	Miles.	Latitude correct.	Whole diff. Lon. made.	Bearings and dist. from the Lizard.	Remarkable observations and accidents.
☿			NbF EbS NNE NEbE	S 31, 31 W	157.4	47° 46'	2° 5' W	At noon the Lizard bore N 31°, 31' E. dist. 157.4 Miles.	Fair weather at four P. M. I took my departure from the Lizard, bearing NNE, and distant five leagues.
♂			West NWbW SWbW	S 34, 10 E	48.2	47° 06'	1° 35' W	At noon the Lizard bore S 17°, 55' W dist. 183 Miles.	Strong gales of wind and variable.

ant, or for want of form, &c. the plaintiff becomes entitled to have a new writ by journeys-accounts, that is, within as little time as he possibly can, after the abatement of the first; in which case, the second writ is a continuance of the cause, as much as if the first writ had never abated. This second writ is to be brought within fifteen days at most, after the abatement of the first, which must have been without any fault of the plaintiff, other-

wise

wife a second writ cannot be brought by journeys-accounts : yet if the abatement be by default of the clerk, in not writing the writ in due form, the plaintiff may have it. The second writ must be brought for the same thing, and also in the same court as the first. This is to be observed, that judicial writs can never be had by journeys-accounts.

**JOYNERY, or JOINERY.** See **JOINERY.**

**IPECACUANHA**, in the materia medica, a west-indian root, of which there are two kinds, distinguished by their colour, and brought from different places, but both possessing the same virtues, though in a different degree. The one is grey, and brought from Peru ; the other is brown, and is brought from the Brazils : and these are indifferently sent into Europe under the general name of *ipecacuanha*.

These two sorts have been by some supposed to be the roots of two different plants, but this is a mistake ; the only difference is, that one grows in a different place, and in a richer and moister soil, and is better supplied with juices than the other.

The grey *ipecacuanha* ought to be chosen for medicinal juices, preferable to the brown, as the latter is apt to operate more roughly. The peruvian, or grey, *ipecacuanha* is a small and irregularly contorted and twisted root ; it is of the thickness of a goose-quill, and rises into a sort of annular ridges, running quite round the root. It is considerably hard, and does not cut easily through with the knife ; but on bending it much, it easily breaks. It is of a dusky greyish colour on the surface, and when broken appears of a clearer and paler grey, and discovers a tough and firm nerve, occupying its center, and running its whole length. The whole root is of a peculiar and somewhat pungent smell ; in taste it is acrid and somewhat bitterish, and upon the whole very disagreeable.

The brown, or brasilian, *ipecacuanha* resembles the other, but is more twisted and convoluted ; it is a smaller and shorter root, of a deep dusky brown on the outside, and white when broken : it is less acrid and more bitter than the grey-kind.

The grey and brown are both of them so acrimonious, that the people employed to pound any quantity of either, if they have not the caution very carefully to avoid the dust that arises from the mortar,

are often seized immediately afterwards with a difficulty of breathing, and spitting of blood, and sometimes with bleeding at the nose, and a great swelling and inflammation of the face, eyes, and throat ; these symptoms generally go off in a day or two of themselves ; but if they are more than ordinary violent, it may be proper to bleed for them.

*Ipecacuanha*, however, is an excellent, mild, and safe emetic ; it is also a noble restraining ; and given in doses too small to vomit, is the greatest of all remedies for a dysentery. Its dose, as an emetic is from six or eight to thirty grains, and the best way of taking it is in white wine, in which it should have first stood four and twenty hours. In dysenteries the patient is first to take such doses of it as will vomit him, and afterwards to continue the use of it for a long time, at the rate of three or four grains, in any form, twice a day. Small doses of *ipecacuanha*, are an excellent remedy in diarrhoeas of a more simple kind ; and in the fluor albus, we hardly know a better medicine.

**IPECACUANHA** is also a name given by the people of Virginia to a species of *filipendula*. See the article **FILIPENDULA**.

**IPOMÆA**, AMERICAN JASMINE, in botany, a genus of the *pentandria monogynia* class of plants, the corolla whereof consists of a single infundibuliform petal ; the tube is nearly cylindric, and very long ; the limb is patent, and divided into five semi-lanceolated plane segments ; the fruit is a roundish capsule, containing three cells ; the seeds, of which there are several in each cell, are of an oval figure. This plant is by some reckoned a species of the *convolvulus*. See plate **CXLIV.** fig. 4.

**IPSWICH**, a borough and port-town of Suffolk, situated on the river Orwel, twenty-four miles south-east of Bury.

It sends two members to parliament.

**IRELAND**, an island of the Atlantic ocean, subject to Great Britain, situated between  $5^{\circ}$  and  $10^{\circ}$  west longit. and between  $51^{\circ}$  and  $56^{\circ}$  north latitude ; being bounded by the Northern ocean on the north, by St. George's channel, which divides it from Great Britain, on the east, and by the Atlantic and Western ocean on the south and west. This country is two hundred and fifty miles long, and one hundred and fifty broad ; distant from Holyhead, in north Wales, fifty miles, and from Galloway, in Scotland, fifteen miles. It is divided into four large provinces,

vinces, viz. Ulster on the north, Leinster on the east, Munster on the south, and Connaught on the west.

**IRIS**, the RAINBOW, in physiology. See the article RAINBOW.

**IRIS**, in anatomy, the anterior coloured part of the uvea of the eye. See EYE.

The iris is a circular variously coloured part, which surrounds the pupil; it is in some persons blue, in others black, brown, grey, &c. each of which has its peculiar beauty, and is suited to the complexion of the person who has it.

**IRIS**, the FLOWER DE LUCE, in botany, a genus of the *triandra-monogynia* class of plants, under which is comprehended the xiphion, sisyrinchium, and hermodactylus of authors, the characters of which are these: the flower is monopetalous, but divided into six long and obtuse segments; the three exterior ones being reflex, or bent back, and the three inner ones erect and more acute; the fruit is an oblong, angular, and trilocular capsule, containing a great number of seeds. See plate CXLIV. fig. 5.

The florentine, or dry iris-root, is an attenuant and expectorant, and accordingly given with success in asthmas and disorders of the breast and lungs; the dose is from ten to fifteen grains in powder. The juice of the fresh root of our common iris is an excellent medicine in dropries; and the best way of giving it is in white wine, an ounce or two for a dose: it works both by vomit and stool, and carries off a very great quantity of phlegm. It is also ordered as a sternutatory, to be snuffed up the nose, in complaints of the head, which it eases very much, by bringing away the over-abundant phlegm:

**IRON**, *ferrum*, in natural history, the lightest of all metals excepting tin, but considerably the hardest of them all.

It is, when pure, naturally malleable and ductile under the hammer; but that in a less degree than either gold, silver, lead, or copper. When wrought into steel, or when in the impure state from its first fusion, in which it is called cast iron, it is scarce malleable at all: the most ductile iron in the world also, on being only heated and suddenly quenched in cold water, loses much of this quality.

Iron is extremely capable of rust; more so than any other metal; it is very sonorous; it requires the strongest fire of all the metals to melt it; it must be a very good furnace that will make iron run without the blast of bellows; but it is

found, when once heated to a proper degree, this blast will effect that without the assistance of the farther heat of any fuel being employed in it; for if an iron-bullet, made red-hot, be suspended at a distance from the fire, and the blast of a strong pair of bellows forcibly directed against it in that condition, it will in a little time melt and run down in drops, by the mere effect of the current of the air they convey to it. Iron is less simple in its composition than any of the heavier metals: it contains, indeed, a sulphur so imperfectly blended with the rest of its constituent matter, that it will readily get loose from it, and in a strong heat will appear in visible flames. It is the most difficult of all the metals to be amalgamated with mercury; the metallurgic authors in general, have said that it will not amalgamate with it at all; but, from the success of some late attempts towards making this union between them, it appears to be not impossible, that a method may be found of doing it.

Iron is less fixed in the fire, than most of the other metals; it manifestly fumes and sparkles, when exposed to a moderately fierce degree of it; it loses also a part of its weight in this heat, and much more when in fusion. Iron is remarkable for the effect fire has on it, in rendering it more ductile; most of the other metals are brittle, while they are hot; but this is most of all malleable, as it approaches nearest to fusion. It grows red-hot long before it melts, and is known to be approaching towards that state, by its becoming whiter, and by its sparkling; if taken from the fire, as soon as it runs, it is found to be more malleable for the fusion; but if it be kept long in that state, its sulphur dissipates in form of a white smoke; the metal after this becomes much more brittle, and in fine runs into a bluish glass.

Iron, exposed to the focus of a great burning glass, instantly grows red-hot, then turns whitish, sparkles and flames, and immediately after melts; soon after this the greatest part of it flies off in sparks, which appear very bright, and, if caught upon paper, are found to be so many little globular bodies, all hollow like bomb-shells: the remainder runs into a bluish or purplish glass; and this glass, exposed again to the same focus, on a piece of charcoal, takes up, from the vegetable fuel, the sulphur or inflammable principle it had lost, and becomes

Fig. 1. IONIC ORDER.

Fig. 2 ISOSCELES.

Fig. 3 JUPITER.

comes true iron again. Upon the whole, the effects of a common, and those of a solar fire, on this body, concur to prove, that it consists of vitriolic salt, a vitrifiable earth, and a peculiar bituminous matter, not found in any of the other metals. When perfectly pure, it readily melts with gold and silver, and unites with them in fusion; but if it be impure, it separates itself, and forms a distinct regulus above the surface of the other.

On being heated red-hot, it increases in bulk and in weight; but it returns to its former gravity and dimensions when cold.

Iron is soluble in all the stronger acids; spirit of nitre, or aqua fortis, succeed most readily in the solution of it; but, beside these, and all the other acids, it is to be dissolved also by a multitude of weaker menstrooms, among the rest even by common water; for on lying long in this fluid, it communicates a manifest taste to it, and contracts a rust, and throws off a yellow ochre. All salts, except the alkaline ones, readily dissolve iron; nay the very air has so much power over it in this respect, that the people who deal in utensils made of it, are obliged to cover them with some oily or fat substance, to make them retain their polish. To this may be added, that iron is the most easily of all metals destroyed by many other means: it neither resists the force of lead nor of antimony; but, on being fused with them, it almost immediately vitrifies, and is carried off in form of scoriae.

The great test of iron, is its answering to, or being attracted by, the magnet or loadstone; but then it must be in its true metalline state, for many of its ores will not answer in any part to this trial. Experiments, however, prove, that iron may be produced by art, out of almost every thing we know. Earths of almost all kinds afford iron by calcination; and all the parts of animals and vegetables, as well their fluids as their solids, yield it by the same means: if any plant, or part, or juice of a plant, be burnt to ashes, or the flesh, bones, blood, or fat of any animal, be treated in the same manner, iron will be found in the ashes, and that in so perfect a state, that it answers readily to the magnet. Honey, wax, and all other vegetable substances, collected by animals, contain iron, and it may be separated from them pure, in the same manner: finally, our Dr. Lister

takes great pains to prove, that this metal is found in, nay, and is the basis of the stone in the bladder.

Iron in the bowels of the earth, when it enters the composition of crystals in spars, seems to be two very different operations of the same metal; they sometimes concur, as there are found purple rhombic crystals of iron, and yellow cubic ones of lead; but in general it is much more frequent to be coloured hexangular sprigs, and colourless cubes and rhombs.

Among the gems, the amethyst, garnet, and hyacinth owe their colours to iron; and this metal has the same effect in the preparation of the facitious gems, as in the natural ones; for, properly managed, it communicates a purple or red colour in various shades and degrees, to glasses and to vitrified substances of all kinds.

True native iron is not to be expected in the midst of masses of its ore, but in detached sprigs or filaments in the fissures of rocks, the whole substance of which is rich in that metal: such have been all the genuine specimens of this rich fossil, and such their place of formation.

The ores of iron generally discover themselves to be such, either by their resemblance to wrought iron in structure and look, or by the yellowish or purplish tinge they are coloured with. Those which have most of all the appearance of the metal they contain, are usually the richest.

There is an iron-ore found in Sweden and Germany, particularly in the Hartsforest, which usually lies in the largest fissures of the strata, in great lumps, and is very hard, heavy, and of a bluish grey colour; this, when broken, has so much of the sparkling appearance of the metal, that a person unaccustomed to these subjects, might easily mistake it for real pure iron. This is the richest iron-ore known, unless we except some of the hæmatites. We have an ore very like this in the forest of Dean, in Gloucestershire, which is at this time worked to great advantage. Another kind we have in Derbyshire, which is also common to Sweden and to Germany; it resembles the former, but that it is harder; and when broken, it is not so bright and sparkling. There are also other very rich ores of a dusky brown colour, with a tinge of purple; of this kind are those worked at this time in Suffex, under the name of the cabala-vein. Another of the rich kinds, less common with us, is of a bluish purple, with a few bright spangles in it; but this is much

inferior.

inferior to the two former of those above-mentioned.

The poorer ores of iron are generally of a more lax and friable texture, and of a yellowish or reddish hue, or else of a mixed colour between these, and with a cast of brownish or blackish in it: but the most singular of all the ores of iron is a white one, which appears only like a debased crystal, having not the least sign of metal in it. The common ochres, as well the yellow as the red, are also to be ranked among the number of the ores of iron; they are very rich in that metal, and are even worked for it in some places to great advantage: nor are we to omit the mention of those elegant bodies which hang from the roofs of caverns in iron-mines, in form of icicles; these are truly stalactites of iron; they are generally produced in large clusters together, and called by the miners brush-ore: these are almost all iron. The cruusted ferruginous bodies, common in our gravel-pits about London, are also very rich in iron, and have been worked for it in places where they are sufficiently plentiful. The red substance called smit, is likewise a very rich iron-ore; this is much like the common Derbyshire reddle, but finer and heavier.

*Method of obtaining IRON from its ore, in a close vessel.* Roast for a few minutes in a test under the muffle, and with a pretty strong fire, two centners of the small weight of your iron-ore grossly pulverised, that the volatiles may be dissipated in part, and the ore itself be softened, in case it should be too hard. When it is grown cold, beat it extremely fine, and roast it a second time, as you do the copper-ore, but in a much stronger fire, till it no longer emits any smell; then let it grow cold again.

Compose a flux of three parts of the white flux with one part of the fusible pulverised glass, or of the like sterile unsulphureous scoriæ, and add glass-gall and coal-dust, of each one half part: add of this flux three times the quantity of your roasted ore, and mix the whole very well together: then choose a very good crucible, well rubbed with lute within, to stop the pores, which may be here and there unseen; put into it your ore mixed with the flux, cover it over with common salt, and shut it close with a tile, and with lute applied to the joints.

Put the wind-furnace upon its bottom part, having a bed made of coal dust.

introduce besides into the furnace, a small grate, supported on its iron-bars, and a stone upon it, on which the crucible may stand as upon a support; surround the whole with hard coals, not very large, and light them at top: when the vessel begins to grow red, which is indicated by the common salt's ceasing to crackle, stop with gross lute, or windsor-loam, the holes of the bottom part, except that in which the nozzle of the bellows is received; blow the fire, and excite it with great force, adding now and then fresh fuel, that the vessel may never be naked at top. Having thus continued your fire in its full strength for three quarters of an hour, or a whole hour, take the vessel out of it, and strike the pavement on which it is set, that the small grains of iron that happen to be dispersed, may be collected into a regulus, which you will find after having broken the vessel.

*Preparations of IRON, in medicine, are, 1.* the crude filings, reduced to an impalpable powder, greatly recommended in female disorders.

2. The crocus martis. See CROCUS.

3. The flores martiales, or flowers of iron. See the article FLOS.

4. The sal martis, or salt of iron, which is prepared thus: mix together a quart of water, and eight ounces of the oil of vitriol; pour the oil of vitriol in by a little at a time: put the mixed liquor into a glass-vessel, and add to it four ounces of the filings of iron: when the ebullition is over, evaporate the liquor to a pellicle, and set it to shoot, there will then be a green vitriol or salt found in fair crystals; dry them for use.

This salt is one of the most powerful preparations of this metal; it opens obstructions of all kinds, strengthens the viscera, is an excellent medicine in cachexies, and destroys worms.

5. Tincture of iron, with spirit of salt, is made thus: take filings of iron, half a pound; Glauber's spirit of sea-salt, three pounds; rectified spirit of wine, three pints: digest the spirit of salt and the filings together, without heat, as long as the spirit will work upon them; then after the fæces have subsided, pour off the clear liquor, evaporate it to one pound, and to this add the spirit of wine.

This has the same virtues as the crocus martis. See the article CROCUS.

6. Chalybeate, or steel-wine, is made in the following manner: take filings of iron, four ounces; cinnamon and mace,

of each half an ounce ; of rhenish wine, two quarts ; infuse them a month, without heat, often shaking the vessel, and then filter it off for use.

This wine is an excellent stomachic and aperient ; a moderate glass may be drank once or twice a day, or it may be mixed in apozems of the aperient vegetables.

**Duties upon IRON.** Amy spanish, spruce, and swedish iron imported in any other ship or vessel than such as is english built, and of which the master, and at least three-fourths of the mariners are english, pays on importation, 2l. 17s. 10 $\frac{6}{100}$ d. the ton, and draws back on exportation, 2l. 14s. 6 $\frac{7}{100}$ d. The same imported in english-built ships, and so navigated, to pay on importation, 2l. 8s. 6 $\frac{1}{100}$ d. the ton, and draw back on exportation, 2l. 5s. 2 $\frac{2}{100}$ d. Iron slit or hammered into rods, commonly known by the name of rod-iron, pays on importation, 8s. 6 $\frac{4}{100}$ d. the hundred wt. and draws back on exportation, 8s. 7 $\frac{5}{100}$ d. Ditto from Ireland, pays 3s. 10 $\frac{2}{100}$ d. and draws back, 3s. 4 $\frac{5}{100}$ d. Iron drawn or hammered, less than three fourths of an inch square, pays on importation, 8s. 6 $\frac{4}{100}$ d. the hundred weight, and draws back on exportation, 8s. 7 $\frac{5}{100}$ d. Unwrought iron of Ireland, pays on importation, 1l. 6s. 11 $\frac{4}{100}$ d. the ton, and draws back on exportation, 1l. 3s. 7 $\frac{5}{100}$ d. Unwrought iron of all other places, not otherwise rated, imported in british ships, pays on importation, 2l. 8s. 6 $\frac{1}{100}$ d. the ton, and draws back on exportation, 2l. 5s. 2 $\frac{2}{100}$ d. and in foreign ships, pays on importation, 2l. 17s. 10 $\frac{6}{100}$ d. and draws back on exportation, 2l. 14s. 6 $\frac{7}{100}$ d. Iron-wares manufactured, not otherwise rated, or not prohibited by law, pay per hundred weight on importation, 12s. 4 $\frac{6}{100}$ d. and draw back on exportation, 11s. 5 $\frac{2}{100}$ d. Iron-ore the ton, pays on importation, 2s. 4 $\frac{72\frac{1}{2}}{100}$ d. and draws back on exportation, 2s. 1 $\frac{87\frac{1}{2}}{100}$ d. Old bushels, broken and cast iron, pays on importation, the ton, 11s. 11 $\frac{62\frac{3}{4}}{100}$ d. and draws back on exportation, 10 s. 9 $\frac{37\frac{1}{2}}{100}$ d. Backs for chimnies, small, the piece, pay on importation, 2s. 4 $\frac{52\frac{1}{2}}{100}$ d. and draw back on exportation, 2s.

2 $\frac{62\frac{1}{2}}{100}$ d. Backs for chimnies, large, the piece, pay on importation, 4s. 9 $\frac{6}{100}$ d. and draw back on exportation, 4s. 5 $\frac{2}{100}$ d. Bands for kettles, the hundred wt. pay on importation, 12s. 4 $\frac{6}{100}$ d. and draw back on exportation, 11s. 5 $\frac{2}{100}$ d. Fire irons, the groce, pay on importation, 1s. 11 $\frac{10}{100}$ d. and draw back on exportation, 1s. 8 $\frac{1}{100}$ d. More for every hundred weight on importation, 4s. 8 $\frac{2}{100}$ d. and draw back on exportation, 4s. 8 $\frac{2}{100}$ d. Hoops the hundred wt. pay on importation, 9s. 9 $\frac{8}{100}$ d. and draw back on exportation, 9s. 2 $\frac{2}{100}$ d. Stoves, the piece, pay on importation, 19s. 3d. and draw back on exportation, 16s. 10 $\frac{5}{100}$ d. More for every hundred weight on importation, 4s. 8 $\frac{2}{100}$ d. and draw back the same. Iron kettles, the piece, pay 1s. 2 $\frac{6\frac{1}{2}}{100}$ d. and

draw back, on exportation, the same ; and besides for every hundred weight on importation, 7s. 8 $\frac{4}{100}$ d. and draw back, on exportation, 6s. 9d.

Pig or bar-iron, from the british plantations in America, is imported free ; but all such iron must be stamped with a mark, denoting the colony, or place where it was made, and a certificate produced of the oath of the exporter, signed by two of the principal officers of such colony ; and the master, or commanding officer of the ship, or vessel, importing such iron, must make oath, that the iron so imported, is the same as that mentioned in the certificate.

**IRON-SICK**, in the sea-language, is said of a ship or boat, when her bolts or nails are so eaten with rust, and so worn away, that they occasion hollows in the planks, whereby the vessel is rendered leaky.

**IRON-WOOD**, *sideroxylum*, in botany. See the article **SIDEROXYLUM**.

**IRON-WORT**, *sideritis*, in botany. See the article **SIDERITIS**.

**IRONY**, in rhetoric, is when a person speaks contrary to his thoughts, in order to add force to his discourse ; whence, Quintilian calls it *diversiloquium*.

Thus, when a notorious villain is scornfully complemented with the titles of a very honest and excellent person ; the character of the person commended, the air of contempt that appears in the speaker, and the exorbitancy of the commendations, sufficiently discover the dissimulation or irony.

Ironical exhortation is a very agreeable kind of trope ; which, after having set the inconveniences of a thing in the clearest light, concludes with a feigned encouragement to pursue it. Such is that of Horace, when, having beautifully described the noise and tumults of Rome, he adds ironically,

Go now, and study tuneful verse at Rome!

**IROQUOIS**, the name of five nations in north America, in alliance with the british colonies. They are bounded by Canada on the north, by the british plantations of New-York and Pensilvania on the east and south, and by the lake Ontario on the west.

**IRRADIATION**, the act of emitting subtle effluvia, like the rays of the sun, every way. See **EFFLUVIA**.

**IRRATIONAL**, an appellation given to surd numbers and quantities. See the articles **NUMBER**, **QUANTITY**, and **SURD**.

**IRREGULAR**, something that deviates from the common forms, or rules ; thus we say an irregular fortification, an irregular building, an irregular figure, &c. See the articles **FORTIFICATION**, &c.

**IRREGULAR**, in grammar, such inflections of words as vary from the general rules ; thus we say, irregular nouns, irregular verbs, &c.

The distinction of irregular nouns, according to Mr. Ruddiman, is into three kinds, *viz.* variable, defective, and abundant ; and that of irregular verbs into anomalous, defective and abundant. See **ABUNDANT**, **DEFECTIVE**, &c.

**IRREGULAR**, among casuists, is applied to a person who is unqualified for entering into orders ; as being base-born, notoriously defamed, &c. and by that means rendered incapable of holding a benefice, or discharging any of the sacred functions.

**IRREGULAR BODIES**, are solids not terminated by equal and similar surfaces.

**IRREGULAR COLUMN**, in architecture, a column which does not only deviate from the proportions of any of the five orders, but whose ornaments, whether in the shaft or capital, are absurd and ill chosen.

**IRREPLEVABLE**, or **IRREPLEVISABLE**, in law, signifies any thing that neither may nor ought to be replevied. It is said, that it is against the nature of a distress for rent, to be irrepleviable.

**IRTI**, a great river, which runs from north to south through Russia, falls into

the river Oby, and makes part of the boundary between Asia and Europe.

**IRWIN**, a port-town of Scotland, in the bailiwick of Cunningham, situated at the mouth of the river Irwin, on the Firth of Clyde : west long.  $4^{\circ} 40'$ , north lat.  $55^{\circ} 35'$ .

**ISABELLA**, a fortress of the Austrian Netherlands, situated on the west side of the river Scheld, opposite to Antwerp, in east long.  $4^{\circ} 10'$ , north lat.  $51^{\circ} 15'$ .

**ISAIAH**, or *Prophecy of ISAIAH*, a canonical book of the Old Testament. Isaiah is the first of the four greater prophets, the other three being Jeremiah, Ezekiel, and Daniel. This prophet was of royal blood, his father Amos being brother to Azariah, king of Judah. The five first chapters of this prophecy relate to the reign of Uzziah ; the vision, in the sixth chapter, happened in the time of Jotham : the next chapters to the fifteenth, include his prophecies under the reign of Ahaz ; and those that were made under the reigns of Hezekiah and Manasseh, are related in the next chapters to the end. The style of this prophet is noble, sublime and florid. Grotius calls him the Demosthenes of the Hebrews. He had the advantage, above the other prophets, of improving his diction by conversing with men of the greatest parts and elocution, and this added a sublimity, force, and majesty to what he said. He impartially reproved the vices of the age in which he lived, and openly displayed the judgments of God that were hanging over the jewish nation ; at the same time denouncing vengeance on the Assyrians, Egyptians, Ethiopians, Moabites, Edomites, Syrians, and Arabians, who were instrumental in inflicting those judgments. He foretold the deliverance of the Jews from their captivity in Babylon, by the hands of Cyrus king of Persia, an hundred years before it came to pass ; but the most remarkable of his predictions are those concerning the Messiah, in which he not only foretold his coming in the flesh, but all the great and memorable circumstances of his life and death.

**ISATIS**, **WOAD**, in botany, a genus of the *tetradynamia filiquosa* class of plants, the corolla whereof consists of four cruciform, oblong, obtuse, patent petals, turning gradually smaller towards the ungues : the fruit is an oblong, lanceolato-obtuse, compressed, small pod, containing two valves, and consisting only of

of one cell : the seed is single, ovated, and contained in the center of the fruit. This plant is much used by dyers, as also in medicine, as an astringent, a vulnerary, and for stopping the menses.

**ISCHÆMUM**, **SCHOENANTH**, in botany, a genus of plants, thus characterized by Scheukzer : the male and female flowers are separate, but stand near each other ; the male is a small bivalve glume, placed on the calyx of the female flower, which is a biflorous glume : the seed is single, and involved in the calyxes and corollulæ.

The whole plant is of a fragrant aromatic smell, and is accounted cephalic, but little used at present.

**ISCHIA**, an island in the Neapolitan Sea, situated fifteen miles west of the city of Naples, in 14° 40', east long. and 41° north lat..

**ISCHIADIC**, in anatomy, a name given to two crural veins, called the greater and lesser ischias. See **VEIN**.

It signifies also a disease or pain of the hip ; being a species of arthritis, seated in the joint of the hip, and commonly called sciatica. See the article **SCIATICA**.

**ISCHIAS**, one of the ischiatic veins. See **VEIN**, and the preceding article.

**ISCHIUM**, in anatomy, the name of a bone described under the article **INNOMINATA ossa**. See **INNOMINATA**.

**ISCHURY**, *ισχουρία*, in medicine, a disease consisting in an entire suppression of urine. As the causes of an ischury are various, they ought, according to Heister, to be carefully distinguished from each other. When it proceeds from an inflammation of the kidneys, the pain and heat are principally in that region attended with a fever ; if from a stone in the kidneys, it is accompanied with vomiting ; if from a stone in the bladder, there is a violent pain in the bladder, which is extended to the very extremity of the urethra ; a mucus, or pus, is excreted with pale urine ; and upon proper examinations, the stone may be felt : but the most certain sign, is searching the bladder with a catheter. When this disorder arises from a stone in the urethra, it may be easily felt. If from an inflammation of the neck of the bladder, there is a tumour and pain in the perinæum, as often as the place is touched ; but it may be best perceived by thrusting the finger into the anus, and turning it up towards the bladder, for a tumour will be perceived by the physician, and by the

patient a burning and pressing pain ; and when a catheter is introduced into the urethra, an impediment will be felt near the neck of the bladder, which will hinder it from proceeding farther. See the article **CATHETER**.

When the urinous passages are obstructed by solid bodies, that is, the pelvis of the kidneys, the ureters or neck of the bladder, or the urethra, from a stone contained therein ; if it be small, those diuretics will be proper which are mentioned in a fit of the gravel or stone, to which may be added a decoction of of eryngo-root and epsom-salt, or selters-waters, taken often therewith. But if the stone is large and cannot be excreted by this means, strong diuretics are highly hurtful ; and it must be cured by section. See the article **LITHOTOMY**.

If the urine is suppressed from an inflammation of the kidneys or bladder, recourse must be had to the treatment and medicines prescribed for the disorders under the article **INFLAMMATION**.

When the spongy substance of the urethra is swelled with blood, and as it were inflated, a copious bleeding is the principal remedy. See **GONORRHOEA**.

When a spasm affects the neck of the bladder, it must be treated with antispasmodic powders, diuretic waters, and infusions with emulsions and lenient oils now and then, such as salad oil, oil of sweet almonds, poppy or linseed ; externally, cataplasms, ointments, clysters, and baths of the emollient and demulcent kind, with gentle opiates. See **SPASM**.

If the disease proceeds from the palsy, as sometimes happens in old persons, wherein there is no pain, the belly and perinæum must be treated with frictions and fomentations of strengthening, nervine and spirituous remedies, with cataplasms of onions, and other stimulators applied to the bladder, with clysters of the same sort of herbs. When the urine is very urgent, it must be evacuated by a catheter, which must be repeated as often as occasion requires. See **PALSY**.

If the disorder proceeds from blood remaining in the bladder, or its neck, the concretion is to be resolved and expelled with warm infusions of digestive herbs drank like tea ; such as ground-ivy, arnica, chervil, with tincture of tartar, liquor of the terra foliata of tartar, with digestive powders of crabs-eyes, saturated with the juice of oranges or lemons, sperma ceti, &c. but if all these fail, the

catheter

catheter is to be introduced into the neck of the bladder, to break the concretion, and evacuate the urine. See the article **RESOLVENTS**, &c.

When there is an ulcer in the bladder, infusions of vulnerary absorbent roots and herbs must be given, with mucilages and soft balsamics, especially balsam of Mecca, with a moderate use of quick-silver, especially if the case is venereal. See the article **ULCER**.

If there is a difficulty of urine in pregnant women, towards the last months, the best remedy is to ease the pressure on the part; but if that will not do, to use a catheter.

Lastly, if it proceeds from a swelling of the prostrate glands, or it becomes scirrhus, it must be treated as such; but if these remedies fail, the bladder must be pierced with a trocar; and when the perforation is made, the water must be evacuated as in the dropsy. This instrument must be left in the wound, and fastened in such a manner, that it does not fall out, so that the urine may be made as often as there is occasion. It is a troublesome operation, but the only one left.

**ISELASTICS**, a kind of games, or combats, celebrated in Greece and Asia, in the time of the roman emperors.

The victor at these games had very considerable privileges conferred on him, after the example of Augustus and the Athenians, who did the like to conquerors at the olympic, pythian, and isthmian games. They were crowned on the spot immediately after their victory, had pensions allowed them, were furnished with provisions at the public cost, and were carried in triumph to their country.

**ISENACH**, a town of Germany in the circle of Upper Saxony, situated in east long.  $10^{\circ} 12'$ , north lat.  $51^{\circ}$ .

**ISENARTS**, a town of Germany, in the circle of Austria, and dukedom of Stiria, situated thirty-five miles north-west of Gratz.

**ISERNIA**, a town of Naples, in the province of Molise, situated in east long.  $15^{\circ} 15'$ , north lat.  $41^{\circ} 36'$ .

**ISIA**, feasts and sacrifices antiently solemnized in honour of the goddess Isis.

The Isia were full of abominable impurities, and for that reason those who were initiated, were obliged to take an oath of secrecy: they held for nine days successively, but were so abominable, that

the senate abolished them at Rome, under the consulship of Piso and Gabinius.

**ISINGLASS**, *ichthyocolla*, in the materia medica, &c. See **ICHTHYOCOLLA**.

**ISIS**, in botany, the name by which Linnaeus calls the coral plant. See **CORAL**.

**ISLAND**, a tract of dry land, encompassed with water, in which sense it stands contradistinguished from continent, or terra firma. See **CONTINENT**.

Several naturalists are of opinion, that the islands were formed at the deluge: others think, that there have been new islands formed by the casting up of vast heaps of clay, mud, sand, &c. others think they have been separated from the continent by violent storms, inundations, and earthquakes. These last have observed, that the East-Indies, which abound in islands more than any other part of the world, are likewise more annoyed with earthquakes, tempests, lightnings, volcanos, &c. than any other part. Others again conclude, that islands are as antient as the world, and that there were some at the beginning, and among other arguments, support their opinion from Gen. x. 5. and other passages of scripture.

Varenius thinks, that there have been islands produced each of these ways. St. Helena, Ascension, and other steep rocky islands, he supposes to have become so by the sea's over-flowing their neighbouring champaigns: but by the heaping up huge quantities of sand, and other terrestrial matter, he thinks the islands of Zealand, Japan, &c. were formed. Sumatra and Ceylon, and most of the East-indian islands, he thinks, were rent off from the main land; and concludes, that the islands of the Archipelago were formed in the same way, imagining it probable, that Deucalion's flood might contribute towards it. The antients had a notion that Delos, and some other few islands, rose from the bottom of the sea, which, how fabulous soever it may appear, agrees with later observations. Seneca takes notice, that the island Therasia rose thus out of the Ægean sea in his time, of which the mariners were eyewitnesses. They had also an opinion that there are some islands which swim in the sea. Thales, indeed, thought that the whole earth which we inhabit floated in the sea: but floating islands are not only probable, but well attested. See the article **FLOATING**.

**ISLE**,

**ISLE**, in general, denotes the same with island, but frequently used in a diminutive sense.

**ISLE DE DIEU**, an island in the Bay of Biscay, on the coast of France, situated fourteen miles west of the coast of Poitou.

**ISLE of France**, a province of that kingdom, in which the capital city of Paris is situated, being bounded by Picardy on the north, by Champain on the east, by Orleans on the south, and by Normandy on the west.

**ISLES**, in architecture, denote the sides or wings of a building. See **BUILDING**.

**ISLOCK**, or **ILOCK**. See **ILOCK**.

**ISNARDIA**, in botany, a genus of the *tetrandria monogynia* class of plants; having no corolla: the fruit is formed of the square base of the cup: it has four cells, and in them a few seeds of an oblong figure.

**ISNY**, a free imperial city of Germany, in the circle of Swabia, situated in east long.  $10^{\circ}$  north lat.  $47^{\circ} 36'$ .

**ISOCHRONAL**, **ISOCHROME**, or **ISOCHRONOUS**, is applied to such vibrations of a pendulum, as are performed in the same space of time, as all the vibrations or swings of the same pendulum are, whether the arches it describes be longer or shorter: for when it describes a shorter arch, it moves so much the slower, and when a long one proportionably faster.

**ISOCHRONAL LINE**, that in which a heavy body is supposed to descend without any acceleration. See **ACCELERATION**.

Mr. Leibnitz, in the *Acta Erud.* Lips. for Feb. 1689, shews, that an heavy body with a degree of velocity acquired by the descent from any height may descend from the same point by an infinite number of isochronal curves, all which are of the same species, differing from one another only in the magnitude of their parameters: such are all the quadrato-cubical paraboloids, and consequently similar to one another. He shews also there, how to find a line in which a heavy body descending shall recede uniformly from a given point, or approach uniformly to it.

**ISOLA**, a port-town and bishop's see of the hither Calabria, fifteen miles south of St. Severino.

**ISOMERIA**, a term sometimes used for the reduction of equations. See the article **EQUATION**.

**ISOPERIMETRICAL FIGURES**, in geometry, are such as have equal peri-

eters, or circumferences. See the article **CIRCUMFERENCE**.

1. Of isoperimetrical figures, that is the greatest that contains the greatest number of sides, or the most angles, and consequently a circle is the greatest of all figures that have the same ambit as it has. See the article **CIRCLE**.

2. Of two isoperimetrical triangles, having the same base, whereof two sides of one are equal, and of the other unequal, that is the greater whose two sides are equal. See **TRIANGLE**.

3. Of isoperimetrical figures, whose sides are equal in number, that is the greatest which is equilateral and equiangular. From hence follows that common problem of making the hedging or walling that will wall in one acre, or even any determinate number of acres,  $a$ , fence or wall in any greater number of acres whatever  $b$ . In order to the solution of this problem, let the greater number  $b$  be supposed a square. Let  $x$  be one side of an oblong, whose area is  $a$ ; then will  $\frac{a}{x}$  be the other side; and  $2\frac{a}{x} + 2x$

will be the ambit of the oblong, which must be equal to four times the square root of  $b$ ; that is,  $2\frac{a}{x} + 2x = 4\sqrt{b}$ .

Whence the value of  $x$  may be easily had, and you may make infinite numbers of squares and oblongs that have the same ambit, and yet shall have different given areas. See the operation:

Let  $\sqrt{b} = d$

$$\text{Then } \frac{2a + 4xx}{x} = 4d$$

$$a + 2xx = 2dx$$

$$2xx - 2dx = -a$$

$$xx - dx = -\frac{a}{2}$$

$$xx - dx + \frac{1}{4}dd = -\frac{a}{2} + \frac{1}{4}dd$$

$$x = \sqrt{-\frac{a}{2} + \frac{1}{4}dd + \frac{1}{4}d^2}$$

Thus if one side of the square be 10; and one side of an oblong be 19, and the other 1: then will the ambits of that square and oblong be equal, viz. each 40, and yet the area of the square will be 100, and of the oblong but 19.

**ISOPYRUM**, in botany, a genus of the *polyandria digynia* class of plants, the corolla of which consists of five equal, ovated and patent petals: the fruit is composed of two crooked, lunated pods, with

with only one cell in each, containing numerous seeds.

**ISOCELES-TRIANGLE**, in geometry, one that has two equal sides, as A B C (pl. CXLVIII. fig. 2.) where the side A B is equal to A C.

In every iscoceles-triangle, the angles A B C, A C B, subtended by the equal sides, are equal; and a line A D bisecting the base B C in D, is perpendicular to it, as is easily demonstrated. See the article **TRIANGLE**.

**ISPAHAN**, or **SPAHAWN**, the capital city of Eyrac Agem, and of all Persia: it is of an oval form, and twelve miles in circumference: east long. 50°, north lat. 32° 30'.

**ISPIDA**, the **KING-FISHER**, in ornithology, a genus of the picæ-order of birds, with a beak of a trigonal figure, somewhat arcuated, compressed, and its two claps equal: there are four toes on each foot, with only one of them placed behind.

This is a very numerous genus, the species of which are chiefly distinguished by their size and different colours.

**ISSUE**, in law, has several significations, it being sometimes taken for the children begotten between a man and his wife; sometimes, for profits arising from amercements and fines; and sometimes, for the profits issuing out of lands or tenements: but this word generally signifies the conclusion, or point of matter, that issues from the allegations and pleas of the plaintiff and defendant in a cause tried by a jury of twelve men.

There are two kinds of issues in relation to causes, that upon a matter of fact, and that upon a matter of law: that of fact is where the plaintiff and defendant have fixed upon a point to be tried by a jury: and that in law is, where there is a demurrer to a declaration, &c. and a joinder in demurrer, which is determinable only by the judges. Issues of fact are either general or special: they are general, when it is left to the jury to find whether the defendant has done any such thing as the plaintiff has alledged against him; and special, where some special matter, or material point alledged by the defendant in his defence, is to be tried. General issue also signifies a plea in which the defendant is allowed to give the special matter in evidence, by way of excuse or justification; this is granted by several statutes, in order to prevent a prolixity in pleading, by allowing the defendant

to give any thing in evidence, to prove that the plaintiff had no cause for his action.

In real actions, the issues are triable by a jury of the county in which the cause of action arises. Issues are to be certain and single, and joined upon the most material point in question, so that the whole matter in dispute between the parties may be tried. On a joint action of trespass by many persons, only one issue must be joined; and where several offences are charged against a defendant, he ought to take all but one by protestation, and then offer an issue on that one, and no more; though in an action for damages, every part, according to the loss the plaintiff has sustained, is to be put in issue. Where a good issue is joined between the parties, it cannot afterwards be waved, without the consent of both parties: but where the defendant pleads the general issue, and does not enter the same, he may within four days of term wave such issue, and plead specially: so if a defendant pleads in abatement, he may any time after wave his special plea, and plead the general issue, except a rule be made for him to plead as he will stand by it: but in case the plaintiff omits entering the issue the term it is joined, the defendant in the first five days of the next term, may alter his plea, and plead de novo: and when the plaintiff will not try the issue, after the same is joined, within the time required by the course of law, the defendant may give him a rule to enter it, and if he does not then try it he shall be nonsuited.

**ISSUES on sheriffs**, are such amercements and fines to the crown, as are levied out of the issues and profits of the lands of sheriffs, for their faults and neglects: but these issues, on shewing a good and sufficient cause, may be taken off before they are estreated into the exchequer.

Issues are also leviable upon jurors, for non-appearance; though upon a reasonable excuse, proved by two witnesses, the justices may discharge the same.

**ISSUES**, in surgery, are little ulcers made designedly by the surgeon in various parts of the body, and kept open by the patient, for the preservation or recovery of his health.

The parts in which issues are generally made, are either the upper part of the head; the neck; the arms, betwixt the biceps and deltoide muscle, and near the insertion of the last; in the thigh, especially

especially within side, immediately above the knee, in a cavity easily felt by the fingers; and, lastly, in the legs, on their interior side, in a cavity immediately below the knee.

There are several methods of making issues, but the most ready one is by incision, which is performed thus: first mark the proper place with ink; then elevating the integuments between the thumb and fore-finger of the surgeon and an assistant on each side, you next proceed to make an incision thro' them, either with the scalpel or lancet, big enough to admit a pea, which being inserted and covered with a plaster and compress, nothing more than your roller is wanting to compleat the operation. Thus by cleaning and dressing the wound every morning and evening with a fresh pea, it by degrees, in a day or two, degenerates into a little ulcer, discharging daily a quantity of purulent matter, which should be carefully cleansed or wiped off at every dressing.

There is a second method of making issues by wounding the skin with an actual cautery, or red hot iron, which is usually included in sort of capsula, or case of iron (plate CXLIX. fig. 2.) to conceal it from terrifying the patient. When the case B B is fixed upon the proper part for the issue, the red-hot iron C, is then pressed down upon the integuments, and the eschar, or burn, is next to be dressed with fresh butter or basilicon, till by repeating the dressing every day, it separates, and then the ulcer formed, is to be filled with a pea, and dressed as before.

The third method of making issues is by the application of potential cauteries, or corroding medicines; in order to which a piece of plaster is first perforated, and then applied, so as its aperture may cover the place marked with ink for the issue: a piece of the caustic is then put into the aperture of the plaster, and retained close down upon the skin, with some scraped lint, a small compress, and a large plaster; and lastly, with a larger compress and bandage. The patient is then to be ordered to rest for about six or eight hours, more or less, according to the strength of the caustic, which time being elapsed, and the dressings removed, the eschar is to be treated as before directed in an actual cautery.

In which ever of these methods the issue is made, it must be dressed at least twice

every day, especially if it runs well, and in the summer-season: and at each dressing you must put in a fresh pea, and cover it with a clean plaster, or a piece of waxed paper or silk, or an ivy-leaf retained with compress and bandage. But the deligation for issues is much more commodiously performed with a leatheren swath, fastened by clasps, than by a circular linnen-roller. In this manner issues are to be kept open, till the patient is recovered of the disorder for which they were made.

Issues are chiefly made for various disorders in the head, eyes, ears, teeth, the sciatica, and other painful disorders, which are this way frequently relieved or cured. But in stubborn disorders it is frequently necessary to make two or more issues to produce any considerable effect, as one in each arm, or in one arm and leg of the same side.

In order to close an issue, little more is required than to discharge the pea, and to refrain from putting in any more, by which means alone it will close up in a short time: but if any proud flesh should arise, it may be amputated, or else removed with burnt alum. Lastly, it is observable, that when the issues of people far advanced in years cease to make their wonted discharge, and turn of a livid and blackish hue, it is a sign that they are invaded by some desperate disorder, and that life itself is very near its period.

**ISTHMA, or ISTHMIAN GAMES,** *ισθμια*, one of the four solemn games which were celebrated every fifth year in Greece; so called from the corinthian isthmus, where they were kept.

These games, according to some, were instituted in honour of Palæmon, or Melicertes the son of Athamas king of Thebes, and Ino. Others report, that they were instituted by Theseus, in honour of Neptune. Others again are of opinion, that there were two distinct solemnities observed in the isthmus, one to Melicertes, and another to Neptune. These games were held so sacred and inviolable, that when they had been intermitted for some time, through the oppression and tyranny of Cypselus king of Corinth, after the tyrant's death the Corinthians, to renew the memory of them, employed their utmost power and industry. The victors were rewarded with garlands of pine-leaves; afterwards, parsley was given them: but at length, the pine was resumed, and to this was

added

added the reward of 100 silver drachmæ. These games were so celebrated, and the concourse at them so great, that only the principals of the most remarkable cities, could have place in them. The Athenians had only as much room allowed them as the sail of a ship, which they sent yearly to Delos, could cover.

**ISTHMUS**, in geography, a narrow neck of land, that joins two continents, or joins a peninsula to the terra firma, and separates two seas. The most celebrated isthmuses are those of Panama, or Darien, which joins north and south America; and that of Suez, which connects Asia and Africa; that of Corinth, of Crim Tartary, &c.

**ISTRIA**, a peninsula in the north part of the gulph of Venice, bounded by Carniola, on the north; and on the south, east, and west, by the sea.

**ITALIAN**, the language spoken in Italy. See the article **LANGUAGE**.

This tongue is derived principally from the latin; and of all the languages formed from the latin, there is none which carries with it more visible marks of its original than the italian. It is accounted one of the most perfect among the modern tongues, containing words and phrases to represent all ideas, to express all sentiments, to deliver ones self on all subjects, to name all the instruments and parts of arts, &c. It is however complained, that it has too many diminutives and superlatives, or rather augmentatives, but without any great reason: for if these words convey nothing farther to the mind than the just ideas of things, they are no more faulty than our pleonasm and hyperboles. The language corresponds to the genius of the people; they are slow and thoughtful, and accordingly their language runs heavily, though smoothly, and many of their words are lengthened out to a great degree. They have a great taste for music, and to gratify their passion this way, have altered abundance of their primitive words, leaving out consonants, taking in vowels, softening and lengthening out their terminations for the sake of the cadence. Hence the language is extremely musical, and succeeds better than any other in operas, and some parts of poetry: but it fails in strength and nerves: hence also, a great part of its words borrowed from the latin, became so far disguised, that they are not easily known again.

**ITALIAN COINS**. See **COIN**.

**ITALIAN MEASURES**. See **MEASURE**.

**ITALIC CHARACTERS**, in printing. See the article **LETTER**.

**ITALIC**, or **ITALIAN HOURS**, the twenty-four hours of the natural day, accounted from the sun-setting of one day, to the same again the next day. See **HOURL**.

**ITALIC SECT**, the name of a sect of ancient philosophers, founded by Pythagoras; so called, because that philosopher taught in Italy, spreading his doctrine among the people of Tarentum, Metapontus, Heraclea, &c. This sect divided itself into four others, viz. the **HERACLITIC**, **ELEATIC**, &c.

**ITALY**, a country situated between seven and nineteen degrees east long. and between thirty-eight and forty-seven degrees north latitude, bounded by Switzerland, and the Alps, which separate it from Germany, on the north; by the gulph of Venice, on the east; by the Mediterranean Sea, on the south; and by the same Sea and the Alps, which separate it from France, on the west; and if we include Savoy, which lies indeed on the west side of the Alps, between Italy and France, we must extend it a degree farther west: this is usually described however with Italy, as it is contiguous to Piedmont, and has the same sovereign, being a province of the king of Sardinia's dominions. Italy is said to resemble a boot, and is in length from north-west to south-east 600 miles; the breadth is very unequal; in the north, which may be called the top of the boot, it is 400 miles broad from east to west, in the calf of the leg, or middle, it is about 120 miles broad; and towards the south, about the instep, eighty miles broad; and comprehends the following countries or subdivisions. 1. In the north are the duchies of Savoy, Piedmont, and Montserrat; the territories of Genoa; the duchies of Milan, Mantua, Parma, Modena, and the territories of Venice. 2. In the middle of Italy, are the duchy of Tuscany, the pope's dominions, and the state of Lucca. 3. And in the south is the kingdom of Naples.

**ITCH**, a cutaneous disease, arising from a corruption of a serous lymphatic matter, sometimes attended with mild, sometimes with more obstinate and dangerous symptoms.

The itch of the milder sort appears either with moist or dry pustules at first about the joints, and from thence spreads by

by degrees over all the body, the head only excepted. In the moist sort, to which children and the sanguineo-phlegmatic are most subject, the pustules are more full of a purulent matter, attended with a slight inflammation, which is manifest from a redness that appears about them, till it suppurates. The dry sort attacks chiefly those that are lean, old, or are of a melancholico-choleric constitution. In these the pustules are much less, and excite a most intolerable itching, especially in the night-time. The most usual places where the eruptions appear very numerous, and the itching is greatest, are between the fingers, on the arms, hams, and thighs.

This disease is truly and properly a disease of the skin, because it often is safely cured by topics alone, if timely applied. It is contagious, and may be caught by drawing on a glove or stocking, wiping on the linnen, or lying in sheets, after persons infected with this malady. Some think it owing to an impurity in the serum, and some to animalcula; but however that be, it often affects such as have been long kept in prison, who lead unactive lives, and are used to live in a stutish, nasty manner; or who constantly eat fish or flesh dried in the smoke or sun, and use any other unwholesome food or drinks; or who live in a cold, moist, and cloudy air, which, hindering a free perspiration, causes a stagnation of humours in the superficies of the body, which are for that reason liable to corrupt.

The milder sort of itch is no way dangerous, and very easy to cure: but the moist kind is more easy than the dry. While it is recent and superficial, it much sooner yields to remedies than when it is deep, and has infected the mass of blood. And the case is still worse, if there be a fault in the viscera: it is more difficult in old persons, than in young; in a leucophlegmatic, or hydropical disposition, as also in a very dry hectic one, it is hard to cure; and when it becomes universal, it may bring on the leprosy.

The patient should avoid shell-fish, and all salted and high-seasoned meats; as also wine, spirituous liquors, strong-beer, and every thing else that may inflame the blood: for this reason a slender diet is best, unless perspiration be obstructed. If the body is plethoric, the cure is begun by bleeding, and afterwards by purging; but instead of purg-

ing, it is common to give flowers of sulphur with good success. Willis, and many others, have a great opinion of the efficacy of sulphur used both internally and externally; to which Turner assents, except in hectic and consumptive cases; but Shaw thinks it not to be depended on, when outwardly used: yet it is very certain, that poor people find a great deal of benefit who drink it inwardly with milk, and use it outwardly with butter or hog's lard.

Juncker, from Stahl, calls the following things specifics against the acrimony of the itch, taken internally, *viz.* sulphur with nitre and arcanum duplicatum, balsam of sulphur with oil of sweet almonds, tincture of sulphur, and crude antimony. Outwardly he advises mercurial ointments, and sulphureous lixiviums; but in the dry itch, he thinks baths more proper made of the root of burdock, the sharp-pointed dock, and mineral fountain-water. Turner prefers the sal. tart. to most other remedies, it thoroughly purging and cleansing the blood if taken inwardly; and made into a lixivium with spring-water, is an excellent wash outwardly. Hartman, in an obstinate itch, proposes a diaphoretic of the white flowers of antimony to be taken twenty days together.

When the blood is thought to be foul, it will be proper to use diet-drinks of the roots of china, sarsaparilla, oxylapathum, scorzonera, chichory, glycyrrhiza, poly-podium, the barks of saffrafas, cinnamon, and the like.

The most stubborn itch will generally yield to the following ointment, if proper evacuations have been premised. Take of quicksilver, three drams; native cinabar, one dram; venice-turpentine, half a dram; hog's lard, half an ounce; oil of sweet almonds, two drams. Mix and divide this into eight equal parts, one of which is to be rubbed into the legs and arms every other night, or at greater intervals, if there are any signs of salivation: great care must be taken that the patient gets no cold, while he uses this medicine; if he feels any griping pains, or if his breath begins to stink, the use of it is immediately to be suspended. It has been a very common practice to cure the itch by quicksilver-girdles, but Turner thinks them too hazardous to be brought into regular practice. See the article GIRDLE.

If this disease should prove so stubborn

as not to give way to the most powerful of the preceding methods, recourse must be had to salivation as the dernier resort. See the article SALIVATION.

But notwithstanding these opinions, Dr. Mead affirms, that neither cathartics nor sweetners of the blood are of any service in this disease; that the whole management of it consists in external applications for destroying the corroding worms, which he takes to be the true cause of the disease. For, he says, that there are certain insects to very small, as hardly to be seen without the assistance of a microscope, which deposit their eggs in the furrows of the cuticle, as in proper nests, where, by the warmth of the place, they are hatched in a short time, and the young ones coming to full growth, penetrate into the cutis, and gnaw and tear the fibres, which cause an intolerable itching; that while they burrow under the cuticle, and lay their eggs in different places, they spread the disease.

This was first discovered by Dr. Bonomo, and by him communicated to the celebrated Redi of Florence; and Dr. Mead having met with Bonomo's letter upon this subject in Italy, made an abstract of it, and communicated it to the Royal Society.

The doctor advises, that the patient should first go into a warm bath, and then have the parts affected every day anointed with ointment of sulphur, or the ointment with precipitate of mercury.

**ITINERANT JUDGES**, a name formerly given to those judges who were sent into several counties to hear causes. See the article JUDGE.

**JUBILEE**, a time of public and solemn festivity among the antient Hebrews.

This was kept every fiftieth year: it began about the autumnal equinox, and was proclaimed by sound of trumpet throughout all the country. At this time all slaves were released, all debts annihilated, and all lands, houses, wives and children, however alienated, were restored to their first owners. During this whole year all kind of agriculture was forbidden, and the poor had the benefit of the harvest, vintage, and other productions of the earth, in the same manner as in the sabbatic, or seventh year. As this was designed to put the Israelites in mind of their Egyptian servitude, and to prevent their imposing the like upon their brethren, it was not observed by the gentile profelytes.

The Christians, in imitation of the Jews, have likewise established jubilees, which began in the time of pope Boniface VIII. in the year 1300, and are now practised every twenty-five years; but these relate only to the pretended forgiveness of sins, and the indulgences granted by the church of Rome: together with the privilege of performing a thousand frolics in masquerade. The ceremony of the jubilee observed at Rome, begins in the following manner: the pope goes to St. Peter's church, to open the holy gate, which is walled up, and opened only on this occasion; and, holding a golden hammer in his hand, he knocks at the gate three times, repeating these words, *aperite mihi portas justitie, &c. Open to me the gates of righteousness; I will go into them, and I will praise the Lord*, Psal. cxviii. 19. upon which the masons fall to work, and break down the wall that stops up the gate: which done, the pope kneels down before it, and the penitentiaries sprinkle him with holy water. Then, taking up the cross, he begins to sing *te deum*, and enters the church, followed by the clergy. In the mean time, three cardinal-legates are sent to open the three other holy gates which are in the churches of St. John of Lateran, St. Paul, and St. Mary the Greater. When the holy year is expired, the holy gates are shut in this manner: the pope, after he has blessed the stones and mortar, lays the first stone, and leaves there twelve boxes of gold and silver medals; after which the holy gates are walled up as before, and continue so till the next jubilee.

**JUCATAN, or YUCATAN**, a peninsula of Mexico, situated between 89° and 94° west long. and between 16° and 21° north lat.

Its chief town is Campeachy. See the article CAMPEACHY.

**JUDÆ AURICULA**. See AURICULA.

**JUDAICUS LAPIS**, in the materia medica, the petrified spine of an echinus. See the article JEW'S STONE.

**JUDAISM**, the religious doctrines and rites of the Jews. See JEWS.

**JUDAS'S TREE**, *siliquastrum*, in botany. See the article SILIQUASTRUM.

**JUDDOCK**, in ornithology, the english name of a small species of snipe, called also the ged or jack-snipe, and by authors *gallinago minima*.

**JUDE**, or *the general epistle of JUDE*, a canonical book of the New Testament, written against the heretics, who by their disorderly

disorderly lives and impious doctrines, corrupted the faith and good morals of the Christians. St. Jude draws them in lively colours, as men given up to their passions, full of vanity, conducting themselves by worldly wisdom, and not by the spirit of God.

In the early ages of christianity, several rejected this epistle because the apocryphal books of Enoch and the ascension of Moses are quoted in it. Nevertheless, it is to be found in all the antient catalogues of the sacred writings; and Clement of Alexandria, Tertullian and Origin, quote it as written by Jude, and reckon it among the books of sacred scripture.

**St. JUDE'S DAY**, the same with that of St. Simon. See the article **SIMON**.

**JUDEA**, or **PALESTINE**. See **PALESTINE**.

**JUDENBURG**, a city of Stiria, in Germany: east long. 15°, north lat. 47° 22'.

**JUDGE**, a chief magistrate of the law, appointed to hear criminal causes, to explain the laws, and to pass sentence according to the verdict brought in by the foreman of the jury. See **JURY**.

A judge, on his being created, takes an oath of office, that he will serve the king, and indifferently administer justice to all men, without respect of persons; that he will take no bribe; give no counsel, where he is a party; nor deny right to any, even though the king by his letters, or by express words, command the contrary; and that he may have no temptation to break his oath, he enjoys his office and a settled salary for life, and it is not in the power of the crown to deprive him of either. He is to execute his office in person, and cannot act by a deputy, nor transfer his power to another: yet where there are several judges in a court of record, the act of any one of them is effectual, provided their commission does not require more: so likewise what is carried by a majority present, is the act of the court: but where they are equally divided in opinion, the cause is to be removed into the exchequer-chamber, and for that purpose a rule is to be made, and the record certified, &c. Some things done by judges at their chambers, are accounted as done by the court: and that they may be prepared to hear what is to come before them, they are to have a paper of the causes to be heard, sent to them by the attorneys the day before they are spoken to; that if upon reading the record of a

cause any special matter that arises should appear doubtful, they may satisfy themselves by consulting books.

To support their dignity and authority, the judges of the courts of record are exempted from all prosecutions whatsoever, except in parliament, where alone they may be punished for any thing they have done amiss in their own courts as judges: but yet if a judge should so far forget his dignity as to turn solicitor in a cause which he is to judge, and extrajudicially tamper with witnesses, or attempt to work upon jurors, he may be dealt with in a manner suitable to the character to which he is to judge, and degraded himself. As the judge is the substitute of the king, and is designed to distribute that justice which he cannot administer in person, he cannot be challenged like a jury, nor have any action brought against him for what he acts as a judge: while he is on the bench his person is in a manner sacred, so that to kill a judge of any of the superior courts of Westminster, or of assize, on the place of administering justice, is treason; and drawing a weapon upon him in any of the courts of law, is to be punished with the loss of the right hand, the forfeiture of lands and goods, and perpetual imprisonment. On the other hand, a judge cannot sit as judge in his own cause: if he is guilty of taking a bribe, he is punishable by loss of office, fines and imprisonment; and if a judge, who has no jurisdiction, passes judgment of death, and his sentence is executed, both he, and the officer who executes it, is guilty of felony.

*Itinerant JUDGES*. See **ITINERANT**.

*Book of JUDGES*, a canonical book of the Old Testament, so called from its relating the state of the Israelites under the administration of many illustrious persons who were called judges, from their being both the civil and military governors of the people, and who were raised up by God upon special occasions; after the death of Joshua, till the time of their making a king. In the time of this peculiar polity, there were several remarkable occurrences, which are recorded in this book. It acquaints us with the gross impiety of a new generation which sprung up after the death of Joshua, and gives us a short view of the dispensations of heaven towards this people, sometimes relieving and delivering them, and at others, severely chastising them by the hands of their enemies.

The book of judges is usually divided into two parts: the one containing the history of the judges from Othniel to Sampson; which ends with the sixteenth chapter: the other containing several memorable actions, which were performed in or about the time of the judges, from the seventeenth chapter to the end of the book. The author of this book is wholly unknown; some ascribe it to Samuel, others to Hezekiah, and others to Ezra.

**JUDGMENT**, among logicians, a faculty or rather act of the human soul, whereby it compares its ideas, and perceives their agreement or disagreement. See the article **KNOWLEDGE**.

Not satisfied with the bare view and contemplation of its ideas, the mind assembles them together, and compares them one with another. In this complicated view of things, it readily discerns that some agree, and others disagree; and accordingly joins or separates them. Thus upon comparing the idea of two added to two, with the idea of four, we at first glance perceive their agreement, and pronounce them equal. Again, that white is not black, and that four and two do not make eight, are truths the mind as readily perceives.

This is the first and simplest act of the mind, in determining the relations of things; when by a bare attention to its own ideas, comparing any two of them together, it can at once see how far they are connected or disjointed. The knowledge thence derived is called intuitive, as requiring no pains or examination; and the act of the mind assembling its ideas together, and joining or disjointing them, according to the result of its perception, is what logicians call judgment. See the articles **IDEA**, **PERCEPTION**, **KNOWLEDGE**, &c.

In common discourse, however, the term judgment is seldom confined to self-evident truths; but rather signifies those conjectures that we form, which do not admit of undoubted certainty, and where we are left to determine by comparing the various probabilities of things. Thus a man of sagacity, who seldom mistakes in the opinions he frames of characters and actions, is said to judge well, or think judiciously. Hence it might not be improper to change the common names of the two first operations of the mind, calling the one simple apprehension, and the other intuition. See the articles **APPREHENSION** and **INTUITION**.

**JUDGMENT**, in law, the sentence of the judges upon a suit, &c.

Judgment may be given not only upon the trial of the issue, but on a default, confession, demurrer, or on an out-lawry, which is a judgment in itself. After issue joined in a cause, the plaintiff may, if he thinks proper, accept of a judgment from the defendant; but on such a judgment, a writ of error may be had without putting in bail, which cannot be done on a judgment after verdict. All judgments given in courts of record must be entered; in order to which the plaintiff's attorney, four days after the record is brought into court, may, if the judgment is out, enter judgment by the usual course of the court; but he cannot do this sooner, because the defendant must have time to bring in a writ of error, or to find out matter for an arrest of judgment. The defendant may oblige the plaintiff to enter his judgment, in order that he may plead it to any other action; and judgment upon a demurrer to a declaration, &c. which does not pass upon the merits of the cause, is no bar to it, though other judgments may be pleaded in bar to any action brought again for the same thing. Judgments are to continue till they are reversed: but an action of debt will lie on a good judgment, as well after a writ of error is brought, as before it. If a plaintiff does not take out an execution within a year and a day after judgment is obtained, the judgment must be revived by a *scire facias*. See the article **SCIRE FACIAS**.

**JUDGMENTS for crimes**, in case of treason or felony, must be by an express sentence, an out-lawry, or abjuration: and no judgment can be inflicted contrary to law, or that is not appointed by act of parliament. These judgments are of very different kinds; as in high treason the offender is sentenced to be drawn, hanged, his entrails taken out and burnt, his head cut off, and his body quartered, &c. In petit treason the judgment is, to be drawn to the place of execution, and there hanged. But a woman in all cases of high and petit treason, is to be drawn and burnt. All persons for felony, are to be hanged by the neck till dead. Judgment in misprision of treason, is imprisonment for life: and for misprision of felony, the offender is subject to a fine and imprisonment; and for crimes of an infamous nature, the judgments are discretionary in the breast of the

the court, and those guilty are punished by a fine, pillory, &c.

**JUDGMENTS for debts**, are acknowledged by a person's giving a general warrant of attorney to any attorney of the court in which it is to be acknowledged, to appear for him at the suit of the party to whom the same is to be done, and to file common bail, receive a declaration, and then to plead, *non sum informatus*, I am not informed; or to let it pass by *nihil dicit*, he says nothing; upon which judgment is entered for want of a plea. Judges that sign judgment of lands, are to set down the day of the month and year in which they do it; and they shall be good against purchasers only from such signing. Where a person has acknowledged a judgment for the security of money, and afterwards on borrowing more money of another person mortgages his lands, &c. without giving any notice of the judgment to the mortgagee; in such case, if the mortgager do not within six months pay off and discharge the judgment, he shall forfeit his equity of redemption, 4 and 5 Will. and Mary. Acknowledging a judgment in the name of another person without his privacy or consent, is made felony, by 21 Jac. I. c. 26.

**JUDICIUM DEI**, judgment of God, in law, a term applied to the trial by combat, by ordeal, &c. See the articles **DUEL**, **COMBAT**, **ORDEAL**, &c.

**JUDOIGNE**, a town of the austrian Netherlands, in the province of Brabant, situated on the river Gheet, thirteen miles south-east of Louvain, and sixteen north of Namur.

**IVES**, or **St. IVES**, a borough and port-town of Cornwall, situated on the Irish channel: it sends two members to parliament: west long. 6°, north lat. 50° 18'.

**JUGALE**, in anatomy, the cheek bone. See the article **MALA**.

**JUGERUM**, in roman antiquity, a square of 120 roman feet; its proportion to the english acre being as 10000 to 16097. See the article **MEASURE**.

**JUGULAR**, in anatomy, an appellation given to two veins of the neck, which arise from the subclavians. 1. The external jugular, distributed over the external parts of the head; and which, in its several parts, receives different denominations from them, as the frontal, temporal, occipital, &c. vein. 2. The internal jugular, which gives ramifications to the larynx, the pharynx, the muscles

of the os hyoides, and to the tongue; those which are under its vertex being called raninæ. But besides these branches, its trunk terminates in a diverticulum, called the jugular sack, and brings back the blood from the sinuses of the dura mater, and from the brain. See **VEIN**. There are also certain glands in the anterior part of the neck, called jugular. See the article **GLAND**.

**IVICA**, or **YVICA**, the capital of an island of the same name, fifty miles east of Valencia in Spain: east long. 1°, north lat. 39°.

**JUICE**, denotes the sap of vegetables when expressed. See the article **SAP**.

Under this head, Quincy tells us, we have nothing either in official or extemporaneous prescription, unless the acacia and liquorice-juice. See **ACACIA** and **LIQUORICE**.

But besides these, there are other inspissated juices, frequently used in medicine; as scammony, aloes, gamboge, opium, catechu, elaterium, &c. See the articles **SCAMMONY**, **ALOES**, &c.

Juice of lemons, the pipe, pays on importation, 1l. 10s. 4<sup>8</sup>/<sub>100</sub>d. and draws back on exportation, 1l. 8s. 6d. Juice of limes, the gallon, pays, on importation, 2<sup>28</sup>/<sub>100</sub>d. and on exportation draws back 2<sup>13<sup>3</sup>/<sub>4</sub>/<sub>100</sub>d.</sup>

**JUICE** is also used to denote the liquors of animals, as the nervous juice, the pancreatic juice, &c.

**JUJUBES**, *jujuba*, in the materia medica, the name of a fruit of the pulpy kind, produced on a tree called by authors ziziphus, which Linnæus makes a species of rhamnus. See **RHAMNUS**.

This fruit is of an oblong figure, and somewhat resembles a large olive in its shape and size: its usual length is about an inch, and its thickness somewhat more than half an inch. It is wrinkled on the surface deeply and irregularly, and when cut or broken, is found to consist of a thick pellicle, of a dusky yellowish red colour, under which there lies a whitish and soft pulpy fungous matter, enclosing a stone of an oblong figure. It has but little smell, but is of a sweetish and resinous taste. It is to be chosen new, large, plump, and full of pulp, and of a sweet and pleasant taste.

The jujubes have been made a general ingredient in pectoral decoctions; but they are now seldom used on these occasions, and

and are scarce at all heard of in prescription, or to be met with in our shops.

**JULEP**, in pharmacy, a medicine composed of some proper liquor, and a syrup or sugar of extemporaneous preparation, without decoction, designed for the concoction or alteration of the humours, or restoring the strength.

Dispensatory writers mention several kinds of juleps. 1. The camphorated julep, thus prepared: take of camphire, one dram; of double refined sugar, half an ounce; of boiling water, a pint. First grind the camphire with a little rectified spirit of wine, till it is softened; then with the sugar, till they are perfectly united; lastly, add the water by degrees; and, when the mixture has stood in a covered vessel, till it is cold, strain it off.

2. Chalk-julep, thus made: take of the whitest chalk prepared, one ounce; of double refined sugar, six drams; of gum arabic, two drams; of water, a quart. Mix all together. 3. The musk-julep, thus prepared: take of damask-rose-water, six ounces; of musk, twelve grains; of double refined sugar, one dram. Grind the musk and sugar together, and gradually add the rose-water. Besides these, there are several other preparations made up in the form of juleps, and denominated from their uses, balsamic, cephalic, carminative, strengthening, &c. juleps.

**JULIA**, or **JULIS**. See **JULIS**.

**JULIAN**, or **St. JULIAN**, a harbour on the coast of Patagonia, in south America, where ships bound to the South seas usually touch: west long. 74°, north lat. 48° 15'.

**JULIAN PERIOD**, in chronology, a system or period of 7980 years, found by multiplying the three cycles of the sun, moon, and indiction into one another. See the article **CYCLE**.

This period was called the julian, not because invented by Julius Cæsar; since the julian epocha was not received till the year 4669, but because the system consists of julian years. This epocha is not historical, but artificial, being invented only for the use of true epochas: for Scaliger considering that the calculation was very intricate in using the years of the creation, the years before Christ, or any other epocha whatever, in regard that another person could not understand what year this or that writer meant; to remove such doubts in the computation of time, he thought of this period; which commencing 710

years before the beginning of the world, the various opinions concerning other epochas may commodiously be referred to it. See **EPOCHA**.

The most remarkable uses of the julian period are as follow. 1. That we can explain our mind to one another, for every year in this period has its peculiar cycles, which no other year in the whole period has; whereas, on the contrary, if we reckon by the years of the world, we must first enquire how many years any other reckons from the creation to the year of Christ, which multiple-inquisition is troublesome and full of difficulties, according to the method of other periods. 2. That the three cycles of the sun, moon, and indiction, are easily found in this period. 3. That if it be known how the chronological characters are to be found in this period, and how the years of any other epocha are to be connected with the years of it, the same characters also may, with little labour, be applied to the years of all other epochas. See **CHARACTER** and **EPOCHA**.

**JULIERS**, the capital of the dutchy of the same name, situated on the river Roer, twenty miles west of Cologne, and as many east of Maestricht: east long. 6°, north lat. 50° 55'.

**JULIS**, or **JULIA**, in ichthyology, names given to the variegated small labrus, with two large teeth in the upper jaw. See the article **LABRUS**.

**JULPHA**, or *Old JULPHA*, once the capital of Armenia, but now in ruins, the inhabitants being transplanted to a town within a mile of Ispahan, called New Julpha, and there they carry on a foreign trade with all the countries in Asia. The situation of Old Julpha was in east long. 46°, north lat. 39°.

**JULUS**, in botany, the same with what is otherwise called catkins or amentaceous flowers. See **AMENTACEOUS**.

**JULUS** is also the name of an insect very common among rubbish, and called in english the gally-worm: it is furnished with a great number of feet, has the power of rolling itself up like a ball when touched, and is esteemed a very valuable medicine in the jaundice and suppression of urine.

**JULY**, in chronology, the seventh month of the year, so called in honour of Julius Cæsar; before whose time it was known by the name of quintilis, as being the fifth month of the old roman year. See the articles **MONTH** and **YEAR**.

**JUMENTA**,

**JUMENTA**, in zoology, the name by which Linnæus calls the fifth order of quadrupeds, the characteristic of which is, that the teeth of all the animals belonging to it are placed in a different manner from the other five orders. See the article **QUADRUPED**.

To this order belong the elephant, rhinoceros, hippopotamus, horse, and hog. See **ELEPHANT**, **RHINOCEROS**, &c.

**JUNCAGO**, in botany, the same with the triglochim of Linnæus. See the article **TRIGLOCHIM**.

**JUNCOIDES**, in botany, the name by which Micheli calls the juncus.

**JUNCUS**, the **RUSH**, in botany, a genus of the *hexandria-monogynia* class of plants, which has no corolla; but the perianthium, when fresh and coloured, greatly imitates one: the fruit is a coloured capsule, of a triquetrous figure, and formed of three valves, containing a few roundish seeds.

Authors have divided the several species of juncus into what they call rushes, and rush-grasses, from their having or wanting leaves; but the fructifications in both are the same.

**JUNCUS ODORATUS**, a name sometimes given to Schoenanth. See the article **SCHOENANTH**.

**JUNGERMANNIA**, a genus of the *cryptogamia-algae* class of plants, consisting usually of stalks furnished with leaves, disposed in a pinnate or squamose manner, sometimes of leaves only: the male flower stands on a long straight pedicle, which arises out of a calyx growing from the upper part of the surface: it has neither calyx nor corolla, but consists of an anthera, which is at first of an oval figure, but afterwards opens into four segments, and remains in this state a long while on the plant; the female flower has no pedicle, there is no visible calyx or corolla, but all that is seen is a number of seeds lying naked in a cluster, and sometimes only a single one.

This is the *lichenastrum* of Dillenius, and the *muscoides* of Micheli.

**JUNIPER**, *juniperus*, in botany, a genus of the *dioecia-monadelphia* class of plants, without any male corolla; the female flower consists of three rigid and acute petals: the fruit is a roundish, fleshy berry; and the seeds are three oblong offshoots, convex on one side, and angulated on the other.

Juniper-berries are to be chosen fresh, plump, full of pulp, and of a strong

taste; and these, when used in medicine, are powerful attenuants, diuretics, and carminatives: they dissolve viscid humours in the first passages, and are consequently a remedy for the flatulencies which these disorders occasion. They are given in cases of the gravel and other nephritic complaints, in infarctions of the viscera, and in suppressions of the menses, and are often made ingredients in clysters. The berries chewed, or the essential oil taken only in a few drops, give the urine the same sweet violet-scent that it has after taking turpentine. But these berries are not to be given indiscriminately; for in hot habits, they often counteract the very purposes intended to be answered by them, and their use succeeded with heat, and even suppression of urine, flatulencies, and swellings of the stomach and intestines: therefore in all cases, where there is danger of an inflammation, either in the primæ viæ, or in the kidneys, the use of juniper-berries is to be avoided. We keep no preparation of them in the shops, except the essential oil made by distillers with water in the usual way; and this is seldom made at home, but the imported kind is commonly adulterated with oil of turpentine. We used to keep a distilled spirituous water of juniper in the shops, but the vulgar getting an opinion of its being a pleasant dram, the making of it became the business not only of the apothecary, but of the distiller, who sold it under the name of geneva. See the article **GENEVA**.

**JUNK**, in the sea-language, old cables cut into short pieces, and given to boat-swains for making swabs, plats, and nippers; as also to the ship-carpenters, and to poor people, to be picked into oakum, for caulking ships, &c.

**JUNO**, in astronomy, the name by which some call the second of jupiter's satellites. See the article **JUPITER**.

**JUNTA**, **JUNTO**, or **JUNCTO**, in matters of government, denotes a select council for taking cognizance of affairs of great consequence, which require secrecy.

In Spain and Portugal, it signifies much the same with convention, assembly, or board among us: thus we meet with the junta of the three estates, of commerce, of tobacco, &c. See **BOARD**, &c.

**IVORY**, *ebur*, in natural history, &c. a hard, solid and firm substance, of a white colour, and capable of a very good polish. It is the tusk of the elephant, and

is hollow from the base to a certain height, the cavity being filled up with a compact medullary substance, seeming to have a great number of glands in it. It is observed that the Ceylon-ivory, and that of the island of Achem do not become yellow in the wearing, as all other ivory does; for this reason the teeth of these places bear a larger price than those of the coast of Guinea.

The duty on ivory, on its being imported into this kingdom, is  $1s. 11. \frac{10}{100}d.$  the pound, out of which a drawback of  $1s. 8. \frac{25}{100}d.$  the pound, is allowed on its exportation.

*To soften IVORY and other bones*, lay them for twelve hours in aqua fortis, and then three days in the juice of beets, and they will become so soft that they may be worked into any form. To harden them again, lay them in strong vinegar. Dioscorides says, that by boiling ivory for the space of six hours with the root of mandragoras, it will become so soft that it may be managed as one pleases.

*To soften and whiten IVORY*, take white wine vinegar, thrice distilled, and boil red sage leaves in it with a little quick-lime; put in the ivory while the liquor is boiling hot, and it will soon become softer and much whiter than it was before. Ivory may also be whitened and cleaned from spots in the following manner: lay it in quick-lime and pour a little water over it, but not too much, that the heat may not be too great, lest it scale and become brittle.

Ivory distilled in a retort yields a small quantity of an insipid and scentless phlegm; then a larger quantity of a pungent liquor, like spirits of harts-horn; after this comes over a brown foetid oil, and a moderate quantity of volatile salt concretes about the sides of the receiver. These have all the same virtues with the preparations of harts-horn; and the raspings of ivory, in the same manner as the shavings of harts-horn, boil into a jelly with water, and have the same restorative virtues.

*Staining and marbling of IVORY.* 1. Of a fine coral-red; make a lye of wood-ashes, of which take two quarts, pour it into a pan upon one pound of brasil; to this add one pound of alum; boil it for half an hour; then take it off, and put in the ivory or bone, and the longer either of these continue in the liquor, the redder they will be. 2. Of a fine green; take two parts of verdgrease, and one

part of sal-armoniac; grind them well together, pour strong white wine vinegar on them, and putting your ivory into this mixture, let it lie covered till the colour has penetrated, and is as deep as you would have it. If you would have it spotted with white, sprinkle it with wax; or if you would have it marbled, cover it with wax, and scrape it off in veins, having all the lines uncovered which you desire to have stained. 3. Of black; take litharge and quick-lime, of each an equal quantity; put them in rain-water over the fire till it begins to boil; in this put the bone or ivory, stirring them well about with a stick; and afterwards, when you see the ivory receive the colour, take the pan from the fire, stirring the ivory all the while till the liquor is cold. 4. Marbling upon ivory is performed thus; melt bees-wax and tallow together, lay it over the ivory, and with an ivory bodkin open the strokes that are to imitate marbling; pour the solution of some metal on them, and when it has stood a short time, pour it off; when it is dry, cover the strokes again with wax, and open some other veins with your bodkin for another metallic solution; and this repeat to the number of colours you design to give it. The solution of gold gives it a purple; of copper, a green; of silver, a lead-black; of iron, a yellow and brown. By this method you may also imitate tortoise-shell and several other substances on ivory.

**IVORY-BLACK.** See *Ivory*. **BLACK.**

**JUPITER**, ♃, in astronomy, one of the superior planets, remarkable for its great brightness. See the articles **PLANET** and **COPERNICAN SYSTEM**.

Jupiter appears almost as large as Venus, but is not altogether so bright; he is eclipsed by the moon, by the sun, and even by mars. He has three appendages, called zones, or belts, which sir Isaac Newton thinks are formed in his atmosphere. In these are several *macule*, or spots; from whose motion the motion of jupiter round its axis is said to have been first determined. See plate CXLVIII. fig. 3.

Its orbit is situated between those of Saturn and mars, and is therefore called one of the superior planets: it has a rotation round its axis in 9 hours 56 minutes; and a periodical revolution round the sun in 4332 days, 12 hours, 20', 9". It is the biggest of all the planets; its diameter to that of the sun appears, by astronomical observations, to be as

Fig. 1. JUPITER'S MOONS.

Fig. 2. An Instrument for making ISSUES.

Fig. 3. KEY.

Fig. 4. KEVEL

Fig. 5. KESTRIL.

1077 is to 10000; to that of saturn, as 1077 to 889; to that of the earth, as 1077 to 104. The force of gravity on its surface is to that on the surface of the sun, as 797.15 to 10000; to that of saturn, as 797.15 to 534.337; to that of the earth, as 797.15 to 407.832. The density of its matter is to that of the sun, as 7404 to 10000; to that of saturn, as 7404 to 6011; to that of the earth, as 7404 to 3921. The quantity of matter contained in its body is to that of the sun as 9.248 to 10000; to that of saturn, as 9.248 to 4.223; to that of the earth, as 9.248 to 0.0044.

The mean distance of jupiter from the sun is 5201 of those parts, whereof the mean distance of the earth from the sun is 1000, though Kepler makes it 5196 of those parts. Mr. Cassini calculates jupiter's mean distance from the earth to be 115000 semidiameters of the earth. Gregory computes the distance of jupiter from the sun to be above five times as great as that of the earth from the sun; whence he gathers, that the diameter of the sun, to an eye placed in jupiter, would not be a fifth part of what it appears to us; and therefore his disk would be twenty-five times less, and his light and heat in the same proportion.

The inclination of jupiter's orbit, that is, the angle formed by the plane of its orbit, with the plane of the ecliptic, is  $1^{\circ} 20'$ ; his excentricity is  $\frac{1}{250}$ ; and Huygens computes his surface to be four hundred times as large as that of the earth.

As jupiter is one of the three superior planets, that is, one of the three which are above the sun, hence it has no parallax, its distance from the earth being too great to have any sensible proportion to the diameter of the earth. Though it be the greatest of all the planets, yet its revolution about its axis is the swiftest. Its polar axis is observed to be shorter than its equatorial diameter; and sir Isaac Newton determines the difference to be as 8 to 9; so that its figure is a spheroid, and the swiftness of its rotation occasions this spheroidism to be more sensible than that of any other of the planets.

Jupiter has four moons, or satellites, that attend him, which, at different distances, and with different periods, perform constant revolutions round him; that which is next to him, is no further removed than  $2\frac{1}{2}$  of his own diameters,

and turns round in 1 day, 18 hours and an half. The second, at the distance of  $4\frac{1}{2}$  diameters, describes its orbit in the space of 3 days and 13 hours. The third is removed from jupiter 7 of his diameters, and finishes its circulation in seven days 4 hours. The furthestmost compleats its period in the space of 16 days,  $16\frac{1}{2}$  hours, at the distance of 12 diameters of jupiter. These *jovial* planets were first discovered by Galileo, by the help of the telescope which he first invented, and by them he increased the number of the celestial bodies, and called them medicean stars, in honour of the dukes of Tuscany, with whose name he dignified them.

The orbits of jupiter's moons lie nearly in the plane of the ecliptic, which is the reason why their motion is apparently in a right line, and not circular, as it really is. To understand this, let S (plate CXLIX. fig. 1.) be the sun, T the earth in its orbit TH, I the planet jupiter in his orbit AIB, and in the center of the four orbits of his moons. Then, because the plane of those orbits does nearly pass through the eye, the real motion of the satellite in the periphery will be apparently in the diameter of the orbit, which is at right angles to the line joining the center of the earth and jupiter.

Thus supposing the earth at R, if DC be drawn through the center of jupiter perpendicular to RI, the motion of each moon and their places will appear to be in that line. Thus, if the exterior moon be at E or F, it will appear to be at I either upon or behind the center of jupiter; if the moon move from E to K, it will appear to have moved from I to L; and when it moves from K to C, it will appear to move from L to C. Again, while the satellite moves from C to M, it will appear to move from C to L; and as it goes from thence to F, it apparently moves from L to I. Thus also, on the other side of the orbit, while the satellite describes the quadrant FD, its apparent motion will be from I to D; and then from D to I again, as its comes from D to E.

Whence, since this is the case of each satellite, it appears, that while each satellite describes the remote half of its orbit CFD, its apparent motion will be direct, or from west to east along the line CD; and while it describes the other half DEC, its apparent motion is retrograde, or from east to west back again along the same

line from D to C; so that each satellite traverses the diameter of its orbit twice in each revolution.

These four moons must make a very pleasing spectacle to the inhabitants of jupiter, if there are any; for sometimes they rise altogether, sometimes they are all in the meridian, ranged one under another; and sometimes all appear in the horizon, and frequently undergo eclipses; the observations whereof are of special use in determining the longitude. The day and night are of the same length in jupiter all over his surface, *viz.* five hours each; the axis of his diurnal rotation being nearly at right angles to the plane of his annual orbit. Though there be four primary planets below jupiter, yet an eye placed on his surface would never perceive any of them; unless, perhaps, as spots passing over the sun's disk, when they happen to come between the eye and the sun. The parallax of the sun, viewed from jupiter, will scarce be sensible, no more than that from saturn, neither being much above twenty seconds; so that the sun's apparent diameter in jupiter will not be above six minutes. The outermost of his satellites will appear almost as big as the moon does to us; *viz.* five times the diameter and twenty-five times the disk of the sun. Doctor Gregory adds, that an astronomer in jupiter would easily distinguish two kinds of planets, four nearer him, *viz.* the satellites; and two, *viz.* the sun and saturn, more remote: the former, however, will fall vastly short of the sun in brightness, notwithstanding the great disproportion in the distances and apparent magnitude. From these four different moons, the inhabitants of jupiter will have four different kinds of months, and the number of moons in their year will not be less than 4500. These moons are eclipsed as often as, being in opposition to the sun, they fall within the shadow of jupiter: and again, as often as, being in conjunction with the sun, they project their shadows to jupiter, they make an eclipse of the sun to an eye placed in that part of jupiter where the shadow falls. But in regard the orbits of these satellites are in a plane which is inclined to, or makes an angle with, the plane of jupiter's orbit, their eclipses become central when the sun is in one of the nodes of these satellites; and when out of this position, the eclipses may be total, though not central, because the

breadth of jupiter's shadow is nearly decuple to that of the breadth of any of the satellites; and the apparent diameter of any of these moons is nearly quintuple the apparent diameter of the sun. It is owing to this remarkable inequality of diameters, and the small inclination the plane of the orbits of the satellites has to the plane of jupiter's orbit, that in each revolution there happen eclipses both of the satellites and of the sun; though the sun be at a considerable distance from the nodes. Further; the inferior among these satellites, even when the sun is at the greatest distance from the nodes, will occasionally eclipse and be eclipsed by the sun to an inhabitant of jupiter; though the remotest of them, in this case, escapes falling into jupiter's shadow, and jupiter into his, for two years together. To this it may be added, that one of these satellites sometimes eclipses another where the phasis must be different, nay frequently opposite to that of the satellite falling into the shadow of jupiter just mentioned; for in this the eastern limb immerses first, and the western immerses last; but in the others, it is just the reverse. The shadow of jupiter, though it reaches far beyond its satellites, yet falls much short of the distance of any planet; nor could any other planet, saturn alone excepted, be immersed in it, even though it were infinite. Nor could the shadow of jupiter reach that of saturn, unless jupiter's diameter were half of that of the sun; whereas, in effect, it is not one ninth of it. The courses of jupiter's satellites, and their various eclipses, would render navigation very sure and easy on the globe of jupiter. Even we, at this distance, can make very good use of them: those eclipses being found one of our best means for determining the longitude at sea. See the article LONGITUDE.

**JUREA**, or **JURA**, a strong city in Italy, in the province of Piedmont, situated on the river Doria, subject to the king of Sardinia: east long.  $7^{\circ}$ ,  $36'$ ; north lat.  $45^{\circ}$ ,  $22'$ .

**JURISDICTION**, in law, signifies the power and authority with which any person is invested in administering justice in cases of complaint laid before him. Jurisdictions are either ecclesiastical or secular; ecclesiastical belongs to bishops and their deputies. See **BISHOP**. Secular jurisdiction belongs to the king and his judges. The courts and judges

at Westminster are not restrained to any county or place, they having jurisdiction all over England; but other courts are confined to their particular jurisdictions, which if they go beyond, all their proceedings become erroneous. As to inferior jurisdictions, they are of several sorts; one of which is to hold pleas, and the plaintiff may either sue there or in the king's courts. Another is the conuſance of pleas; where a right is invested in the lord of the franchise to hold pleas. A third kind is an exempt jurisdiction, as where the king grants to the inhabitants of a particular city or corporation, the privilege of being sued only within their own city, &c.

**JURISPRUDENCE**, the science of what is just or unjust; or the knowledge of laws, rights, customs, statutes, &c. necessary for the administration of justice.

**JURIS UTRUM**, in law, is a writ in behalf of a clergyman whose predecessor has alienated the lands belonging to his church. This writ is also granted in order to try whether free alms belong to a church where they are transferred. A successor of a deceased clergyman may also have this writ against a man, who intrudes into lands and tenements; a vicar may also have this writ even against the parson, for the glebe of his vicarage, &c.

**JUROR**, in law, signifies any person sworn on a jury. See the next article.

**JURY**, a certain number of men sworn to enquire into and try a matter of fact, and to declare the truth upon such evidence as shall appear before them.

Juries are, in these kingdoms, the supreme judges in all courts and in all causes in which either the life, property or reputation of any man is concerned: this is the distinguishing privilege of every Briton, and one of the most glorious advantages of our constitution; for as every one is tried by his peers, the meanest subject is as safe and as free as the greatest.

All criminal causes must first be tried by a grand jury, which commonly consists of twenty-four men of greater note than the petit jury, who are chosen indifferently out of the whole county, and no man can suffer the disgrace of being tried in any ignominious cause, without their first finding him guilty; if they find him innocent, he is immediately discharged; but if otherwise, they only find an indictment, on which he is tried, and

finally acquitted or convicted by the verdict of the petit jury, who are not only to be returned from the county where the fact was done, but near neighbours, such as are most sufficient and least suspicious; to prevent partiality, the names of the persons impannelled are wrote on several pieces of paper of equal size, and delivered by the under-sheriff to the judge's martial, who causes them to be rolled up, all in the same manner, and put together in a box, and when any cause is brought to trial, some indifferent person is to draw out twelve of these papers, and the persons whose names are drawn, if not challenged, are to be the jury to try the cause; and in case any are challenged, and set aside, or do not appear, then a further number is to be drawn till there is a full jury. See the article CHALLENGE.

When a jury-man is sworn, he must not depart from the bar on any account whatsoever till the evidence is given, without leave of the court; and if that be obtained, he must have a keeper with him. As soon as the whole evidence is summed up, the jury are to be kept together till they are all of one mind, and unanimous in bringing in their verdict, without being admitted to the speech of any person, and without meat, drink, fire or candle. They are fineable if they agree to cast lots for their verdict, and also for being tampered with in relation to it. But as they are the sole judges of the fact, they are not fineable for giving a verdict contrary to the sentiments of the court; nor even for giving it contrary to what may appear plain evidence, because the law presumes that they may have some other evidence besides what is given in court: but where any corruption appears, a jury may be attainted for going contrary to evidence; and if a juror takes any thing either of the plaintiff or defendant for giving a verdict, he is to pay ten times as much as he has taken, or suffer a year's imprisonment; yet in trying causes, juries are to have their charges allowed them by the court. In all cases of difficulty, it is safest for the jury to find the special matter, and to leave it to the judges to determine how the law stands upon the fact.

Infants, persons of seventy years of age, and upwards, clergymen, apothecaries, &c. are exempted from serving upon juries; and barons, and all above them, are not to serve in an ordinary jury.

jurors, in London, must not only be housekeepers, but must have land or goods worth one hundred pounds; and they may be examined on oath as to that point. 3 Geo. II. c. 25.

The qualifications of a jury-man for a county, is ten pounds *per annum*, either in freehold or copyhold-estate within the same county; but cities, boroughs, and corporate towns, are excepted by the statutes: however, no jury is obliged to appear upon a trial at Westminster where the offence was committed thirty miles off, except it be required by the king's attorney-general. According to usage, the sheriff should return twenty-four jurors, in order to speed the trial in case of challenge, sickness, &c. and should he only return twelve, pursuant to the writ, he is liable to be amerced. By 4 and 5 W. and M. no sheriff, bailiff, &c. under the penalty of ten pounds, shall return any person to serve on a jury, who has not been duly summoned six days before his appearance, nor under the like penalty shall he accept of money or other reward for excusing the appearance of a jurymen: jurymen neglecting to appear, shall be fined in a sum not exceeding five pounds, nor less than forty shillings; except they can give a reasonable excuse for their non-appearance: and, in case a jurymen does appear, but refuses to be sworn, or to give a verdict, an attachment may be issued against him. Lists of jurors, according to the statutes of 4 and 5 W. and M. and 7 and 8 W. III. are now to be made from the rates of each parish, and fixed on the doors of churches, &c. twenty days before Michaelmas, that public notice may be given of persons omitted who are qualified, or of persons inserted who are not so: after which, the lists being settled by the justices of the peace at the quarter-sessions, duplicates are to be delivered to the sheriffs by the clerks of the peace; and the names contained in these lists must be entered alphabetically by the sheriffs in a book to be kept for that purpose, together with their additions and places of abode. The sheriffs are liable to be fined for returning other persons; and also if they return jurors that have served two years before. Sheriffs, on the return of writs of *venire facias*, are to annex a pannel of the names of a competent number of jurors, mentioned in the lists, and not less than forty-eight in any county, nor more than seventy-two, un-

less they are otherwise directed by the judges, which jurors shall be summoned to serve at the assizes, &c.

When it is conceived that an indifferent and impartial jury will not be returned by the sheriff, a special jury is allowed; in which case the court, upon a motion made, will order the sheriff to attend the secondary of the king's bench with his book of freeholders of the county, and the secondary is to mark a jury, in the presence of the attorneys on both sides: also, if a cause of consequence is to be tried, the court of king's bench, on a motion upon an affidavit made, will make a rule for the secondary to name forty-eight freeholders, out of which each party is to strike out twelve, one at a time, the plaintiff's attorney beginning first, and the remainder of the jurors will be the jury for the trial: though the nomination of a special jury ought to be in the presence of the attorneys on each side; yet in case either of them neglects, or refuses to attend, the secondary may proceed, and strike out twelve for the attorney that makes default. By 3 G. II. c. 25. on the motion of the prosecutor, plaintiff or defendant, on trials of issues on indictments, and in all actions whatsoever, the courts of Westminster are authorized to order a special jury to be struck in the same manner as upon trials at bar. Where a special jury is ordered by a rule of court, in any cause arising in a city, corporation, &c. this jury is to be taken out of the lists or books of the persons qualified, which are to be produced by the sheriffs, &c. before the proper officer. The same indulgence is granted both to merchants and foreigners; for where two merchants are plaintiff and defendant, the court may be moved for a jury of merchants to try the issue between them; and if either of the parties in the suit be an alien, the jury, at the desire of the party, is to be composed of half foreigners and half English. See the articles PEERS and VERDICT.

**JURY-MAST**, whatever is set up in room of a mast that has been lost in a storm or in an engagement, and to which a lesser yard, ropes and sails are fixed.

**JUS**, in its general acceptation, signifies law or right.

**JUS ACCRESCENDI**, in law, is the right of survivorship between two joint tenants.

**JUS CORONÆ**, signifies, in general, the rights of the crown. These are a part of the laws of the kingdom, though they

they differ in many things from the general laws relating to the subject. See the article KING.

**JUS DUPLICATUM**, in law, is a double right, and is used when a person has the possession of a thing, as well as a right to it.

**JUS GENTIUM**, the law of nations, or the laws established between different kingdoms and states, in relation to each other. See the article LAW.

**JUS HEREDITATIS**, the right or law of inheritance.

**JUS PATRONATUS**, in the canon-law, is the right of presenting a clerk to a benefice; or a kind of commission granted by the bishop to inquire who is the rightful patron of a church. This commission is directed to six clergymen, and six laymen who reside near the church, and these are to inquire, 1. Whether the church is void? 2. Who made the last presentation? 3. Who is the rightful patron? &c. See the article PATRON.

**JUS POSSESSIONIS**, in law, is a right of seisin or possession, as *jus proprietatis* is the right of ownership of lands, &c.

**JUS PRESENTATIONIS**, in law, the right a patron enjoys of presenting his clerk to the ordinary, to be admitted, instituted, and inducted into a church.

**JUS RECUPERANDI, INTRANDI, &c.** signify a right of recovering and entering into lands, &c.

**JUST**, a sportive combat on horseback, man against man, armed with lances.

The difference between jousts and tournaments, according to Du Cange, consists in this, that the latter is a genus of which the former is only a species. Tournaments included all kinds of military sports and engagements, which were made out of gallantry and diversion. Jousts were those particular combats, where the parties were near each other, and engaged with lance and sword: add, that the tournament was frequently performed by a number of cavaliers, who fought in a body; whereas the joust was a single combat of one man against another. Though the jousts were usually made in tournaments, after a general rencounter of all the cavaliers, yet they were sometimes singly and independent of any tournament.

Antiently jousts and tournaments made a part of the entertainment of all solemn feasts and rejoicings. The Spaniards borrowed these exercises from the Moors, and call them *juego de canas*, reed or

cane-plays. Some take them to be the same with the *ludus trojanus*, antiently practised by the youth of Rome.

He who appeared for the first time at a joust, forfeited his helmet, or casque, unless he had forfeited before at a tournament.

**JUSTICE**, *justitia*, in a moral sense, is one of the four cardinal virtues, which gives every person his due.

**JUSTICE**, *justiciarius*, in a legal sense, a person deputed by the king to administer justice to his subjects, whose authority arises from his deputation, and not by right of magistracy.

In the courts of king's bench and common pleas there are two judges styled justices, each of whom retains the title of lord during the time of his continuing in office. The first of these, who is styled lord chief justice of England, has a very extensive power and jurisdiction in pleas of the crown, and is particularly intrusted not only with the prerogative of the king, but likewise the liberty of the subject. He hears all pleas in civil causes brought before him in the court of king's bench, and also the pleas of the crown; while, on the other hand, the lord chief justice of the common pleas has the hearing of all civil causes between common persons. Besides the lords chief justices, there are several other justices appointed by the king for the execution of the laws; such as the lords justices in eyre of the forests, who are two justices appointed to determine all offences committed in the king's forests; justices of assize, who, by a special commission, were formerly sent to hear causes in this or that county, for the ease of the subject; and these judges continue twice a year to pass the circuits by two and two throughout all England, dispatching the different business they meet with by different commissions; for they have one commission to take assizes, another of oyer and terminer, that is, to hear and determine causes, and another of goal-delivery: from whence they are called justices of oyer and terminer, of goal-delivery, &c. They are also called justices of nisi prius, and so denominated from the words used in a common form of adjournment of a cause in the court of common pleas. See NISI PRIUS.

**JUSTICES of the peace**, are persons appointed by the king's commission to keep the peace of the county in which they reside; and some of these, who are of superior rank or quality, are called justices

justices of the quorum, and without the presence or assent of these, or at least one of them, no business of importance can be dispatched. Justices of the peace ought to be appointed out of the most sufficient persons in the county, as well as those of the greatest reputation. They ought to possess an estate of at least 100*l.* *per annum*, in freehold or copyhold, for life, or for the term of twenty-one years, without incumbrances; and if a justice of the peace, not thus qualified, presumes to act in that office, he is liable to the penalty of 100*l.* Every justice of the peace has a separate authority for doing all the different acts relating to his office, as for commitments, binding to the good behaviour, &c. they are authorized to take informations against persons committing treason, to grant warrants for apprehending them, and committing them to prison: they may also commit all felons in order to bring them to trial; and at the same time, they are to bind over the accusers to prosecute at the assizes: and if they neglect to certify such examinations and informations at the next goal-delivery, or do not bind over the prosecutors, they are liable to be fined. Where any person is esteemed dangerous, and likely to break the peace, a justice may require a recognizance with a large penalty of such person for his keeping the peace, and on his not procuring sureties for his good behaviour, he may send him to prison: but where a person hears of a peace-warrant being out against him, he may go to another justice, and there give surety of the peace, by which means he will prevent his being held on the first warrant. Justices of the peace frequently make up petty quarrels and breaches, where the king is not intitled to a fine; but they are not to take money for making agreements: if a justice is guilty of any misdemeanor, an information will lie against him in the king's bench, where he may be punished by fine and imprisonment. Two or more justices of the peace have power jointly to take indictments, and try offenders at the quarter-sessions: and in many cases they are empowered, by statute, to act where their commission does not extend: they are to hold their sessions four times a year, on the first week after Epiphany, Easter, St. Thomas a Becket, which is the 7th of July, and Michaelmas: at the quarter-sessions they may try persons for petit-larceny, and

other small felonies; but felonies of a higher nature are to be tried at the assizes.

**JUSTICES** *within liberties*, are justices of the peace who have the same authority in cities or other corporate towns, as the others have in counties, and their power is the same, only these last have the assize of ale and beer, wood and victuals, &c.

**JUSTICE-SEAT**, is the highest forest court, always held before the lord chief justice in eyre of the forest; in which court fines are set for offences, and judgments given.

**JUSTICIA**, in botany, a genus of the *diandria monogynia* class of plants, the corolla whereof consists of a single petal; the tube is gibbous; the limb ringent; the upper lip is oblong and emarginated; the lower lip is of the same length with that, and is reflex and obtusely trifid: the fruit is an oblong, obtuse capsule, narrow at the base, composed of two valves, and containing two cells; the partition placed contrarywise to the valves, opens by an elastic unguis: the seeds are roundish.

**JUSTICIAR**, in our old laws, an officer instituted by William the conqueror, as the chief officer of state, who principally determined in all cases civil and criminal. He was called in latin *capitalis justiciarius totius anglie*.

**JUSTICIARY**, or *court of JUSTICIARY*, in Scotland, a court of supreme jurisdiction in all criminal cases.

This court came in place of the justice-eyre or justice-general, which was last in the person of the earl of Argyle, who transacted for it with king Charles I. but being made justice-general of all the islands, which gave rise to great debates between him and some hereditary sheriffs there, that jurisdiction was taken away by parliament in 1672, and was erected into a justice or criminal court, consisting of a justice-general alterable at the monarch's pleasure, justice clerk, and five other judges, who are lords of the session.

This court commonly sits upon Mondays, and has an ordinary clerk, who has his commission from the justice-clerk. They have four macers, and a doomster appointed by the lords of the session.

The form of the process is this: the clerk raises a libel or indictment upon a bill passed by any of the lords of that court, at the instance of the pursuer, against the defendant or criminal, who is immediately committed to prison after citation.

citation. When the party, witnesses, great assize, or jury of forty-five men, are cited, the day of compearance being come, fifteen of the great assize is chosen to be the assize upon the pannel, or prisoner at the bar. The assize sits with the judges to hear the libel read, witnesses examined, and the debates on both sides, which is written verbatim in the adjournal books. The king's advocate pleads for the pursuer, being the king's cause, and other advocates for the pannel. The debates being closed, the judges find the libel or indictment either non-relevant, in which case they desert the diet, and absolve or absolve the party accused; or, if relevant, then the assize or jury of fifteen is removed into a closer room, none being present with them, where they choose their chancellor and clerk, and consider the libel, deposition, and debates; and bring in their verdict of the pannel sealed guilty or not guilty: if not guilty, the lords absolve; if guilty, they condemn and declare their sentence of condemnation, and command the sentence to be pronounced against the pannel by a macer and the mouth of the doomster.

The lords of the justiciary, likewise go circuits twice a year into the country. See the article **CIRCUIT**.

**JUSTICIES**, a writ directed to a sheriff, by virtue of which he is impowered to hold a plea of debt in his county-court for a sum above 40s. tho' by his ordinary power he has only cognizance of sums under 40s.

**JUSTIFICATION**, in law, signifies a maintaining, or shewing a sufficient reason in court, why the defendant did what he is called to answer. Pleas in justification must set forth some special matter: thus, on being sued for a trespass, a person may justify it by proving, that the land is his own freehold; that he entered a house, in order to apprehend a felon; or by virtue of a warrant, to levy a forfeiture; or, in order to take a distress; and in an assault, that he did it out of necessity.

**JUTES**, the antient inhabitants of Jutland, in Denmark.

**JUTLAND**, a peninsula of Denmark, antiently called the Cimbric Cherionese, situated between  $8^{\circ}$  and  $11^{\circ}$  of east long. and between  $55^{\circ}$  and  $58^{\circ}$  of north lat. bounded by the Categate sea, which separates it from Norway, on the north;

by the same sea, which divides it from the danish islands and Sweden, on the east; by Holstein, on the south; and by the German ocean, on the west. It is divided into north and south Jutland; the south being usually called Sleswic. The whole is about 180 miles in length, and 90 in breadth.

**IVY**, *hedera*, in botany, a genus of the *pentandria-monogynia* class of plants, the corolla whereof consists of five oblong, patent petals, with their points bent: the fruit is a globose berry, having only one cell: the seeds are five in number, large, gibbous, and angulated on one part.

The qualities of this plant, in medicine, are drying and astringent; but it is rarely taken inwardly: it is more frequently used externally, for drying and healing achors: the berries are frequently given by the common people as a febrifuge: they purge up and down. A gum that distills from the trunk of the ivy-tree, upon being any ways cut, is reckoned a notable caustic, and is said to destroy the nits of the head.

*Ground-IVY*, *hedera terrestris*. See the article **GROUND-IVY**.

**IXIA**, in botany, a genus of the *triandria-monogynia* class of plants, the corolla whereof consists of six oblong, equal, lanceolated petals: the fruit is a roundish, triquetrous capsule, composed of three valves, and containing three compressed cells, in each of which is a single roundish seed.

**IXORA**, in botany, a genus of the *tetrandria-monogynia* class of plants, the corolla whereof consists of a single petal; the tube is cylindric, very long and slender; the limb is plane, and divided into four oval segments; the fruit is a berry of a roundish figure, with only one cell; the seeds are four in number, convex on one side, and angular on the other.

**JYNX**, the **WRY-NECK**, in ornithology, a genus of bird of the pye-kind, the beak of which is smooth, and the nostrils hollowed: the tongue is very long, and of a rounded form, resembling a worm: the toes are four in number, two before and two behind.

Of this genus there is only one known species, called, from its singular manner of twisting its head about, the wry-neck. It is about the size of a lark, and is called by authors *jynx*, *torquilla*, *turbo*, &c.

## K.

**K**, or *k*, the tenth letter, and seventh consonant of our alphabet; being formed by the voice, by a guttural expression of the breath through the mouth, together with a depression of the lower jaw, and opening of the teeth. Its sound is much the same with that of the hard *c*, or *qu*; and it is used, for the most part, only before *e*, *i*, and *n* in the beginning of words; as *ken*, *kill*, *know*, &c. It used formerly to be always joined with *c* at the end of words, but is at present very properly omitted: thus, for *publick*, *musick*, &c. we say, *public*, *music*, &c. However, in monosyllables, it is still retained, as *jack*, *block*, *mock*, &c. Tho' it is seldom used in words derived from the French, as being altogether wanting in that language, yet we meet with *risk*, *burlesk*, &c. in very good authors, instead of *risque*, *burlesque*: and, indeed, the former orthography is certainly most agreeable to the genius of the english language.

The letter *k* is derived from the greek kappa, *κ* or *κ*; it being unknown to the Romans, tho' we sometimes meet with *kalendæ* instead of *calendæ*.

As a numeral, *K* denotes 250; and with a line over it, *K̄* 250000.

**KAABA**, or **CAABA**. See **CAABA**.

**KABBALA**, or **CABBALA**. See the article **CABBALA**.

**KADARI**, or **CADARI**. See **CADARI**.

**KÆMPFERIA**, in botany, a genus of the *monandria-monogynia* class of plants, the flower of which consists of a single petal, with a long slender tube, and the limb is divided into six segments: the fruit is a roundish and somewhat trigonal capsule with three cells, each containing a considerable number of seeds.

The roots of this plant are the galangals of the shops. See **GALANGALS**.

**KAFFA**, or **CAFFA**. See **CAFFA**.

**KAKENHAUSEN**, a city of Livonia, subject to Russia: east long. 26°, north lat. 57°.

**KALENBURG**, or **CALENBURG**. See the article **CALENBURG**.

**KALENDAR** and **KALENDS**. See the articles **CALENDAR** and **CALENDS**.

**KALI**, **GLASSWORT**, in botany, a genus of the *pentandria-digynia* class of plants,

which has no corolla or flower-petals: the fruit is a globose, unilocular capsule, covered by the cup, and containing a single, large, and spiral seed.

Of the ashes of kali is made soap, glass, alkali-salt, potash, &c. See the articles **SOAP**, **GLASS**, &c.

The method of preparing it is this: when dry, they burn it in certain pits, dug in the ground, which are close covered up with earth, so that no air can come at the fire: by this means the matter is not only reduced to ashes, but made into a very hard stone, like rock-salt, which they are forced to break with hammers to get it out. The best sort is in little dry stones, of a blueish-grey colour, and full of little eyes or holes. See the article **ALKALI**.

**KALIPH**, or **CALIPH**. See **CALIPH** and **CALIPHATE**.

**KALLO**, a town of upper Hungary, situated in a lake twenty miles south-east of Tockay.

**KAM**, **KAN**, or **CHAM**. See the article **CHAM**.

**KAMINECK**, a city of Poland, in the province of upper Podolia, and palatinate of Kamineck, situated on the frontiers of Moldavia: east long. 26° 30', north lat. 48°.

**KANISHIA**, a town situated on the river Drave, in lower Hungary, 100 miles south-west of Buda: east long. 17° 6', north lat. 47°.

**KANOF**, or **KANIOW**, a town of Russia, situated on the river Nieper, in the Ukrain, seventy miles south-east of Kiow: east long. 32°, north lat. 50°.

**KAOLIN**, one of the substances whereof china-ware is made; being no other than a kind of talc reduced to powder, and made into a paste with water.

The peculiar property of kaolin is, that it is very difficultly, if at all vitrifiable: so that being mixed with petunse, a substance easily vitrifiable, the mixture produces a semi-vitrification in the fire, which is what we call china or porcelain. See the article **PORCELAIN**.

Talc, therefore, seems the only substance capable of supplying the place of kaolin, in the manufacture of european porcelain; as being not only very difficultly vitrified,

Vitrified, but keeping its transparency after the action of the most violent fire.

**KASTREL**, or **KESTREL**. See the article **KESTREL**.

**KATOVINDEL**, in botany, the same with the phoenix of Linnæus. See the article **PHOENIX**.

**KAUSBEUREN**, an imperial city of Germany, thirty-two miles south of Augsburg: east long.  $10^{\circ} 45'$ , north lat.  $47^{\circ} 50'$ .

**KAY**, or **KEY**, the same with wharf. See the article **WHARF**.

**KEBLA**, an appellation given by the mahometans to that part of the world where the temple of Mecca is situated, towards which they are obliged to turn themselves when they pray.

**KECKLE**, or **KECKLING**, in the sea-language, is the winding of old ropes about cables, to prevent them from galling.

**KEDGE-ANCHOR**, a small one used in kedging. See the next article.

**KEDGING**, in the sea-language, is when a ship is brought up or down a narrow river by means of the tide, the wind being contrary. To do this, they use to set their fore-course, or fore-top-sail and misen, that so they may flat her about; and if she happens to come too near the shore, they let fall a kedge-anchor, with a hawser fastened to it from the ship, in order to turn her head about; which work is called kedging.

**KEEL**, the lowest piece of timber in a ship, running her whole length from the lower part of her stem to the lower part of her stern-post. Into it are all the lower futtocks fastened; and under part of it, a false keel is often used.

**KEELERS**, among seamen, are small tubs, which hold stuff for the caulking of ships.

**KEELSON**, a principal timber in a ship, fayed within-side cross all the floor-timbers; and being adjusted to the keel with suitable scarfs, it serves to strengthen the bottom of the ship.

**KEEPER of the forest**, an officer that has the chief management of every thing belonging to a royal forest, as well as the government of all the other officers. See the article **FOREST**.

**KEEPER of the great seal**, is a lord by his office, is stiled lord-keeper of the great seal of Great-Britain, and is always one of the privy-council. All grants, charters and commissions of the king under the great seal, pass through the hands of the lord-keeper, for without that seal, many of those grants, &c. would be of no force; the king being, in the interpreta-

tion of the law, a corporation, and therefore passes nothing but by the great seal, which is also said, to be the public faith of the kingdom, being in the highest esteem and reputation.

Whenever there is a lord-keeper, he is invested with the same place, authority, preheminance, jurisdiction, or execution of laws, as the lord chancellor of Great-Britain is vested with.

The lord-keeper is constituted by the delivery of the great seal, &c.

**KEEPER of the privy seal**, is also a lord by his office, thro' whose hands all grants, pardons, &c. pass before they come to the great seal, and even some things pass this officer's hands which do not pass the great seal at all. This officer is also one of the privy-council, yet was antiently called clerk of the privy seal. His duty is to put the seal to no grant, &c. without a proper warrant, nor with warrant where it is against law, or inconvenient, but shall first acquaint the king therewith.

**KEEPERS of the liberties of England**, &c. See **CUSTODES LIBERTATIS**.

**KEIL**, a fortress situated on the Rhine, in the circle of Swabia, in Germany, opposite to Strasburg.

**KEISERWAERT**, a strong town of Germany in the circle of Westphalia, and duchy of Berg, situated on the Rhine, twenty-five miles north of Cologne: east long.  $6^{\circ} 8'$ , north lat.  $51^{\circ} 20'$ .

**KELLINGTON**, a borough-town of Cornwall, thirteen miles south of Launceston, which sends two members to parliament.

**KELP**, a fixed salt, or particular species of pot-ash, procured by burning the weed called kali. See **KALI**.

Kelp, the ton, containing twenty hundred weight, each hundred weight containing 112 lb. pays on importation, 14s. 4  $\frac{13}{100}$  d. and draws back on exportation, 12s. 11  $\frac{25}{100}$  d.

**KELSO**, a town of Scotland, in the shire of Mers, or Roxburgh, situated on the north side the Tweed, twenty miles south-west of Berwick.

**KEMPFERIA**, or **KÆMPFERIA**, in botany. See **KÆMPFERIA**.

**KEMPTEN**, a city of Germany, in the circle of Swabia, situated on the river Iser: east long.  $10^{\circ} 7'$ , north lat.  $47^{\circ} 38'$ .

**KENDAL**, a market-town of Westmoreland, twenty-two miles south-west of Appleby.

**KENKS**, in the sea-language, doublings in a rope or cable, when handed in and cut, so that it does not run easy; or when any rope makes turns or twists, and does not run free in the block, then it is said to make kenks:

**KENSINGTON**, a pleasant village in the county of Middlesex, two miles west of London; where is a royal palace, with large and fine gardens.

**KENT**, a county bounded by the river Thames, on the north; by the ocean, on the east; by Suffex, and the Straits of Dover, on the south; and by Surrey on the west.

**KERMAN**, the capital of the province of Kerman, or Carmania, in Persia: east long.  $56^{\circ} 30'$ , north lat.  $30^{\circ}$ .

**KERMES**, according to the arrangement of Linnæus, is a species of the coccus. See the article *Coccus*.

The female of this species, which is what we know by the name *kermes* in the shops, is, when full grown, of a roundish figure, and of a deep purplish blue colour, covered with a fine whitish or greyish dust, like that on the surface of a ripe plum; in this state it is not easy to distinguish its limbs, or indeed its natural form; its being distended by young at this period altering, and in a manner destroying its figure. It adheres in this state to the leaves and young shoots of the *ilex*, and is collected thence for the shops: before this period, it runs about on the branches, and has its form more regular. The male is a very small fly, which would scarce be thought to belong to the same species, if it were not seen impregnating the females; its body is oblong, its head small, its eyes little and black, and its wings whitish, and full of brown and somewhat rigid nerves. It is the female that is gathered for use.

*Kermes*, as brought to us, is a small roundish body, of the bigness of a pea: when cut, it is found to be a mere membranaceous bag, containing a multitude of little distinct granules, which are soft and juicy. It is a very valuable commodity, and serves to two very great uses; the dyers in scarlet finding it as valuable in their way, as the physicians in theirs. The *kermes* intended for the dyers is best kept whole, only destroying the principle of life in the eggs, by means of vinegar; but that intended for medicinal purposes, is more properly managed in another way: they are to be gathered when fully distended, and

while yet perfectly covered with bloom, and are to be immediately put into a mortar, and bruised to pieces. After which they are to be set in a cool place for seven or eight hours, in which time their juice will be rendered much less tough and viscous than it was on the first bruising; after this, it is to be pressed pretty strongly, in order to get out the whole. The liquor thus drawn, is to be set by for some hours to settle; the clear juice is then to be decanted off, and an equal quantity of fine sugar is to be added to it, with which it is to be boiled over a very gentle fire, to the consistence of a syrup, which is called *kermes-juice* in the shops. It will keep a long time, and the confecton of *alkermes* is generally made from it. See *ALKERMES*.

The *kermes* is in great esteem as a restorative, and is said to strengthen the stomach, and assist digestion, at the same time that it invigorates and enlivens in an uncommon manner. It is also in great esteem among the midwives, as a cordial and strengthener for lying-in-women, and as a preventer of abortions.

The people who prepare *kermes* for the dyers, often let the eggs hatch as they lie in drying, and then sprinkling them with vinegar, they kill them, and form them into a sort of cakes, which keep very well a long time.

**KERMES-MINERAL**, *pulvis carthusianorum*, in pharmacy, a preparation of antimony, made up in the following manner. Take of antimony, four pounds; solution of fixt nitre per deliquium, one pound; rain water, three pounds; boil them two hours, and then filter the boiling decoction through paper; let it stand at rest twenty-four hours, and it will let fall a yellowish or saffron-coloured powder, the fluid becoming clear. This fluid being then poured off by inclination, the powder must be washed by repeated affusions of warm water, and four ounces of spirit of wine being burnt upon it, afterwards kept for use.

This powder, according to Quincy, is a most efficacious deobstruent, and therefore extremely useful in scrophulous obstinate, scorbutic, and all such cases as arise from glandular obstruction, as likewise in chloretic, cachectic, and hysterical habits, where the vitiated crasis of the blood has impaired the *vis vitæ*, and debilitated the secretive powers: it has been recommended also in fevers; but the use of medicines of this class, is not yet enough

enough authorized by experience, to render such a practice eligible.

The doses given, have been from one grain to four; but it is best to begin first with the smallest dose, especially with young persons, as the force of its operation varies greatly in different constitutions.

**KERNING**, among salt-makers, the crytallizing of salt. See **SALT**.

**KERRY**, a county of Ireland, in the province of Munster, bounded by the river Shannon, which divides it from Clare, on the north; by Limeric and Cork, on the east; by another part of Cork, on the south; and by the Atlantic Ocean, on the west.

**KESSEL**, a town of Upper Gelderland, in the quarter of Roermonde, situated on the river Meuse: east long. 6°, north lat. 51° 25'.

**KESTRIL**, or **KASTRIL**, in ornithology, the yellow-legged falcon, with a brown back, a spotted breast, and a rounded tail, with a broad black fascia, towards the end. It is a very beautiful bird, about the size of a pigeon, and very bold. It is known among authors, by the names of *tinnunculus* and *cenchris*, and is also called in english, the *stannel* or *windhover*. See plate CXLIX. fig. 5.

**KETCH-DOLT**, a game with dice and tables, wherein the first throws, and lays down from the heap of men without the tables, more or less, according to what he threw, suppose six deuce; then if the other throw either six or deuce, and draw them not from his adversaries tables to the same point in his own, but takes them from the heap, and lays the ace down, he is *dolted*, and so loseth the game: nay, if he but touch a man of the heap, and then recollect himself, the loss is the same. Good gamesters will never be *dolted*; in which case, they strive who shall fill up their tables first, and he that bears them off first wins the game. See **BACK-GAMMON**.

**KETMIA**, in botany, a genus of plants called by Linnaeus *hibiscus*. See the article **HIBISCUS**.

**KETTERING**, a market-town of Northamptonshire, ten miles north-east of Northampton.

**KETTLE**, a well known metalline vessel, for boiling any thing in.

**KETTLE-DRUMS**, in the art of war. See the article **DRUM**.

**KETCH**, in naval architecture, a vessel with two masts. See **SHIP**.

**KEVEL**, in ship-building, a piece of plank layed against the quickwork on the quarter-deck, in the shape of a semi-circle; about which the running rigging is belaid. See plate CXLIX. fig. 4.

**KEXHOLME**, the capital of the province of the same name in Finland, situated on the lake Ladoga, eighty miles north of Petersburg: east long. 30°, north lat. 61° 30'.

**KEY**, *clavis*, a well known instrument, for opening and shutting the locks of doors, chests, buroes, and the like. See the article **LOCK**.

The names of the several parts of a key are these: A (plate CXLIX. fig. 3.) is the pin-hole, drilled into the end of the shank H; B is the step, or dap ward; C, the hook ward; D, the middle-ward; E E, the cross-ward; F, the main-ward; G G, cross-wards; I, the pot; K, the bow-ward; L, the bow, or handle; and B F E D, &c. the piece of steel containing the wards, is called the bit of the key.

Keys are prohibited to be imported.

**KEY**, in music, a certain fundamental note, or tone, to which the whole piece, be it in concerto, sonata, cantata, &c. is accommodated, and with which it usually begins, but always ends. See **CLEF**.

To get an idea of the use of the key, it may be observed, that as in an oration there is a subject, *viz.* some principal person or thing to which the discourse is referred, and which is always kept in view, that nothing unnatural or foreign to the subject may be brought in, so in every regular piece of music, there is one sound, *viz.* the key, which regulates all the rest. Again, as in an oration there are several distinct articles, which all refer to different subjects, yet so as they may have a visible connection with the principal subject, which regulates and influences the whole; so in music, there may be various subaltern subjects, that is various keys, to which the different parts of the piece may belong: but then they must be all under the influence of the first and principal key, and have a sensible connection with it.

Now to give a more distinct notion of the key, we must observe, that the octave contains in it the whole principles of music, both with respect to consonance and melody; and that if the scale be continued to a doable octave, there will

in that case be seven different orders of the degrees of an octave, proceeding from the seven different letters, with which the terms of the scale are marked. Any given sound therefore, *i. e.* a sound of any determinate pitch of tune, may be made the key of the piece, by applying it to the seven natural notes arising from the division of an octave, and repeating the octave above and below at pleasure : the given note is applied as the principal note or key to the piece, by making frequent closes or cadences upon it ; and in the progress of the melody, no other than these seven natural sounds can be admitted, while the piece continues in that key.

Here too it must be added with respect to the two different divisions of the octave, that a sound may belong to the same key, that is, have a just musical relation to the same fundamental in the one kind of division, and be out of the key in respect of the other. Now a piece of music may be carried through several keys, that is, it may begin in one key, and be led out of that into another, by introducing some sound foreign to the first, and so on to another : but a regular piece of music must not only return to the first key, but those keys too must have a particular connection with the first. It may be added, that those other keys must be some of the natural sounds of the principal key, though not any of them at pleasure.

From the distinctions already observed, it is evident, that there are but two different species of keys, which arise according as we join the greater or lesser third, these being always accompanied with the sixth and seventh of the same species ; the third greater, for instance, with the sixth and seventh greater, and the third lesser with the sixth and seventh lesser. And this distinction is expressed under the name of a sharp key, which is that with the third greater, &c. and the flat key with the third lesser, &c. whence it is plain, that how many different cases soever there be in a piece, there can be but two keys, if we consider the essential difference of keys ; every key being either flat or sharp, and every sharp key being the same as to melody, as well as a flat one. See MODULATION, and HARMONY.

To distinguish accurately between a mode and a key, Mr. Malcolm has given us this definition, *viz.* An octave with all its natural and essential degrees, is a

mode with respect to the constitution or manner of dividing it : but with respect to its place in the scale of music, it is a key. See MODE and MELODY.

KEY, is also used for an index, or explanation of a cipher. See CIPHER.

KEYS of an organ, harpsichord, &c. those little pieces in the forepart of those instruments, by means whereof the jacks play, so as to strike the strings. These are in number twenty-eight, or twenty-nine. In large organs, there are several sets of the keys, some to play the secondary organ, some for the main body, some for the trumpet, and some for the echoing trumpet, &c. in some there are but a part that play, and the rest are only for ornament. There are twenty flits in the large keys, which make half notes. See the article ORGAN, &c.

KEY-STONE of an arch, or vault, that placed at the top or vertex of an arch, to bind the two sweeps together.

This, in the tuscan and doric orders, is only a plain stone, projecting a little ; in the ionic, it is cut and waved somewhat like consoles ; and, in the corinthian and composite orders, it is a console, enriched with sculpture.

Key-stones made in the manner of consoles, and placed projecting in the middle of arches and porticos, are particularly designed to sustain the weight and pressure of the entablature, where it happens to be very great between the columns ; for which reason, they should be made so as to be a real support, and not stand for mere ornaments, as they too frequently do.

KIAM, a great river of China, which, taking its rise near the west frontier, crosses the whole kingdom eastward, and falls into the bay or gulph of Nanking, a little below that city.

KIAMSI, a province of China, bounded by that of Nanking on the north, and by that of Canton on the south.

KIDDERMINSTER, a market-town twelve miles north of Worcester.

KIDNEYS, *rems.* in anatomy, are two red viscera of an oblong figure, situated at the loins, one on each side ; their hollow side being turned inward, and their convex side outward. They are placed near the lowest spurious ribs ; but their situation is not exactly regular ; for in some subjects they are a little higher, and in others a little lower ; and one of them is not unfrequently placed a little above the other : it is not always the same kidney

*Fig. 1. The KIDNEYS, &c.*

*Fig. 2 LUXATION of the KNEE.*

*Fig. 3. KNIVES.*

kidney that is placed highest ; but sometimes the right, and sometimes the left ; however, they are sometimes perfectly even.

The kidneys are connected with the loins, the lower ribs, the colon, the succenturiati, the renal vessels, and the ureters. They have two membranes, the one robust and common, called the adipose membrane : this surrounds them but loosely, and is furnished with its own proper vessels. The other membrane is proper, and is very thin, and every where applied closely to the substance of the kidneys.

The length of the kidneys is five or six fingers, the breadth three, and the thickness about a finger and a half. Its surface, in adults, is smooth and equal ; but in the foetus in human subjects, and in grown animals of many kinds, it is irregularly divided, as it were, into a number of lobes.

The vessels of the kidneys, are, like those of the liver, included in a membrane, from the peritonæum. The arteries and veins are large, and called emulgents, and venal vessels ; these are produced from the aorta and vena cava. The nerves are from the plexus renalis ; and there is a large excretory duct, called the ureter. There are also a number of lymphatics, passing to the receptaculum chyli. The substance of the kidneys is firm and hard, and is of two kinds. 1. The exterior, or cortical, which, according to Malpighi, is glandulous ; but according to the discoveries of Ruysch, is throughout elegantly vasculous. 2. The interior, which is tubulous, and expressed by the name of tubuli urinarii Bellini : this terminates in ten or twelve papillæ, which open by a multitude of apertures into the pelvis ; but these papillæ are not found in all subjects.

The use of the kidneys is to secrete the urine from the blood, into the pelvis. See the articles PELVIS, SUCCENTURIATI, URETTERS, BLADDER, and URETHRA. In plate CL. fig. 1. are represented the kidneys, glandulæ succenturiatæ, bladder, and male-organs of generation, with their vessels. A, A, are the kidneys ; B, B, the glandulæ succenturiatæ ; C, C, the emulgent vessels, together with those distributed over the membranes of the kidneys ; D, D, the hypogastric vessels, which branching off from the iliacs, are distributed in the urinary bladder and penis ; E, E, the course of the ureters ;

F, F, the course of the spermatic vessels, in which several appear cut off, being those distributed in the peritonæum ; G, the urinary bladder ; H, H, the vasa deferentia ; I, I, the testicles ; K, the urachus cut off ; L, the penis, M, M, the erector-muscles.

*Inflammation of the KIDNIES.* See the article NEPHRITIS.

**KIGGELARIA**, in botany, a genus of the *dioecia decandria* class of plants, in which the corolla of both the male and female flower consists of five lanceolated, hollow petals ; and its fruit is a coriaceous globose and unilocular capsule, containing a number of roundish seeds.

**KILDARE**, the capital of a county of the same name, in Ireland, twenty-seven miles south west of Dublin.

**KILDERKIN**, a liquid measure, containing two firkins. See the articles FIRKIN and MEASURE.

**KILKENNY**, a county of Ireland, in the province of Leinster, bounded by Queen's County, on the north ; by the county of Wexford, on the east ; by Waterford, on the south ; and by the county of Tipperary, on the west. It is also the name of the capital of that county, and is situated in west long. 7° 15', north lat. 52° 30'.

**KIMBOLTON**, a market-town of Huntingdonshire, nine miles south-west of Huntingdon.

**KINDRED**, in law, persons related to another, whereof the law of England reckons three degrees or lines, *viz.* the descending, ascending, and collateral line. See LINE, DEGREE, DIRECT, &c.

On there being no kindred in the descending line, the inheritance passes to the collateral one. See INHERITANCE.

**KING**, in the general acceptation of the word, is a person who has a supreme authority, with the power of levying taxes, making laws, and enforcing an obedience to them : but in England, which is a limited monarchy, the power of the king is greatly restrained ; which is so far from diminishing his honour, that it adds a glory to his crown ; for while other kings are absolute monarchs over innumerable multitudes of slaves, the king of England has the distinguished glory of governing a free people, the least of whom is protected by the laws : he has great prerogatives, and a boundless power in doing good ; and is at the same time only restrained from acting inconsistently with his own happiness, and that of his people. He has all the ensigns of royal-

ty,

ty, and all the marks of sovereignty : but while he has the power of making treaties, of sending and receiving ambassadors, of conferring titles of honour, creating privy counsellors, officers of state, and judges, and may raise men and arms both for sea and land, he cannot force his subjects to maintain them, or raise one tax by his sole authority : he has the privilege of coining money, but he cannot force the meanest subject to part with his property : he can pardon a criminal, but he cannot put a subject to death, till he is condemned by his peers : he may at his pleasure call, continue, prorogue, and dissolve parliaments, and without his royal assent no bill in parliament can pass into a law ; yet he can neither act contrary to law, nor make new laws by his sole authority ; on the contrary, he may even be sued and cast in his own courts. At his coronation, he takes an oath to govern his people according to the statutes agreed on in parliament, to cause law and justice in mercy to be executed in all his judgments ; to maintain, as much as in him lies, the laws of God, the true profession of the Gospel, and the protestant reformed religion by law established, and to preserve to the bishops and clergy all their rights and privileges. But tho' he may mitigate the rigour of the law, and forgive offenders, he cannot pardon murder, where an appeal is brought by the subject ; nor any other crime, when the offender is impeached by the house of commons. He may lay an embargo on shipping, but then it ought to be for the public good, and not for the private advantage of any particular traders. Writs, processes, commissions, &c. are in his name ; and he has a power not only to make courts, but to create universities, colleges, and boroughs, to incorporate a city or town, and to grant franchises to such corporations ; but they must not, under colour thereof, set up a monopoly. He is esteemed the head of the church ; in him is lodged the supreme right of patronage throughout England, and he may be the founder as well as patron of bishoprics. But notwithstanding these and other prerogatives, the king can take what he has a right to, only by due course of law. In short, he has a principal share in the legislative power, and the whole executive power is lodged in him ; he is supposed present in all his courts, he can do no wrong, and, according to the laws of England, he never dies.

**KING'S BENCH**, a court in which the king was formerly accustomed to sit in person, and on that account was moved with the king's household. This was originally the only court in Westminster-hall, and from this it is thought that the courts of common pleas and exchequer were derived. As the king in person is still presumed in law to sit in this court, though only represented by his judges, it is said to have supreme authority, and the proceedings in it are supposed to be *coram nobis*, that is, before the king. This court consists of a lord chief justice and three other justices or judges, who are invested with a sovereign jurisdiction over all matters, whether of a criminal or public nature. All crimes against the public good, though they do not injure any particular person, are under the cognizance of this court ; and no private subject can suffer any unlawful violence or injury against his person, liberty, or possessions, but a proper remedy is afforded him here ; not only for satisfaction of damages sustained, but for the punishment of the offender : and wherever this court meets with an offence contrary to the first principles of justice, it may punish it. It frequently proceeds on indictments found before other courts, and removed by *certiorari* into this. Persons illegally committed to prison, though by the king and council, or either of the houses of parliament, may be bailed in it ; and in some cases, even upon legal commitments. Writs of *mandamus* are issued by this court, for the restoring of officers in corporations, &c. unjustly turned out, and freemen wrongfully disfranchised.

The court of king's bench is now divided into a crown side and plea-side ; the one determining criminal, and the other civil causes : in the first it determines criminal matters of all kinds, where the king is plaintiff ; such as treasons, felonies, murders, rapes, robberies, riots, breaches of the peace, and all other causes that are prosecuted by indictment, information, &c. On the plea-side, it determines all personal actions commenced by bill or writ ; as actions of debt, upon the case, detinue, trover, ejectment, trespass, waste, &c. against any person in the custody of the marshal of the court, as every person sued here is supposed to be by law.

The officers of this court on the crown-side are the clerk and secondary of the crown ;

crown; and on the side of the pleas there are two chief clerks or prothonotaries, and their secondary and deputy, the custos brevium, two clerks of the papers, the clerk of the declarations, the signer and sealer of bills, the clerk of the rules, clerk of the errors, and clerk of the bails; to which may be added the filazers, the marshal of the court, and the crier.

*Books of KINGS*, two canonical books of the Old Testament, so called because they contain the history of the kings of Israel and Judah, from the beginning of the reign of Solomon, down to the babylonish captivity, for the space of near six hundred years. The first book of Kings contains the latter part of the life of David, and his death; the flourishing state of the Israelites under Solomon, his building and dedicating the temple of Jerusalem, his shameful defection from the true religion, and the sudden decay of the jewish nation after his death, when it was divided into two kingdoms: the rest of the book is taken up in relating the acts of four kings of Judah and eight of Israel. The second book, which is a continuation of the same history, is a relation of the memorable acts of sixteen kings of Judah, and twelve of Israel, and the end of both kingdoms, by the carrying of the ten tribes captive into Assyria by Salmanassar, and the other two into Babylon by Nebuchadnezzar.

It is probable that these books were composed by Ezra, who extracted them out of the public records, which were kept of what passed in that nation.

**KING'S COUNTY**, a county of Ireland, in the province of Leinster, bounded by West-meath on the north, by the county of Kildare on the east, by Queen's county and Tipperary on the south, and by the river Shannon, which separates it from Galway, on the west.

**KING'S FISHER**, *ispida*, in ornithology. See the article *ISPIDA*.

**KINGHORN**, a town of Scotland, on the coast of Fife, nine miles north of Edinburgh.

**KINGSTON**, a market-town of Surry, situated on the river Thames, twelve miles west of London.

**KINGSTON**, a port-town of Jamaica, situated on the north side of the bay of Port-royal: west lon.  $77^{\circ}$ , north lat.  $17^{\circ} 32'$ .

**KINGSTON upon Hull**. See **HULL**.

**KINNOR**, **CINNOR**, or **CINYRA**. See the articles **CINYRA**.

**KINKROSS**, a town of Scotland, in the shire of Fife, situated on the lake of Loch-Leven, twenty miles north of Edinburgh.

**KINSALE**, a port-town of Ireland, in the county of Cork and province of Munster, situated on the river Bandon, fourteen miles south of the city of Cork: west lon.  $8^{\circ} 25'$ , and north lat.  $51^{\circ} 32'$ .

**KIOF**, or **KIOW**, the capital of the Russian Ukraine, on the frontiers of Poland: east lon.  $30^{\circ} 30'$ , and north lat.  $51^{\circ}$ .

**KIRK**, a saxon term, signifying the same with church. See the article **CHURCH**.

**KIRK-MOTE**, a term formerly used for a synod. See the article **SYNOD**.

**KIRK-OSWALD**, a market-town of Cumberland, twelve miles south of Carlisle.

**KIRK-SESSIONS**, an inferior church-judicatory, in Scotland, consisting of the ministers, elders, and deacons of a parish. It regulates matters relating to public worship, catechising, visitations, &c. and judges in cases of fornication and lesser scandals; but adultery, and the like, are left to the presbytery. See **PRESBYTERY**.

**KIRKALDY**, a town of Fifeshire, in Scotland, ten miles north of Edinburgh.

**KIRKHAM**, a market-town of Lancashire, sixteen miles south of Lancaster.

**KIRKUDBRIGHT**, a parliament-town of Scotland, which ranks with Dumfries, Annan, &c. situated on a bay of the Irish sea, sixty miles west of Carlisle: west lon.  $4^{\circ} 5'$ , and north lat.  $54^{\circ} 38'$ .

**KIRKWALL**, the capital of the Orkney-islands, and situated in that of Pomona, is a parliament-town, which classes with Dingwall, Tain, &c. west lon.  $25'$ , and north lat.  $59^{\circ} 45'$ .

**KITCHEN**, a room appropriated for dressing meat, and furnished with suitable accommodations and utensils for that purpose.

*Clerk of the KITCHEN*, an officer of the king's household, whose office is to buy provisions.

**KITCHEN-GARDEN**, a piece of ground laid out for the cultivation of fruit, herbs, pulse, and other vegetables used in the kitchen.

A kitchen-garden ought to be situated on one side of the house, near the stables, from whence the dung may be easily conveyed into it; and after having built the wall, borders should be made under them, which, according to Miller, ought to be eight or ten feet broad: upon those borders exposed to the south, many sorts of early plants may be sown; and upon those

those exposed to the north, you may have some late crops, taking care not to plant any sort of deep-rooting plants, especially beans and peas, too near the fruit-trees. You should next proceed to divide the ground into quarters; the best figures for these is a square, or an oblong, if the ground will admit of it; otherwise they may be of that shape which will be most advantageous to the ground: the size of these quarters should be proportioned to that of the garden; if they are too small, your ground will be lost in walks, and the quarters being enclosed by espaliers of fruit-trees, the plants will draw up slender, for want of a more open exposure. The walks should also be proportioned to the size of the ground; these in a small garden should be six feet broad, but in a larger one ten; and on each side of the walk there should be allowed a border three or four feet wide, between it and the espalier, and in these borders may be sown some small fallads, or any other herbs that do not take deep root, or continue long: but these quarters should not be sown or planted with the same crop two years together. In one of these quarters, situated nearest to the stables, and best defended from the cold winds, should be the hot-beds, for early cucumbers, melons, &c. and to these there should be a passage from the stables, and a gate through which a small cart may enter. The most important points of general culture consist in well digging and manuring the soil, giving a proper distance to each plant, according to their different growths, as also in keeping them clear from weeds; for this purpose you should always observe to keep your dung-hills clear from them; if this is not done, their seeds will be constantly brought in, and spread with the dung.

**KITE**, *milvus*. See **MILVUS**.

**KLEINIA**, in botany, a genus of the *syngnesia-polygamia* class of plants, the compound flower of which is uniform, consisting of about twenty monopetalous infundibuliform floscules, quinque-dentate at the limb; the stamina are five very short filaments; and the seed is single, and crowned with a simple downy filament.

**KNARESBOROUGH**, a borough-town in the north riding of Yorkshire, fifteen miles north of York.

It sends two members to parliament.

**KNAVE**, in old law-books, an appellation given to a man servant, or even to a male child.

**KNAUTIA**, in botany, a genus of the *tetrandria-monogynia* class of plants, the compound flower of which is equal, whereas the proper corolla is unequal, monopetalous, and quadrifid at the limb, with a tube of the length of the cup; the seeds are single, or one for each proper corolla, tetragonal; they are hairy at the top, and contained in a common receptacle.

**KNEE**, *genu*, in anatomy, the articulation of the thigh and leg-bones. See the articles **FEMUR**, **TIBIA**, **PATELLA**, &c. The two principal motions of this joint are flexion and extension: in the former of these the leg may be brought to a very acute angle with the thigh, by the condyles of the thigh-bone being round and smoothed so far backwards; and in performing this, the patella is pulled down by the tibia. When the leg is to be extended, the patella is drawn upwards, and the tibia forwards, by the extensor-muscles, which, by means of the protuberant joint, and this thick bone with its ligament, have the chord with which they act, at a considerable angle, and therefore act with advantage: but, in order that the body may be supported by a firm perpendicular column, they are restrained by the posterior cross-ligament, from pulling the leg farther than to a straight line with the thigh; and when this is done, the thigh and leg are almost as immoveable as if they were one continued bone: but when the joint is a little bent, the posterior ligament is relaxed, and the patella not tightly braced; therefore the superficial cavities of the tibia will allow this bone to be moved a little to either side, or with a small rotation; which is done by the motion of the external cavity backwards and forwards on the internal, which serves as a kind of axis. The rotation of the leg outwards, is of great advantage to us, in crossing our legs on several necessary occasions; though it is wisely ordered by providence, that this motion should not be very great, since this would have occasioned frequent luxations. While all these motions are performing, the only part of the tibia that moves immediately on the condyles, is only so much as is within the cartilaginous rings, which by the thickness of their outfides, make the cavities of the tibia more horizontal, by raising their external side, where the surface of the tibia slants downwards; by which means the motions of this joint are more equal and steady than

than they would otherwise have been. The cartilages are fitted to do this good office in the different motions and postures of the member, by being capable of changing a little their situation ; and this also contributes to make the motions larger and quicker.

*Luxation of the KNEE*, in surgery, is the receding of the tibia from under the lower extremity of the thigh-bone ; which happens sometimes on the outside, sometimes on the inside, and sometimes backwards, but very rarely or never forwards, by reason the patella prevents it.

When the knee is but slightly luxated, the patient is to be seated on a bed, bench, or table, and one assistant is to hold the thigh firm above the knee, and the other to extend the leg, while the surgeon in the mean time replaces the bones by his hand and knee : but when this method is not sufficient, surgeons make use of slings, pulleys, and other instruments. See plate CL. fig. 2. which represents a poly-spaston, or compound pulley, A and B being two hooks, by which the instrument is fastened on both sides ; C, the rope, by drawing which an extension is made in the luxated limb ; and D and E, the two pullies, consisting of several wheels, whereby the force of the drawer is greatly increased. See PULLY.

They ought, however, to be here very careful, lest they make the extension so violent in children and young people, as to separate the epiphyses from the bones, to which they are not yet firmly united, for by that means a worse disorder and lameness will be brought on. After the luxation of the knee is rightly reduced, it is to be properly bound up, and placed in a straw-case ; and the rest must be managed as in the luxation of the patella. See the article PATELLA.

*KNEE*, in a ship, a crooked piece of timber, bent like a knee, used to bind the beams and futtocks together, by being bolted fast into them both. These are used about all the decks.

*Carling-KNEES*, in a ship, those timbers which extend from the sides to the hatchway, and bear up the deck on both sides.

*KNIFE*, a well known instrument, made for cutting.

Surgeons have several kinds of knives ; some for dividing the flesh to the bone, in the upper and lower extremities ; these are commonly falciform, or hooked, as represented in plate CL. fig. 3. n° 1.

though Heister, in most cases, prefers the small straight knife, *ibid.* n° 2. Other incision-knives are double-edged, like that represented *ibid.* n° 3. and, finally, there are other lesser falciform incision-knives, for cutting away excrescences, which the others cannot conveniently reach.

All sorts of knives are prohibited to be imported.

*KNIGHT*, *equus*, among the Romans, a person of the second degree of nobility, following immediately that of the senators. See the article *EQUES*.

Part of the ceremony whereby this honour was conferred, was the giving of an horse ; for each had an horse at the public charge, and received the stipend of a horseman, to serve in the wars.

When the knights were taken in among the senators, they resigned the privilege of having an horse kept for them at the charge of the public : then it became necessary, in order to be a knight, that they should have a certain revenue, that their poverty might not disgrace the order ; and when they failed of the prescribed revenue, they were expunged out of the list of knights, and thrust down among the plebeians. Ten thousand crowns is computed to have been the revenue required.

The knights at length grew so very powerful, that they became a ballance between the power of the senate and people : they neglected the exercises of war, and betook themselves principally to civil employments in Rome.

*KNIGHT*, in a more modern sense, properly signifies a person, who, for his virtue and martial prowess, is by the king raised above the rank of gentlemen, into an higher class of dignity and honour.

Knighthood was formerly the first degree of honour in the army, and usually conferred with a great deal of ceremony, on those who had distinguished themselves by some notable exploit in arms : the ceremonies at their creation have been various ; the principal was a box on the ear, and a stroke with a sword on the shoulder ; they put on him a shoulder-belt, and a gilt sword, spurs, and other military accoutrements ; after which being armed as a knight, he was led to the church in great pomp. Camden describes the manner of making a knight-bachelor among us, which is the lowest, though the most ancient order of knighthood, to be thus : the person kneeling, was gently struck on the shoulder by the prince, and accosted

in these words, "Rise, or be a knight, in the name of God." For the several kinds of knights among us, see the articles *BATCHÉLOW*, *BANNERET*, *BARONET*, *BATH*, *GARTER*, &c.

**KNIGHT** is also understood of a person admitted into any order, either purely military, or military and religious, instituted by some king or prince, with certain marks and tokens of honour and distinction, as the knights of the garter, knights of the thistle, knights of Malta, the knights of the Holy Ghost, &c. all which may be seen under their several heads.

**KNIGHTS-ERRANT**, a pretended order of chivalry, much talked of in old romances, being a kind of heroes that travelled the world in search of adventures, redressing wrongs, rescuing damsels, and taking all occasions of signalizing their prowess. Of this kind of knights was Don Quixote, the hero of a celebrated romance, known by that name. This romantic bravery of the old knights was heretofore the chimerica of the Spaniards.

**KNIGHTS of the shire**, or **KNIGHTS of parliament**, in the british polity, are two knights or gentlemen of estate, who are elected, on the king's writ, by the freeholders of every county, to represent them in parliament.

The qualifications of a knight of the shire, is to be possessed of 600*l.* *per an.* in a freehold estate. Their expences during their sitting, were, by a statute of Hen. VIII. to be defrayed by the county; but this is now scarce ever required.

**KNIGHT-MARSHAL**, an officer in the king's household, who has jurisdiction and cognizance of any transgression within the king's household and verge; as also of contracts made there, whereof one of the house is party.

**KNIGHTS**, in a ship, two thick short pieces of wood, commonly carved like a man's head, having four thivers in each, three for the halcyards, and one for the top-ropes to run in: one of them stands fast bolted on the beams abaft the foremast, and is therefore called the fore-knight; and the other, standing abaft the main-mast, is called the main knight.

**KNOT**, a part of a tree, from which shoots out branches, roots, or even fruit. The use of the knots of plants, is to strengthen the stem: they serve also as sea-scaes, to filtrate, purify, and refine the juices raised up for the nourishment of the plant.

**KNOTS of a rope**, among seamen, are distinguished into three kinds, *viz.* whole-knot, that made so with the lays of a rope that it cannot slip, serving for sheets, tacks, and stoppers: bow-line-knot, that so firmly made, and fastened to the cringles of the sails, that they must break or the sail split before it slips: and sheep-shank-knot, that made by shortening a rope without cutting it, which may be presently loosened, and the rope not the worse for it.

**KNOT of the log line**, at sea, are the divisions of it. See the article *LOG*.

**KNOWLEDGE**, is defined, by Mr. Locke, to be the perception of the connection and agreement, or disagreement and repugnancy, of our ideas. See *IDEA*.

In the introduction to this work, we have given a general distribution of knowledge, according to its objects; and shall here consider it with regard to its foundation, degrees, extent, reality, and manner of improvement.

*Foundation and degrees of KNOWLEDGE.*

There are several ways wherein the mind becomes possessed of truth, each of which is called knowledge.

1. There is actual knowledge, when the mind has a present view of the agreement or disagreement of any of its ideas, or of the relations they have one with another. This is called intuitive knowledge; and whatever is deduced from our intuitive perceptions, by a clear and connected series of proofs, is said to be demonstrated, and produces absolute certainty in the mind; and hence the knowledge, obtained in this manner, is called science, because, in each step of the procedure, it carries its own evidence along with it, and leaves no room for doubt or hesitation. And what is highly worthy of notice, as the truths of this class express the relations between our ideas, and the same relations must ever and invariably subsist between the same ideas, our deductions in the way of science, constitute what we call eternal, necessary, and immutable truths. If it be true that the whole is equal to all its parts, it must be so unchangeably; because the relation of equality being attached to the ideas themselves, must ever intervene where the same ideas are compared. Of this nature all are the truths of natural religion, morality and mathematics, and in general, whatever may be gathered from the bare view and consideration of our ideas. See *INTUITION* and *DEMONSTRATION*.

2. Another

2. Another ground of human knowledge is experience ; from which we infer the existence of those objects that surround us, and fall under the immediate notice of our senses. When we see the sun, or cast our eyes towards a building, we not only have ideas of those objects within ourselves, but ascribe to them a real existence out of the mind. It is also by the information of the senses, that we judge of the qualities of bodies ; as when we say that snow is white, fire hot, or steel hard. For as we are wholly unacquainted with the internal structure and constitution of the bodies that produce these sensations in us, nay, and are unable to trace any connection between that structure and the sensations themselves, it is evident, that we build our judgments altogether upon observation, ascribing to bodies such qualities as are answerable to the perceptions they excite in us. But this is not the only advantage derived from experience, for to that too we are indebted for all our knowledge regarding the co-existence of sensible qualities in objects, and the operations of bodies one upon another. Ivory, for instance, is hard and elastic ; this we know by experience, and, indeed, by that alone : for being altogether strangers to the true nature both of elasticity and hardness, we cannot, by the bare contemplation of our ideas, determine how far the one necessarily implies the other, or whether there may not be a repugnance between them : but when we observe them to exist both in the same object, we are then assured, from experience, that they are not incompatible ; and when we also find that a stone is hard and not elastic, and that air, though elastic, is not hard, we also conclude, upon the same foundation, that these ideas are not necessarily conjoined, but may exist separately in different objects. In like manner, with regard to the operations of bodies one upon another, it is evident, that our knowledge this way is all derived from observation. Aqua-regia dissolves gold, as has been found by frequent trial, nor is there any other way of arriving at the discovery. Naturalists may tell us, if they please, that the parts of aqua-regia are of a texture apt to insinuate between the corpuscles of gold, and thereby loosen and shake them asunder. If this be a true account of the matter, I believe it will, notwithstanding, be allowed, that our conjecture in

regard to the conformation of these bodies, is deduced from the experiment, and not the experiment from the conjecture. To this head we may likewise refer whatever knowledge arises from testimony. See the article EXPERIMENTAL PHILOSOPHY.

3. A third foundation of knowledge is memory : when a man, having once evidently perceived certain truths, he ever afterwards readily assents to them whenever they come to be reflected on. This may be called habitual knowledge, whereby a man may be said to know all those truths which are lodged in his memory, by a former, clear and full perception ; and is of two sorts : the one is of such truths laid up in the memory, as whenever they occur to the mind, it actually perceives the relation there is between those ideas ; and this is in all those truths where the ideas themselves, by an immediate view, discover their agreement or disagreement one with another. The other is of such truths, of which the mind having been convinced, it retains the memory of the conviction without the proofs. Thus a man that remembers certainly, that he once perceived the demonstration that the three angles of a triangle are equal to two right ones, knows it to be true when that demonstration is gone out of his mind, and possibly cannot be recollected ; but he knows it in a different way from what he did before ; namely, not by the intervention of those intermediate ideas whereby the agreement or disagreement of those in the proposition was at first perceived ; but by remembering, that is knowing, that he was once certain of the truth of this proposition, that the three angles of a triangle are equal to two right ones. The immutability of the same relations between the same immutable things, is now the idea that shews him, that if the three angles of a triangle were once equal to two right ones, they will always be so. And hence he comes to be certain, that what was once true is always true ; what ideas once agreed will always agree ; and consequently, what he once knew to be true, he will always know to be true as long as he can remember that he once knew it.

#### *Extent and limits of human KNOWLEDGE.*

1. It is evident that we can have no knowledge farther than we have perception of the agreement or disagreement of our ideas, whether by intuition, demon-

stration, or sensation. 2. We cannot have an intuitive knowledge that shall extend itself to all our ideas and all that we know about them, because we cannot examine and perceive all the relations they have to each other; thus we cannot intuitively perceive the equality of two extensions, the difference of whole figures makes their parts incapable of an exact immediate application. 3. Demonstrative knowledge cannot reach to the whole extent of our ideas, because we cannot always find such proofs as will connect them together, with an intuitive knowledge in all the parts of the deduction. Thus, though we have the ideas of a square, a circle, and equality, yet we, perhaps, shall never be able to find a square exactly to a circle. The affirmations, or negations we make concerning the ideas we have, being reduced by Mr. Locke to these four, *viz.* identity, co-existence, relation and real existence, he examines how far our knowledge extends to each of these.

1. As to identity and diversity, our intuitive knowledge is so far extended as our ideas themselves, and there can be no idea in the mind which it does not presently, by an intuitive knowledge, perceive to be what it is, and to be different from any other.

2. As to the agreement or disagreement of our ideas of co-existence, our knowledge herein is very defective, though the greatest and most material part of our knowledge concerning substances consists in it.

As to the powers of substances, which makes a great part of our enquiries about them, our knowledge reaches little further than experience, because they consist in a texture and motion of parts which we cannot by any means come to discover.

3. As to the third sort, the agreement or disagreement of our ideas in any other relation; this is the largest field of knowledge, and it is hard to determine how far it may extend. This part depending on our sagacity in finding intermediate ideas, that may shew the habits and relations of ideas, it is difficult to tell when we are at an end in such discoveries.

4. As to the fourth part of knowledge, *viz.* of the real actual existence of things, we have an intuitive knowledge of our own existence, a demonstrative knowledge of the existence of God, and a sensitive knowledge of the objects that

present themselves to our senses. See the article EXISTENCE.

*Reality of human KNOWLEDGE.* It is evident, says Mr. Locke, that the mind knows not things immediately, but by the intervention of the ideas it has of them. Our knowledge therefore is real only so far as there is a conformity between our ideas and the reality of things. But how shall we know when our ideas agree with things themselves? It is answered, there are two sorts of ideas that we may be assured agree with things: these are,

1. Simple ideas; which, since the mind can by no means make to itself, must be the effect of things operating upon the mind in a natural way, and producing therein those perceptions which, by the will of our maker, they are ordained and adapted to. Hence it follows, that simple ideas are not fictions of our fancies, but the natural and regular productions of things without us really operating upon us, which carry with them all the conformity our state requires, which is to represent things under those appearances they are fitted to produce in us. Thus the idea of whiteness, as it is in the mind, exactly answers to that power which is in any body to produce it there. And this conformity between our simple ideas and the existence of things, is sufficient for real knowledge. See IDEA.

2. All our complex ideas, except only those of substances, being archetypes of the mind's own making, and not referred to the existence of things as to their originals, cannot want any conformity necessary to real knowledge.

3. But the complex ideas which we refer to archetypes without us, may differ from them, and so our knowledge about them may come short of being real, and such are our ideas of substances. These must be taken from something that does or has existed, and not be made up of ideas arbitrarily put together, without any real pattern. Herein, therefore, is founded the reality of our knowledge concerning substances, that all our complex ideas of them must be such, and such only, as are made up of single ones, as have been discovered to co-exist in nature; and our ideas being thus true, though not perhaps very exact copies, are the subjects of real knowledge of them. Whatever ideas we have, the agreement we find they have with others, will be knowledge: if those ideas be abstract, it will

will be general knowledge; but to make it real concerning substances, it must be taken from the real existence of things: wherever therefore, we perceive the agreement or disagreement of our ideas, there is certain knowledge, and wherever we are sure these ideas agree with the reality of things, there is certain real knowledge.

*Improvement of human KNOWLEDGE.* The sentiments of the same author upon the improvement of our knowledge are as follow: it being the received opinion among men of letters, that maxims are the foundations of all knowledge, and that sciences are each of them built upon certain *præcognita*, from whence the understanding was to take its rise, and by which it was to conduct itself in its enquiries in the matters belonging to that science, the beaten road of the schools was to lay down, in the beginning, one or more general propositions called principles or foundations, whereon to build the knowledge that was to be had of that subject.

That which gave occasion to this way of proceeding, he supposes to have been the good success it seemed to have in the mathematics, which of all other sciences have the greatest clearness, certainty, and evidence in them; but if we consider it, we shall find that the great advancement and certainty of real knowledge men arrive at, in these sciences, was not owing to the influence of these principles, but to the clear, distinct, and complete ideas their thoughts were employed about, and the relation of equality and excess so clear between some of them, that they had an intuitive knowledge, and by that a way to discover it in others, and this without the help of those maxims. See the article *AXIOM*.

The way to improve in knowledge, is not to swallow principles with an implicit faith, and without examination, which would be apt to mislead men, instead of guiding them into truth; but to get and fix in our minds clear and complete ideas, as far as they are to be had, and annex to them proper and constant names, and thus barely by considering our ideas, and comparing them together, and observing their agreement or disagreement, their habitudes and relations, we shall get more true and clear knowledge by the conduct of this one rule, than by taking up principles, and thereby putting the mind into the disposal of others.

We must, therefore, if we proceed as reason activities, adapt our methods of in-

quiry to the nature of the ideas we examine, and the truth we search after. General and certain truths are only founded in the habitudes and relations of abstract ideas; therefore a sagacious methodical application of our thoughts, for the finding out these relations, is the only way to discover all that can with truth and certainty be put into general propositions. By what steps we are to proceed in these, is to be learned in the schools of the mathematicians, who from very plain and easy beginnings, by gentle degrees, and a continued chain of reasonings, proceed to the discovery and demonstration of truths, that appear at first sight above human capacity. This may reasonably be said, that if other ideas, that are real as well as nominal essences of their species, were pursued in the way familiar to mathematicians, they would carry our thoughts farther, and with greater evidence and clearness, than probably we are apt to imagine.

In our knowledge of substances, we are to proceed in quite a different method; the bare contemplation of their abstract ideas (which are but nominal essences) will carry us but a very little way in the search of truth and certainty: here experience much teach us what reason cannot, and it is by trying alone that we can certainly know what other qualities co-exist with those of our complex idea; for instance, whether that yellow, heavy, fusible body we call gold, be malleable or not, which experience (however it prove in that particular body we examine) makes us not certain that it is so in all or any other yellow, heavy, fusible bodies, but that which we have tried; because it is no consequence, one way or other, from our complex idea. As far as our experience reaches, we may have certain knowledge, and no farther. It is not denied, but that a man accustomed to rational and regular experiments, shall be able to see farther into the nature of bodies and their unknown properties, than one that is a stranger to them; but this is only judgment and opinion, not knowledge and certainty. This makes our author suspect that natural philosophy is not capable of being made a science from experiments and historical observations: we may draw advantages of ease and health, and thereby increase our stock of conveniences for this life; but beyond this, he fears, our talents do not reach, and guesses that our faculties are

not

not able to advance farther. See the article EXPERIMENTAL PHILOSOPHY.

The ways to enlarge our knowledge as far as we are capable, seem, to be these two: the first is, to get and settle in our minds, as far as we can, clear, distinct, and constant ideas of those things we would consider and know. For it being evident, that our knowledge cannot exceed our ideas; where they are either imperfect, confused, or obscure, we cannot expect to have certain, perfect, or clear knowledge. The other is the art of finding out the intermediate ideas, which may shew us the agreement or disagreement, or repugnancy, of other ideas, which cannot be immediately compared. That these two, and not the relying on maxims, and drawing consequences from some general propositions, are the right method of improving our knowledge in the ideas of other modes, besides those of quantity, the consideration of mathematical knowledge will easily inform us; where we shall find, that he who has not clear and perfect ideas of those angles or figures, of which he desires to know any thing, is thereby utterly incapable of any knowledge about them.

Our knowledge, as in other things, so in this also, has so great a conformity with our sight, that it is neither wholly necessary, nor wholly voluntary. Men that have senses, cannot choose but receive some ideas by them; and if they have memory, they cannot but retain some of them; and if they have any distinguishing faculty, they cannot but perceive the agreement or disagreement of some of them, one with another: as he that has eyes, if he will open them by day, cannot but see some objects, and perceive a difference in them, yet he may choose whether he will turn his eye towards an object, curiously survey it, and observe accurately all that

is visible in it; but what he does see, he cannot see otherwise than he does: it depends not on his will to see that black, which appears yellow. Just thus it is with our understanding; all that is voluntary in our knowledge is the employing or withholding any of our faculties from this or that sort of objects; and a more or less accurate survey of them; but they being employed, our will hath no power to determine the knowledge of the mind one way or other; that is done only by the objects themselves, as far as they are clearly discovered.

**KNOXIA**, in botany, a genus of the *tetrandria-monogynia* class of plants, the flower of which consists of a single infundibuliform petal; and its seeds are two, and sulcated.

**KOLLOW**, the name of a black kind of earth found in several parts of the kingdom. See the article EARTH.

**KONINGSBURG**, a city of Poland, the capital of ducal Prussia and of the king of Prussia's polish dominions, situated on the river Pregel, near a bay of the Baltic sea, seventy miles north-east of Dantzick: east lon. 21°, and north lat. 54° 40'.

**KORAN**, or **ALCORAN**. See **ALCORAN**.

**KOS**, in jewish antiquity, a measure of capacity, containing about four cubic inches: this was the cup of blessing, out of which they drank when they gave thanks after solemn meals, like that of the passover.

**KUR**, the ancient Cyrus, a river of Persia, which rises in the mountains of Georgia, and running south-east by Teflis, unites its streams with the river Arras (the ancient Arraxes) and falls into the Caspian sea, south of Baku.

**KUTUCHTA**, among the Calmuc-Tartars, the name of their high-priest, or sovereign pontiff; formerly only the deputy of the delai-lama, or high-priest of the Tartars, but at present independent on him.
